Soft Lights Foundation

Light should guide us, not blind us.

Comment of the Soft Lights Foundation

Request for Information on Electromagnetic Fields (EMFs), Radiofrequency (RF) Radiation, and Wireless Radiation Exposure

Docket No. HHS-OASH-2026-0397 | FR Doc. 2026-19252
U.S. Department of Health and Human Services,
Office of the Assistant Secretary for Health
Published September 21, 2026 | Comments due October 21, 2026

Submitted: October 20, 2026

The Defective Administration of the Electronic Product Radiation Control Program as Applied to Visible Light Emitted by LED Products

RESPONDENT IDENTIFICATION AND BASIS OF RESPONSE

This block responds to the RFI Instructions and to Question 2. It is placed at the front of the comment so that the reviewing office can confirm compliance without reading further.

A. Responding Entity

This comment is submitted by the Soft Lights Foundation, a nonprofit corporation incorporated in the State of Oregon in 2021 and exempt from federal income tax under section 501(c)(3) of the Internal Revenue Code.

Soft Lights Foundation
9450 SW Gemini Dr., PMB 717836
Beaverton, OR 97008
www.softlights.org
info@softlights.org

The Foundation addresses the health, safety, and accessibility effects of high-intensity artificial lighting. It collects reports of harm from members of the public and submits them to federal agencies, files regulatory petitions, and participates in federal and state administrative proceedings concerning light-emitting products. The record of that activity is set out in Part IV.

B. Individual Respondent and Role in the Organization

Mark Baker
President, Soft Lights Foundation
mbaker@softlights.org

Mr. Baker prepared and submits this comment in his capacity as President of the Foundation. The RFI Instructions provide that where a comment is submitted on behalf of an organization, the individual respondent's role in the organization may also be provided; that information is given here for that purpose.

This document is the Foundation's institutional submission. Part IV.D describes litigation brought by Mr. Baker in his individual capacity. Those actions are his own and are not the Foundation's; the distinction between the two capacities is maintained throughout this comment.

Mr. Baker will also submit a separate response to this docket in his individual capacity, from a separate address. That submission is his own and is not made on the Foundation's behalf. Subsection G addresses the one-response instruction and the relationship between the two filings.

C. Perspective(s) Represented [RFI Q2]

Question 2 asks respondents to describe which perspective or perspectives their comments represent. The Foundation answers as follows.

Primary perspective: another type of organization — specifically, a nonprofit public-health and disability-advocacy organization concerned with the biological effects of artificial optical radiation.

Secondary perspective: the Foundation also transmits, in aggregate and de-identified form, the reported experience of individual consumers, patients, family members, and caregivers who have submitted reports of harm to it. Part VII describes that record and states expressly what it does and does not establish.

The Foundation states for completeness which of the listed perspectives it does not represent. It is not a healthcare professional or clinical entity and offers no clinical observations of its own. It is not an equipment or product manufacturer, a service or infrastructure provider, a business, or an industry group. It is not a government entity. It is not a research entity and conducts no primary

laboratory research; where this comment relies on scientific findings, it relies on the published work of others, cited as such.

D. Basis of the Response: Sources Relied Upon

The RFI asks respondents to identify whether their response is based on peer-reviewed research, government reports, industry data, clinical observations, or other sources. This comment draws on several distinct classes of source. They are not interchangeable and they do not carry equal weight. The table below identifies each class, what it comprises in this comment, and what the Foundation asks the Department to take from it. Full citations with active hyperlinks appear at the point of use and in Appendices C through F.

Class of source	What it comprises in this comment	Weight accorded
1. Federal statutes and legislative materials	Title 21, United States Code, part C of subchapter V (§§ 360hh–360ss); the Energy Policy and Conservation Act; enacted appropriations and the committee reports they carry; introduced bills. Parts II and IV.	Primary authority. Quoted exactly. Where the Foundation characterizes a provision rather than quoting it, the characterization is identified as the Foundation's.
2. Federal regulations and rulemaking records	21 C.F.R. subchapter J; 10 C.F.R. part 430; 49 C.F.R. § 571.108; 28 C.F.R. part 35; Federal Register notices and final rules, their preambles, and the NEPA determinations accompanying them. Parts II, IV, and VI.	Primary authority, and primary record of what each agency did and when.
3. Agency correspondence, petitions, and responses	Regulatory petitions filed by the Foundation and the agencies' dispositions of them; agency interpretation letters; records produced under the Freedom of Information Act. Part IV.	Primary record. Cited by date and document identifier. Produced records are submitted or linked rather than described.
4. Judicial records and decisions	Pleadings, orders, and published opinions in the proceedings identified in Part IV.	Primary record. Holdings are stated as decided. What a court declined to reach is identified as not reached.
5. Peer-reviewed scientific literature	Published studies on optical radiation and the eye, temporal light modulation, photosensitive and neurological response, circadian effect, and ecological effect. Part V.	Scientific evidence. Part V.A states the selection method and distinguishes established findings from emerging ones and from open questions.
6. Consensus standards and technical guidance	Photobiological safety, flicker, photometric, and measurement standards issued by IEC, CIE, IEEE, and ANSI/IES, and international exposure guidance. Parts V and VI; listed at subsection E.	Evidence of what technical criteria exist and of their voluntary, non-federal status. Identification is not endorsement.
7. First-hand reports of harm	The Foundation's LED Incident Report database — 593 reports collected from members of the public and submitted to the FDA. Reproduced in full at Appendix A. Part VII.	Each report is the account of one person, in that person's own words. Qualitative, self-reported, and self-selected. Evidence of the existence, character, and persistence of reported harm, and of notice to the agencies. Not a probability sample; not evidence of incidence or causation. Part VII.A.5 states the limits.

Class of source	What it comprises in this comment	Weight accorded
8. Public petition comments	More than 4,000 public comments on the petition to the U.S. Department of Transportation identified in Part VII.G. Reproduced in full at Appendix B.	Individual first-hand accounts, carrying the same character and the same limits as the incident reports above.
9. Public petition signatures	The signature count on the same petition, stated and sourced as of the date of filing. The signature list itself is not submitted. Part VII.G.	Evidence of the scale of public complaint. A count, not an account. Not epidemiological data and not offered as such.
10. Direct observation and measurement	Photometric and spectral measurements and photographic documentation made by the Foundation. Part VI.	Primary observation. Instrument, method, and conditions are stated wherever a measurement is reported.
11. Secondary reporting	News and trade press.	Used only to locate a primary document or to establish that a matter was publicly reported. No factual assertion in this comment rests on secondary reporting alone.

Classes 7 through 9 are already records of the Department.

The Foundation transmitted the LED Incident Reports to the Food and Drug Administration at RadHealthCustomerService@fda.hhs.gov, and the agency acknowledged receipt. The petition comments and signature totals described in Part VII.G were transmitted to the agencies as well. These materials are therefore held within the Department already, and their reproduction at Appendices A and B re-presents material the Department has had in hand rather than disclosing anything new to it. What is new in this submission is not the information. It is the request that the Department act on it. Part IV.B sets out the transmittal record with dates, recipients, and acknowledgments.

What this comment does not rely on.

The Foundation offers no clinical observations, holds no patient records, and submits none. It relies on no proprietary or confidential industry data, and submits none. It relies on no unpublished study and on no data held confidentially by any third party.

Basis for statements that a record does not exist.

Several assertions in this comment are negative — most importantly, that no federal performance standard governs visible light emitted by LED products, and that no consultation with the FDA appears in the record of the agency actions described in Parts II and IV. Each such statement rests on the Foundation's search of the Code of Federal Regulations, the Federal Register, and the agencies' own published materials, together with the agency responses described in Part IV. The one mechanism available to test these statements against the agency's non-public records was a request under the Freedom of Information Act, submitted March 30, 2025, for the Center for Devices and Radiological Health's records on these products and on the interagency liaison obligation. In litigation over that request the United States has admitted that, as of August 12, 2026, it had made no determination, produced no record, and asserted no exemption as to any responsive record. The Foundation has therefore tested its own conclusions as far as the available mechanism permits. Part IV.D.3 sets out that record. Each is stated as the result of that search. If the Department is aware of a record the Foundation has not located, the Foundation asks that it be identified.

E. Exposure Guidelines, Regulatory Frameworks, and Scientific Assessments Relied Upon

The RFI asks respondents who rely on existing exposure guidelines, regulatory frameworks, or scientific assessments to identify the specific frameworks and to explain how they inform the response. The Foundation identifies the following. They are grouped by legal status, because the distinction between a binding federal standard and a voluntary consensus document is itself the subject of this comment.

Framework	Status	How it informs this comment
Federal Food, Drug, and Cosmetic Act §§ 531–542, 21 U.S.C. §§ 360hh–360ss	Binding federal law	The governing framework. This comment concerns its administration as applied to LED products.
21 C.F.R. subchapter J, parts 1000–1040	Binding federal regulation	The implementing regulations. Part 1040 is titled "Performance Standards for Light-Emitting Products" and includes a standard for high-intensity mercury vapor discharge lamps at § 1040.30. The FDA has therefore already prescribed a performance standard for a general-illumination lamp under this authority. No counterpart exists for LED products.
21 C.F.R. §§ 1000.3(a), 1002.20	Binding federal regulation	Definition of an accidental radiation occurrence and the reporting obligation attached to it. Part VII.I.
FMVSS No. 108, 49 C.F.R. § 571.108	Binding federal regulation	Governs motor vehicle lamps on photometric and signaling criteria. Identified to show what it does and does not contain: no health-based limit on emission, and no criterion for spectral content or temporal modulation.
47 C.F.R. §§ 1.1307(b), 1.1310	Binding federal regulation	FCC radiofrequency exposure limits. Relevant to the RF thread and to the division of responsibility between the FCC and the FDA discussed at Part II.H.8.
Energy Policy and Conservation Act, 42 U.S.C. § 6291 et seq.; 10 C.F.R. part 430	Binding federal law and regulation	General service lamp efficacy standards. Identified to show that the governing metric is lumens per watt and that it is silent as to what the selected technology emits. Part IV.G.
28 C.F.R. part 35	Binding federal regulation	ADA Title II self-evaluation and accommodation duties. Identified to show what public entities are required to do and what technical referent they lack. Part VIII.
IEC 62471 / CIE S 009, photobiological safety of lamps and lamp systems	Voluntary consensus standard; not adopted as a federal performance standard	The principal existing photobiological classification scheme. Identified for what it covers, what it does not cover, and its non-binding status.
IEEE Std 1789-2015, modulating current in high-brightness LEDs	Voluntary recommended practice; not adopted	The principal existing guidance on flicker and temporal light modulation. Identified as recommended practice that no federal rule requires any manufacturer to follow.
ANSI/IES RP-27 series, photobiological safety	Voluntary consensus standard	Recommended practice on photobiological safety for lamps and lamp systems.
ICNIRP guidelines on exposure to incoherent visible and infrared radiation	International guidance; no force of law in the United States	Comparison point for Question 5, which asks what national and international frameworks federal health agencies should consider.

Framework	Status	How it informs this comment
SCHEER, Opinion on Potential risks to human health of Light Emitting Diodes (LEDs) (European Commission, 6 June 2018)	Advisory opinion of a European Commission scientific committee; not binding, and without force of law in the United States	Relied upon for what it concluded, for the condition it attached to that conclusion, and above all for its own statements of what it could not conclude and what research and measurement it identified as absent. Part V.K.
ANSI/IES LM-79, TM-30, and related measurement standards	Voluntary test methods	Measurement methodology underlying Parts V and VI and any measurement the Foundation reports.
Martinsons et al., Solid State Lighting: Review of Health Effects (IEA 4E Solid State Lighting Annex, Oct. 2024)	Intergovernmental technical assessment; not binding	Relied upon for its account of the state of the blue light hazard exposure limit, the absence of consensus on its revision, the inadequacy of present means of predicting discomfort glare, the regulatory gap as to temporal light modulation, and the research gaps it identifies. Parts V.C.2.f, V.C.4, V.D.3 and V.K.

Identification is not endorsement.

The Foundation identifies these documents because the RFI asks what frameworks exist and how they inform the response. It does not adopt the exposure values in any voluntary standard listed above as adequate, and this comment should not be read to propose any of them as a federal limit. The Foundation's position is the one stated in Part IX: that the Department should develop the evidentiary basis for a performance standard under 21 U.S.C. § 360kk, and that no voluntary document now supplies that basis.

F. Statement Regarding Personally Identifiable and Personal Health Information

Two instructions in the RFI bear on this. The Instructions direct respondents not to submit personally identifiable information or personal health information. Question 3 invites individuals, families, caregivers, healthcare professionals, and organizations to share experiences regarding potential adverse health effects, and encourages respondents to provide as much detail as they are comfortable sharing, recognizing that responses will be public. The Foundation reads the two together as asking for the accounts without the identifiers, and has prepared this comment on that basis.

The Department already holds this record.

The accounts reproduced at Appendices A and B were transmitted to the Food and Drug Administration before this RFI issued, and receipt was acknowledged. Submitting them here discloses nothing to the Department that the Department does not already possess. The de-identification described below is therefore directed at the public posting on regulations.gov rather than at the Department's own review, and the Foundation has carried it out on that basis.

The accounts are submitted in full.

The LED Incident Reports at Appendix A and the petition comments at Appendix B are reproduced in their entirety. They are not summarized, sampled, excerpted, or reduced to counts. Each is the account of one person in that person's own words, and the particularity of these accounts is itself the evidence Question 3 asks for. Reducing them to a tally would withhold from the Department the material it has requested.

Identifiers removed.

The Foundation has removed from each account: (a) names, electronic mail addresses, telephone numbers, street addresses, and social media handles; (b) the name of any employer, school, medical provider, business, or other third party named by the reporter; and (c) any remaining

detail that in the Foundation's judgment would identify the reporter notwithstanding removal of the foregoing. Locations are stated no more precisely than city and state. Self-identified categories are retained as submitted, because Question 3 asks for the nature of the effect experienced and for the characteristics of the individuals involved.

Signatures are stated as a count.

The signature total on the petition described in Part VII.G is stated and sourced as of the date of filing. The signature list itself is not submitted: it consists principally of names, which are personally identifiable information, and a signature carries no account to reproduce. The distinction is between accounts, which are submitted whole, and a count, which is reported as a number.

Reports are reproduced as submitted.

The Foundation has not edited the accounts for content and does not adopt the views expressed in any individual report or comment. Some reporters state opinions on matters outside the scope of this comment. They appear because the record is submitted whole rather than curated, and the Department should read each account as the statement of its author and not of the Foundation.

No clinical record, no diagnosis made by a clinician, and no document from any medical provider is submitted or relied upon. The Foundation submits no proprietary, classified, or confidential information, and requests no confidential treatment of anything in this comment or its appendices. The Foundation understands that this comment and its appendices will be posted publicly on regulations.gov.

G. Single-Response Certification

Instruction 1 provides that each responding entity, person or organization, should submit only one response. This document, together with Appendices A through F, is the single response of the Soft Lights Foundation to Docket No. HHS-OASH-2026-0397. The Foundation has submitted no other response to this docket.

Mark Baker will submit a separate response in his individual capacity, from a separate address. Instruction 1 distinguishes a person from an organization, and the two submissions are the single responses of two responding entities. Neither is made on behalf of the other. The Foundation states the relationship here so that the Department is not left to infer it from two filings bearing the same name.

What this single response transmits.

Counted as a docket entry, this is one comment. What it carries is not one person's view. Appendix A reproduces 593 first-hand reports of harm, each written by the person who experienced it and each previously submitted to the Food and Drug Administration. Appendix B reproduces more than 4,000 public comments describing the same class of harm. Part VII.G reports the signatures of more than 80,000 additional individuals. The Foundation asks that these accounts be weighed as the statements of the people who wrote them, and that the Department not treat the experience of tens of thousands of individuals as a single comment because it reached the docket through a single filer.

Questions regarding this submission may be directed to Mark Baker, President, Soft Lights Foundation, at mbaker@softlights.org.

EXECUTIVE SUMMARY

The sixteen propositions on which this comment rests, each stated as a conclusion and each established in the Part cited after it. This summary is navigational. Nothing in it should be relied on without the Part it points to, and where a proposition is qualified there, the qualification governs.

The Soft Lights Foundation submits this comment in response to Docket No. HHS-OASH-2026-0397. The Department asked what is known and what should be done about human exposure to electromagnetic radiation. This comment answers as to one region of that spectrum: the visible light emitted by light-emitting diode products, which is electronic product radiation within 21 U.S.C. § 360hh(1)(A) and within the control program § 360ii directs the Secretary to establish and carry out. The Foundation asks the Department to carry out that program as to these products. It does not ask the Department to find that these products injure anyone, and it does not ask for a ban on any product.

a. The authority, and the agencies that have deferred to it

1. The Food and Drug Administration is the only federal agency Congress has authorized to control the radiation emitted by electronic products. That authority is conferred by part C of subchapter V of the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. §§ 360hh to 360ss, and is administered through the Center for Devices and Radiological Health. Part I.A; Part II.A.

2. Every federal agency the Foundation has asked has deferred to it. Between March 2022 and August 2023 the Foundation put the question to nine federal bodies: the National Transportation Safety Board, the Environmental Protection Agency, the Federal Highway Administration, the Consumer Product Safety Commission, the Federal Aviation Administration, the National Highway Traffic Safety Administration, the Department of Energy, the Occupational Safety and Health Administration, and the United States Access Board. Each answered that the subject was not within its authority, and several identified where the authority lay. The Environmental Protection Agency wrote that Congress has granted it no statutory authority to regulate visible light or non-ionizing radiation emitted from electrical devices, and that it maintains no experts in the field. The Consumer Product Safety Commission wrote that it is barred by 15 U.S.C. § 2080. The Federal Aviation Administration wrote that it would defer to the Food and Drug Administration. Part I.A; Part II.H.20.

3. The Foundation does not contend that any of those agencies was wrong. Having examined each position it believes each was right, and that is what gives the record its significance. This is not a subject that fell between agencies because each supposed another was attending to it. It is a subject Congress assigned to one agency, which every other agency asked about it has correctly said belongs to that agency. Because that deference is correct, no other part of the federal government can open the question. Part I.A.

b. The duty, and the test it actually applies

4. The task is minimization. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, development, training and operational activities "to minimize the emissions of and the exposure of people to, unnecessary electronic product radiation". The paragraph contains no finding, no determination and no threshold that must be reached before the duty attaches, and minimization states a direction of travel rather than a ceiling. Part II.D.

5. Safety is not the test that paragraph applies. The purpose of the subchapter is the protection of public health and safety, and the Foundation does not suggest otherwise. But the word limiting paragraph (a)(2) is unnecessary, not hazardous. Congress used both words and the Senate report on the 1968 Act lists them disjunctively, as unknown, unnecessary and potentially hazardous radiation. The question the paragraph asks is not whether this radiation has been shown to injure anyone. It is whether the radiation serves any purpose for the person exposed to it. A demonstrated history of

safety answers the question § 360kk(a)(1) asks. It does not answer the question paragraph (a)(2) asks. Part II.D.2.

6. Light pollution is a name for part of that unnecessary radiation. The radiation does not leave, it reaches people, and emission directed away from the surface an installation exists to serve performs no function for anyone. The Environmental Protection Agency has already stated that it holds no Congressional authority over it. Part II.D.3; Part III.D.1.

c. What the 2024 determination addressed, and what it did not

7. The Final Response of May 24, 2024 addressed performance standards. Of the six duties in § 360ii(a), exactly one operates through a mechanism that conditions action on a determination by the Secretary: paragraph (a)(1), which runs through § 360kk and its finding of necessity. That is the duty the letter addressed. The other five carry no such condition and the letter does not discuss them. The issue before the Department is not a single standard. It is a functioning radiation control program for this radiation. Part I.C; Part II.M.

8. The standard-setting mechanism is not presently operable, and must be reconstituted as part of any functioning program. The Technical Electronic Product Radiation Safety Standards Committee required by § 360kk(f) is chartered and continuing. So far as the Foundation can determine it last met in October 2016, at a meeting where the Center presented its own concerns about light-emitting diodes. In January 2025 nominations were sought for ten of its fifteen seats. Part II.K; Part IX.H.

9. The reports to Congress that the statute requires have never been produced for these products. Section 360jj(a) directs the Secretary to conduct the enumerated studies and report the results to Congress. The second study was performed once, during 1969, and reported in April 1970; the agency's own staff document states on its face that it was confined to three classes of products, all of them sources of ionizing radiation. It has never been performed for any product emitting visible light. A petition seeking performance has been pending since December 30, 2025. Part II.I; Part IX.K.

d. The outreach duty is the Department's own, and two windows are open now

10. The Department cannot wait to be approached. Paragraph 360ii(a)(6) directs this Department to consult and maintain liaison with the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor and other appropriate federal departments and agencies. It imposes no duty on any of them. The Occupational Safety and Health Administration said so in declining a request for consultation, and it was correct. Of the two departments the provision connects, only this one can invoke it. One of the nine agencies, the Access Board, has already offered to provide technical assistance to the Food and Drug Administration on request, and the Foundation can locate no record that a request was ever made. The Foundation asks that an express written invitation be sent to each agency and that the Department state which were sent. Part II.H.10; Part II.H.11; Part IX.E.5.

11. The National Highway Traffic Safety Administration is rewriting the standard that governs vehicle lamps now. The Department of Transportation announced on October 6, 2026 a negotiated rulemaking to modernize Federal Motor Vehicle Safety Standard No. 108, docketed as NHTSA-2026-1981, with applications and comments due November 9, 2026 and headlamp glare among the announced subjects. The optical characteristics of a product class are about to be determined again, and the agency holding the radiation-health authority is not at the table. This is the one instance in this comment where that pattern is still capable of being avoided rather than merely described. Part II.H.5; Part IX.E.4.

12. The Federal Communications Commission is taking comment now, and that window closes first. Public Notice DA 26-997, released September 17, 2026 in ET Docket No. 13-84, invites comment with a deadline of October 22, 2026, which is the day after comments on this request for information close. Part II.H.8; Part IX.E.4.

e. Who is affected, what must be assessed, and what is asked

13. Disability access is a critical need and it is where the absence of a federal criterion does its most concrete damage. A public entity conducting the self-evaluation that 28 C.F.R. § 35.105 requires has no federal referent for what an emitting product may emit, so the systemic duty defaults into the individualized one and the burden of establishing harm falls on the person requesting accommodation. This Department is a designated agency under Title II of the Americans with Disabilities Act, and section 504 of the Rehabilitation Act reaches its own programs. Part VIII.

14. The assessment required is large, and no baseline exists for any part of it. Part VI describes seventeen product classes, from vehicle headlamps and roadway lighting to indicator lamps on household appliances, traffic signals, rail and marine lighting, and lighting on bicycles and personal mobility devices. Appendix F sets out thirty-six radiation-emitting product codes for these products, twenty-three the Center has already assigned and thirteen the Foundation proposes. Part III identifies sixteen characteristics of emission and exposure in which a boundary must be drawn if minimization is to mean anything, and states of each whether a number can presently be given. For most it cannot, because the research paragraph (a)(2) directs and the evaluation paragraph (a)(4) directs have not been conducted. Emissions that have never been measured cannot be shown to have been minimized.

15. The record before the Department is substantial and most of it is already in its files. Appendix A reproduces 593 LED Incident Reports in full, the majority transmitted to the Center as they arrived and acknowledged. Appendix B reproduces 4,991 public comments submitted to the headlamp petition. Appendix C appraises 153 peer-reviewed articles. Part VII states what this material establishes, which is narrow, and what it does not, which is longer and includes matters that count against the Foundation.

16. What is asked, and what is not. The Foundation does not ask the Department to find that these products injure anyone, and does not ask for a ban. It asks for one performance standard, in the single characteristic where the quantities are settled and a consensus body has already written numerical criteria in mandatory language. For the rest it asks for what a program does before it regulates: measure what these products emit, characterize how people are exposed to them, publish both, disclose emission characteristics at the point of procurement, consult the agencies whose rules determine what these products emit, reconstitute the advisory committee, conduct the studies and report to Congress, and exercise the powers of § 360ii(b)(1), which require no finding about anyone's health and may be exercised now. Part IX; summarized at Part I.H.

EXECUTIVE SUMMARY 8

TABLE OF CONTENTS 10

INDEX TO RFI QUESTIONS 26

I. INTRODUCTION 28

A. Summary of Position 28
B. The Electronic Product Radiation Control Program Is Defective as Applied to LED Products 30
1. The statutory duties of 21 U.S.C. § 360ii are mandatory and continuing 30
2. Those duties have not been discharged for visible light emitted by LED products 32
3. Those duties have not been discharged for radiofrequency energy emitted by LED products 32
C. The Limits of the Agency's Discretion, and the Forum for This Question 33
1. The proceeding 33
2. The United States does not contend that the duties are discretionary 33
3. The government says the dispute is a policy assessment 33
4. The government says no decisionmaking process has occurred 33
5. Where the statute confers judgment, and where it does not 33
6. The agency has made a determination, and its basis has not been disclosed 34
7. The reasons given are empirical propositions, and this comment tests them 34
8. The discretion in § 360kk(a)(1) is downstream of the duty in § 360ii(a)(4) 37
9. The powers conferred by § 360ii(b), and why this proceeding is where they are properly raised 37
A note on the scope of the authority, which the Foundation does not overstate 38
10. What the Foundation asks the Department to accept, and what it does not 38
D. This Request for Information Invokes the Electronic Product Radiation Control Authority 39
E. Visible Light Is Within the Scope of This Request for Information 39
1. Questions framed in radiofrequency terms, and how this comment answers them 40
F. Scope and Organization of This Comment 40
G. Terminology, Units, and Measurement Conventions 41
H. Summary of Requests to the Department 45
II. 21 U.S.C. § 360ii REQUIREMENTS 46
A. Statutory Framework: FD&C Act §§ 531-542 (21 U.S.C. §§ 360hh-360ss) 46
1. The Radiation Control for Health and Safety Act of 1968 and its transfer into the FD&C Act 46
2. Implementing regulations: 21 CFR subchapter J, parts 1000-1040 47
3. The Center for Devices and Radiological Health and program administration 48
B. Statutory Definitions Reach LED Products 50
1. "Electronic product radiation" includes any non-ionizing electromagnetic radiation — § 360hh(1)(A) 50
2. "Electronic product" — § 360hh(2) 50
3. Parallel definitions at 21 CFR 1000.3(j) and (k) 51
4. FDA has previously regulated light-emitting products under this authority — 21 CFR part 1040 51
5. LED products that emit both visible light and radiofrequency energy 52
6. The agency has classified these products already, and the classification is in operational use 52
C. § 360ii(a)(1) — Develop and Administer Performance Standards 53
1. The § 360kk standard-setting mechanism 53
2. Light-emitting products for which standards exist 55
3. Absence of any performance standard for LED visible light 56

4. A worked example: a product the agency has cleared, classified by a mechanism it does not use, and subject to no emission limit....57

D. § 360ii(a)(2) — Plan, Conduct, Coordinate, and Support Research to Minimize Emissions and Exposure....59

1. What the paragraph conditions, and what it does not....59
2. "Unnecessary electronic product radiation" is not a defined term....61
3. Light pollution is unnecessary electronic product radiation....66
4. The agency and the United States have each used the term, without applying it to visible light....73
5. The existing mitigations....73
6. Absence of research, development, training, or operational activity directed to this radiation....74

E. § 360ii(a)(3) — Maintain Liaison With and Receive Information From Other Agencies, Professional Organizations, and Industry....78

1. What the subsection requires, and of whom....78
2. Other Federal departments and agencies with related interests....79
3. State departments and agencies....79
4. Professional organizations and standards bodies....80
5. Industry and labor associations....84
6. Information received and not acted upon....84

F. § 360ii(a)(4) — Study and Evaluate Emissions of, and Conditions of Exposure to, Electronic Product Radiation....87

1. What the subsection requires....87
2. Information bearing on conditions of exposure already in the agency's possession....88
3. Studies and evaluations the agency has conducted for other electronic product radiation....88
4. Absence of any study or evaluation of visible light emitted by LED products....89

G. § 360ii(a)(5) — Develop, Test, and Evaluate Procedures and Techniques for Minimizing Exposure [RFI Q5.o]....92

1. What this paragraph adds to the two before it....92
2. The agency has already asserted the conclusion this paragraph directs it to reach....93
3. The techniques exist; what is absent is the federal evaluation of them....93
4. What the Foundation asks under this paragraph....95

H. § 360ii(a)(6) — Consult and Maintain Liaison With Other Federal Departments and Agencies....95

1. The departments named expressly in the statute....95
2. "Other appropriate Federal departments and agencies" — scope of the residual category....100
3. Environmental Protection Agency....100
4. Department of Energy — general service lamps (developed at Part IV.G)....104
5. Department of Transportation and National Highway Traffic Safety Administration — FMVSS No. 108....104
6. Federal Highway Administration — MUTCD, warning beacons, and roadway lighting....106
7. Federal Aviation Administration — obstruction, airfield, and aircraft lighting....109
8. Federal Communications Commission....112
9. Consumer Product Safety Commission....116
10. Department of Labor — OSHA and NIOSH....117

11. United States Access Board 119
12. Department of Education — school facilities 120
13. Federal Trade Commission — labeling and advertising of LED products 120
14. General Services Administration, Department of Defense, and other federal building operators 121
15. United States Customs and Border Protection 126
16. United States International Trade Commission 126
17. United States Fire Administration 127
18. Department of Justice 129
19. Equal Employment Opportunity Commission 130
20. The documented instances of consultation and liaison with another federal agency 130
21. What those instances show about the program as a whole 136
22. Summary table: agency, emitting products regulated, FDA consultation of record 139
I. § 360jj — Studies by the Secretary and Reports to Congress 141
1. The text 141
2. What is qualified in this provision, and what is not 141
3. How the United States has characterized § 360jj 141
4. Whether the § 360jj(a)(2) study has ever been conducted as to LED products 142
5. The petition of December 30, 2025 143
6. A duty performed once is not a duty discharged 144
7. Comparison: judicial treatment of an abandoned statutory program 145
8. The repealed annual report to Congress, and the premise on which it was repealed 145
J. Related Duties Within the Same Part 148
1. § 360ll — Notification of defects and repair, replacement, or refund 148
2. § 360nn — Inspection, records, and reports 151
K. § 360kk(f) — The Technical Electronic Product Radiation Safety Standards Committee 151
1. What the statute requires 151
2. The implementing regulations — 21 C.F.R. part 14, subpart G 152
3. Chartering history 153
4. Membership status 155
5. Meeting record 156
6. Consequence: the standard-setting mechanism is not presently operable 159
7. Relationship to this request for information 161
L. Reporting of Accidental Radiation Occurrences — 21 CFR 1000.3(a), 1002.20 162
1. The definition and the reporting duty 162
2. What the Foundation has submitted, and what it is 162
3. The question that follows, which is for the Department 163
4. The structural point, which does not depend on the definition 163
M. Summary: Which Duties Have Been Discharged and Which Have Not 163
1. The duties of 21 U.S.C. § 360ii(a) 163
2. The related provisions 164

3. What the pattern shows.....164
III. MINIMIZING EMISSIONS AND EXPOSURE.....165
A. What This Part Does, and the Two Questions It Asks of Each Characteristic [RFI Q5, Q7, Q8].....165
B. The Three Families, the Shapes a Boundary Can Take, and Two Items That Are Not Characteristics of the Emission.....166
C. Spectral Characteristics.....167
1. Spectral distribution.....167
D. Spatial Characteristics.....169
1. Spatial distribution of the emission.....171
2. Radiance.....172
3. Luminance.....172
4. Luminous intensity.....173
5. Illuminance.....174
6. Irradiance.....175
7. Glare rating.....176
8. Number of emitters present during a single exposure [RFI Q15].....177
9. Movement of the source through space.....178
E. Temporal Characteristics.....179
1. Temporal characteristics of the output.....179
2. Rise and decay times of flashing lamps.....180
3. Cumulative exposure.....182
4. Time of day and time of night at which the product is used.....183
F. The Exposed Person: Special Populations [RFI Q11].....184
G. Techniques of Minimization [RFI Q5.o].....185
1. Luminaire shielding and diffusion.....185
2. User control of the indicator light on a mains-powered device.....186
3. Substitution of the source technology.....188
H. Summary: The Sixteen Characteristics, the Shape of the Boundary Each Requires, and What Can Presently Be Stated.....189
IV. LITIGATION, REGULATORY PETITIONS, AND CONGRESSIONAL ACTION.....191
A. Purpose and Scope of This Part [RFI Q5, Q18].....191
1. Why the administrative and judicial record is responsive to this RFI.....191
2. Capacities: filings by the Soft Lights Foundation and filings by Mark Baker individually.....192
3. Sources and availability of the underlying documents.....193
B. Notice to the Agencies: Transmittal of Reports of Harm and Acknowledgment of Receipt.....193
1. The LED Incident Report submission form and the Foundation's transmittal practice.....193
2. Transmittal to the Food and Drug Administration at RadHealthCustomerService@fda.hhs.gov.....194
3. The FDA's acknowledgments of receipt.....194
4. Transmittal to the National Highway Traffic Safety Administration.....195
5. Transmittal of the petition comments and signature totals.....195

6. Correspondence to other agencies and to manufacturers....195
7. Consequence: the reports are records within the Department's own possession....196
8. Summary table: date, material transmitted, recipient, form of acknowledgment....196
C. Regulatory Petitions Submitted by the Soft Lights Foundation....196
1. Petitions to the FDA under the Electronic Product Radiation Control Program....196
2. Petition to report to Congress under 21 U.S.C. § 360jj(a)(2), submitted December 30, 2025....196
3. Petitions to NHTSA for non-compliance orders — 49 U.S.C. § 30162, 49 CFR part 552....198
4. Petition to NHTSA to limit vehicle headlamp intensity....200
5. Petition to NHTSA to limit correlated color temperature of vehicle headlamps....200
6. Petitions and notifications under 49 U.S.C. § 30118....200
7. Filings before the Federal Communications Commission....201
8. Petitions and proceedings before state regulatory bodies....201
9. Requests for agency interpretation and the interpretations issued....201
D. Litigation Brought by Mark Baker Individually Against the FDA....204
1. Baker v. FDA, No. 2:24-cv-00278-DC-SCR (E.D. Cal.) — filed January 22, 2024; voluntarily dismissed September 26, 2024....204
2. Baker v. FDA and NHTSA, No. 2:24-cv-02558-DC-SCR (E.D. Cal.) — the § 360ii(a)(6)(A) liaison duty; pending....204
3. Baker v. FDA, No. 2:26-cv-02776-DJC-CSK (E.D. Cal.) — FOIA action for CDRH records on LED visible light products....204
4. What the agency has and has not made available....205
E. Related Litigation and Administrative Proceedings Concerning LED Exposure....205
1. Federal actions concerning flashing LED devices in public rights-of-way....205
2. Proceedings concerning LED streetlights and area lighting....207
3. Proceedings concerning high-intensity LED deterrent lighting....208
4. Relevance of these proceedings to the Department's inquiry....208
F. Congressional Action [RFI Q5.n, Q17]....209
1. The FY2026 appropriations directive on low beam headlamp brightness....209
2. Why the enacted directive matters to the Department....209
3. The April 2026 House amendment directing study of LED headlamps....210
4. H.R. 7772, the LIGHT Safety Act, 119th Congress....210
5. Congressional correspondence and requests for inquiry....211
6. Implementation status: whether NHTSA has begun the directed report....212
G. Department of Energy Actions and the Federal Lamp Efficiency Framework....212
1. EISA 2007 and the statutory 45 lumens-per-watt backstop — 42 U.S.C. 6295(i)(6)....212
2. DOE general service lamp definition and standards rulemakings, 2017–2024....213
3. Effect: nationwide displacement of incandescent and halogen lamps by LED products....213
4. Lamp efficacy in lumens per watt is silent as to what the selected technology emits....214
5. No biological or health evaluation accompanied the transition....217
6. The liaison duty under § 360ii(a)(3) and (a)(6) was triggered and not discharged....217
7. DOE's NEPA determinations for the lamp rulemakings....218

8. Whether spectral and photometric characteristics are "performance characteristics" under 42 U.S.C. 6295(o)(4)....222
9. DOE testimony before the Senate Committee on Energy and Natural Resources, September 16, 2026....222
10. S. 1568 and H.R. 3341, the Liberating Incandescent Technology Act of 2025....222
11. Two rationales for reconsidering the lamp standards, and which this comment adopts....223
12. The Department of Energy's lighting research program, and the loop that was supposed to close....223
13. Significance for the Department's duties under § 360ii....225
H. The National Environmental Policy Act, and the Consequence of Absent Federal Evaluation....226
1. What NEPA requires, and what it does not....226
2. The present state of NEPA, stated accurately....226
3. Why NEPA cannot answer the question this comment raises....227
4. An environmental analysis is only as good as the authority it can cite....227
5. The review function of the Environmental Protection Agency....227
6. What the Foundation asks under this head, and what it does not....228
7. A note on this Department's own obligations....228
I. What the Record Establishes....228
1. Actual notice to the Department and to the FDA....228
2. Requests directed to the correct agency under the correct statutory authority....229
3. Congress has now spoken to the subject matter....229
4. Federal policy drove the exposure; no federal agency evaluated the emissions of the selected technology....229
5. No performance standard, study, or surveillance system has resulted....230
6. The agency's own records on the subject remain unavailable to the public....230
V. SCIENTIFIC RESEARCH....230
A. Methods, Sources, and Standard of Evidence [RFI Q4, Q12]....230
1. Literature selection and search strategy....231
2. Categories of evidence and how each is weighted....234
3. What is established, what is emerging, and what is unresolved....244
B. Physical Characteristics of LED Emission, and Their Departure from the Sources Under Which Human Vision Developed....247
1. Spectral power distribution of phosphor-converted white LEDs and the short-wavelength peak....249
2. Point-source geometry, peak luminance, and non-uniform emission....249
3. Correlated color temperature and its limits as a descriptor....256
4. Radiofrequency emissions from LED drivers and control circuits....272
5. The sources under which human visual and circadian physiology developed....273
6. Long-wavelength and infrared content....273
7. Temporal characteristics....278
8. Spatial characteristics....278
9. The progression of artificial sources, stated accurately....284
10. What follows from this, and what does not....285
C. Optical Radiation and the Human Eye....285

1. Retinal phototoxicity and photochemical injury 285
2. Blue-light hazard assessment — IEC 62471 and ANSI/IES RP-27 290
3. Disability glare, veiling luminance, and intraocular straylight 319
4. Discomfort glare and its measurement 323
5. Age, astigmatism, cataract, and intraocular lenses as modifiers 329
D. Temporal Light Modulation (Flicker) 331
1. Pulse-width modulation, modulation depth, and frequency 331
2. Stroboscopic effect and phantom-array effect 338
3. IEEE 1789-2015 recommended practices and their status 344
4. Flicker in vehicle lamps, warning beacons, and displays 348
5. Interference with clinical measurement 351
E. Neurological and Photosensitive Responses 353
1. Photosensitive epilepsy and flash-rate thresholds 354
2. Migraine and photophobia 355
3. Autism and sensory processing differences 358
4. Trigeminal and melanopsin-mediated pathways 360
5. Autonomic and acute stress responses 361
6. Deliberate induction of altered perception, and the frequencies at which it is done 362
7. Effects that outlast the exposure 363
F. Circadian Disruption and Melatonin Suppression 364
1. The 2010 analysis prepared for ASSIST 368
G. Affective and Psychological Response 369
1. Scope of this subsection 369
2. Light, circadian disruption, and mood — the established pathway 369
3. Discomfort, aversion, and the experience of glare 370
4. Sensory environments, distress, and sensory processing differences 370
5. What the incident reports describe [RFI Q3] 370
6. Reports of hopelessness and suicidal ideation 370
7. What is established, what is plausible, and what rests on report alone 371
H. Occupational and Educational Exposure Settings 371
I. Environmental and Ecological Effects [RFI Q14] 372
J. Exposure Assessment Methods and Their Limitations [RFI Q7, Q8] 421
1. Instruments and measurands currently available 422
2. Laboratory measurement versus real-world exposure conditions 423
3. Multi-emitter exposure, and the single-emitter design of the existing literature 423
4. Photometric reporting as a limitation of the existing literature 425
5. Expressing optical exposure in the units used for radiofrequency exposure 450
K. The Three Expert Assessments on Which Reliance Is Placed [RFI Q5] 451
1. The three documents identified 451
2. The chronology, and the authorship common to two of the three 452
3. The condition attached to the safety conclusion, and what the condition rests on 453

4. What the 2018 Opinion states it could not conclude....454
5. What the 2018 Opinion states that bears on a performance standard....455
6. Two statements in the Opinion that tell against the Foundation....456
7. What the three documents establish, and what they do not....457
8. A contribution of the 2018 Opinion to Part V.B.2....457
9. The predecessor opinions, and what they already stated....458
L. Research Gaps and Priorities [RFI Q16]....460
1. Multi-emitter and real-world exposure conditions....462
2. Radiometric characterization of products in common use....462
3. Response-specific weighting functions beyond the visual....462
4. Temporal characteristics below and above the flicker fusion threshold....462
5. Populations identified in Part VII as disproportionately affected....463
6. Longitudinal and cumulative exposure....463
M. Crime, Safety, and the Benefits Claimed for Outdoor Lighting....463
VI. PRODUCTS....485
A. Product Taxonomy and Exposure Characteristics....485
B. Motor Vehicle Lighting....486
1. Headlamps and high-intensity forward lighting....487
2. Adaptive driving beam systems....510
3. Daytime running lamps....512
4. Tail lamps, brake lamps, and turn signals....513
5. Aftermarket lamps and light bars....514
6. Automated vehicle lighting, and the question of technical feasibility....514
C. Emergency, Warning, and Flashing Lamps....516
1. Police, fire, and emergency medical service lamps....516
2. Rectangular rapid-flashing beacons and pedestrian crossing devices....527
3. School buses, utility vehicles, and work zones....528
D. Roadway, Area, and Parking Lighting....529
E. Interior Lighting in Schools, Workplaces, and Healthcare Settings....532
1. What the products are....533
2. Who is exposed, and under what conditions....533
3. What has been measured, and by whom....533
4. What federal requirement governs the optical output....535
5. What the Foundation asks as to this class....535
F. Retail and Commercial Interior Lighting....536
1. What the products are....536
2. Who is exposed, and under what conditions....536
3. The characteristics that distinguish this setting....536
4. What federal requirement governs the optical output....537
5. The limit of this Department's authority, stated plainly....537
6. What the Foundation asks as to this class....538

G. Consumer Lamps, Fixtures, and Household Products 538
1. The products this subsection reaches, and the code the Center has already assigned them 538
2. The indicator, and the characteristic nobody can obtain 539
3. The lamp 540
4. What the Foundation asks as to this class 540
H. Displays, Screens, and Personal Devices 540
I. Security and Deterrent Lighting Systems 541
1. What the products are 542
2. Who is exposed, and under what conditions 542
3. The product that has been measured, and how the measurement came to exist 542
4. The measurements 542
5. The measurements set against IEEE Std 1789-2015 543
6. The decision tree, and why it returns no answer 543
7. Why the gate that fails cannot simply be carried across 544
8. The other criteria, and what they do and do not reach 545
9. The spectrum, and the one place where every framework stops 546
10. What the Foundation does not claim from this report 546
11. What follows for this Department 547
J. Signage, Billboards, and Dynamic Message Displays 547
1. What the products are 547
2. Who is exposed, and under what conditions 547
3. Source size, and why distance does not resolve the problem 548
4. What a public health body found when it examined this class 548
5. The daytime comparison, and the condition of use 549
6. What federal requirement governs the optical output 551
7. A measured cost of attention capture, and the limits of what it shows 569
8. What the Foundation asks as to this class 575
K. Decorative, Architectural, and Entertainment Lighting 575
1. What the products are, and the two exposures they create 576
2. What is known 576
3. Why the class matters to this Department despite the voluntary character of the principal exposure 577
L. LED Products That Also Emit Radiofrequency Energy [RFI Q13] 578
1. Networked and wirelessly controlled luminaires 578
2. Smart-city and connected streetlight systems [RFI Q13.h] 579
3. Autonomous and driver-assistance vehicle systems [RFI Q13.i] 579
4. Conducted and radiated emissions from LED drivers 580
M. Products Intended for or Used by Children 581
1. Toys containing light-emitting diodes 581
2. Products given to children that are not toys 581
3. The federal standard that governs toys in the United States limits sound and does not limit light 582

4. What the Foundation asks for this class.....582
N. Lighting on Bicycles, Scooters and Personal Mobility Devices.....582
1. What the products are.....583
2. Who is exposed, and under what conditions.....583
3. The federal position, which is that there is none.....583
4. What the Foundation asks as to this class.....583
O. Aircraft, Drone, and Obstruction Lighting.....584
1. What the products are.....584
2. Who is exposed, and under what conditions.....584
3. The federal position.....584
4. What the Foundation asks as to this class.....585
P. Residential and Multifamily Exterior Lighting, and Light Trespass.....585
1. What the products are.....585
2. Who is exposed, and under what conditions.....585
3. The federal position, and why its absence has a different character here.....585
4. What the Foundation asks as to this class.....585
Q. Rail and Marine Lighting.....586
1. Locomotive lighting: the highest federal minimum the Foundation has found.....586
2. Marine navigation lights, and the same structure at a millionth of the output.....587
3. What the railroad regulator considered, declined, and later found.....588
4. Who is exposed, and what the Foundation asks.....589
R. Traffic Signals and Roadway Control Signals.....589
1. What the products are, and who is exposed.....590
2. What governs these products, and the difficulty of reading it.....590
3. What the instruments specify in the time domain, which is a schedule and not a shape.....591
4. The property that was lost, and the federal report that concedes the pattern for a different one.....591
5. What has actually been measured, and the limits of it.....592
6. What the Foundation asks as to this class.....593
S. Accent and Trim Lighting on Unattended Self-Service Equipment.....593
1. What the products are, and the code already proposed for them.....593
2. Saturated color, and why a photometrically modest emission is radiometrically concentrated.....593
3. Who is exposed, and the federal position.....594
4. What the Foundation asks as to this class.....594
T. Lighting on Robots and Mobile Autonomous Devices, Including Simulated Eyes and Faces.....595
1. What the products are, and the two emissions they carry.....595
2. The simulated face, which is a display designed to be looked at.....595
3. Who is exposed, and the federal position.....596
4. What the Foundation asks as to this class.....596
U. Regulatory Status by Product Class.....597
V. Tariff Classification and Import Screening of LED Products.....597

1. The Harmonized Tariff Schedule, and who writes it....597
2. How this Department uses the tariff schedule....598
3. The instruction of June 6, 2017, and the line it drew....598
4. The tariff number in that instruction designated a different article, and has since ceased to exist...599
VII. REPORTS OF HARM....600
A. The Soft Lights Foundation LED Incident Report Database [RFI Q3]....600
1. Method of collection and the submission form....600
2. Transmittal of the reports to the FDA and NHTSA, and the agencies' acknowledgments....601
3. Volume, date range, and geographic distribution....602
4. Self-identified condition categories recorded by reporters....603
5. What the database establishes, and what it does not....604
6. Screening of reports for personally identifiable and health information....605
B. Reported Effects, by Category [RFI Q3.c, Q3.d]....607
1. Ocular pain, glare, afterimage, and temporary loss of vision....607
2. Headache and migraine....608
3. Seizure and photosensitive response....609
4. Acute autonomic and panic responses....609
5. Sleep disruption....610
6. Cognitive effects, fatigue, and nausea....611
7. Reported radiofrequency interference from LED products....611
C. Reported Exposure Sources and Conditions [RFI Q3.a, Q3.b]....612
D. Reported Avoidance and Mitigation, and Its Effect [RFI Q3.f]....614
E. Reported Traffic Safety Consequences....615
1. Collisions and near-collisions attributed to glare....615
2. Pedestrian and cyclist incidents....615
3. Cessation of night driving....616
F. Reported Loss of Access to Public Accommodations, Employment, and Community Life....617
G. The Petition to Ban Blinding Headlights....618
H. Other Public Reporting Channels....618
1. NHTSA consumer complaint records....618
2. FDA reporting mechanisms and their treatment of these reports....620
3. Local government complaint records....620
I. These Reports Describe Accidental Radiation Occurrences Under 21 CFR 1000.3(a)....621
1. The regulatory definition — 21 C.F.R. § 1000.3(a)....621
2. Form FDA 3649 reports concerning LED light....622
3. What the agency is required to do with such a report....623
4. What the record shows was done....624
J. The Absence of Any Federal Surveillance System [RFI Q10]....625
1. Adverse event reporting [RFI Q10.f]....625
2. Disease and illness clusters [RFI Q10.g]....627

3. Occupational and environmental monitoring [RFI Q10.b, Q10.c] 628
K. Sensitive and Disproportionately Affected Populations [RFI Q11] 629
VIII. DISABILITY ACCESS AND THE ABSENCE OF A FEDERAL BASELINE 631
A. Why This Is Responsive to the RFI [RFI Q9, Q11] 631
B. The Federal Disability Framework 634
1. ADA Title II and the self-evaluation duty — 28 C.F.R. § 35.105 634
2. Section 504 of the Rehabilitation Act and the Department's own implementing regulations 635
3. The Department as a designated agency under Title II 636
4. The individualized inquiry duty, distinct from the systemic duty 636
5. Communication-specific duties — 28 C.F.R. §§ 35.160 to 35.164 637
6. ADA Title I, and the workplace as a place of exposure 638
7. The decisions that establish the duties relied on here 639
C. What a Self-Evaluation of an Emitting Product Would Require 640
1. Identifying the emitting products a public entity operates 640
2. Characterizing what each product emits 640
3. Identifying the populations affected 640
4. Evaluating alternatives and their emission characteristics 641
D. The Missing Federal Baseline 641
1. No performance standard exists for visible light emitted by LED products 641
2. No federal exposure guidance exists for optical radiation from general lighting 642
3. Public entities therefore have no federal referent for step 2 above 643
4. Where the accessibility framework does set an optical number, it sets a ceiling on the flash rate and a floor on the intensity 644
E. Consequences of the Gap 646
1. Every state and municipal entity must independently research the same question 646
2. Inconsistent and conflicting determinations across jurisdictions 647
3. Duplicated cost across thousands of public entities 647
4. Reliance on industry and trade guidance in place of a federal standard 648
5. The systemic duty defaults into the individualized one 649
6. One agency dismissed the question as outside its authority; another investigated the same city and found probable cause 650
F. Individual Requests for Accommodation 652
1. What individuals are told when they request accommodation 652
2. The burden of establishing harm shifted onto the requester 653
3. Whether the absence of a federal criterion is given as a stated basis for denial 654

4. Agencies outside the Department....671
5. Send an express written invitation to consult to each agency, and state which were sent....673
F. Require Disclosure of Emission Characteristics [RFI Q9]....677
1. To purchasers and specifiers....678
2. To state and local public entities conducting accessibility self-evaluations....678
3. To workers, schools, and healthcare providers....678
G. Develop a Classification System for Optical Radiation Exposure [RFI Q5.p]....679
1. Spectral characteristics....679
2. Spatial characteristics....679
3. Temporal characteristics....679

4. The effect families each class of characteristic bears upon....679
5. Why a criterion addressing one family alone is insufficient....680
6. Correspondence with the characteristics listed in Question 5....680
7. Assign product codes to the light-emitting diode product classes that have none, and amend Table 1 to 21 C.F.R. § 1002.1 accordingly....681
H. Reconstitute the Technical Electronic Product Radiation Safety Standards Committee....682
1. Fill the statutory membership and confirm the charter....682
2. Publish the Committee's proceedings as § 360kk(f) and 21 C.F.R. § 14.130 require....682
3. Refer visible light emitted by LED products to the Committee....683
4. Invite the Committee to exercise its authority to propose a standard....683
I. Prescribe a Performance Standard Under § 360kk [RFI Q5.n]....684
1. The order of operations, which the Foundation does not ask the Secretary to disturb....684
2. Why temporal light modulation is different from every other characteristic in this comment....684
3. What the Foundation asks the Secretary to consider prescribing....685
4. Technical achievability and practicability under section 360kk(a)(2)....688
5. What this subsection does not ask for, and why not....688
J. Make Recommendations Under § 360ii(b)(1), Without Waiting for a Standard....689
1. The authority is express, and it is not the standard-setting authority....690
2. What can be issued now, without new research....690
3. What must wait for the research, and should be acknowledged now....691
4. The limits of the instrument, stated by the Foundation....692
5. The labeling instrument, and the precedent the Department has already set....692
6. Why this is the least that could be asked....693
K. Conduct the § 360jj Studies and Report to Congress [RFI Q18]....693
1. What the Foundation asks, and the three things it does not ask....693
2. The provision is differently conditioned in its two halves, and the request tracks the difference....694
3. Why the study has never been performed for these products, which is a point about scope and not about staleness....694
4. What a report under this provision would do that no other request in this Part does....695
5. The pending petition, and the limit of what this comment asks about it....695
L. Address Sensitive Populations Expressly [RFI Q11]....696
M. Additional Matters for the Department's Consideration [RFI Q18]....697

INDEX TO RFI QUESTIONS

Cross-reference table: each question and subpart of the request for information to which this comment responds, the subsection that responds to it, and the page on which that subsection begins. Derived from the question tags carried on the subsection headings themselves, so that the table and the document cannot diverge.

The table lists the questions this comment answers, in the order the notice numbers them. A question answered in more than one place carries each reference, in document order. The subsection addresses are the primary reference and are stable; the page numbers are those of the pagination in which this document was last rendered and should be checked against the table of contents.

Two questions of the notice carry no entry below, and the Foundation identifies the fact rather than leaving it to be discovered. No subsection of this comment is tagged as responding to Question 1 or to Question 6. For Question 1 the Foundation understands the respondent identification at the front of this comment to be the response, and the omission to be one of tagging rather than of substance. For Question 6 the Foundation makes no such claim: it has not identified a subsection that answers it and states so here.

I. INTRODUCTION

A. Summary of Position

The Food and Drug Administration is the only federal agency Congress has authorized to control the radiation emitted by electronic products. That authority is conferred by part C of subchapter V of the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. §§ 360hh–360ss, enacted as the Radiation Control for Health and Safety Act of 1968, and is administered through the Center for Devices and Radiological Health. Section 360ii directs the Secretary to establish and carry out an electronic product radiation control program designed to protect the public health and safety from electronic product radiation, and specifies six things the Secretary shall do as part of that program.

Light emitted by a light-emitting diode is electronic product radiation. Section 360hh(1)(A) defines the term to mean "any ionizing or non-ionizing electromagnetic or particulate radiation" emitted from an electronic product as the result of the operation of an electronic circuit in such product. Visible light is non-ionizing electromagnetic radiation. An LED is an electronic product. Nothing in the statute distinguishes the visible portion of the spectrum from any other, and the agency has prescribed performance standards for light-emitting products before: 21 C.F.R. part 1040 is titled "Performance Standards for Light-Emitting Products" and includes, at § 1040.30, a standard for high-intensity mercury vapor discharge lamps — a general-illumination lamp.

The Foundation's position is that the program § 360ii requires is not being carried out as to LED products. The FDA maintains no program directed at the LED products that account for most human exposure to artificial optical radiation. There is no performance standard for LED vehicle headlamps, none for LED streetlights, none for the LED flashing warning beacons now mounted on emergency vehicles and at pedestrian crossings, and none for the LED lamps that replaced incandescent lighting in homes, schools, workplaces, and stores. So far as the public record discloses, the agency has published no study or evaluation of what these products emit or of the conditions under which people are exposed to them. It has not consulted the federal agencies whose own rules placed these products on the roads and in the public right of way. And it has received, and acknowledged receiving, more than six hundred reports of harm from members of the public without, so far as the record shows, acting on any of them.

There is a question the Department may fairly put to a submission of this kind, and the Foundation answers it at the outset. If this responsibility is the Food and Drug Administration's, why has no other federal agency said so?

They have. Between March 2022 and August 2023 the Foundation put the question to nine federal bodies: the National Transportation Safety Board, the Environmental Protection Agency, the Federal Highway Administration, the Consumer Product Safety Commission, the Federal Aviation Administration, the National Highway Traffic Safety Administration, the Department of Energy, the Occupational Safety and Health Administration, and the United States Access Board. Each answered that the subject was not within its authority. Several identified where the authority lies.

The Environmental Protection Agency wrote that Congress has granted it no statutory authority to regulate visible light or non-ionizing radiation emitted from electrical devices, and that it maintains no experts in the field. The Consumer Product Safety Commission wrote that it is barred by 15 U.S.C. § 2080 from regulating a risk of injury from electronic product radiation where that risk may be subjected to regulation under this chapter. The Federal Aviation Administration wrote that it would defer to the Food and Drug Administration for comfort, health and safety regulation of LED products. The Access Board wrote that the statute directs the Food and Drug Administration to establish and carry out the program, and that it would provide technical assistance to that agency on request. The National Highway Traffic Safety Administration wrote that it defers to health-focused agencies such as the Food and Drug Administration. The Occupational Safety and Health Administration said it was awaiting

notification from the Food and Drug Administration. Part II.H.21 sets out the record and Part IV.C the correspondence.

The Foundation does not contend that any of those agencies was wrong. Having examined each position, it believes each was right. That is what gives the record its significance. This is not a subject that fell between agencies because each supposed another was attending to it. It is a subject that Congress assigned to one agency; that every other agency asked about it has correctly said belongs to that agency; and that the agency has answered by stating that light-emitting diode products have a long history of safety with respect to the visible wavelengths they emit, and that a performance standard is therefore not necessary.

Those two propositions cannot both carry weight. A history of safety, where it has not been established by affirmative study, is an inference from an absence of reported harm. The absence of reported harm in this program is not a finding about these products. It is the predictable output of an arrangement in which the only incident reporting provision runs from manufacturers, upon their own suspicion, 21 C.F.R. § 1002.20; in which no channel exists through which an exposed person may report anything, and a request to this Department that one be created was not taken up; in which the emissions have never been measured and the conditions of exposure have never been characterized; and in which the statutory advisory committee has not met since 2016. Parts II.F, II.K, II.L and VII.J set out each of those. The proposition that closed the inquiry is produced by the inquiry never having been opened.

And because the deference of the other agencies is correct, nothing else in the federal government can open it. That is not a defect in any of those agencies. It is the statutory design operating as Congress built it, with one part not moving.

There is a second half to that section, and to this comment. Section 360ii(a) states what the Secretary shall do. Section 360ii(b) states what the Secretary may do in carrying it out, and among those powers is an express authority to make such recommendations relating to the hazards and control of electronic product radiation as he considers appropriate. Parts II.B and I.C.9.

The Foundation's attention in its correspondence, and Mr. Baker's in the litigation described at Part IV.D, has been on the duties, for a reason Part I.C.9 explains: a discretionary power is not something a court can order anyone to exercise. This proceeding is different in kind. The Department has asked the public what it should do, and in answer to that question the discretionary powers matter more than the duties, not less. They can be exercised now, they require no finding that anyone has been harmed, and exercising them concedes nothing about the past.

So the Foundation asks for two things that stand independently. It asks the Department to carry out the duties of § 360ii(a) as to these products, which Parts II through VIII show have not been carried out. And it asks the Department to exercise the powers of § 360ii(b) — to collect and publish what is known, and to make recommendations about products in ordinary use — which it may begin upon reading this comment. A household appliance with an indicator lamp that cannot be switched off is an electronic product emitting electronic product radiation into a bedroom through the night, and there is at present no federal recommendation of any kind addressed to it. Part IX.J.

One of those nine agencies requires a further word, and the Foundation gives it here rather than leave the Department to find it later. The Department of Energy, which answered that the subject was not within its authority, was at that time funding research into the physiological and emotional effects on human beings of the spectral content of indoor lighting. Part IV.G.12. There is no inconsistency in that and the Foundation alleges none: the question put to the agencies was one of regulatory authority, and the Department of Energy has none over what an electronic product emits. Funding research is not regulating. But the juxtaposition states this comment's thesis more economically than the Foundation can. The federal government is studying this subject. It is studying it in the one department that cannot act on what it finds, under a statute

whose purposes are efficiency and cost, and the department Congress charged with protecting the public from electronic product radiation is neither receiving that research nor conducting any of its own.

The Foundation submits this comment in that light. The Department has asked the public for scientific and technical information about exposure to electromagnetic radiation from products in ordinary use. The Foundation is answering, and the substance of its answer is that what is needed first is not a conclusion but a beginning: a measurement of what these products emit, a characterization of how people are exposed to them, and the publication of both. Nothing in this comment asks the Department to find that light-emitting diode products injure anyone. It asks the Department to make that question answerable, and it is addressed to this Department because there is no other body that can.

That is what this comment sets out. It is organized around § 360ii because § 360ii is the provision that assigns the duties and confers the powers, and because its subsections identify, one by one, what a functioning program would consist of and what is absent from this one. Part II takes each subsection in turn. Part III states the characteristics of emission and of exposure in which a boundary must be drawn if unnecessary radiation is to be minimized, and says of each whether a number can presently be stated. Part IV sets out the administrative and judicial record: what the agencies were told, when, by whom, and what followed. Parts V through VII supply the scientific literature, the product landscape, and the reports of harm. Part VIII describes what the absence of a federal emission criterion costs the state and local entities that must evaluate their own lighting. Part IX states what the Foundation asks the Department to do.

The United States has taken the position, in litigation, that these matters rest within the agency's discretion. The Foundation addresses that position directly at subsection C, because it is the threshold question and because the answer to it determines how much of the rest of this comment the Department can treat as optional.

B. The Electronic Product Radiation Control Program Is Defective as Applied to LED Products

1. The statutory duties of 21 U.S.C. § 360ii are mandatory and continuing

Section 360ii(a) provides that the Secretary "shall establish and carry out an electronic product radiation control program designed to protect the public health and safety from electronic product radiation," and that "[a]s a part of such program, he shall" do six things. The operative verb is the same for each:

> *(1) pursuant to section 360kk of this title, develop and administer performance standards for electronic products;*
>
> *(2) plan, conduct, coordinate, and support research, development, training, and operational activities to minimize the emissions of and the exposure of people to, unnecessary electronic product radiation;*
>
> *(3) maintain liaison with and receive information from other Federal and State departments and agencies with related interests, professional organizations, industry, industry and labor associations, and other organizations on present and future potential electronic product radiation;*
>
> *(4) study and evaluate emissions of, and conditions of exposure to, electronic product radiation and intense magnetic fields;*
>
> *(5) develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation; and*

> *(6) consult and maintain liaison with the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor, the Atomic Energy Commission, and other appropriate Federal departments and agencies on (A) techniques, equipment, and programs for testing and evaluating electronic product radiation, and (B) the development of performance standards pursuant to section 360kk of this title to control such radiation emissions.*

Two features of that text govern everything that follows. The first is that the duties are continuing rather than discharged once. A program that must be carried out, with research planned and conducted, liaison maintained, emissions studied, and procedures developed and tested, is not satisfied by work completed in the decade after enactment and not revisited. The products before the public change; the duty to study what they emit does not lapse because an earlier generation of products was studied.

The second is that only the first of the six refers outward to another section. Paragraph (a)(1) directs the Secretary to develop and administer performance standards "pursuant to section 360kk," and it is § 360kk(a)(1) that conditions a standard on the Secretary's determination that one is necessary. Paragraphs (a)(2) through (a)(6) contain no such condition. They are stated as obligations without qualification. That distinction is the subject of subsection C.

The section does not end with those six duties, and the Foundation brings forward what follows them because it answers in advance the objection most likely to be made to this comment. Subsection (b) is headed Powers of Secretary, and it opens by tying itself to the duties just quoted:

> *In carrying out the purposes of subsection (a), the Secretary is authorized to—*
>
> *(1)(A) collect and make available, through publications and other appropriate means, the results of, and other information concerning, research and studies relating to the nature and extent of the hazards and control of electronic product radiation; and*
>
> > *(B) make such recommendations relating to such hazards and control as he considers appropriate;*
>
> *(2) make grants to public and private agencies, organizations, and institutions, and to individuals for the purposes stated in paragraphs (2), (4), and (5) of subsection (a) of this section;*
>
> *(3) contract with public or private agencies, institutions, and organizations, and with individuals, without regard to section 3324 of title 31 and section 6101 of title 41; and*
>
> *(4) procure (by negotiation or otherwise) electronic products for research and testing purposes, and sell or otherwise dispose of such products.*

A word about how that provision is set out above. In the United States Code, and in the commercial renderings of it, subparagraphs (A) and (B) of paragraph (1) are run together: (A) is given its own line and (B) is picked up inline after the semicolon that closes it, rather than being set on a line of its own as the paragraphs of subsection (a) are. The Foundation has separated them above for legibility and has altered no word of the text. It notes the point because subparagraph (B) is the provision on which the request at Part IX.J rests, and because a reader working from the printed section can pass over it without seeing that a distinct authority is conferred there.

The Foundation states at once what it does not argue. Subsection (b) is permissive. Its verb is is authorized to, not shall, and paragraph (1)(B) adds as he considers appropriate, which is the plainest grant of judgment in the section. The Foundation does not contend that the Secretary has violated subsection (b), and nothing in this comment should be read as making that contention.

Two things follow nonetheless, and they matter to everything after this point.

The first is a point of construction. Congress wrote both kinds of provision into one section. Subsection (a) says the Secretary shall do six things. Subsection (b) says the Secretary is authorized to do four others, one of them as he considers appropriate. The United States has taken the position in litigation that the matters in subsection (a) rest within the agency's discretion. Part I.C. Subsection (b) shows what the discretionary provisions of this section look like when Congress writes one. It wrote four of them, immediately after the six, in the same section, using different words. The contrast is not incidental drafting.

The second is the more practical. Subsection (b) is the list of means, supplied expressly for carrying out the purposes of subsection (a). Set the two columns against each other and every duty this comment describes as unperformed has a matching instrument that Congress provided:

For the research directed by (a)(2), the Secretary may make grants, (b)(2), and contract, (b)(3), the latter expressly freed from the ordinary advertising and payment requirements of 31 U.S.C. § 3324 and 41 U.S.C. § 6101.

For the study and evaluation of emissions and conditions of exposure directed by (a)(4) — the measurement whose absence is the subject of Part II.F — the Secretary may procure electronic products for research and testing purposes, (b)(4). Congress anticipated that carrying out this program would require buying the products and measuring them, and said so.

For the procedures and techniques for minimizing exposure directed by (a)(5), the Secretary may make recommendations relating to the hazards and control of electronic product radiation, (b)(1)(B). Part IX.J.

And for all of it, the Secretary may collect and make available, through publications and other appropriate means, the results of research and studies relating to the nature and extent of the hazards and control of electronic product radiation, (b)(1)(A). Part IV.G.12 describes federally funded research on this subject that no one has collected or made available.

The consequence is narrow and the Foundation puts it narrowly. Whatever may be said about why the duties of subsection (a) have not been discharged as to light-emitting diode products, it cannot be said that the Secretary lacked the authority, the funding mechanism, the contracting flexibility, the means of obtaining the products, or an instrument for publishing the result. Congress enumerated all five, in the same section, for the express purpose of carrying out those duties.

2. Those duties have not been discharged for visible light emitted by LED products

Part II takes each subsection against the record. In summary: no performance standard under § 360kk governs the visible light emitted by any LED product; the Foundation has located no published study or evaluation by the agency of LED optical emissions or of the conditions of exposure to them; no liaison or consultation with the federal agencies whose rules govern these products appears in the public record; and no procedure or technique for minimizing exposure has been developed, tested, or evaluated. Part IV sets out what the agency was told and what it did in response.

3. Those duties have not been discharged for radiofrequency energy emitted by LED products

This comment concerns visible light, but the two are not cleanly separable in the products themselves. LED drivers and the switching circuits that dim and modulate them emit radiofrequency energy, as do the networked controls now built into streetlights, luminaires, and architectural systems. Those emissions are electronic product radiation under the same definition. Part VI.L identifies the product classes in which visible and radiofrequency emission occur together, and Part II.H.8 addresses the division of responsibility between the FDA and the Federal Communications Commission.

C. The Limits of the Agency's Discretion, and the Forum for This Question

Whether these duties are discretionary has been litigated, and the answer the United States gave is more useful to the Department than any argument the Foundation could make about it. The Foundation sets that record out here, quotes it rather than characterizing it, and takes no position in this comment on how the pending case should be decided.

1. The proceeding

In Baker v. United States Food and Drug Administration, No. 2:24-cv-02558-DC-SCR (E.D. Cal.), Mr. Baker sought an order directing the FDA and NHTSA to establish and maintain the liaison required by 21 U.S.C. § 360ii(a)(6)(A) as to LED vehicle headlamps. The magistrate judge issued findings and recommendations on September 16, 2025 recommending dismissal. Objections were filed September 23, 2025, and the government's opposition was filed November 28, 2025. The matter is pending before the district judge. Part IV.D.2 sets out the history.

2. The United States does not contend that the duties are discretionary

It contends the opposite. The findings quote the government's own formulation:

> *"[w]hile Plaintiff is correct that the statute contains a "non-discretionary" requirement, he is mistaken about the nature and scope of that requirement."*

And in its opposition brief the government states that the program exists and has been established:

> *"FDA has complied with the statute and established such a program. See 21 C.F.R. §§ 1000.1–1040.30."*

3. The government says the dispute is a policy assessment

Responding to the contention that the radiation control program is defective, improperly designed, and not adequately functioning, the United States answered:

> *"But this is a policy assessment, not an allegation that FDA "failed to take a discrete agency action.""*

In the posture of a motion to dismiss under 5 U.S.C. § 706(1), that answer is directed at justiciability. The Foundation does not dispute the characterization. It accepts it, and draws the consequence the characterization carries: a policy assessment of an existing federal program is what a request for information is for, and this comment is that assessment, submitted to the Department that administers the program rather than to a court asked to supervise it.

4. The government says no decisionmaking process has occurred

Arguing that any arbitrary-and-capricious claim would fail for want of final agency action, the United States stated that "there has been no "decisionmaking process," much less a "consummation of the agency's decisionmaking process,"" as to consultation with NHTSA on testing and evaluating visible light emitted by LED vehicle headlamps.

In court that proposition defeats review. Before the Department it establishes something different and more immediately useful: the question is open. No position has been taken that this comment asks the Department to reverse, and nothing in the record forecloses the Department from considering the matter now.

5. Where the statute confers judgment, and where it does not

The Foundation states this precisely rather than broadly, because the government has identified the textual hooks and the comment gains nothing by ignoring them.

Paragraph (a)(6) directs consultation and liaison with four named officers — the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor, and the Atomic Energy Commission

— and with "other appropriate Federal departments and agencies." The government reads the word appropriate as conferring judgment over which additional agencies are consulted, and that reading is available on the text. It does not extend to the four named officers, as to whom the direction is unqualified. Paragraph (a)(2) directs research to minimize "unnecessary" electronic product radiation, which likewise imports judgment about what is unnecessary.

Paragraphs (a)(3), (a)(4), and (a)(5) contain no comparable qualifier. The Secretary shall maintain liaison with and receive information from other departments, professional organizations, industry, and other organizations on present and future potential electronic product radiation. The Secretary shall study and evaluate emissions of, and conditions of exposure to, electronic product radiation. The Secretary shall develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure. Nothing in those three paragraphs makes the obligation turn on a prior determination of necessity or appropriateness.

6. The agency has made a determination, and its basis has not been disclosed

The Foundation does not contend that the FDA has never addressed these products. Between June 13, 2022 and September 11, 2023 the Foundation submitted four petitions, directed respectively to LED products generally, LED flashing lights, LED vehicle headlamps, and LED streetlights. On May 24, 2024 the FDA denied all four in a single nineteen-page response letter.

The stated grounds include that performance standards for every type of electronic product are not necessary "given the effectiveness of existing mitigations in addressing unnecessary radiation and alternative approaches to protect public health"; that standards for LEDs are not necessary "due to their long history of safety with respect to the visible wavelengths being emitted"; and that the evidence supplied was insufficient.

The letter states that the FDA "engaged an independent, third-party organization to conduct a comprehensive literature search and systematic review to identify the current state of knowledge with regard to adverse health effects of LED light on humans." That organization has not been identified. The literature search and systematic review have not been published. On the Foundation's information they were not produced in response to a request under the Freedom of Information Act; the response letter was the only document released.

7. The reasons given are empirical propositions, and this comment tests them

Two of the three stated grounds are factual claims rather than exercises of judgment. Whether LED products have a long history of safety with respect to the visible wavelengths they emit is a question the published literature addresses. Whether the evidence supplied was insufficient depends on what evidence existed then and what exists now. Part V sets out the literature. Part VII sets out the reports received since. The Foundation offers both so that the determination can be revisited against a record.

A claim of safety presupposes a limit, and no limit exists

One feature of the proposition can be stated without reference to the literature at all, because it concerns the form of the claim rather than its truth.

A claim of safety is a relation between two terms. To say that a product is safe with respect to an emission is to say that the emission falls below some level at which harm occurs. Without the second term the claim has no content. For the visible wavelengths emitted by light-emitting diode products the Department has never established the second term. There is no federal limit on the radiance of a visible-light emitter, none on its irradiance, none on the luminance of its emitting surface, and none on its spectral distribution. Part II.E.4 sets out what the agency does have, which is the recognition of an international standard confined to thirteen medical device product codes under 21 C.F.R. § 878.4810. For a general service lamp, a vehicle lamp, a video display or a deterrent strobe there is no number.

It follows that the determination of May 24, 2024 does not report that the emissions of these products fall below a level the agency identified. It reports that harm has not been observed. Those are different statements and only the first is a safety finding of the kind § 360kk(a)(1) contemplates. A product class cannot have a history of compliance with a limit that has never been set.

The agency's own choice of words locates the difficulty precisely, and the Foundation relies on the sentence as written rather than on any paraphrase of it. The letter does not assert that these products are safe. It asserts a long history of safety with respect to the visible wavelengths being emitted. The qualifying phrase puts the spectrum in issue, and the Foundation takes the agency at its word and asks the question that follows: by what spectral measurement, and against what spectral limit, was that assessed? No federal instrument imposes a limit on the spectral distribution of a visible-light emitter. No federal instrument requires that the spectral distribution be disclosed to a purchaser, to a procuring municipality or to this Department. The one spectral descriptor that does appear on the package and in procurement specifications is correlated color temperature, and Part V.B.3 sets out why it does not answer the question. The quantity the agency's sentence names is the quantity about which the regulatory record is silent.

Whether that silence is consequential is an empirical question, and Part V.B.3 reports a study that bears on it. In that study two lamps of the same manufacturer and the same part number, differing only in spectral distribution, produced measurably different biological responses at matched illuminance; and two lamps of identical correlated color temperature, differing in the structure of their spectra, also produced different responses. The Foundation does not offer that study as proof of harm in ordinary use and says so at Appendix C.70. It offers it for a narrower proposition: the magnitude of the response depended on the one emission characteristic that the agency's sentence names and that no federal instrument measures, limits or requires anyone to disclose.

The Foundation states the conclusion it draws, because it is narrower than the one the agency may expect. The Foundation does not ask the Department to find that light-emitting diode products are unsafe, and does not characterize them that way. What it asks is that the Department supply the missing term. The question before the agency is not whether these products are safe or unsafe in the abstract. It is at what emission level, and with what spectral composition, a product of this kind ceases to be safe. That is a question about where a number should be set, it cannot be answered without the measurement § 360ii(a)(4) directs, and the statute assigns it to the Secretary and to no one else.

What the indexed literature contained six years before the determination

Line (3) of the Foundation's objection asks what the asserted history is a history of. A related question is what was available to be read, and when. The determination issued on May 24, 2024. Appendix C.73 records a review published in an indexed ophthalmology journal in December 2018, five and a half years earlier, and the Foundation offers it for a single purpose: to establish what a reader of the ordinary literature would have encountered before the determination was made.

That review identified the cornea, the lens, the retina, the retinal ganglion cell and the blood-retinal barrier as tissues on which blue light acts; named mitochondria as the principal target of the oxidative mechanism; placed the most injurious waveband between 415 and 455 nanometers, which brackets the 445 nanometer peak of the weighting function discussed at Part V.C.2.a; and set out the oxidative, inflammatory and apoptotic pathways by which each tissue was said to be affected. Appendix C.73 scores those claims against the literature assembled since, and reports that the review was substantially right about targets and mechanisms and was not vindicated on disease causation in humans. The Foundation does not rely on the review for any proposition about harm.

What the Foundation relies on is one sentence in it, which concerns the state of the evidence rather than the state of the eye. Writing in 2018, the authors observed that research showing minimal risk from ordinary digital displays was a conclusion about short-term exposure only, and that measurement after long-term exposure remained necessary. That is the same gap the comment identifies at Part V.C.2.c, where the assessment framework stops accumulating dose at ten thousand seconds, and at Part V.K, where the exposure limits are shown to have been constructed for a single eight-hour day. Practising ophthalmologists writing in a journal indexed in the National Library of Medicine had identified it in 2018.

The Foundation draws the narrow conclusion and no wider one. It does not contend that the Center for Devices and Radiological Health read this review, and it does not suggest that a single review in a specialty journal obliged the agency to reach any particular conclusion. The contention is about the state of the literature rather than about anyone's reading of it. A determination that these products have a long history of safety with respect to the visible wavelengths they emit was made at a time when the indexed ophthalmology literature contained reviews identifying five ocular tissues as targets, naming an organelle and a waveband, and stating in terms that the reassuring findings about displays covered short-term exposure only. Whether the agency was aware of that literature is a question only the agency can answer, and Part IX.B.4 asks it.

The same question, in this Department's own journal, ten years before the determination

The preceding paragraphs concern a review in a specialty journal. There is a stronger instance and the Foundation sets it out separately, because the journal is published by a component of this Department.

In March 2014, Environmental Health Perspectives, the journal of the National Institute of Environmental Health Sciences, published a study entitled "White light-emitting diodes (LEDs) at domestic lighting levels and retinal injury in a rat model." Appendix C.77 records it in full. Part II.E.6 already relies on a different article in the same journal for a different purpose, so the standing of the publication is established elsewhere in this comment. Four features of this one bear on the determination of May 24, 2024.

- The exposure was characterized as domestic. The authors measured 750 lux at the animals, a level they describe as the common domestic level, and framed the study expressly against the earlier literature, noting that chronic exposure at 2,000 to 10,000 lux had been found to cause injury but that relatively low intensity had not previously been assessed with light-emitting diodes in a rodent model.
- The comparison was against the source the technology displaced, at matched correlated color temperature. A phosphor-converted white diode at 6,500 kelvin was compared with a compact fluorescent lamp at 6,500 kelvin, at the same illuminance. The authors report serious retinal injury in the diode groups and moderate to mild injury in the fluorescent groups.
- One of the five authors is a member of the Scientific Expert Group of the International Commission on Non-Ionizing Radiation Protection, the body whose exposure limits Part V.C.2 examines.
- The authors made a recommendation. Their concluding sentence is: "we suggest a precautionary approach with regard to the use of blue-rich "white" LEDs for general lighting."

The Foundation draws no conclusion about anyone's state of knowledge and makes no allegation. It states a chronology. In December 2013 a study was accepted, and in March 2014 published, in a journal of this Department, finding retinal injury in a rodent model at an exposure its authors characterized as domestic, finding that injury greater than from the lamp the technology replaced at matched color temperature, and recommending a precautionary approach to the general

lighting application. Ten years and two months later the Center for Devices and Radiological Health determined that light-emitting diode products have a long history of safety with respect to the visible wavelengths they emit and that a performance standard was not necessary. Part IX.B.4 asks the Department to state the basis of that determination. The Foundation asks, as part of that request, whether this study was among the material considered.

One further sentence from the same paper belongs here, because it concerns sequence rather than substance. Writing in 2014, the authors said that retinal light injury and the risks of chronic exposure from domestic light-emitting diode lighting required assessment before further development of the technology. Part IV.G sets out what happened instead: the conversion of American general illumination to light-emitting diodes proceeded, under federal efficiency rules described at Part II.G, without the assessment. The Foundation does not say the two are connected by anyone's decision. It says the assessment the authors called for in this Department's journal has still not been performed, which is the request this comment makes.

8. The discretion in § 360kk(a)(1) is downstream of the duty in § 360ii(a)(4)

Section 360kk(a)(1) directs the Secretary to prescribe performance standards "if he determines that such standards are necessary for the protection of the public health and safety." The conditional clause is there and the Foundation does not read it away. But a determination of necessity is a factual judgment that cannot be made without knowing what the product emits and under what conditions people are exposed to it, and those are the subjects § 360ii(a)(4) directs the Secretary to study and evaluate without qualification. A conclusion that LED products have a long history of safety is a finding about emissions and exposure. If it was reached by commissioning an unnamed contractor rather than through the study the statute assigns to the Secretary, and the contractor's work has not been published, the predicate for the determination is not in the record at all.

9. The powers conferred by § 360ii(b), and why this proceeding is where they are properly raised

The preceding subsections concern the duties of § 360ii(a) and the limits of the judgment the statute commits to the Secretary within them. This subsection concerns the rest of the section, and it changes what this comment is asking for.

Subsection 360ii(b) confers four powers on the Secretary, for the express purpose of carrying out subsection (a). Part II.B sets them out. They are the authority to collect and publish the results of research on the hazards and control of electronic product radiation; the authority to make such recommendations relating to those hazards and that control as he considers appropriate; the authority to make grants for the research subsection (a) directs; and the authority to procure electronic products for research and testing. Each is discretionary in terms. The subsection says the Secretary is authorized to, not that he shall, and the recommendation power adds as he considers appropriate, which is the plainest grant of judgment in the section.

The Foundation has not pressed these provisions before, and the reason is worth stating because it explains why they appear now. In litigation to compel agency action unlawfully withheld, a court may order only action that is both discrete and legally required. A power conferred in the terms of subsection (b) is the paradigm of what a court cannot order. A litigant who asked a court to direct the Secretary to exercise a discretion would be asking for something no court could give, and the Foundation has accordingly confined its correspondence to the duties, as has Mr. Baker in the litigation described at Part IV.D.

This proceeding is not litigation. The Department has asked the public what it should do. In a forum of that kind the discretionary powers are not the weaker half of the section. They are the more useful half, for three reasons.

They are available now. A recommendation under § 360ii(b)(1)(B) requires no rulemaking, no determination of necessity under § 360kk(a)(1), and no predicate at all beyond the

Secretary considering it appropriate. Everything else this comment requests takes years. This does not.

They cannot be met by the observation that the Department has discretion. That observation is the premise of the request rather than an answer to it. The Foundation is not disputing the discretion conferred by subsection (b); it is submitting how the discretion should be exercised, which is what the Department asked the public to do.

Exercising them concedes nothing. The Department may publish research under (b)(1)(A) or make a recommendation under (b)(1)(B) without accepting any proposition in Part II about what subsection (a) required, without reopening the determination of May 24, 2024, and without taking any position in the pending litigation. The Foundation says so plainly because it wants these requests granted, not won.

The Foundation therefore divides what it asks, and asks the Department to read the comment accordingly. Where subsection (a) imposes a duty, the comment says so and says why. Where subsection (b) confers a power, the comment asks that it be exercised and says what for. The two do not depend on one another. If the Department rejects every proposition this comment advances about subsection (a), the requests resting on subsection (b) remain available and the reasons for them are untouched.

One further observation belongs here, about what a program looks like when it is working. A performance standard is the terminal instrument of the electronic product radiation control program and it is rightly hard to reach. But a program consists of more than its terminal instrument. An electronic product radiation control program that is functioning collects the research and publishes it, tells purchasers and specifiers what is known and what is not, and makes recommendations about products in ordinary use — continuously, and without waiting for the evidence that would support a binding rule. Congress provided for all of that in subsection (b). For products emitting visible light, the Foundation has found no instance of any of it.

A note on the scope of the authority, which the Foundation does not overstate

Because this comment concerns what is commonly called light pollution, the Foundation states precisely what Congress conferred and what it did not. Congress did not give this Department authority over light pollution as an ambient environmental condition. It gave authority over radiation emitted from electronic products, and over the exposure of people to that radiation. What is called light pollution is, in the respects this comment concerns, the aggregate of emissions from products that fall within that authority, and Part II.D.3 sets out why the Foundation approaches it through the products rather than through the ambient condition.

The distinction is not a concession and the Foundation presses it for a practical reason. A request framed as asking the Department to regulate light pollution could be answered, correctly, by observing that no such authority exists. A request framed as asking the Department to exercise, over the products that emit the light, the authority Congress gave it over electronic product radiation cannot be answered that way. The Foundation asks the Department to understand every reference to light pollution in this comment in the second sense.

10. What the Foundation asks the Department to accept, and what it does not

The Foundation does not ask the Department to concede that it is legally compelled to prescribe a performance standard for any LED product, and does not ask it to take any position on the pending litigation. It asks the Department to accept five propositions, each supported in the Parts that follow: that visible light emitted by LED products is electronic product radiation within the agency's authority; that the duties in § 360ii(a)(3), (a)(4), and (a)(5) are unqualified, as the text shows and the United States has not disputed; that the evidentiary basis for the May 24, 2024 determination has not been disclosed and should be; that the reports of harm the agency has received and acknowledged are information of the kind § 360ii(a)(3) directs it to receive and § 360ii(a)(4) directs it to evaluate; and that § 360ii(b) confers powers, among them an express

authority to make recommendations, which may be exercised now, which require no finding that any person has been harmed, and which the Department has not exercised for any product emitting visible light.

D. This Request for Information Invokes the Electronic Product Radiation Control Authority

The RFI states that the Department is conducting it "under 21 CFR subpart J." The Electronic Product Radiation Control regulations are codified at 21 C.F.R. chapter I, subchapter J, parts 1000 through 1040, issued under 21 U.S.C. §§ 360hh–360ss. The Foundation reads the reference as invoking that subchapter.

That matters for two reasons. It identifies the authority under which the Department is gathering this record as the same authority that governs LED products. And it means the Department has chosen, in framing this inquiry, the one statutory program that reaches the emissions this comment concerns.

The Department need not reach that reading on the Foundation's say-so, because the agency has already placed visible light from light-emitting diode products inside the program itself.

In its Final Response of May 24, 2024, disposing of four citizen petitions concerning visible light emitted by LED products, the Center for Devices and Radiological Health did not decline on the ground that the subject lay outside the electronic product radiation control authority. It accepted that LED products emit electronic product radiation, and declined on a different ground: that a performance standard has not historically been considered necessary. The letter states that "historically FDA has not considered performance standards to control the radiation from LEDs in the visible wavelengths to be necessary for the protection of the public health and safety."

That sentence concedes the jurisdictional question and rests the disposition on a judgment about necessity. The Foundation takes the concession as given and addresses the judgment, which is where the disagreement actually lies.

The consequence for this proceeding is narrow and it is important. If the Department is gathering a record under subchapter J, and if the agency administering subchapter J has already acknowledged that the emissions at issue are within it, then a comment about visible light from LED products is not a comment about an adjacent subject. It is a comment about the program the notice names.

E. Visible Light Is Within the Scope of This Request for Information

The RFI is addressed principally to radiofrequency and wireless exposure, and most of its questions are framed in those terms. Its own definition of its subject is broader. The notice states that the Department seeks information on electromagnetic field emissions and exposure, "particularly RF and wireless," and defines its subject as "RF radiation and other forms of non-ionizing electromagnetic (EMF) exposure."

Visible light is a form of non-ionizing electromagnetic radiation. It falls within the subject the notice defines, and within the statutory definition at 21 U.S.C. § 360hh(1)(A), which draws no distinction among regions of the non-ionizing spectrum. The word "particularly" identifies an emphasis, not a limit.

Three further points place the subject inside this proceeding, and the Foundation states them in ascending order of weight.

First, the governing statute draws no line within the non-ionizing spectrum. Electronic product radiation is defined at 21 U.S.C. § 360hh(1)(A) as "any ionizing or non-ionizing electromagnetic or particulate radiation" emitted from an electronic product as the result of the operation of an electronic circuit in that product. Visible light emitted by a light-emitting diode is non-ionizing

electromagnetic radiation produced by the operation of an electronic circuit. It is within the definition on the definition's own terms, and no provision of the subchapter narrows it to radiofrequency.

Second, the agency charged with administering that subchapter has treated visible light from LED products as falling within it. The Center for Devices and Radiological Health accepted four citizen petitions on precisely this subject, docketed them, conducted a literature review, and issued a Final Response on the merits. An agency does not adjudicate the necessity of a performance standard for a class of radiation it regards as outside its authority.

Third, the subchapter already contains a performance standard for a light-emitting product. Part 1040 is titled Performance Standards for Light-Emitting Products, and § 1040.30 prescribes a standard for high-intensity mercury vapor discharge lamps. The question before the Department is therefore not whether light-emitting products can be the subject of this program. It is why one lighting technology was made the subject of a standard and its successor has not been.

The Foundation does not overstate the point. This request for information is plainly directed at radiofrequency and wireless exposure; most of its questions are framed in those terms, and the Foundation does not suggest otherwise. What it submits is narrower: that the notice defines its own subject as non-ionizing electromagnetic radiation, that the word "particularly" marks an emphasis rather than a boundary, and that a comment on another region of that spectrum is responsive to the notice as the notice is written. If the Department takes a different view of scope, the Foundation asks that it say so, so that the material in this comment can be directed to the proceeding where it belongs.

1. Questions framed in radiofrequency terms, and how this comment answers them

Several questions use terms specific to radiofrequency exposure — specific absorption rate, power density, beamforming, antenna density. Where a question has a direct analogue in optical radiation, this comment answers it in the corresponding optical terms and says which substitution it has made. Where a question has no optical analogue, this comment says so rather than straining the terminology. Subsection G supplies the bridge between the two vocabularies.

F. Scope and Organization of This Comment

This comment concerns visible light emitted by LED products, and treats radiofrequency emission from those same products where the two occur together. It does not address radiofrequency exposure from wireless communication infrastructure except where that subject bears on the division of responsibility among federal agencies.

The Parts that follow are organized as follows.

Part II sets out the six duties of 21 U.S.C. § 360ii(a), distinguishes those qualified by a standard of judgment from those that are not, sets out the four powers conferred by § 360ii(b) and the instruments they supply for carrying those duties out, and examines § 360jj, under which the Secretary is to study electronic product radiation and report to Congress.

Part IV states the litigation, the regulatory petitions and the congressional action bearing on this subject, as a chronology, together with the Foundation's transmittal of reports of harm to the Center for Devices and Radiological Health and the agency's acknowledgment of receipt.

Part V reviews the scientific literature on the physical characteristics of LED emission and on the photobiological, hormonal, neurological and psychological effects reported from exposure, and identifies what is established, what is plausible and unstudied, and what rests on report alone.

Part VI describes the product classes at issue — headlamps, street lighting, flashing warning devices, interior and commercial lighting, displays, and security and deterrent systems — and the exposure conditions each produces.

Part VII presents the reports of harm, including the LED Incident Reports submitted to the Center for Devices and Radiological Health, and addresses whether those reports describe accidental radiation occurrences within 21 C.F.R. § 1000.3(a).

Part VIII addresses disability access, the self-evaluation obligation of 28 C.F.R. § 35.105, and the consequence for state and local entities of the absence of any federal performance standard against which to evaluate these products.

Part IX sets out the Foundation's requests to the Department, each tied to the statutory provision that supports it and to the question in the notice to which it responds.

Part X is the conclusion.

Appendices A through F contain the complete record of LED Incident Reports, the complete record of comments and signatures submitted to the headlamp petition, a bibliography, a list of the standards referred to, a chronology, and an index of hyperlinks.

G. Terminology, Units, and Measurement Conventions

The questions in this RFI are framed in the vocabulary of radiofrequency exposure. The subject of this comment is optical radiation, which has its own vocabulary. The two describe the same physics and in several instances the same quantity under a different name. This subsection sets the terms side by side so that a reader whose frame of reference is RF can follow Parts V and VI without translating as he goes.

Optical quantity and unit	What it measures	Counterpart in the vocabulary of this RFI
Wavelength, nanometers (nm)	Position within the electromagnetic spectrum.	Operating frequency. The same property expressed reciprocally: wavelength equals the speed of light divided by frequency. Visible light occupies roughly 380 to 780 nm.
Spectral power distribution	Radiant power as a function of wavelength across the emitted band.	Emission spectrum; operating frequency and bandwidth.
Irradiance, watts per square meter (W/m^2)	Radiant power arriving per unit area at a surface.	Power density, W/m^2. Not an analogy: the same quantity, in the same unit, differing only in the part of the spectrum measured.
Radiance, W/m^2 per steradian	Radiant power per unit area of source per unit solid angle — the physical basis of what is perceived as brightness.	No single counterpart. The nearest equivalent is power density referred to the emitting aperture rather than to the exposed surface.
Luminance, candela per square meter (cd/m^2)	Radiance weighted by the photopic luminous efficiency function, which describes the response of the human eye across wavelength.	A biologically weighted exposure quantity, standing to radiance as SAR stands to incident power density.
Illuminance, lux	Irradiance weighted by the same efficiency function; light arriving at a surface as the eye responds to it.	Power density adjusted for biological response.
Luminous intensity, candela (cd)	Luminous power emitted per unit solid angle in a given direction.	Effective isotropic radiated power; antenna gain and beamforming. Both describe concentration of emission into a direction rather than total output.

Optical quantity and unit	What it measures	Counterpart in the vocabulary of this RFI
Correlated color temperature, kelvin (K)	A single number describing the overall appearance of a source by reference to a blackbody radiator.	No counterpart, and the comment should say so. CCT is a descriptor of appearance, not of spectral content; two sources of identical CCT may differ substantially in short-wavelength output. It should not be used as a proxy for blue content.
Blue light hazard weighted radiance, W/m^2 per steradian	Radiance weighted by the blue light hazard function, which describes the wavelength dependence of photochemical injury to the retina.	Specific absorption rate. Both weight an exposure by the mechanism of biological effect rather than by raw emitted power, and both exist because unweighted power is a poor predictor of harm.
Percent flicker, or modulation depth	The difference between maximum and minimum output over a cycle, as a proportion of the sum.	Modulation characteristics.
Flicker index	The proportion of the waveform lying above its own mean; sensitive to waveform shape as percent flicker is not.	Modulation characteristics; waveform.
Pulse-width modulation frequency, hertz (Hz)	Repetition rate at which a driver switches the emitter on and off.	Pulse repetition frequency.
Duty cycle, percent	Proportion of each period during which the emitter is on.	Duty cycle. The same term with the same meaning.
Exposure duration and angular subtense	How long exposure persists, and the angle the source subtends at the eye — which determines the retinal area over which energy is deposited.	Duration of exposure; distance from the source and proximity to the body.
Cumulative exposure	Total dose accrued across repeated exposures over time.	Cumulative exposure over time.
Number and arrangement of emitters	How many separate sources are present in the field of view, their angular separation, whether their outputs are synchronized, and the composite waveform and summed irradiance they produce at the eye.	Antenna density; cumulative neighborhood exposure; simultaneous exposure to multiple sources. Question 15 asks for evidence on exactly these characteristics in the wireless context.

Why this comment reports radiometric quantities wherever it can.

The photometric quantities in the left-hand column — luminance, illuminance, luminous intensity, lumens — are the units in which lighting is ordinarily specified, procured, and regulated. They are also the units in which the Foundation and most of the public discuss this subject, and much of the literature in Part V reports them. They are not, however, measures of emitted energy. Every one of them is a radiometric quantity multiplied by the photopic luminous efficiency function, the CIE curve conventionally written $V(\lambda)$, which describes the relative brightness the cone-mediated visual system attributes to each wavelength in daylight conditions.

That weighting is appropriate to the question it was built for, which is how bright something looks. It is a poor instrument for the questions this comment raises, for four reasons.

First, $V(\lambda)$ is normalized to unity at 555 nanometers and falls steeply toward the short-wavelength end. A watt radiated at 450 nanometers, in the region where phosphor-converted white LEDs place their emission peak, contributes only a small fraction of the luminous output that the same watt contributes at 555 nanometers. A photometric measurement therefore discounts precisely

the part of the spectrum this comment is concerned with. Two sources of identical measured luminance may differ substantially in blue radiance, and the photometric figure will not disclose the difference. The function has long been acknowledged in the field to underestimate the contribution of the blue end of the spectrum, and successive corrections have been proposed for that reason.

Second, V(λ) models the photopic system. The conditions under which glare from vehicle headlamps and roadway lighting matters most are mesopic or scotopic, where the relevant response shifts toward shorter wavelengths. A unit calibrated to daylight cone response is being applied to night driving.

Third, visual brightness is not the only response at issue. Photochemical injury to the retina, melanopsin-mediated circadian and neuroendocrine effects, and the trigeminal and autonomic responses described in Part V each follow their own wavelength dependence, and none of them follows V(λ). Weighting an exposure by a brightness function and then reasoning about photochemical or circadian effect is a category error.

Fourth, photometric quantities describe luminous flux without describing the geometry that produces it. An LED emits from a small, flat, highly directional surface. For a given luminous output the source is smaller and the emission more concentrated than the incandescent and discharge sources the photometric conventions grew up around, so the radiance at the source and the irradiance at the retina can be far higher at equal measured lumens. Spectral power distribution, radiance, and source geometry are not recoverable from a photometric figure.

For those reasons this comment reports radiometric quantities — spectral power distribution, radiance, irradiance, and power density — wherever the underlying source permits, and reports photometric quantities where the source reports only those, identifying them as such. The same reasoning underlies the request at Part IX.C that the Department express its own studies in radiometric terms, which would also render them directly comparable with the radiofrequency exposure literature this RFI is principally addressed to.

The objection to radiometric specification, and the answer to it.

The Foundation states the counterargument because the comment is stronger for having met it. Photometric units are not wrong. They quantify light as the daytime visual system responds to it, which is what they were devised to do, and a great deal of existing regulation is written in them. Federal Motor Vehicle Safety Standard No. 108 specifies lamp output in candela. Roadway lighting practice is expressed in lux and in candela per square meter. A proposal to specify emissions radiometrically is a significant change to established practice, and the Foundation does not present it as a small one.

The objection to photometric specification is not that it is inaccurate. It is that it is answer-specific. Every photometric quantity is obtained by weighting spectral radiometric data through V(λ), the photopic luminous efficiency function. Any quantity so derived describes what a source does to daytime foveal vision and discards everything else in the spectrum as a matter of arithmetic. Where the response at issue is daytime visual response, that is exactly right. Where the response at issue is melanopsin-mediated circadian regulation, or photochemical injury to the retina, or a neurological response to modulation, the weighting removes precisely the information the question requires.

The consequence is concrete rather than theoretical. Two sources of identical luminous output can differ substantially in short-wavelength content, because V(λ) assigns little weight to the region where melanopic sensitivity and the blue-light-hazard function are greatest. A specification written in lumens or candela cannot distinguish them. A specification written in spectral irradiance, or in a quantity weighted for the response under consideration, can.

The precedent for doing so exists inside this subchapter. Part 1040 is titled Performance Standards for Light-Emitting Products, and the standard it prescribes at § 1040.30 for high-

intensity mercury vapor discharge lamps is not written in photometric terms at all. It addresses shortwave ultraviolet emission, requiring self-extinguishing lamps to cease operation within a cumulative operating time not exceeding fifteen minutes following complete breakage or removal of the outer envelope, and requiring non-self-extinguishing lamps to bear a warning that the lamp can cause serious skin burn and eye inflammation from shortwave ultraviolet radiation if the outer envelope is broken or punctured. The Department has already written a lighting standard around a radiometric hazard that luminous output does not describe.

The Foundation therefore does not ask the Department to abandon photometric units, and does not ask it to re-specify existing standards. It asks that where a criterion is intended to control a response other than daytime visual response, the quantity specified be the one that corresponds to that response, weighted by the appropriate action spectrum and reported with the spectral data from which it was derived.

Three families of characteristics, and four families of effect.

The quantities in the table group into three families, and this comment uses that grouping throughout. Spectral characteristics describe what wavelengths are emitted and in what proportion. Spatial characteristics describe the geometry of the emission: the radiance of the emitting surface, its apparent size and the angle it subtends at the eye, the directionality of the beam, the uniformity of output across the surface, and the number, separation, and arrangement of emitters within the field of view. Temporal characteristics describe how the output varies in time: modulation depth and waveform, drive and flash frequency, duty cycle, rise and fall times, the duration of a single exposure, and exposure accumulated across repetitions.

Those three families bear on four families of effect, which the Foundation identifies as photobiological, hormonal, neurological, and psychological. The mapping between them is not one to one. Short wavelength content bears on photochemical retinal injury and on melanopsin-mediated hormonal response; source radiance and apparent size bear on retinal irradiance and on disability glare; flash rate and waveform bear on photosensitive and other neurological response; and several of the responses reported in Part VII appear to depend on combinations across families rather than on any single characteristic.

The Foundation submits that evaluation and, in due course, standards must address all three families. A criterion that limits one while leaving the others unconstrained does not protect against the harms described in Part VII. A luminous output limit that permits any spectrum and any flash rate, or a spectral limit that permits any radiance, leaves the mechanism of injury untouched.

The four terms are used in this comment as follows. Photobiological refers to effects on ocular tissue, principally photochemical and thermal injury to the retina. Hormonal refers to effects mediated by the non-visual photoreceptive pathway, principally melatonin suppression and circadian phase shift. Neurological refers to effects on the nervous system, including photosensitive seizure, migraine, sensory processing responses, and the autonomic stress response. Psychological refers to the affective and emotional responses that exposed individuals report: loss of a sense of wellbeing, agitation, fear, panic, and, in a small number of the reports described in Part VII, hopelessness and suicidal ideation.

The four are used descriptively, to name domains of reported effect. They are not mutually exclusive and the boundaries between them are not sharp. An acute stress response has both an autonomic component, which is measurable, and an experienced component, which is reported; this comment treats the first as neurological and the second as psychological, and says so wherever both appear.

One consequence of this table is worth stating rather than leaving to be noticed. Question 5 asks how a classification system should account for operating frequency, power density, specific absorption rate, modulation and pulse characteristics, duty cycle, beamforming, duration of

exposure, distance from the source, proximity to the body, and cumulative exposure over time. Every one of those has a counterpart in the column above. The framework the question proposes transfers to optical radiation with the substitution of units, and Part IX.G answers the question on that basis.

H. Summary of Requests to the Department

The Foundation's requests are developed at Part IX and summarized here. In each case the request is addressed to the Department, and in each case the Foundation identifies the statutory provision it understands to support it.

1. Confirm that visible light emitted by light-emitting diode products is electronic product radiation within 21 U.S.C. § 360hh(1)(A), and that it is subject to the duties of § 360ii. The Final Response of May 24, 2024 proceeds on that footing; the Foundation asks that it be stated. (Part IX.A.)

2. Publish the evidentiary basis for the determination of May 24, 2024 — the literature search protocol, the databases and date ranges searched, the inclusion and exclusion criteria, the studies identified, and the appraisal applied to them. The determination rests on a review the public has not seen. (Part IX.B.)

3. Undertake the research the statute directs: the testing and evaluation of emissions and conditions of exposure required by § 360ii(a)(4), the development of control measures under § 360ii(a)(5), and the control measures and evaluations those paragraphs require. The studies and reports to Congress directed by § 360jj, none of which has been performed for visible light from LED products. (Part IX.C.)

4. Establish adverse event reporting and surveillance for optical radiation, and determine whether the reports described in Part VII are accidental radiation occurrences within 21 C.F.R. § 1000.3(a), reportable under § 1002.20. (Part IX.D.)

5. Exercise the interagency liaison duty of § 360ii(a)(3) and (a)(6) with the agencies whose programs place these products in the public way, including the Department of Transportation, the National Highway Traffic Safety Administration, the Federal Highway Administration, the Department of Energy, the Environmental Protection Agency, the Consumer Product Safety Commission, the Access Board and the Department of Labor; and send each an express written invitation to consult, stating on the record which invitations were sent and what replies were received. (Part IX.E.)

6. Require disclosure of the emission characteristics of LED products — spectral power distribution, source radiance, modulation depth and waveform, flash rate, and rise and decay times — so that purchasers, public entities and exposed individuals can know what a product emits. (Part IX.F.)

7. Develop a classification system for optical radiation exposure organized by the spatial, spectral and temporal characteristics set out at Part I.G, rather than by luminous output alone; and, as the immediately available part of that, assign radiation-emitting product codes to the light-emitting diode product classes that presently have none, and amend Table 1 to 21 C.F.R. § 1002.1 so that those classes report. Thirteen codes are proposed in the Center's own form at Appendix F.2, against the census of those already assigned at Appendix F.1. (Part IX.G.)

8. Reconstitute the Technical Electronic Product Radiation Safety Standards Committee, with the membership balance its charter requires, so that the statutory advisory mechanism is available for this subject. (Part IX.H.)

9. Prescribe a performance standard under § 360kk limiting the temporal light modulation of general illumination and display products, for which the quantities are settled and a consensus body has already written a numerical criterion; and prescribe standards on the spectral, intensity

and geometric characteristics of the product classes identified in Part VI once the research in Part IX.C supplies the quantities in which they could be expressed. (Part IX.I.)

10. Conduct the study directed by § 360jj(a)(2) as it bears on products emitting visible light, which the agency's own 1970 report shows was confined to three classes of ionizing radiation sources, and report the result to Congress under § 360jj(a), inviting the participation of other Federal departments and agencies as subsections (b) and (c) direct. (Part IX.K.)

11. Address expressly the populations identified in Part VII as disproportionately affected, including people with photosensitive epilepsy, migraine and photophobia, traumatic brain injury, and autism and other sensory processing differences. (Part IX.L.)

12. Consider the additional matters set out at Part IX.M, including the division of responsibility between this Department and the agencies that have declined the question as lying outside their authority. (Part IX.M.)

II. 21 U.S.C. § 360ii REQUIREMENTS

A. Statutory Framework: FD&C Act §§ 531-542 (21 U.S.C. §§ 360hh-360ss)

This Part sets out the duties the statute imposes and asks, for each, whether it has been discharged for the products this comment concerns. Subsection A describes the statutory and regulatory architecture within which those duties sit, because the architecture itself answers one question the Foundation is often asked: where, in the federal regulatory system, a standard for light-emitting diode products would go.

1. The Radiation Control for Health and Safety Act of 1968 and its transfer into the FD&C Act

The Radiation Control for Health and Safety Act of 1968, Public Law 90-602, established a federal program to control radiation emitted by electronic products. It was not originally part of the Federal Food, Drug, and Cosmetic Act. It was enacted as part of the Public Health Service Act and classified to subpart 3 of part F of subchapter II of chapter 6A of title 42 of the United States Code, at 42 U.S.C. § 263c and following.

It was renumbered into the Federal Food, Drug, and Cosmetic Act by section 19(a)(4) of Public Law 101-629, November 28, 1990, 104 Stat. 4530, as subsequently amended by section 4(a)(2) of Public Law 103-80, August 13, 1993. The provisions now appear as sections 531 through 542 of that Act, codified at 21 U.S.C. §§ 360hh through 360ss, as follows.

§ 360hh (FD&C § 531) — Definitions.
§ 360ii (FD&C § 532) — Program of control.
§ 360jj (FD&C § 533) — Studies by Secretary.
§ 360kk (FD&C § 534) — Performance standards for electronic products.
§ 360ll (FD&C § 535) — Notification of defects in and repair or replacement of electronic products.
§ 360mm (FD&C § 536) — Imports.
§ 360nn (FD&C § 537) — Inspection, records, and reports.
§ 360oo (FD&C § 538) — Prohibited acts.
§ 360pp (FD&C § 539) — Enforcement.
§ 360qq (FD&C § 540) — Repealed.
§ 360rr (FD&C § 541) — Federal-State cooperation.
§ 360ss (FD&C § 542) — State standards.

One of those sections no longer exists. Section 360qq required an annual report to Congress on the administration of this part. It was repealed by section 601(a)(2)(A) of title VI of Public Law 105-362, November 10, 1998. Part II.I addresses what follows from that repeal, and what does

not, because the repeal of a recurring reporting requirement is sometimes offered as though it had removed the study obligations that remain in §§ 360ii and 360jj. It did not.

The architecture, and why the distinction matters.

Read together, these sections do four things. Section 360hh defines the subject matter. Section 360ii states the program: a set of duties the Secretary is to carry out. Sections 360jj and 360kk supply two instruments — studies and reports to Congress, and performance standards. The remaining sections provide the machinery by which a standard, once prescribed, is enforced: notification and repair, imports, inspection and records, prohibited acts, enforcement, and the relationship with the States.

The distinction between the program and its instruments is the one on which much of this comment turns. The duties in § 360ii do not depend on a performance standard having been prescribed. They are the duties under which an agency would determine whether a standard is needed at all: to plan and support research, to maintain liaison with other federal bodies, to study and evaluate emissions and conditions of exposure, and to develop and evaluate control measures. Section 360kk is what the Secretary may do once those duties have been discharged. It is not a precondition to performing them.

The Foundation makes this point at the outset because the agency's responses have tended to treat the two as a single question. The Final Response of May 24, 2024 declined on the ground that a performance standard has not historically been considered necessary. That is an answer about § 360kk. It is not an answer about whether the research, liaison, study and evaluation duties of § 360ii(a) have been carried out, and Parts II.C through II.G ask that question separately for each of them.

2. Implementing regulations: 21 CFR subchapter J, parts 1000-1040

The implementing regulations appear in subchapter J of chapter I of title 21 of the Code of Federal Regulations, which is titled Radiological Health. It comprises the following parts.

Part 1000 — General.
Part 1002 — Records and Reports.
Part 1003 — Notification of Defects or Failure to Comply.
Part 1004 — Repurchase, Repairs, or Replacement of Electronic Products.
Part 1005 — Importation of Electronic Products.
Part 1010 — Performance Standards for Electronic Products: General.
Part 1020 — Performance Standards for Ionizing Radiation Emitting Products.
Part 1030 — Performance Standards for Microwave and Radio Frequency Emitting Products.
Part 1040 — Performance Standards for Light-Emitting Products.

Part 1040 is the regulatory home of the standard this comment concerns.

Part 1040 is titled Performance Standards for Light-Emitting Products. It is not empty. It contains four standards:

§ 1040.10 — Laser products.
§ 1040.11 — Specific purpose laser products.
§ 1040.20 — Sunlamp products and ultraviolet lamps intended for use in sunlamp products.
§ 1040.30 — High-intensity mercury vapor discharge lamps.

The Foundation asks the Department to hold those four titles alongside the subject of this comment. The part exists. It is named for the class of product at issue. It is populated. It contains a standard for a coherent-light source, a standard for a particular application of that source, a standard for a product that emits ultraviolet radiation deliberately, and a standard for a discharge lamp used in general illumination. It contains nothing for the light-emitting diode, which in the

years since the last of those standards was written has displaced the discharge lamp and the incandescent lamp across essentially all of general, roadway, vehicular and signalling illumination.

The question this Part asks is therefore not whether such a standard would be novel in kind, or whether it would require a new regulatory structure. It would be the fifth entry in an existing part, issued under an existing statutory authority, administered by an existing center. The question is why the duties that precede such a standard have not been carried out.

3. The Center for Devices and Radiological Health and program administration

The Food and Drug Administration states that these provisions are administered by the Center for Devices and Radiological Health. The agency describes the radiation control provisions as "originally enacted as the Radiation Control for Health and Safety Act of 1968" and as "located in Sections 531 through 542 of the FD&C Act."

The Center was formed in 1982, when the organizational units of the agency that regulated medical devices and radiation-emitting products were merged. Its predecessors were the Bureau of Medical Devices and the Bureau of Radiological Health.

That lineage is not incidental to this comment. The Bureau of Radiological Health is the body that performed the one study conducted under the predecessor of § 360jj, published as BRH/DEP 70-30 and described at Part II.I. The program that performed that study in 1969, and the program that has declined to perform another for light-emitting diode products, are the same program under different names.

Every agency action described in Part IV sits within this Center. The Final Response of May 24, 2024 was issued by its Office of Policy. The interim response of June 18, 2026 was issued by the same office. The LED Incident Reports described in Part VII were transmitted to its customer service address and acknowledged from it. The records sought in the Freedom of Information Act litigation described at Part IV.D are its records.

The Foundation does not submit that this program lacks a statutory basis, a regulatory home, or an administering body. All three exist, and have existed since 1968, 1969 and 1982 respectively. The submission is narrower and is the subject of the subsections that follow: that the duties stated in 21 U.S.C. § 360ii(a) have not been discharged for the class of product this comment concerns.

A structural recommendation, offered once

The Foundation raises an organizational question here, states the limits on it, and does not return to it.

The Center administers two bodies of law that differ in almost every operational respect.

Medical device regulation operates through premarket review. A manufacturer that wishes to market a device must come to the agency. There are statutory timeframes for review, a queue of pending submissions, and a user fee program that funds a substantial part of the work. The regulated party has a continuing reason to engage the agency, and the agency works against deadlines.

Electronic product radiation control operates through none of those things. There is no premarket clearance. A manufacturer of luminaires, headlamps or transmitters need never approach the agency at all. There is no fee, no queue and no clock. The people exposed to the radiation have no transaction with the agency of any kind, and no procedural occasion on which their interest is required to be considered.

The funding asymmetry is worth stating concretely, because it is the mechanism by which the structural point operates. Medical device review is supported in substantial part by fees paid by the industry whose products are reviewed, under a statutory program reauthorized by Congress at

intervals, and the program carries performance goals negotiated as part of each reauthorization. Electronic product radiation control has no fee, no reauthorization cycle, and no negotiated performance goal. A manufacturer of luminaires or transmitters pays the agency nothing and asks it for nothing.

Where two functions of that description are administered by one Center, the one with fees, deadlines and a queue will receive attention and the one with none of them will receive what is left. The Foundation offers no view about anyone's intentions and makes no criticism of any official. It observes the outcome, which Part II.M sets out: no new performance standard for any lamp since 1979; a statutory advisory committee that last convened in 2016; the study directed by § 360jj performed once, in 1969; and one documented instance of interagency consultation in the history of the program.

The required expertise differs as well. The products this comment concerns — roadway and area lighting, vehicle lamps, flashing warning devices, retail and workplace luminaires, consumer lamps and displays, and on the radiofrequency side the transmitters and wireless equipment this request for information is directed at — are not clinical products and are not assessed clinically. The disciplines are photometry and radiometry, radiofrequency engineering, photobiology, occupational and environmental exposure assessment, and human factors. Those are not the disciplines of premarket device review.

One detail illustrates the position better than the general argument does. The paper the Center presented to its statutory advisory committee in 2016 on light-emitting diodes and ultraviolet lamps, described at Part II.K.5, was prepared within the Office of In Vitro Diagnostics and Radiological Health. Radiological health was, at that time, administratively joined to in vitro diagnostics, a field with which it has nothing in common.

The subject matter of this request for information is the non-medical half. The Department has asked the public about exposure to electromagnetic radiation from products in ordinary use, in homes, workplaces, vehicles and public rights-of-way. That is the subject which has no organizational home of its own.

The Foundation accordingly recommends that the Department consider separating the two functions: one organizational unit responsible for medical devices, and a second responsible for electronic product radiation from non-medical products — lighting, vehicle lamps, displays and consumer products, and radiofrequency emitters including transmitters and wireless networking equipment — with its own leadership, its own appropriation and its own reporting line.

Three limits on that recommendation, which the Foundation states rather than leaving to be supplied.

- It is a recommendation and not a contention. Nothing in 21 U.S.C. §§ 360hh to 360ss requires any particular organizational arrangement, and how the Department arranges itself is for the Secretary and the Commissioner, and in some respects for Congress. The Foundation asserts no entitlement and alleges no violation.
- It would cost money, and the Foundation does not pretend otherwise. What it asks the Department to weigh against that cost is the cost of the present arrangement, which falls on people who have no procedural means of registering it.
- And it is not a precondition to anything else in this comment. Every duty described in this Part can be performed within the existing structure, beginning immediately. The Foundation raises the structural question because it appears to explain the record, not because the record excuses postponement pending a reorganization. If this recommendation is taken up it should be taken up alongside the requests at Part IX and not instead of them.

Short of a new center, a lesser step would address much of what Part II describes: a distinct office for electronic product radiation control, with its own budget line, its own director, and a published

annual accounting of what has been done during the year under each paragraph of § 360ii(a). The absence of such an accounting is why this comment has had to assemble one from the outside.

B. Statutory Definitions Reach LED Products

The duties examined in the subsections that follow attach to electronic products that emit electronic product radiation. Whether a light-emitting diode product is such a product is therefore the threshold question for this Part. It is also, as matters stand, not a contested one, and the Foundation sets out the definitions here not to win an argument but to fix the premise from which the rest of Part II proceeds.

1. "Electronic product radiation" includes any non-ionizing electromagnetic radiation — § 360hh(1)(A)

Section 360hh(1) defines electronic product radiation in two subparagraphs. Subparagraph (A) covers:

> "any ionizing or non-ionizing electromagnetic or particulate radiation"

and subparagraph (B) covers any sonic, infrasonic, or ultrasonic wave, in each case where the radiation or wave is emitted from an electronic product as the result of the operation of an electronic circuit.

Three features of subparagraph (A) bear on this comment.

The first is the word any, which appears at the head of the subparagraph and governs everything after it. The definition is not drawn by reference to a particular hazard, a particular technology, or a particular part of the spectrum.

The second is that the subparagraph divides the electromagnetic spectrum once, into ionizing and non-ionizing, and then includes both. Having made the only division it makes, it declines to treat it as a limit. Visible light is non-ionizing electromagnetic radiation. It falls on the non-ionizing side of the one distinction the definition draws, and that side is expressly included.

The third is what the subparagraph does not contain. There is no wavelength boundary, no frequency boundary, and no exclusion for radiation that is visible, intended to be seen, or emitted for the purpose of illumination. A definition that reaches ionizing radiation at one end and, through subparagraph (B), infrasonic waves at the other, does not plausibly stop at the edges of the visible band.

2. "Electronic product" — § 360hh(2)

Section 360hh(2) defines an electronic product as a manufactured or assembled product which, when in operation, contains or acts as part of an electronic circuit and emits electronic product radiation, together with any component, part or accessory intended for use in such a product.

A light-emitting diode luminaire satisfies both elements, and satisfies them in the ordinary course of its operation rather than in some unusual condition. It contains an electronic circuit: a driver, which converts supply power to the regulated current the diode requires and which in most contemporary products switches at high frequency. And it emits electronic product radiation as a result of that circuit's operation: the diode emits visible light precisely because current is passed through it.

The relationship between circuit and emission is more direct here than in several products already regulated under this part. In a television receiver with a cathode ray tube, x-radiation is an unintended by-product of the accelerating voltage. In a microwave oven, the emission the standard controls is leakage from a cavity designed to contain it. In a light-emitting diode product the radiation at issue is the output the circuit exists to produce. If the statutory phrase as the

result of the operation of an electronic circuit reaches an unintended by-product, it reaches an intended output.

The definition also extends to components, parts and accessories intended for use in such a product. That reaches the diode packages, modules, drivers and lamps sold for incorporation into finished luminaires and vehicles, which is where many of the characteristics described in Part V are in fact determined.

3. Parallel definitions at 21 CFR 1000.3(j) and (k)

The regulations repeat the statutory definitions in substantially the same words. Section 1000.3(k) defines electronic product radiation as any ionizing or nonionizing electromagnetic or particulate radiation, or any sonic, infrasonic, or ultrasonic wave, that is emitted from an electronic product as the result of the operation of an electronic circuit. Section 1000.3(j) defines an electronic product as any manufactured or assembled product which, when in operation, contains or acts as part of an electronic circuit and emits, or in the absence of effective shielding or other controls would emit, electronic product radiation.

One phrase in § 1000.3(j) is worth pausing on, because it answers an objection that might otherwise be made. The regulation reaches a product that emits electronic product radiation "or in the absence of effective shielding or other controls would emit" it. The definition therefore contemplates that emission may be controlled, and treats the product as within the program either way. A product is not removed from the definition by the fact that its emission is deliberate, nor by the fact that it could be controlled and is not.

4. FDA has previously regulated light-emitting products under this authority — 21 CFR part 1040

The Department need not accept this reading on the Foundation's account of the text, because the agency has acted on it, twice over.

It has acted on it in the regulations. Part 1040, described at Part II.A.2, is titled Performance Standards for Light-Emitting Products and prescribes standards for laser products, specific purpose laser products, sunlamp products and ultraviolet lamps, and high-intensity mercury vapor discharge lamps. Those are light-emitting products regulated under this authority. The last of them is a general illumination source.

And it has acted on it for light-emitting diode products specifically. The Center for Devices and Radiological Health docketed four citizen petitions concerning visible light emitted by LED products, reviewed them, and issued a Final Response on the merits on May 24, 2024. That response did not decline on the ground that the subject lay outside the electronic product radiation control authority. It declined on a different ground, stating that "historically FDA has not considered performance standards to control the radiation from LEDs in the visible wavelengths to be necessary for the protection of the public health and safety."

A statement that a standard has not been considered necessary is a statement about necessity. It presupposes the authority to prescribe one. An agency does not reach the question whether a standard is necessary for a class of radiation it regards as outside its program.

What follows from the definitions, and what does not.

The Foundation does not contend that the definitions decide anything about whether a performance standard should issue. They do not. What they decide is which duties attach.

The duties in § 360ii(a) are stated as duties of the Secretary with respect to electronic product radiation. They are not conferred product by product, and they do not wait upon a decision to bring a product within the program. Where the definition is satisfied, the duties attach by operation of the statute. The agency has discretion in how it discharges several of them, and Part

II.C through Part II.G examine that discretion provision by provision. It does not have discretion to treat a product the definition reaches as though the definition did not reach it.

5. LED products that emit both visible light and radiofrequency energy

A further feature of these products bears on which parts of the subchapter they engage. Many LED products emit in two regions of the spectrum at once.

The visible emission is the intended output. The radiofrequency emission arises from the driver. Contemporary LED drivers are switching power supplies, converting supply power by switching at frequencies typically in the tens to hundreds of kilohertz, and switching circuits radiate. A growing proportion of installed luminaires, streetlights and signage also contain deliberate radiofrequency transmitters for networked control and telemetry.

Both emissions are electronic product radiation within § 360hh(1)(A), and both arise from the operation of an electronic circuit within the same product. The consequence for this Part is that a single product may engage the performance standards of part 1030, governing microwave and radiofrequency emitting products, and the part 1040 standards for light-emitting products, and that the duties of § 360ii(a) attach as to both.

The Foundation notes this here for a practical reason. This request for information is directed principally at radiofrequency and wireless exposure. The products this comment concerns are, in a substantial and growing proportion of cases, radiofrequency emitters as well as light emitters. They are not an adjacent subject to the one the Department has asked about. They are in part the same subject.

6. The agency has classified these products already, and the classification is in operational use

Subsections 1 through 3 show that the statutory and regulatory definitions reach light-emitting diode products as a matter of text. Subsection 4 shows that the agency has regulated light-emitting products under this authority before. This subsection shows something narrower and, the Foundation suggests, harder to answer: that the question is not open as a matter of the agency's own practice, because the agency has already classified these products as radiation-emitting electronic products and uses that classification every working day.

The Center for Devices and Radiological Health maintains a classification of radiation-emitting electronic products, published at https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfPCD_RH/classification.cfm. For each class it records a product code, a definition, the type of radiation emitted, the reports required and the performance standard applicable. The Foundation has read it and sets out the whole of the relevant category at Appendix F.1.

Five of its classes are light-emitting diode products. They are the illumination lamp; the diode used for signaling, tracking or triggering; the diode in toys and entertainment products; the bare diode and diode array sold as a component; and the low-emission diode used as an indicator or decoration, a class whose definition expressly reaches display backlighting and seasonal light strings. Three further classes are displays, one of which is defined to include, in the Center's own words, light-emitting diode, organic light-emitting diode, liquid crystal and plasma technology televisions and monitors.

Each of those eight classes records the radiation type as Optical and states that the general radiological health requirements at parts 1000 to 1005 apply to it. That is the agency, in its own operational record, characterizing the visible light emitted by a light-emitting diode product as radiation emitted by an electronic product, and applying this subchapter to it. Each of the eight also records that no performance standard applies, which is the subject of Part IX.I and not of this subsection.

The classification is not notional. The complete FDA Product Code must be transmitted to Customs and Border Protection at the time of entry for every regulated article imported into the United States, under the rule this Department promulgated at 81 Fed. Reg. 85,854 (Nov. 29, 2016), effective December 29, 2016, which added subpart D to 21 C.F.R. part 1 and which identifies section 536 of the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. § 360mm, as its authority as to radiation-emitting electronic products. The Department described the product code in that rulemaking as a critical data element for its admissibility review. A light-emitting diode lamp entering the United States is therefore identified to this Department, by a code this Department assigned, under a rule this Department wrote, as a radiation-emitting electronic product. Part II.H.20 sets out the interagency relationship through which that happens and Part VI.V the tariff mechanism.

The Foundation states the limits of the point in the same breath. A product code is an administrative classification and not a rule; it binds nobody and is not a determination under any provision of the Act. The entries recording that no performance standard applies are statements about the standards that exist, not concessions that one is required. And a classification maintained for entry and reporting purposes does not by itself determine which of the duties in § 360ii(a) attach. What it does establish is that the premise on which those duties would rest is not in doubt in the agency's own records, and that is why the request at Part IX.A asks only that the Department say so.

C. § 360ii(a)(1) — Develop and Administer Performance Standards

Paragraph (a)(1) directs the Secretary to develop and administer performance standards for electronic products. Unlike paragraph (a)(2), it operates through a particular mechanism, and that mechanism carries a condition. This subsection sets out the mechanism, what has been done under it for light-emitting products, and what has not been done for visible light emitted by LED products. It is the one duty in § 360ii(a) that the Final Response of May 24, 2024 addressed, and the Foundation sets it out first for that reason.

1. The § 360kk standard-setting mechanism

Section 360kk(a)(1) provides, in its first sentence:

> The Secretary shall by regulation prescribe performance standards for electronic products to control the emission of electronic product radiation from such products if he determines that such standards are necessary for the protection of the public health and safety.

The structure is conditional and the condition is a determination. Once the Secretary determines that a standard is necessary, prescription is mandatory; the word is shall. Until that determination is made, prescription is not required. The Foundation accepts that reading without qualification. What follows from it is set out at Part I.C.8: the judgment committed to the Secretary here is downstream of the research and evaluation directed by § 360ii(a)(4), and a determination that a standard is not necessary is not a determination that the research is not required.

Four further features of the section bear on this comment.

First, the same sentence that confers the judgment also constrains how it is to be exercised. The paragraph continues:

> In the development of such standards, the Secretary shall consult with Federal and State departments and agencies having related responsibilities or interests and with appropriate professional organizations and interested persons, including representatives of industries and labor organizations which would be affected by such standards, and shall give consideration to —

and then enumerates five considerations. Two of them are directly engaged by this comment. Subparagraph (A) requires consideration of:

> the latest available scientific and medical data in the field of electronic product radiation

and subparagraph (D) requires consideration of:

> the adaptability of such standards to the need for uniformity and reliability of testing and measuring procedures and equipment

Subparagraph (B) directs attention to the standards currently recommended by other Federal agencies and by public or private groups having expertise in the field; subparagraph (C) to reasonableness and technical feasibility; and subparagraph (E) to the performance of components and accessories in the products for which they are designed.

Subparagraph (A) is worth pausing on. The latest available scientific and medical data is a mandatory consideration, and the Final Response characterized the available literature as low in quality, small in sample, and inconsistent in result. A characterization of the data is not a substitute for considering it, and the Foundation asks the Department to publish what was considered and how. Part IX.H.2.

Subparagraph (D) is worth pausing on for a different reason. It presupposes testing and measuring procedures to which a standard could be adapted. For the emission characteristics at issue here the measurement conventions in general use are photometric, and photometric quantities are weighted by the spectral sensitivity of daytime human vision rather than by the quantity relevant to any biological effect. Part II.G and Part V.A address this. The consequence for this subsection is that developing the measurement procedure is itself part of what the statute contemplates, not a precondition the agency may treat as unmet.

Second, Congress set a deadline for the first exercise of the authority. The same paragraph provides that standards "may be prescribed from time to time whenever such determinations are made, but the first of such standards shall be prescribed prior to January 1, 1970." That deadline was met and is long past. The Foundation notes it only for what it shows about the expected tempo of the program: the authority was given to be used, promptly, and not held in reserve against a future showing.

Third, the section anticipates product-by-product treatment and revision. Paragraph (a)(2) permits "different and individual performance standards, to the extent appropriate and feasible, for different electronic products so as to recognize their different operating characteristics and uses," and paragraph (a)(4) permits the Secretary to amend or revoke any standard prescribed. The breadth of a product category is therefore not an obstacle to acting, and a standard once prescribed is not an irrevocable commitment. Subsection (c) provides that a standard takes effect not less than one and not more than two years after issuance, so a standard prescribed today would not bind manufacturers for at least a year.

Fourth, and this is the feature with the most immediate practical consequence, the mechanism contains a mandatory consultation step. Subsection (f) directs the Secretary to establish the Technical Electronic Product Radiation Safety Standards Committee, "which he shall consult before prescribing any standard under this section." The direction is unqualified and admits of no exception.

The Foundation sets out what performing that step involves, because the requirement is more than a formality and the detail is in the agency's own regulations. Part II.K.2.

> The Commissioner must submit the proposed standard to the Committee, together with other relevant information, before issuing a proposed regulation in the Federal Register. 21 C.F.R. § 14.125(a).
>
> The Committee must be able to deliberate, which requires a quorum. The regulation fixes it at ten of the fifteen members, of whom at least three must come from each of the government, industry and general public categories. § 14.125(c).

The consultation is completed by a report. The Chairperson of the Committee ordinarily submits it to the Commissioner within sixty days, extendable by thirty. § 14.125(d). The officer who makes that report is the Chair.

The deliberation must occur at a meeting, and a meeting of this Committee requires public notice and a record that is available for public inspection. § 14.130, and the Federal Advisory Committee Act.

So the step requires a constituted committee, a quorum drawn from three categories, a Chair to report, a noticed meeting, and a report delivered within a period measured in days.

The Department publishes the Committee's roster, and Part II.K.4 sets out what it states. In short: the roster records twelve of the fifteen seats as vacant; three members are listed, two in the government category and one in the general public category; no person at all is listed in the industry category; the office of Chairperson is shown as vacant; all three members were appointed on April 11, 2022 and all three terms ended on December 31, 2025; and no notice of any meeting of this Committee has been published since September 22, 2016.

The consequence follows as arithmetic and not as argument. The quorum of this Committee is fixed by regulation at ten members including at least three from each of the three categories, 21 C.F.R. § 14.125(c). Three members are listed and the industry category is empty. A quorum cannot be constituted from the membership the Department's own roster shows; the officer who is to report the consultation to the Commissioner under § 14.125(d) is not in office; and the consultation that § 360kk(f) makes a precondition to prescribing any standard therefore cannot presently be performed.

The Foundation states the limits of that conclusion. The roster records that vacancies may be in the nomination process and bears no date of revision, so appointments may have been made that it does not show; but the shortfall is twelve appointments, and the industry category requires three members where there are none. Whether a member whose term has expired may continue to serve pending replacement is a question the Foundation does not resolve; but if all three continue to serve the number is still three. And the Foundation does not say the Committee is empty or defunct, only that it cannot presently reach a quorum. Part II.K.4.

If the Department's position is that the Committee can nevertheless be convened, the Foundation invites it to say so in response to this comment, and to state the number of members then seated, whether a Chair is in office, and whether anyone has been appointed to the industry category. That would dispose of this subsection's concern entirely and the Foundation would welcome it. Absent such a statement, the position is that a standard cannot lawfully be prescribed until the seats are filled, and the delay falls not on the science but on the composition of a committee of fifteen people whose operation the charter costs at approximately one hundred and thirty thousand dollars a year, all in. Part II.K.3.

The consequence is therefore structural rather than argumentative, and it is why this request appears in Part IX independently of every other. Whatever view the Department takes of whether a standard for any light-emitting product is necessary, seating the Committee and convening it resolves no contested question about the underlying science, commits the Department to no conclusion, and is a step it can take on its own motion. The Foundation asks it to. Part IX.H.

2. Light-emitting products for which standards exist

The standards prescribed under this authority are collected in 21 C.F.R. subchapter J. One part of it is addressed to this subject by its title: part 1040, Performance Standards for Light-Emitting Products. It contains four sections.

§ 1040.10, laser products, and § 1040.11, specific purpose laser products.

§ 1040.20, sunlamp products and ultraviolet lamps intended for use in sunlamp products.

§ 1040.30, high-intensity mercury vapor discharge lamps.

Four things these standards establish are worth stating, because each answers an objection that might otherwise be made to regulating LED products under this authority.

The first is that the agency already regulates emission in the visible band. Laser products emit visible light, and §§ 1040.10 and 1040.11 regulate them. The Foundation does not suggest that LED products are lasers; they differ in coherence and in collimation, and the difference is real, though Part V.C.2.k sets out why it is a difference of degree along a measurable axis rather than a difference in kind. The point here is about the criterion rather than the product. What brought laser products within a performance standard was the manner in which the energy is delivered — its concentration, its radiance, the duration of exposure — and not the question whether the radiation is visible or is intended to be seen. Nothing in part 1040 treats visibility, or an illumination purpose, as a reason not to regulate.

The second is that the agency already specifies limits in radiometric and spectrally resolved terms. Section 1040.20 expresses irradiance in watts per square centimeter and imposes a limit on the ratio of irradiance in one wavelength interval to irradiance in another: the ratio of irradiance in the range above 200 through 260 nanometers to irradiance in the range above 260 through 320 nanometers may not exceed 0.003. That is a standard written in the units of the radiation rather than in the units of its appearance to a human observer, and it divides the spectrum where the biology divides it. A standard for LED products of the kind the Foundation has described would take the same form. The precedent for it is inside subchapter J.

The third is that the agency already regulates a lamp product for an effect that is not visual. Sunlamp products are regulated because of what their ultraviolet output does to skin and eyes, not because of anything to do with seeing. The subject matter of a light-emitting product standard has never been confined to visual performance.

The fourth is that the form of control need not be an emission limit. Section 1040.30 addresses the hazard from high-intensity mercury vapor discharge lamps through an operational requirement: a self-extinguishing lamp must cease operation within a cumulative operating time not exceeding fifteen minutes after breakage of the outer envelope. Where the hazard arose from a condition rather than from a level, the agency wrote a standard addressed to the condition.

3. Absence of any performance standard for LED visible light

No section of part 1040 reaches incoherent visible light emitted by light-emitting diode products. For that radiation there is no emission limit, no prescribed measurement method, no labeling requirement, and no requirement that a manufacturer disclose the spectral power distribution, the source radiance, or the temporal characteristics of what its product emits. Part VI describes the product classes at issue and Part IX.F states the disclosure the Foundation asks for.

The agency declined to prescribe such a standard by the Final Response of May 24, 2024, on the ground that standards for every type of electronic product are not necessary. Part I.C examines the reasons given. Two observations belong here rather than there.

The first concerns what the declination settles. Paragraph (a)(1) is the only one of the six duties in § 360ii(a) whose mechanism carries a condition of necessity, and it is the only one the Final Response addressed. The letter is a disposition of the request for a performance standard. It is not a disposition of the duties in paragraphs (a)(2) through (a)(6), which the letter does not discuss and which carry no comparable condition. Parts II.D through II.H take each in turn.

The second concerns the mechanism's present condition. Even if the Department were persuaded tomorrow that a standard is necessary, the consultation that § 360kk(f) requires before prescribing one could not be carried out, for the reasons set out at Part II.K. A determination of necessity would not, as things stand, produce a standard. That is worth the Department's attention independently of anything in this comment about LED products.

The Foundation is not asking the Department to prescribe a performance standard for LED products in response to this request for information, and it wishes to be clear about that. The request it makes under this paragraph, stated at Part IX.I, is that a standard be prescribed for the product classes identified in Part VI once the research and evaluation directed by § 360ii(a)(2) and (a)(4) have been carried out. The sequence is the substance of the request. A determination of necessity under § 360kk(a)(1) is to be made on a record, and the record the statute contemplates is the one paragraphs (a)(2) and (a)(4) direct the Secretary to produce. The Foundation asks for the record first.

4. A worked example: a product the agency has cleared, classified by a mechanism it does not use, and subject to no emission limit

The three preceding subsections state the position in the abstract: the mechanism exists, it has been used for other light-emitting products, and it has not been used for this one. A single product class shows all of it at once, and the Foundation sets it out because it is concrete, because the record is documentary, and because it is a product the agency already has in its hands.

Light-accelerated tooth whitening devices emit blue optical radiation from light-emitting diodes. The FDA classifies them at 21 C.F.R. § 872.6475 under product code EEG, in Class I, assigned to the dental panel. The regulation reads in full:

> § 872.6475 Heat source for bleaching teeth. (a) Identification. A heat source for bleaching teeth is an AC-powered device that consists of a light or an electric heater intended to apply heat to a tooth after it is treated with a bleaching agent. (b) Classification. Class I (general controls). The device is exempt from the premarket notification procedures in subpart E of part 807 of this chapter subject to the limitations in § 872.9.

Two features of that text matter and the Foundation takes them in turn. The identification expressly contemplates that the device may be a light, and then characterizes what the light does as applying heat. And the class is exempt from premarket notification. The agency has nevertheless recorded a series of premarket notification determinations under this product code, the earliest in 1979 and the most recent in 2012, all of them decided as substantially equivalent; more than a hundred establishments are registered to the code. The Foundation does not presently know whether those later clearances reflect devices bearing additional claims that removed them from the exemption, or devices combining this function with another, and it does not assert an explanation it cannot support. What is not in doubt is the position today: a product class that emits blue optical radiation, classified by reference to heat, and exempt from premarket review.

Three features of that record bear on paragraph (a)(1), and the Foundation takes them in order of increasing consequence.

First, what a clearance is. A premarket notification under section 510(k) of the Act is a determination that a device is substantially equivalent to a device already legally marketed. It is a comparison against a predicate, not an evaluation of an emission. The agency does not perform or commission a study of radiation hazard in that pathway, and Class I designation means the agency has determined that general controls alone suffice, so there is no special control, no performance standard and no mandated emission testing. The Foundation states this without complaint about the device program, which was not built to answer radiological questions. It states it because the public, and the Foundation's own correspondents, read the word cleared as a finding about safety, and it is not one.

Second, the classification names a mechanism the product does not use. The device name the agency assigned to this product code is Heat Source For Bleaching Teeth. The classification is framed on a thermal model, and the predicate chain bears that out: one of the early cleared devices, in 1983, is identified in the agency's own record as a hot probe. The manufacturer's own peer-reviewed research, described at Appendix C.45, reports that the active principle of a modern

device of this type is not heat. It is wavelength-specific photochemistry at a peak of 456 nanometers, operating in parallel to chemical oxidation and reaching compounds the chemistry does not reach. A light-emitting diode emitting in the blue was therefore admitted to the market by equivalence to a family of devices characterized by the heat they produce, and equivalence to a thermal device cannot evaluate a photochemical emission, because the predicate has no wavelength worth specifying.

Third, and this is the point of the example, the same agency reached this product under one authority and does not reach it under the other. Under the device provisions it has a classification, a product code, a panel and a clearance history. Under the electronic product radiation control provisions, which are the subject of this comment, it has nothing. No section of part 1040 applies to it, for the reason given at subsection 3 above. And the records and reports requirements do not apply to it either. Table 1 to 21 C.F.R. § 1002.1 assigns reporting obligations by product category, and the category headed OPTICAL contains laser products under §§ 1040.10 and 1040.11 in four classes, sunlamp products under § 1040.20, and mercury vapor R and T lamps under § 1040.30. A product emitting incoherent blue light from a light-emitting diode appears nowhere in the table. No product report, supplemental report, abbreviated report, annual report or test record is required of its manufacturer. The single radiological obligation that attaches is the one that attaches to every electronic product under § 1002.1(a): the duty to report accidental radiation occurrences under § 1002.20, addressed at Part II.L. The manufacturer must report an accident. Nothing requires it to characterize, measure, disclose or limit what the product emits in ordinary use.

The Foundation puts the consequence as a question rather than as an accusation. The agency has in its files a product class it has reviewed eleven times over thirty-three years, which it classified by reference to heat, which in fact emits blue optical radiation at a known peak wavelength and a known irradiance, and for which it holds no emission data because it has never required any. Paragraph (a)(1) directs the Secretary to develop and administer performance standards, and § 360kk(a)(1) conditions prescription on a determination of necessity informed by the latest available scientific and medical data. On what data concerning this emission was any such determination made?

The magnitude is calculable, and the Foundation sets out the calculation so that the Department can check it rather than accept it. The study at Appendix C.45 reports an irradiance of 190 milliwatts per square centimeter at a peak wavelength of 456 nanometers, which is 1,900 watts per square meter. The blue light hazard weighting function has a tabulated value of 0.90 at 455 nanometers and 0.80 at 460 nanometers; interpolated at 456 nanometers it is approximately 0.88, giving a blue-light-weighted irradiance of approximately 1,670 watts per square meter. The exposure limits for the retinal photochemical hazard, in the small-source irradiance formulation, are a weighted radiant exposure of 100 joules per square meter for exposures up to 100 seconds, and a weighted irradiance of 1.0 watt per square meter for longer exposures. On those figures:

> the 100 joule per square meter limit is reached in approximately 0.06 seconds; and
>
> continuous exposure would be approximately 1,670 times the permissible weighted irradiance.

Four qualifications apply and the Foundation states them before drawing any conclusion. The figure of 190 milliwatts per square centimeter is the irradiance delivered to the tooth, which is the target surface. It is not a measured ocular exposure; what reaches an eye depends on distance, angle and shielding, and no such measurement is reported. The weighting value at 456 nanometers is interpolated and should be taken from the published table. The irradiance formulation applies to sources of small angular subtense, and for an extended source viewed at close range the radiance formulation governs instead, which requires the emitting area and the viewing geometry; neither is reported. And the arithmetic is sensitive to none of this at the order of magnitude that matters: an emission three orders of magnitude above the continuous ocular limit is not brought within it by refinements of this kind.

The fourth qualification is the one the Foundation asks the Department to sit with. The limits used in the calculation above are not the Department's. They are the limits of an international commission and an international electrotechnical standard, described at Part I.E and at Part V.C.2. To ask whether a device the FDA has cleared exceeds an ocular exposure limit, the Foundation has to borrow a limit from a non-governmental body, because the Department has prescribed none that applies. That is the condition this comment describes, stated in the narrowest possible compass: a federal agency has reviewed a blue-light-emitting product eleven times, and the only yardstick against which its emission can be assessed was written by someone else.

D. § 360ii(a)(2) — Plan, Conduct, Coordinate, and Support Research to Minimize Emissions and Exposure

Of the six paragraphs of § 360ii(a), paragraph (2) is the one that answers the Department's inquiry most directly, because it is the one least encumbered by conditions. It directs the Secretary to:

> (2) plan, conduct, coordinate, and support research, development, training, and operational activities to minimize the emissions of and the exposure of people to, unnecessary electronic product radiation;

1. What the paragraph conditions, and what it does not

The paragraph contains four verbs — plan, conduct, coordinate, support — four objects — research, development, training, operational activities — and one purpose: to minimize the emissions of, and the exposure of people to, unnecessary electronic product radiation. It contains no finding, determination, or threshold that must be reached before the duty attaches.

The contrast with the neighboring paragraphs is the point. Paragraph (a)(1) directs the development and administration of performance standards, and operates through § 360kk, which conditions prescription of a standard on a determination that it "is necessary for the protection of the public health." 21 U.S.C. § 360kk(a)(1). Paragraph (a)(6) qualifies the residual class of agencies by the word appropriate. Paragraph (a)(2) carries no such qualifier. Its only limiting word is the adjective unnecessary, which describes the radiation to be minimized. It is not a precondition to acting. Part I.C.5 sets out the general distinction between the provisions of this section that confer judgment and those that do not.

Two consequences follow. The first is that discharging paragraph (a)(2) requires no rulemaking. Research, development, training and operational activities are not regulatory acts. The agency need not find anything, propose anything, or prohibit anything in order to comply.

The second is that the ground on which the agency declined the Foundation's petitions does not reach this paragraph. The Final Response of May 24, 2024 declined to prescribe performance standards, on the ground that standards were not necessary. Necessity is the condition in § 360kk(a)(1). It is not a condition in (a)(2). A determination that a performance standard is unnecessary is not a determination that research is unnecessary, and the letter did not purport to make the second.

One further feature of the text bears on the scope of this comment. The paragraph names people. Its object is "the exposure of people to" unnecessary electronic product radiation. This matters because the subject addressed in the next subsection is often discussed in ecological and astronomical terms. Those effects are real and they are not what paragraph (a)(2) addresses. The Foundation's submissions concern human exposure: glare in the visual field of drivers and pedestrians, light entering residences from street lighting and neighboring installations, and flashing devices in the public right-of-way. Each is a condition of exposure of people.

There remains the objection the United States has pressed, and the Foundation meets it here rather than leaving it to be raised. The objection is that paragraph (a)(2) identifies no product,

from which it is said to follow that the paragraph states a programmatic aspiration rather than a duty, and that nothing in it requires the agency to research any particular technology.

Two propositions have to be separated, because the first is sound and the second does not follow from it.

The first is that the paragraph commits judgment to the Secretary about which radiation is unnecessary. The Foundation concedes that, has conceded it at Part I.C.5, and does not retreat from it here. The adjective is in the text and it has to be given work to do.

The second is that the paragraph is therefore wholly discretionary, because it names no product. That does not follow, and the structure of the section and the agency's own conduct both refute it.

Begin with the structure. Subsection (a) opens:

> The Secretary shall establish and carry out an electronic product radiation control program designed to protect the public health and safety from electronic product radiation. As a part of such program, he shall—

The program is mandatory, its purpose is stated, and each of the six paragraphs that follow is introduced by the word shall as a component of it. Not one of the six names a product. Paragraph (a)(1) speaks of "performance standards for electronic products"; paragraph (a)(4) of "emissions of, and conditions of exposure to, electronic product radiation and intense magnetic fields". If the absence of a named product rendered a paragraph unperformable, the section would contain no performable duty at all, and the program the first sentence directs the Secretary to carry out would have no content.

Then consider what the agency has actually done. It has performed paragraph (a)(1) repeatedly, and in every instance by selecting products that Congress never named: diagnostic x-ray systems, microwave ovens, laser products, sunlamp products, and high-intensity mercury vapor discharge lamps, among the others collected in parts 1020 through 1040. Selecting the subject matter is how these paragraphs are performed. It is not a condition that must be satisfied before they impose anything.

The point is sharpest in the agency's own words. Asked in litigation whether it had complied with § 360ii, the United States answered:

> FDA has complied with the statute and established such a program. See 21 C.F.R. §§ 1000.1—1040.30.

That citation is a list of products the agency chose for itself. The proof of compliance offered is itself the demonstration that these duties are discharged by selection. An agency cannot establish that it has carried out a program by pointing to the products it selected under a paragraph that names none, and in the same breath maintain that a paragraph naming none imposes nothing.

The paragraph is also, on its face, indifferent to technology. It is defined by the radiation and by the people exposed to it, not by the means of emission. A technology that did not exist in 1968 is not outside a duty framed in those terms, and the breadth of the definition at § 360hh(1)(A) was deliberate for that reason. Part II.B.

The Foundation states what follows at its proper width, and no wider. It does not contend that paragraph (a)(2) obliges the agency to conduct research into every electronic product. It does not contend that a court could compel research into any particular one; that is a question about the availability of a remedy under 5 U.S.C. § 706(1), and Part I.C.1 describes the posture in which it has been litigated. The contention is narrower, and it is addressed to the Department rather than to a court.

The paragraph directs a program designed to minimize the exposure of people to unnecessary electronic product radiation. Visible light emitted by light-emitting diode products is now among

the most widely encountered forms of electronic product radiation in the country, placed there in substantial part by federal policy, as Part IV.G describes. The agency has conducted no research, no development, no training and no operational activity directed to it. Whatever latitude the word unnecessary confers in deciding which radiation to address, a program that has never examined this exposure is not, as to this exposure, a program that minimizes it.

One further observation forecloses an answer that might otherwise be made. Subsection (b) of the same section authorizes the Secretary to collect and disseminate the results of research, to make grants, to contract with public and private entities, and to procure electronic products for purposes of research and testing. Congress supplied the means along with the direction. Whatever obstacles may stand in the way of performing paragraph (a)(2) as to this radiation, want of authority to fund the work, to contract for it, or to obtain the products is not among them.

2. "Unnecessary electronic product radiation" is not a defined term

Section 360hh defines five terms: electronic product radiation, electronic product, manufacturer, commerce, and State. It does not define unnecessary. Neither does 21 C.F.R. § 1000.3.

An undefined statutory term is not a term without content. It is a term whose content the administering agency is charged with developing — here, through the research and evaluation that paragraphs (a)(2) and (a)(4) direct. The Foundation is aware of no published agency interpretation of unnecessary electronic product radiation as applied to optical radiation, and asks the Department to state whether one exists.

The legislative history treats the term as a category distinct from hazard. The Senate report describes the subject of the Radiation Control for Health and Safety Act of 1968 as "unknown, unnecessary and potentially hazardous radiation from electronic products." S. Rep. No. 90-1432, at 3 (1968). The three adjectives are disjunctive. Radiation may be unnecessary without having been shown to be hazardous, and the structure of paragraph (a)(2) reflects that: the activity it directs is research, which is what an agency undertakes when the effects are not yet established.

Two features of the drafting follow from that premise, and together they determine what paragraph (a)(2) requires.

The first is the word Congress chose. It could have written hazardous electronic product radiation. It wrote unnecessary. The two are not synonyms and the choice was available: the Senate report uses both words in the same phrase, as separate members of a list. Radiation that serves no purpose is to be minimized because it serves no purpose. Whether it has also been shown to injure anyone is a different question, and the paragraph does not ask it.

The second is the verb. Paragraph (a)(2) directs the Secretary to minimize emissions and exposure. Minimization is not a threshold concept. A limit can be satisfied by remaining beneath it, and once a party is beneath it there is nothing further to do; that is the architecture of § 360kk, which authorizes standards to "control the emission" of electronic product radiation and conditions them on a determination of necessity. Paragraph (a)(2) is written differently. It states a direction of travel rather than a ceiling, and it attaches no condition. The statute uses two different verbs because it is doing two different things.

The consequence for the Final Response of May 24, 2024 is direct. That letter rests in part on the proposition that LED products have a long history of safety with respect to the visible wavelengths they emit. Part I.C.7 sets out why the Foundation regards that proposition as unsupported. But the point here does not depend on its being wrong. Suppose it is accepted in full. It is still not an answer to paragraph (a)(2), because (a)(2) does not condition the duty to minimize on a finding of harm. An agency that has established a history of safety has answered the question § 360kk(a)(1) asks. It has not answered the question (a)(2) asks, which is what is being done to minimize emissions of, and the exposure of people to, radiation that serves no purpose.

This is why the Foundation characterizes the 1968 Act as resting on a premise about potential rather than demonstrated harm. The subject the Senate report identified was radiation that was unknown, unnecessary and potentially hazardous. A statute addressed to radiation whose effects are unknown cannot sensibly be read to require proof of effect before its research and minimization duties attach. The duties exist in order to resolve the unknown, and reading them to await its resolution would leave them with nothing to operate on.

That distinction bears on one of the stated grounds of the Final Response. The letter states that regulations prescribing performance standards for every type of electronic product are not necessary "given the effectiveness of existing mitigations in addressing unnecessary radiation and alternative approaches to protect public health," and in light of "the fact that most products do not produce types of levels of unnecessary radiation that pose a risk to public health." The second clause reads unnecessary as though it meant harmful. On the statute's own terms the two are separate categories, and the minimization directed by paragraph (a)(2) is not conditioned on a prior showing of risk.

a. Two senses of the word, and which one this subchapter uses

The word unnecessary carries a settled meaning in energy policy and a different one in this subchapter, and the difference turns out to be the subject of this comment.

In energy policy the meaning is straightforward, and the Foundation states it as that field states it rather than adopting it. Radiation that a lamp emits outside the band the eye uses to form images contributes no lumens. The governing metric is luminous efficacy, expressed in lumens per watt, and a quantity that adds to the denominator and not to the numerator is loss by the construction of the metric. Part IV.G.4. The standards described at Part IV.G are built on that metric, and the infrared output of an incandescent lamp is accordingly classified by them as waste.

What followed is a matter of record rather than of characterization. Those standards removed that component from American general illumination, and by the measure they employ they did so successfully: the lamps that replaced the incandescent lamp deliver far more lumens for each watt, and they do it substantially by not emitting outside the visible band. The Foundation does not dispute that arithmetic and does not suggest the program failed at what it set out to do.

What the Foundation disputes is the premise, and it says so here rather than leaving a reader to reach Part V.B.6 before learning that the premise is contested. A metric that counts only lumens can classify a wavelength as waste only because it is never asked whether that wavelength does anything for the person standing under the lamp. That is a question about human physiology and not about illumination. The published work set out at Part V.B.6 addresses it directly, in experimental studies on human subjects, several of them by Jeffery and colleagues and one of them funded by the Department of Energy itself, reporting measurable physiological and visual effects attributable to the long-wavelength component that the efficacy metric treats as valueless. The Foundation does not assert that this work is settled, and Part V.B.6 states the limits of each study in terms. It asserts only that the question the metric does not ask is a real one, and that the word unnecessary cannot be carried from the one context to the other as though it meant the same thing in both.

In paragraph 360ii(a)(2) the word does different work. It qualifies the radiation whose emission, and whose exposure of people, the Secretary is directed to minimize, in a subchapter whose stated purpose is to protect the public health and safety from electronic product radiation. The question the word asks there is not whether the radiation serves the lamp's purpose. It is whether it serves any purpose for the person exposed to it.

Those two senses can therefore point in opposite directions, and on the evidence described at Part V.B.6 they appear to do so here. What one federal program classified as waste and eliminated is the long-wavelength component for which a physiological function has now been reported in human subjects. What remains, concentrated in the short-wavelength region, is the component

about which the hazard literature exists. If that is right, then the one federal program that has addressed the spectral content of American lighting removed the part that may have been necessary and retained the part that may be unnecessary in the sense this subchapter uses. Two federal programs were applying the same word to the same radiation and meaning opposite things by it.

The Foundation does not assert that this is settled, and Part V.A.3 places the question among those that are open. It asserts something narrower and, it submits, unanswerable: the statute assigns this determination to the Secretary, the term was left undefined so that the administering agency would give it content through the research paragraph (a)(2) directs and the evaluation paragraph (a)(4) directs, and no such determination has been made.

Where necessary radiation fits in this scheme, and where it does not

The preceding paragraphs raise a question the Foundation should answer rather than leave open, because a reader will ask it. If some electronic product radiation is not merely permissible but affirmatively necessary, what does this subchapter do about that? The Foundation gives the answer it believes to be correct, including the part of it that is adverse to the Foundation.

The first point is textual and it is favorable. The subchapter already assumes that some electronic product radiation is necessary. Paragraph (a)(2) does not direct the Secretary to minimize electronic product radiation. It directs the development of criteria to minimize exposures to and emissions of unnecessary electronic product radiation, and the adjective is a limitation on the duty. A lamp must emit light in order to illuminate, and nothing in the paragraph asks the Secretary to reduce the light by which people see. Congress wrote a minimization duty that applies to part of the emission and not to the rest, which means Congress assumed the administering agency would be able to tell one from the other.

That assumption is the Foundation's point throughout this Part, and it is worth stating in its strongest form. The word unnecessary is doing limiting work. A limitation that nobody has ever applied is not a limitation; it is an unexamined word. The Department cannot know what is unnecessary in any emission without knowing what in that emission is necessary, and no determination of either kind has been made as to visible light from light-emitting diode products. Part II.D.2.

The second point is adverse and the Foundation states it plainly. Nothing in this subchapter empowers the Secretary to require a product to emit anything. Paragraph (a)(2) is a minimization provision. Section 360kk authorizes performance standards to control the emission of electronic product radiation, and while control is a broader word than limit, the Foundation does not contend that it authorizes a floor, and is aware of no standard prescribed under that section which has ever set one. A conclusion that near-infrared radiation benefits human beings would not, without more, give this Department authority to require that lamps emit it.

So the Foundation does not ask for that, and asks the Department to note that it does not. It makes no request that any product be required to emit any wavelength. Three things do follow, and each is within authority the Department already has.

- The research and evaluation duties reach the question directly. Paragraph (a)(2) directs research to minimize unnecessary radiation, which requires knowing what is necessary. Paragraph (a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, without qualification as to hazard or as to direction of effect. The spectral composition of the light under which the American population now lives, including what that light no longer contains, is squarely within both. Part II.D and Part II.F.
- The recommendation power reaches it without a standard. Section 360ii(b)(1) permits the Secretary to make recommendations, and a recommendation about spectral composition requires no rulemaking, no finding of hazard and no exercise of the standard-setting power. Part IX.J asks for recommendations on that footing.

The liaison duties reach the agency whose program produced the change. Paragraphs (a)(3) and (a)(6) direct consultation with other federal departments, and the Department of Energy administers the efficacy standards described at Part IV.G. If the two meanings of unnecessary are in conflict, those paragraphs are the mechanism Congress provided for noticing it. Part II.H.4 records what consultation has occurred.

The Foundation accordingly frames its submission on this subject as narrowly as the record permits. It does not ask the Department to find that near-infrared radiation is necessary. It does not ask the Department to require it. It asks the Department to determine what in this emission is necessary and what is not, because paragraph (a)(2) cannot be administered without that determination, and because a term that has gone unexamined for fifty-seven years cannot be invoked to explain why no standard is needed. Part I.C.7.

b. Why a hazard model cannot reach the question

This bears on the method by which the agency has approached the subject, and the Foundation puts the point structurally rather than as a criticism of anyone's judgment.

A hazard model asks whether an emission exceeds a level at which injury occurs. It is the right model for the products for which this Department has prescribed standards, and the blue light hazard framework described at Part V.C.2 is a well-built instance of it. But its question has a fixed shape. It can ask whether there is too much of something. It cannot ask whether something that is absent was serving a purpose, because an absence produces no exposure to measure and exceeds no limit.

Paragraphs (a)(2) and (a)(4) are not framed that way. Paragraph (a)(2) is framed around necessity, which requires knowing what the radiation is for. Paragraph (a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, without qualification as to hazard. Both can ask what a hazard model cannot, and Congress placed both before the standard-setting authority of § 360kk rather than after it. Part I.C.8.

The Foundation accordingly asks the Department to recognize that the hazard framework, however well constructed, is a subset of what subchapter C directs and not a substitute for it. A determination that no emission exceeds a hazard limit is not a determination that exposure to the radiation is necessary, that it has been minimized, or that the conditions of exposure have been evaluated.

c. The Department has prescribed a standard governing spectral composition before

One existing standard is worth identifying here, because it answers in advance an objection that might otherwise be made to anything that follows from this subsection.

The sunlamp standard at 21 C.F.R. § 1040.20 does not merely cap intensity. It limits the ratio of the shorter-wavelength to the longer-wavelength ultraviolet irradiance a product may produce. That is a requirement about the relative spectral composition of an emission rather than about its quantity. The Department has therefore already prescribed, under this authority, a performance standard that regulates what proportions of the spectrum a lamp may deliver.

The Foundation draws no request from that precedent in this comment. It identifies it so that the record is clear on one point: a performance standard addressed to the spectral composition of a general service lamp would not be a novel exercise of this authority. Whether any such standard is warranted is a question for after the research, and Part IX.I is framed accordingly.

d. What a determination of necessity would involve, and why none has been made

The preceding subsections establish that the term is undefined and that its content is for the administering agency to develop. This subsection states the operational consequence, which is more practical than it may first appear.

Paragraph (a)(2) directs the Secretary to minimize the emissions of and the exposure of people to unnecessary electronic product radiation. The adjective is not ornament. It identifies the subset to be minimized. A duty to minimize a subset cannot be performed by an agency that has not identified the subset, and the identification is therefore not a question the paragraph leaves open for later. It is the paragraph's first step.

The Foundation has found no determination of that kind for any product emitting visible light. Not a rule, not a guidance document, not a published interpretation, not a worked example in any agency document it has been able to locate. The agency has never stated, of any lamp, luminaire, display or indicator, which part of what the product emits is necessary and which part is not.

What such a determination would look like is not mysterious. Take a street luminaire, which Part VI.B describes. Its purpose is to deliver a stated illuminance to a roadway and footway for the visual tasks performed there. Measured against that purpose, the components of its emission divide:

Light reaching the roadway and footway at the specified illuminance. Necessary on any reading of the word. It is what the product is for.

Light emitted above the horizontal. This cannot reach the roadway. Whatever else may be said about it, it does not serve the purpose for which the luminaire was installed.

Light falling outside the area to be lit — into bedroom windows, gardens, watercourses, habitat. The same analysis applies, and Part VII contains first-hand accounts of it.

Output maintained during hours in which the area carries no traffic and no pedestrians.

Source luminance in excess of what is required to deliver the specified illuminance. The same illuminance can be delivered from a larger and dimmer emitting surface. The excess is a property of the source, not of the lighting it provides. Part V.B.2.

Short-wavelength content beyond what the visual task requires. This is the component the literature in Part V concerns.

e. Most of that determination requires no finding of harm

The Foundation asks the Department to notice what that list shows, because it bears on the objection that the evidence is not yet sufficient.

Five of the six items can be resolved without a single health study. Light emitted above the horizontal does not illuminate a roadway; that is geometry. Light falling on a bedroom window is not performing the function for which the luminaire was installed; that is also geometry. Output at an hour when no one is present serves no one. Luminance beyond what the specified illuminance requires is surplus by arithmetic. None of those propositions depends on knowing whether the radiation injures anybody.

That separation matters because the Final Response of May 24, 2024 ran the two questions together. Whether radiation is unnecessary and whether it is harmful are different questions, as subsection a sets out, and paragraph (a)(2) asks the first. A determination that a component of a product's emission serves no purpose for the person exposed to it is available on the engineering record alone. The Foundation is aware of no such determination having been made.

The sixth item is different, and the Foundation says so rather than claiming more than it can. Whether the short-wavelength content of a street luminaire exceeds what the visual task requires, and what follows for the people under it, cannot be settled without the research that paragraphs (a)(2) and (a)(4) direct. The Foundation does not ask the Department to decide that today. It asks the Department to begin the work by which it is decided, and in the meantime to make the determinations that do not depend on it.

The request is accordingly in two parts, and they are severable. First, that the Department state what it regards as necessary and unnecessary in the emission of the product classes described in Part VI, to the extent that question can be answered on the engineering record. Second, that it undertake the research by which the remainder is answered. Part IX.C. A Department that declined the second could still perform the first, and the Foundation would regard that as progress.

f. The objection that not every source need be addressed, and what follows from it

In the liaison litigation described at Part IV.D, the United States has argued that the Department is not required to address every source of electronic product radiation. The Foundation accepts that proposition. It does not contend that paragraph (a)(2) obliges the Secretary to reach every emitter of every wavelength, and nothing in this comment should be read as making that contention.

What follows from the proposition is narrower than its use suggests. A duty that need not be performed as to every source must still be performed as to some, or it is not a duty. The question is therefore not whether the Department was obliged to reach this source. It is on what basis this source was not reached. The Foundation asks the Department to supply that basis, and observes that the Final Response does not contain it.

The Foundation also identifies why it asks about this product class rather than asking about all of them, using criteria the Department can test. Light-emitting diode products account for the majority of human exposure to artificial optical radiation, Part VI. They displaced the technology they replaced through federal action rather than through the market alone, Part IV.G. The scientific literature assembled in Part V concerns them. And the Department has already accepted that what they emit is electronic product radiation within this authority, Part I.D. The Foundation is not asking the Department to begin everywhere. It is asking why it has not begun here.

One distinction remains, because the Final Response turned on it. Paragraph (a)(2) directs a program — research, development, training and operational activities — to minimize unnecessary radiation. Section 360kk authorizes performance standards to control emissions. They are different provisions with different predicates. A determination that a performance standard is not necessary under § 360kk(a)(1) does not discharge the duty at paragraph (a)(2), does not address it, and does not survive it. The letter of May 24, 2024 answered the standards question. The Foundation has found no answer to the other.

3. Light pollution is unnecessary electronic product radiation

Lighting engineering has a settled term for optical radiation emitted in excess of what the intended visual task requires, or directed where it serves no visual task. The term is light pollution. Its standard taxonomy divides it into glare, light trespass, uplight and the resulting skyglow, over-illumination, and clutter. CIE 150:2017, Guide on the Limitation of the Effects of Obtrusive Light from Outdoor Lighting Installations; Illuminating Engineering Society and International Dark-Sky Association, Model Lighting Ordinance (2011).

Each category describes radiation that serves no illumination purpose, and the first two describe radiation that defeats one.

Glare is radiation reaching the eye at an angle and intensity that reduces visual performance rather than supporting it. Disability glare raises the veiling luminance against which a target must be discriminated, so the contrast of the very object the installation was built to reveal is reduced. Part V.C.3.

Light trespass is radiation crossing onto persons who are not the intended beneficiaries of the installation and who cannot switch it off. That is exposure of people, in the paragraph's own words, and it is involuntary.

Uplight is radiation emitted above the horizontal, which reaches no task surface at all.

Over-illumination is radiation in excess of the illuminance the task requires.

The mapping between the two terms is therefore not an extension of the statute. Light pollution is the name that engineering practice gives, within the visible band, to the subject paragraph (a)(2) names in statutory terms. An installation that produces glare, trespass, or uplight is emitting electronic product radiation that is unnecessary by the standards of the discipline that designs such installations.

It follows that minimizing light pollution from LED products is a federal statutory duty assigned to the Secretary. The Foundation states plainly what that does not mean. It does not displace the authority of States and municipalities over lighting design, zoning, and roadway standards, and the Foundation does not ask the Department to assume that authority. What paragraphs (a)(2) and (a)(5) direct is the antecedent work: a definition of the quantity to be minimized, measurement methods referred to the point of human exposure, evaluation of the conditions under which people are exposed, and techniques for reducing that exposure. None of it has been done, and States and municipalities have been legislating in its absence.

The equivalence has been before the agency since the petition comments, which stated it in terms: "The FDA is required to limit the exposure to, and emissions of, unnecessary Visible Light radiation from LED products. 'Unnecessary' light is also known as light pollution." The agency acknowledged receipt of the comments. Part IV.B. The Final Response does not address light pollution.

a. The objection that this is an environmental matter, and why it does not arise

One objection to the whole of this comment is foreseeable and the Foundation answers it here rather than leaving it to be made. It would run as follows: the research set out in Part V is research into light pollution, or into artificial light at night; those are environmental subjects; environmental subjects belong to environmental agencies; and the authority of this Department over electronic products is therefore not engaged.

Each step of that argument fails, and the third fails on the record of this proceeding.

The vocabulary of a research field does not determine jurisdiction. The physical quantity these studies measure is optical radiation emitted by electronic products and received by people. Section 360hh(1)(A) defines electronic product radiation to include any electromagnetic radiation emitted from an electronic product, and Part II.B establishes that visible light emitted by an LED product falls within that definition. A study that measures that radiation is a study of electronic product radiation whatever its authors call it in the title.

The statute regulates the product, not the land. The Foundation does not ask this Department to regulate lighting design, fixture placement, mounting heights, curfews, zoning or the outdoor lighting ordinance of any jurisdiction, and it repeats here what it has already said in this subsection: those are matters for States and municipalities. What it asks is what subchapter C provides. That the Secretary study what these products emit, and, if the research supports it, prescribe what they may emit. A performance standard addressed to a lamp is not a land use regulation, and a manufacturer is not a municipality.

The deflection has already been tried, and it failed. The proposition that this subject belongs to an environmental agency was put to the environmental agency. The Director of the Radiation Protection Division of the Environmental Protection Agency replied that Congress has granted that agency no statutory authority to regulate visible light or non-ionizing radiation emitted from electrical devices, including LEDs, and that it does not maintain experts in the field. Part II.H.3. The Consumer Product Safety Commission is removed by statute rather than by choice: 15 U.S.C. § 2080 withholds from that Commission authority over any risk of injury associated with

electronic product radiation emitted from an electronic product where the risk may be subjected to regulation under this subchapter. Part II.H.9.

The Foundation puts the consequence plainly. If this subject is not within the authority of this Department, it is within the authority of no federal agency at all. The Foundation has asked, and Part II.H records the answers.

b. The claim the Foundation makes, and the one it does not

The Foundation is careful about the form of the equivalence it asserts, because a claim stated too broadly can be defeated by a single counter-example and would take the rest of the argument with it.

It does not contend that light pollution and unnecessary electronic product radiation are synonyms. They are not coextensive in either direction. Light pollution, as the term is used in astronomy and ecology, includes sky glow and effects on other species that involve no human exposure, and it includes light from sources that are not electronic products. Unnecessary electronic product radiation extends well beyond the visible band, including to the radiofrequency emissions to which this request for information is principally directed.

What the Foundation contends is narrower. Within the overlap of the two — visible light emitted by an electronic product and received by a person — the phenomena that lighting engineering calls light pollution are instances of what paragraph (a)(2) calls unnecessary electronic product radiation. Glare, light trespass, uplight and over-illumination are each radiation that serves no visual task or exceeds what the task requires, and that is what the word unnecessary describes. The narrower claim is sufficient for every purpose this comment has.

A practical consequence follows, and the Foundation states it because it removes an obstacle rather than raising one. The Department need never use the term light pollution. It is a colloquial expression, it has no statutory definition, and nothing in this comment asks the Department to adopt it or to defend it. Every action the Foundation requests can be described, performed and justified entirely in the language Congress enacted: the emissions of, and the exposure of people to, unnecessary electronic product radiation.

The term appears in this comment for two reasons only. It is the term by which the public, the press, and the state and local bodies described at Part VIII refer to this subject, so the Department should be able to see that the two are the same thing. And it is the term under which much of the scientific literature in Part V was published, so a reader searching that literature will not find it under any other name. If the Department prefers to carry out these duties and exercise these powers without ever using the phrase, the Foundation has no objection of any kind. What matters is the radiation, not the word.

c. Why light-emitting diode products are the class this comment addresses

The Foundation does not argue that the Department's authority over these products follows from their prevalence. The authority follows from the statutory definitions and would reach a single lamp sold to a single purchaser. Part II.B.

Prevalence bears on a different question, which is where a duty to minimize exposure should be directed first. Paragraph (a)(2) speaks of minimizing the exposure of people. Where one technology now produces the substantial majority of the artificial light to which the American population is exposed, as Part IV.G.3 describes, the exposure that paragraph names is, as a matter of fact, predominantly exposure to that technology. An agency ordering its work under a minimization duty would begin there.

The same reasoning governs how the research in Part V should be read. Those studies are studies of artificial light at night because that is the exposure people have. That exposure is now produced overwhelmingly by light-emitting diode products. A finding about the one is, in the present state of the built environment, largely a finding about the other. The Foundation does not ask the

Department to treat that as an identity, and Part V.J.4 sets out the measurement gap that prevents the literature from attributing effects to particular sources. It asks the Department to notice that the gap is itself a reason to conduct the research, not a reason to decline the subject.

d. Radiation emitted upward, and where it actually goes

The clearest instance of unnecessary electronic product radiation in this entire subject is also the easiest to detect, and it has been detected continuously from orbit for decades.

Light emitted above the horizontal reaches no task surface. Whatever purpose the installation below was built to serve, that radiation did not serve it. No judgment is required to reach that conclusion and no study is needed to support it; it follows from the geometry. That is what makes direct uplight the clearest instance of unnecessary radiation available to this Department.

The radiation does not leave, and it reaches people

It might be supposed that radiation directed upward escapes into space and exposes nobody, so that a public health statute has no occasion to address it. That supposition is false as a matter of physics, and the Foundation sets out why before reaching the statutory text, because the physical answer is the stronger one.

A substantial part of upward-directed light does not leave the atmosphere at all. It is scattered by air molecules and aerosols and, far more strongly, by cloud, and returns to the ground as diffuse illumination of the night sky. The effect is not marginal and it has been quantified.

Kyba, Ruhtz, Fischer and Hölker measured sky luminance under cloud and clear conditions and found that cloud cover amplified it by a factor of 10.1 at a location inside Berlin and by 2.8 at 32 kilometers from the city center. They also found that overcast nights inside the city were brighter than clear rural moonlit nights by a factor of 4.1. Cloud coverage acts as an amplifier for ecological light pollution in urban ecosystems, PLoS ONE 2011;6(3):e17307.

Kocifaj, Falchi and Kundracik, modeling a full range of cloud distributions, report that clouds can amplify zenith artificial radiance by more than fifteen times and, critically for this comment, the irradiance incident at ground level by more than four times compared with clear conditions. An all-sky light pollution model for global-scale applications that embraces a full range of cloud distributions, Proceedings of the National Academy of Sciences 2025;122:e2508001122.

The second of those quantities is the one the Department should attend to. Irradiance incident at ground level is exposure. It is what reaches a person standing outside, and what enters a window. A fourfold amplification of it under cloud means that the nocturnal optical exposure of a population is determined in substantial part by emissions from fixtures those people cannot see, do not control and may be miles away from, and that the exposure is greatest on the nights when the sky is overcast.

There is a second route by which upward emission reaches people, and it is more direct. A luminaire that sends light above the horizontal is, by the same defect in its distribution, sending light at high angles just below the horizontal. That near-horizontal light is the component that travels laterally at eye level, and it is the component that produces disability glare, discomfort glare and light trespass. Parts V.C.3 and V.C.4. The upward measurement is therefore an index of the sideways emission as well as a quantity in its own right. Light measured leaving a city is a proxy for light arriving at the eyes of the people in it.

Upward emission has a third consequence, in the atmosphere itself. Scientists at the National Oceanic and Atmospheric Administration reported in 2011 that artificial light destroys the nitrate radical, the oxidant that removes nitrogen oxides and volatile organic compounds from the air overnight, and that over Los Angeles city lights reduce nitrate radical concentrations by several percent. Part II.H.3 sets out the finding, its magnitude, and the limits of what the Foundation

draws from it. What belongs here is the cause the authors identify: the effect is produced by light projecting skyward, and shielded fixtures directing light downward would prevent it. The radiation at issue is again the radiation that served no one.

The text of paragraph (a)(2) reaches it in any event

The Foundation does not need the statutory text to answer the objection, having answered it on the facts. The text answers it again, and independently.

Paragraph (a)(2) directs the Secretary to support activities to minimize two things, not one: "the emissions of" and "the exposure of people to" unnecessary electronic product radiation. The two objects are coordinate. Emissions are named separately from exposure, and a reading that confines the paragraph to exposure deletes one of its two objects. Direct uplight falls within the first limb whether or not any person is exposed to it, and it falls there on the plainest possible facts, because it is emission that serves no purpose.

What the Foundation claims about satellite measurements, and what it does not

The Foundation states a limit on this argument before it is put to the Foundation, because the limit is real and a reader who found it unaided would discount the rest.

Not all of the light detected from orbit is direct uplight. A substantial part of it is light that was emitted downward, illuminated a road, a parking surface or a building as intended, and then scattered upward from those surfaces. That portion is the residue of illumination that did its work, and the Foundation does not contend that it is unnecessary in the sense paragraph (a)(2) uses. Reflected light is the price of lighting a surface at all.

What the Foundation contends is this. The direct uplight component — radiation emitted above the horizontal by a fixture that fails to control its distribution — is unnecessary by definition, is a distinct and estimable component of the total, and is the component that engineering practice has long known how to eliminate. Satellite radiance is an upper bound on it, not a measurement of it, and the comment uses it as such.

The split, and the impact of the half that is unnecessary, both now supplied

The preceding paragraph asserts a split between direct uplight and reflected ground light, and the Foundation would not leave an assertion of that kind unsourced. The measurement and modeling literature of observatory site protection has quantified it. Green R.F., Luginbuhl C.B., Wainscoat R.J. and Duriscoe D., The growing threat of light pollution to ground-based observatories, The Astronomy and Astrophysics Review, volume 30, article 1 (2022), open access. Described at Appendix D.7.

The reflectance first. Since the first physical model of skyglow was published in 1986, this literature has taken 15 percent as the representative reflectivity of illuminated surfaces: concrete, asphalt, vegetation. Of the light a fixture sends downward and which does the work the fixture was installed to do, about fifteen parts in a hundred come back up.

Then the direct fraction. Across an installed stock, direct upward emission averages about 10 percent. The arithmetic the review performs is simple and the Foundation reproduces it: ninety percent of the flux is sent downward and fifteen percent of that is reflected, which is 13.5 percent of the total; ten percent is sent upward directly. The flux propagating upward from a lit area is therefore divided roughly equally between radiation that illuminated something first and radiation that illuminated nothing at all. That is the proportion the note following this subsection asked for, and it now has a source.

The two halves are not equal in effect, and the inequality is the point. Neglecting angle, radiation that never strikes a surface avoids the fifteen percent reflectance and so carries about six and seven tenths times the consequence of an equal flux sent downward. Angle makes it far worse, because unshielded fixtures emit most of their uplight at small angles above the horizontal, where the path

through the atmosphere is longest. Modeling predicted that direct upward emission causes between 40 and more than 150 times the zenith skyglow impact of an equal flux directed downward, when observed at distance in an environment with little blocking. Measurement in the field gave a smaller but still large range, from about 1.5 to about 16 times, with the larger ratios at the greater distances. In real environments with buildings and vegetation the ratio falls, and it stays well above one.

The figure that bears most directly on a performance standard

The same modeling was applied to a lighting-design question, and the Foundation sets the answer out on its own because of what it implies for the form of a limit. A fixture emitting one percent of its flux directly above the horizontal was found to increase artificial sky brightness by 30 percent at fifty kilometers, and by 100 percent at two hundred kilometers, compared with the same fixture fully shielded. One percent, not ten.

The Foundation asks the Department to hold that figure against two others already in this comment. At Appendix C.134 a group of marine scientists, writing in an engineering journal and with no interest in this proceeding, recommended an upward light output ratio of zero percent. At Appendix C.130 volunteers walking German streets found that fifty-eight percent of floodlights were unshielded, rising to seventy percent in continuous urban fabric. The interval between zero and one percent is not a rounding difference, and the installed stock is not near either end of it.

Why that bears on the request this comment makes. Section 360kk requires that a performance standard prescribe a characteristic of the emission. The upward light output ratio of a luminaire is such a characteristic. It is a property of the product, measurable on a goniophotometer before the product leaves the factory, and it does not depend on where the product is installed, by whom, at what height or under whose ordinance. It is not a land-use question and it is not a lighting-design question. It is the kind of quantity subchapter C was written to govern, and the figures above establish that the quantity matters at values most people would round to zero.

What the Foundation says about skyglow, which is narrower than it may appear

Skyglow is not itself an emission of a product. It is that radiation after the atmosphere has scattered it, and the authority Congress gave the Secretary is over what a product emits rather than over what the atmosphere does with it afterwards. The Foundation therefore does not ask that skyglow be regulated, and the paragraph above says so. It asks for two things that do follow, and it states them separately because they rest on different grounds.

The first is that the emission which produces skyglow is electronic product radiation within section 360hh, is unnecessary by the standards of the discipline that designs lighting installations, and is accordingly within the first limb of paragraph 360ii(a)(2), which directs the Secretary to support activities to minimize the emissions of unnecessary electronic product radiation. That limb is satisfied without reference to any person and without reference to any finding of injury. A duty to minimize radiation that serves no purpose does not wait upon proof that the radiation is harmful, and the Foundation does not rely on such proof for this part of its case.

The second is that skyglow is the measurable indicator by which the magnitude of that emission, and the effectiveness of any technique for reducing it, can be established. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of electronic product radiation, and paragraph (a)(5) to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure to it. Neither duty can be discharged without a quantity that can be measured before and after. Skyglow is that quantity for this emission, and it is already being measured.

That sequence has been carried out once, in the United States, and the outcome was measured

In 1989 the City of Flagstaff, Arizona and the surrounding Coconino County adopted what this review describes as the first outdoor lighting code with standards based on limiting sky brightness at an observatory site, and, to the authors' knowledge, the only lighting codes anywhere with standards

designed to achieve a sky brightness management target. The target was to hold the increase in zenith sky brightness over the United States Naval Observatory Flagstaff Station to thirty percent above the then-current condition. Modeling converted that target into a prescribable quantity: 25,000 lamp lumens per acre within a radius of two and a half miles of the station, rising by factors of two in the outer zones. The authors record that the conceptual basis for the innermost cap was not lighting needs and not lighting industry recommendations.

Measurement in June 2015 found not an increase of thirty percent but a decrease of approximately ten percent against the late nineteen-eighties. The target was met and exceeded, which the authors attribute to the shift to low-pressure sodium, to improved shielding whose benefit the original modeling had understated, and to near-ground blocking that the original modeling had not included. The community has since adopted a stricter target of ten percent, converting the limits from lamp lumens to fixture lumens, tightening shielding in the innermost zone, halving the cap in the outermost zone, and eliminating the requirement for roadway lighting in residential areas.

The Foundation states the limit of that example before it states the use. Lumens per acre is a land-use quantity and not a characteristic of a product. Flagstaff is therefore not a template for a standard under section 360kk and the Foundation does not offer it as one. What it is, is a worked demonstration of the method that paragraphs 360ii(a)(4) and (a)(5) describe. A protected quantity was identified. A numerical threshold was set against it. A prescribable limit was derived from that threshold by modeling rather than by consulting the industry. The limit was imposed. The outcome was measured, and it was found to have been achieved. The Foundation is aware of no occasion on which a federal agency has performed that sequence for this emission, and it is the sequence Part IX asks for.

One comparison from the same measurements, made by the night sky team of the National Park Service, shows what the difference amounts to. Measured from 27 kilometers, the integrated artificial sky brightness of Flagstaff, population 70,320, is given as one eleventh and a little more — the authors write 1/11.9 — of that of Cheyenne, Wyoming, population 63,335, measured from 31 kilometers. Two cities of nearly the same size, one with a long history of lighting regulation and one without. The authors describe it as a single point comparison and the Foundation repeats that caution with it.

A claim the Foundation does not make, because this review says it is wrong

It is commonly said that the conversion to white light-emitting diodes worsens skyglow because short wavelengths scatter more strongly. These authors state that this is not the dominant mechanism and that the causes are commonly misunderstood. Within about ten kilometers of a source the increased scattering of short wavelengths is approximately balanced by the increased extinction that accompanies it; beyond that distance extinction dominates, and a white source of given luminous output has less impact on radiant skyglow than a yellow one. The increased visual impact of white sources is real and large — two to three times that of high-pressure sodium at equal lumens, near and far — but it arises from the greater sensitivity of the dark-adapted human eye to blue and green light, and not from scattering.

Three statements have to be kept apart there, and the Foundation keeps them apart because conflating them is what produces the incorrect version. Integrated radiant skyglow at distance: a white source may produce less of it than a yellow source of equal lumens. Visual skyglow: a white source produces two to three times as much. And radiant skyglow within the short-wavelength band itself, between 350 and 500 nanometers, where white diodes were found to increase it by a factor of about two or more against high-pressure sodium. The third is the one this comment is about, because the comment is about short-wavelength content and not about the visibility of stars. The Foundation records the correction because the incorrect version is in wide circulation, because a reviewer who knows the subject would notice it, and because nothing in this comment rests on it.

Why this bears on human health and not only on the night sky

The Foundation is advancing a health argument and does not ask this Department to take an interest in astronomy. The connection is through the fixture rather than through the sky, and it is direct.

The property of a luminaire that sends light above the horizontal is the same property that places a high-luminance emitting surface in the field of view of a person standing at ground level some distance away. A fixture that spills light into orbit is a fixture whose source is visible where it should not be. The radiation that escapes upward and the radiation that produces disability glare, discomfort glare and light trespass are produced by one and the same failure to control distribution, and they are corrected by one and the same intervention. Parts V.C.3 and V.C.4.

Three consequences follow for this comment.

A quantity that is unnecessary by definition is being measured globally, continuously, and has been for decades. Part V.J and Appendix C.3. The Secretary has a statutory duty to minimize emissions of unnecessary electronic product radiation and has never used that measurement for the purpose.

The techniques for reducing it exist, are commercially available and are not in dispute. Part II.G.3. What is absent is the federal testing and evaluation of their effectiveness that paragraph (a)(5) directs.

Because the same fixture property drives all of it, a reduction in direct uplight is not a trade-off against human exposure. It reduces the lateral emission that reaches the eye directly, and it reduces the scattered skyglow that returns to ground level as the irradiance described above. One intervention, three effects, all in the same direction. That is an unusual feature in regulatory design and the Foundation asks the Department to notice it.

The Foundation does not ask this Department to regulate the night sky, which is not within its authority and which it has no wish to see attempted. It asks the Department to recognize direct uplight as a measurable instance of the quantity paragraph (a)(2) names, and to include it in the study and evaluation that paragraph (a)(4) directs. Part IX.C.

4. The agency and the United States have each used the term, without applying it to visible light

The Final Response invoked the statutory category twice, in the two clauses quoted in subsection 2. The agency therefore used the term unnecessary radiation in disposing of petitions concerning visible light emitted by LED products. It did not identify the existing mitigations on which it relied, and it did not state which products were included in most.

In litigation the United States has relied on the same paragraph. Arguing against a broad construction of the liaison duty, it stated that such a construction "would also be irreconcilable with § 360ii(a)(2), which requires FDA to use its judgment by 'plan[ning] … operational activities' to minimize 'unnecessary electronic product radiation,' not all such radiation."

The Foundation does not dispute that reading. Judgment about which radiation is unnecessary is judgment the paragraph assigns. But the reading has a consequence the government did not address. A duty to exercise judgment is discharged by exercising it. The United States has also represented that no decisionmaking process has occurred with respect to these products. Part I.C.4. The two positions do not sit together. Either the agency has made the judgment paragraph (a)(2) requires, in which case the Department should produce it and state its basis, or it has not, in which case the paragraph is unperformed.

5. The existing mitigations

For the electronic products as to which the agency has prescribed performance standards, the mitigation is the standard: 21 C.F.R. part 1020 (ionizing radiation emitting products), § 1030.10 (microwave ovens), §§ 1040.10 and 1040.11 (laser products), § 1040.20 (sunlamp products and

ultraviolet lamps intended for use in sunlamp products), and § 1040.30 (high-intensity mercury vapor discharge lamps). For visible light emitted by LED products there is no federal performance standard, no federal measurement requirement, no federal disclosure requirement, and no federal exposure limit. Part II.C.3.

What exists is voluntary and non-federal: recommended practice published by the Illuminating Engineering Society; the blue-light hazard exposure limits of IEC 62471 and ANSI/IES RP-27, which are consensus documents the Department does not administer, Part V.C.2; State and municipal outdoor lighting ordinances of widely varying stringency; and a model ordinance, which is a model. None of these was adopted following the study and evaluation that § 360ii(a)(4) directs, and none is enforceable by the Department.

The Foundation is not alone in that characterization, and offers one corroboration from outside its own analysis. Cao, Xu and Yin, reviewing the health threats of light pollution and the regulatory response to them in the Journal of Environmental Sciences in 2023, open with this observation:

> "Although there are regulations and standards concerning light pollution, few of them are based on the potential contribution of improper lighting to diseases."

That is a survey of the field reaching the conclusion this subsection reaches about the United States: instruments exist, and they are not health-based. The authors state the purpose of their review as promoting risk assessment and better regulation of artificial lights, and say they aim to provide perspectives for future research and guidance for relevant regulations and standards. Appendix C.29. The Foundation notes that an invitation of that kind, addressed by researchers to whichever regulator will take it up, has in the United States only one possible addressee for electronic products, and that § 360ii(a)(3) directs that Department to receive information from organizations on present and future potential electronic product radiation.

The Foundation accordingly asks the Department to identify the existing mitigations on which the determination of May 24, 2024 rested, as applied to visible light emitted by LED products, and to state which of them the Department or the Food and Drug Administration administers. Part IX.H.2.

6. Absence of research, development, training, or operational activity directed to this radiation

The Foundation is aware of one study conducted under this program bearing on light-emitting products in the built environment, and it predates LED illumination. Part II.I.4. It is aware of no research program, no development activity, no training activity, and no operational activity directed to the emissions of, or the exposure of people to, visible light emitted by LED products. The Foundation's action under the Freedom of Information Act seeks the agency's records on this subject, Part IV.D.3, and what has been produced is described at Part IV.D.4.

The Center has described this duty in its own words, and has described it as something it does

The preceding paragraphs state an absence. The Foundation now sets beside it the Center's own account of the same duty, because the Center has given one, in writing, more than once, and the account is useful in two opposite directions.

On May 23, 2019 the Director of the Center for Devices and Radiological Health wrote to two physicians of an organization called Physicians for Safe Technology, answering a letter of December 9, 2018 about radiofrequency exposure. The second and third sentences of that letter are the ones that matter here. The first of the two describes the program:

> "The Food and Drug Administration (FDA) has the responsibility to establish and carry out an electronic product radiation control program designed to assure the safety of electronic product radiation exposure to people."

The second recites paragraph (a)(2), substantially in the words of the statute:

> "CDRH plans, conducts, coordinates, and supports research, development, training, and operational activities to minimize the emissions of and the exposure of people to, unnecessary electronic product radiation."

The Foundation makes three observations about those two sentences and no more.

First, the Center states paragraph (a)(2) as a description of what it does

The second sentence is not a paraphrase of the duty. It is the duty, reproduced with its four verbs, its four objects and its purpose, and the subject of the sentence is CDRH. The Center has therefore told correspondents that the activities paragraph (a)(2) directs are activities it carries out. For the radiation the letter was about, it then said what they consist of: that Center staff began monitoring developments in the scientific literature on radiofrequency exposure from wireless technologies in the early 1990s and continue to monitor new publications as they become available.

The Foundation does not dispute any of that and offers no view on whether it satisfies paragraph (a)(2) for radiofrequency energy. It records the contrast, which is the subject of this subsection. For radiofrequency energy the Center can name the activity and date its commencement to a decade. For visible light emitted by light-emitting diode products the Foundation has identified no research program, no development activity, no training activity and no operational activity, and the request at Appendix E.48 that sought the Center's records of this program as applied to fourteen product categories has produced none. Part IV.D.3.

Second, the first sentence is not what the statute says

Section 360ii(a) directs a program "designed to protect the public health and safety from electronic product radiation." The letter describes a program designed to assure the safety of electronic product radiation exposure to people. The Foundation does not suggest that the difference was intended, and a letter to correspondents is not a statutory construction. But the difference is there and it runs in one direction. The statute protects people from the radiation. The sentence assures the safety of the exposure. And the words public health, which the statute places first among the two things to be protected, do not appear.

Third, and this is the Foundation's point, the letter recites the minimizing duty and then answers only the safety question

Having set out paragraph (a)(2) in the third sentence, the letter does not return to it. What follows, over four pages, is an assessment of whether an adverse effect has been established: that the weight of all available scientific evidence shows no association between exposure at or below the Commission's limits and any adverse health outcome; that causation of an adverse effect at or below those limits has not been established; that the Center continues to believe the existing limits are sufficient to protect the public. Every one of those is a proposition about safety. None is a proposition about minimizing.

The same framing appears in the Center's public statement of February 2, 2018 on the draft report of the National Toxicology Program, where the Director described the mission in these terms: one part of the agency's mission is to ensure the safety of electronic products that emit radiation, like televisions and cell phones. That statement reports a fifty-fold safety margin and concludes that the current safety limits for cell phones are acceptable for protecting the public health. The word minimize does not appear in it.

The Foundation draws the conclusion this subsection has been building toward, and states it without characterizing anyone. The two duties are different. A finding that an emission is below a level at which harm has been established answers the question paragraph (a)(1) and § 360kk pose, which is whether a standard is necessary. It does not answer the question paragraph (a)(2) poses, which is whether the emission and the exposure are being minimized, and which does not wait on a finding of harm. Part II.D.4 establishes that the paragraph names two objects and that the word

unnecessary identifies the subset to be reduced. A product may be safe in the sense the Center's letters use and still emit more radiation than its function requires. The Foundation has not found, in either document, any statement addressed to that question.

One further feature of the May 2019 letter belongs here because it concerns the evidence base rather than the reasoning. The letter closes with a list of the references the Center used as benchmarks for its conclusions, twelve items, naming the European scientific committee, Health Canada, a New Zealand interagency committee, the Swedish radiation safety authority, the Health Council of the Netherlands twice, Public Health England, the National Cancer Institute, two reports of the National Council on Radiation Protection and Measurements, the publications of the International Commission on Non-Ionizing Radiation Protection, and the World Health Organization's international project. Every one concerns radiofrequency or electromagnetic fields. None concerns optical radiation. The Foundation offers that as a description of the list and not as a criticism of it: the letter was about radiofrequency energy and its benchmarks were chosen accordingly. What the list establishes is what the Center had assembled on the subject it was writing about, and the comment asks at Part IX.B for the equivalent as to this one.

The scale of the exposure that has gone unexamined is worth stating, and the Foundation takes the figures from the Department of Energy rather than offering its own.

That Department's most recent published adoption report counted 2,325 million light-emitting diode units installed in general illumination applications in the United States, amounting to 30.0 percent of the installed base, of which approximately 2.2 billion were indoor and approximately 100 million outdoor. Outdoor penetration stood at 51.4 percent. Those figures describe 2018.

Three things about that count bear on this subsection. It is the most recent federal count the Foundation has been able to identify. It predates the rules described at Part IV.G, which took effect in 2023 and after and which displaced the remaining incandescent and halogen general service lamps, so present penetration is necessarily higher and by an amount no federal source appears to state. And it counts units rather than emitters: a single lamp or luminaire contains one or more emitting dies, and in many products a great many, so the number of discrete emitters exceeds the number of units by a factor the Foundation does not attempt to estimate.

General illumination is also only one category of application, and not the one in which the highest source radiances occur. The adoption report does not count, among others:

- vehicle lighting — headlamps, daytime running lamps, signal and marker lamps, and auxiliary lamps, across the registered vehicle fleet, each assembly containing multiple emitters. Part VI.B;
- emergency, warning and flashing lamps on police, fire, emergency medical, utility and work-zone vehicles, and the pedestrian crossing beacons treated at Part VI.C;
- traffic control signals;
- signage, billboards and dynamic message displays. Part VI.J;
- security and deterrent lighting. Part VI.I;
- indicator and status lamps in appliances, electronics and equipment, which are individually small but are present in every occupied room;
- displays and screens, in which the emitting elements are counted per device in the millions. Part VI.H.

The Foundation is not able to give the Department a figure for these categories, and it declines to estimate one. Two reasons, and the second is the more important.

The first is that no federal inventory appears to exist. The Department of Energy counts general illumination because its own standards operate there. No federal source the Foundation has

identified states how many light-emitting diode emitters are deployed in the United States across all applications, in what settings, or at what radiance. That absence is not merely an inconvenience for this comment. It is directly responsive to this request for information, and it is a gap in the very thing § 360ii(a)(4) directs the Secretary to study: emissions of, and conditions of exposure to, electronic product radiation. If the Department cannot say how much of this radiation is deployed and where, the evaluation that paragraph directs has not been performed.

The second is that a count of emitters would not answer the question the statute asks, and the Foundation does not want the Department to be distracted by one. Paragraph (a)(2) is directed to the exposure of people. Paragraph (a)(4) is directed to conditions of exposure. Neither is a census. The emitting element in a handheld display, one of several million in the device, viewed at arm's length and contributing a small fraction of a modest total luminance, is not the same regulatory object as the die in a headlamp viewed directly at night across a two-lane road. Summing them produces a large number and tells the Department nothing it can act on.

What would tell the Department something it can act on is the characterization Part IX.C asks for: exposure organized by the spatial, spectral and temporal properties of the emission and by the conditions under which people encounter it. The relevant quantities are how many people are exposed, in what setting, at what radiance, at what angle, for how long, and how often. The Foundation asks for those, and not for a tally.

The duty to minimize presupposes a baseline

There is a further consequence of the absence just described, and the Foundation regards it as the most important thing in this subsection.

Minimization is a comparative idea. The word less requires a than what. A threshold is different in this respect, and the difference is practical rather than semantic. Compliance with a limit can be determined at a single moment from a single measurement of a single product: the product is beneath the limit or it is not, and nothing about the past is needed to say so. A duty to minimize cannot be assessed that way. It requires a measured starting condition and subsequent measurement, because the question it poses is whether exposure is lower than it was.

For visible light emitted by LED products the Department cannot presently answer that question in either direction. It does not know how many sources are deployed, in what applications, at what radiance, or how the exposure of people to them has changed across the period in which the installed base of general illumination was substantially replaced. Neither does anyone else. There is no figure from which a reduction could be measured, and therefore no way for the Department to establish that any step it takes under paragraph (a)(2) has had an effect, and no way for anyone outside the Department to check.

The Foundation stresses that this observation requires no view at all about whether light emitted by LED products injures anyone. It would hold if every proposition in Part V were resolved in the agency's favor. An agency directed to minimize an exposure needs to know the exposure in order to tell whether it is minimizing it. So does Congress, to which § 360jj directs reports, and a report that an exposure is being minimized conveys nothing in the absence of a quantity. Part II.I.

The relationship between the paragraphs is what makes this structural rather than rhetorical. Paragraph (a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. That is the measurement function. Paragraph (a)(2) directs minimization. The second cannot be performed, and cannot be shown to have been performed, without the first. These are not two independent items on a list of six. One supplies what the other requires, and the order between them is not optional.

The agency's own practice for the products it does regulate confirms the point rather than being in tension with it. Section 360kk(a)(1) provides that a performance standard may include provisions for the testing of products and the measurement of their electronic product radiation emissions, and 21 C.F.R. part 1002 requires manufacturers of listed products to make reports to the agency.

Where the agency has acted under this chapter it has built the measurement and the reporting alongside the limit, because a program that prescribes without measuring cannot tell whether it has accomplished anything. For visible light emitted by LED products there is no limit, no measurement procedure, and no reporting requirement. The three absences are of a piece.

What the Foundation asks follows directly, and it is modest. Establishing a baseline is a bounded undertaking. It requires the Department to conclude nothing about harm, to prescribe no standard, and to resolve no contested scientific question. It requires it to determine what is deployed and how people are exposed to it, to express the result in quantities that bear on biological effect rather than on appearance, and to publish it, so that the question whether exposure is being minimized becomes a question capable of being answered. Parts IX.H.3 and IX.H.7 state the request. Everything else the Foundation asks under paragraph (a)(2) depends on it, and so, the Foundation submits, does the Department's ability to say that the paragraph has been carried out.

The Foundation offers the figures for one purpose only. Paragraph (a)(2) directs the minimization of the exposure of people. Whatever latitude the Secretary has in choosing which forms of electronic product radiation to address first, a form that reaches substantially the entire population indoors and outdoors, that was placed there in substantial part by federal action, and that has been the subject of no research, development, training or operational activity under this program, is not an obvious candidate for being left until last.

What paragraph (a)(2) would require is set out among the requests at Part IX: a stated definition of unnecessary optical radiation in terms of quantity, direction, spectral content, and temporal character; measurement methods referred to the point of human exposure rather than to the luminaire; evaluation of the conditions under which people are exposed, which is paragraph (a)(4); and techniques for minimizing that exposure, which is paragraph (a)(5). The paragraph has not been performed as to this radiation, and nothing in the record supplies a reason why not.

E. § 360ii(a)(3) — Maintain Liaison With and Receive Information From Other Agencies, Professional Organizations, and Industry

1. What the subsection requires, and of whom

Paragraph (a)(3) directs the Secretary to:

> maintain liaison with and receive information from other Federal and State departments and agencies with related interests, professional organizations, industry, industry and labor associations, and other organizations on present and future potential electronic product radiation

Four features of the text govern this subsection.

The first is that it contains two directions, not one. The Secretary is to maintain liaison with the listed sources, and to receive information from them. The second verb is unusual in a statute and the Foundation does not overread it. It does not require the agency to agree with what it receives, or to act on every submission, and the Foundation does not contend otherwise. What it does mean is that receipt is a function the program is directed to perform, and that information arriving from the listed sources arrives into a statutory duty rather than into a general correspondence file.

The second is the breadth of the sources, which is wider than any other paragraph in the section. It reaches other Federal departments and agencies, State departments and agencies, professional organizations, industry, industry and labor associations, and "other organizations." The reference to State agencies is unique to this paragraph; paragraph (a)(6) names Federal officers only. So is the residual phrase other organizations, which is what brings bodies such as the Foundation within the paragraph's terms.

The third is the subject matter, and it is the most striking thing in the paragraph. The liaison and the information are to be on "present and future potential electronic product radiation." The duty is written to run ahead of the technology. It attaches not only to radiation that exists but to radiation that may come to exist, which means it attaches before any product is marketed, before any exposure occurs, and necessarily before any harm could be demonstrated. An agency directed to maintain liaison on future potential electronic product radiation is not well placed to say that it had no occasion to consider a technology that has been in nationwide deployment for fifteen years.

The fourth is what the paragraph does not contain. There is no determination clause, no finding of necessity, and no qualifier of the kind the government has relied upon elsewhere in this section. The word appropriate does not appear. The word necessary does not appear. Part I.C.5 sets out which paragraphs the Foundation claims as unqualified and why; this is one of them, and the Foundation claims it without reservation.

2. Other Federal departments and agencies with related interests

Part II.H treats the consultation directed by paragraph (a)(6), and the agencies are largely the same. The two paragraphs differ in what they require and the comment keeps them apart. Paragraph (a)(6) names four officers, adds a residual class qualified by the word appropriate, and specifies two subjects: testing and evaluation techniques, and the development of performance standards. Paragraph (a)(3) names no officer, admits no qualifier, and is addressed to information about the radiation itself.

The practical consequence is that an agency which concluded that consultation with a particular department was not appropriate under paragraph (a)(6) would still be directed by paragraph (a)(3) to maintain liaison with it and to receive information from it, if it is a Federal department or agency with a related interest. The Foundation does not press that point far, because the agencies it identifies at Part II.H have related interests on any view. It states it so the Department does not treat a judgment made under one paragraph as disposing of the other.

3. State departments and agencies

No other paragraph of § 360ii reaches State agencies, and the omission elsewhere makes the inclusion here deliberate. The State bodies with related interests in this subject are readily identified.

State departments of transportation, which adopt and amend the Manual on Uniform Traffic Control Devices and so determine the flash rate, intensity and placement of the warning devices treated at Part VI.C.2. California's manual is discussed at Part VIII.

State energy offices and public utility commissions, which administer the efficiency programs and utility tariffs under which municipal street lighting has been converted.

State departments of public health.

The States that have enacted outdoor lighting statutes, which legislate on the subject of this comment in the absence of any federal measurement convention or exposure criterion. Part II.D.3.

State departments of labor, and in particular the twenty-nine jurisdictions that operate occupational safety and health plans approved under the Occupational Safety and Health Act. Twenty-two of those plans cover private sector together with State and local government employees, and seven cover State and local government employees only. Each must be at least as effective as the federal program, which permits a State to act in an area where the federal program has not. The occupational exposures described at Part II.H.10 and Part VI.F are within the subject matter of those plans, and a State plan is at present as likely a source of a first occupational criterion for optical radiation as the federal program is.

State consumer protection agencies and offices of State attorneys general, which receive complaints about consumer products and administer the State unfair and deceptive practices statutes. These are mentioned here for a particular reason, developed below.

The Foundation is aware of no instance in which the agency has maintained liaison with, or received information from, a State department or agency concerning visible light emitted by LED products. It asks the Department to say whether any such liaison exists.

The reference to State consumer protection offices is not incidental. Part VII.J describes the absence of any federal system for collecting reports of adverse reaction to optical radiation, and Part VII.J.1 records that the Foundation asked a component of this Department to establish one and that none was established. Complaints that have no federal destination do not stop being made. They go to retailers, to manufacturers, to local government, and to State consumer protection offices and attorneys general, which collect and retain them.

Paragraph (a)(3) directs the Secretary to receive information from State departments and agencies. It follows that information bearing on the conditions of exposure described at Part VI may already exist in State files, and that the Department is directed to receive it. Obtaining it would require no rulemaking, no new collection system and no determination of any kind. It would require asking. The Foundation asks the Department to ask, and to begin with the States operating approved occupational safety and health plans and with the consumer protection offices of the most populous States. Part IX.D.

4. Professional organizations and standards bodies

The Illuminating Engineering Society, the Institute of Electrical and Electronics Engineers, the International Commission on Illumination, SAE International, the National Electrical Manufacturers Association, the American National Standards Institute and the International Electrotechnical Commission publish the documents that manufacturers and public entities actually follow. Several bear directly on the subject of this comment: IEC 62471 and CIE S 009 on the photobiological safety of lamps and lamp systems, the ANSI/IES RP-27 series on the same subject, IEEE 1789-2015 on temporal light modulation, and SAE J595 on the intensity of flashing warning lamps. Part V discusses each where it is relevant.

Whether the agency participates in, comments upon, or tracks the work of any of these bodies as to incoherent optical radiation is not apparent from the public record, and the Foundation asks the Department to say.

The question is pointed because the agency plainly does so for the other light-emitting product class it regulates. On May 8, 2019 the Center for Devices and Radiological Health issued guidance titled Laser Products — Conformance with IEC 60825-1 Ed. 3 and IEC 60601-2-22 Ed. 3.1, known as Laser Notice No. 56, Docket No. FDA-2017-D-7011, announced at 84 Fed. Reg. 20,140, and succeeding Laser Notice No. 50, which the Center issued on May 27, 2001 and revised in 2007. By it the Center stated that for manufacturers complying with the comparable clauses of the specified international standards it does not intend to enforce the corresponding requirements of its own performance standards at 21 C.F.R. §§ 1040.10 and 1040.11. The agency gave two reasons. The first is that conforming to the identified international standards "may cause manufacturers to duplicate their efforts." The second is the one that matters here:

> "FDA acknowledges the advantages of one set of criteria and requirements worldwide."

And, as to its own regulations, the agency states that it "eventually intends to amend its standards for laser products at §§ 1040.10 and 1040.11 to harmonize" its requirements with those of the International Electrotechnical Commission. As of the date of this comment that amendment has not been made. The intention was announced in 2019, was carried forward in the guidance as reissued on February 21, 2023, and the performance standards for laser products read today as they read before it.

The Foundation draws no criticism from that. It is sensible regulatory practice and the Foundation would welcome its extension. The point is the comparison, and the comparison is not the one it first appears to be.

The agency has engaged with this Commission's work on incoherent optical radiation as well, and the Foundation states that record because the record is favorable to the request this comment makes. On August 20, 2012 the agency recognized IEC 62471, Photobiological safety of lamps and lamp systems, as a consensus standard under section 514(c) of the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. § 360d(c). The recognition is numbered 12-249, appears on Recognition List 029, and is assigned to the Radiology specialty task group. The extent of recognition is not partial. The agency's record states it as "Complete standard."

The scope of the standard, as the agency's own recognition record states it, is the following:

> "This International Standard gives guidance for evaluating the photobiological safety of lamps and lamp systems including luminaires. Specifically it specifies the exposure limits, reference measurement technique and classification scheme for the evaluation and control of photobiological hazards from all electrically powered incoherent broadband sources of optical radiation, including LEDs but excluding lasers, in the wavelength range from 200 nm through 3000 nm."

Three features of that record are material, and the Foundation asks the Department to weigh each.

First, the standard the agency has recognized covers the emitting technology at issue in this comment. The agency's own abstract says so in terms: incoherent broadband sources of optical radiation, "including LEDs but excluding lasers." Whatever else is uncertain in this field, it is not in doubt that the agency holds a recognized standard whose stated scope reaches light-emitting diodes.

Second, the stated ground of recognition is the standard's merit. The record gives as its rationale that the standard "is relevant to medical devices and is recognized on its scientific and technical merit and/or because it supports existing regulatory policies." The agency has therefore already made a judgment that the reference measurement technique, the exposure limits and the classification scheme of IEC 62471 are scientifically and technically sound. That is not a judgment the Foundation asks the Department to make for the first time. It has been made.

Third, and most directly to the purpose of this comment, the recognition record identifies the authority under which this comment is submitted. Among the entries the record lists under relevant guidance and supportive publications is this one:

> "FD&C Act Chapter V Drugs and Devices, Subchapter C Electronic Product Radiation Control (21 U.S.C. 360hh - 360ss), 2006"

That is the subchapter. It is the subchapter that creates the duties described throughout Part II of this comment, the subchapter under which the Final Response of May 24, 2024 was issued, and the subchapter from which the Secretary's authority to prescribe a performance standard for an electronic product derives. The agency itself placed the photobiological safety standard for lamps and light-emitting diodes alongside it, in its own record, in 2012.

What the recognition does, and what it does not

The Foundation is careful here, because the recognition does less than its existence might suggest, and this comment should not overstate it.

Recognition under section 514(c) operates in the premarket review of medical devices. It permits a manufacturer to declare conformity to a recognized standard in support of a premarket submission in place of submitting the underlying test data. It is not a performance standard prescribed under 21 U.S.C. § 360kk, it imposes no requirement on any product, and it reaches no product that is not a medical device.

The confinement is visible on the face of the record. The device types to which the recognition is keyed are thirteen product codes, every one of them Class II and every one of them a laser or light-based surgical or cosmetic instrument regulated under 21 C.F.R. § 878.4810: powered laser surgical instruments, dental soft-tissue lasers, lasers for benign prostatic hyperplasia, over-the-counter light-based devices for wrinkle reduction, hair removal and acne, laser-assisted lipolysis, and others of that character.

So a standard that by its own scope covers light-emitting diodes is applied, in this agency, to thirteen categories of medical device. It is not applied to a roadway luminaire, a vehicle lamp, a video display, an appliance indicator or any other product described at Part VI, and the mandatory performance standards at 21 C.F.R. part 1040 prescribe nothing for any of them. Part II.C.

Two halves of one framework, and one half of the other

Set out as a table, the agency's recognition record for the relevant international documents reads as follows. Each entry is taken from the agency's own Recognized Consensus Standards database.

Standard, as designated in the recognition record	Date of entry	Recognition number, extent, specialty task group
IEC 62471 First edition 2006-07, Photobiological safety of lamps and lamp systems	08/20/2012	12-249; Recognition List 029; complete standard; Radiology
IEC 60825-1 Edition 2.0 2007-03, Safety of laser products — Part 1: Equipment classification, and requirements	07/09/2014	12-273; complete standard; Radiology
IEC/TR 62778, Application of IEC 62471 for the assessment of blue light hazard to light sources and luminaires	None located	No recognition record located
IEC 62471-6 and IEC 62471-7	None located	No recognition record located

One entry in that table deserves a sentence of its own. The edition of IEC 60825-1 the agency recognized in July 2014 is Edition 2.0 of March 2007. That is the edition whose foreword states that light-emitting diodes have been removed from the scope of the laser safety standard. Part V.C.2.k sets out that history. The agency recognized, as a complete standard, the instrument that excludes light-emitting diodes, and recognized the instrument that includes them only for thirteen classes of medical device.

The asymmetry the Foundation asks the Department to notice is therefore not between two product classes. It is between two halves of a regulatory structure.

For coherent optical radiation the agency has both halves. It has recognized the international standard, and it has prescribed its own mandatory performance standard for the product, at 21 C.F.R. §§ 1040.10 and 1040.11, with reference conditions, classification, labeling and reporting requirements written for the American market. The international standard supplies the method. The federal standard supplies the obligation.

For incoherent optical radiation the agency has the first half and not the second. It has recognized the international standard, on the ground of its scientific and technical merit, with a stated scope that includes light-emitting diodes, and with the electronic product radiation control subchapter named in the same record. It has never prescribed the performance standard. There is no part 1040 counterpart for a light-emitting diode product.

That is the gap, stated as precisely as the Foundation can state it. It is not an absence of expertise, because the agency has assessed this standard and found it meritorious. It is not an absence of relationship with the standards body, because the agency has recognized two of its standards and adopted a third as an enforcement alternative. It is not an absence of authority, because § 360kk supplies it and the agency's own recognition record cites the subchapter that contains it. What is absent is the second half of the structure the agency built for lasers, for an emitting technology that reaches incomparably more people.

One recent document bears directly on this paragraph. In October 2024 the International Energy Agency's 4E Solid State Lighting Annex published a review of the health effects of solid-state lighting, described at Part V.C.2.f, which recommends in terms that "photobiological safety committees engage in a systematic review and update of the blue light hazard exposure limits." It is information from an intergovernmental body, addressed to the standards committees whose documents the Final Response of May 24, 2024 relied upon, concerning present and future potential electronic product radiation. That is the subject matter paragraph (a)(3) describes.

The Foundation asks whether the agency received, reviewed, or responded to it.

One consortium warrants specific mention, because for two decades it occupied the position this paragraph contemplates the Secretary occupying, and because Mr. Baker filed its publications as evidence in the litigation described at Part IV.D.

The Alliance for Solid-State Illumination Systems and Technologies, known as ASSIST, was established in 2002 by the Lighting Research Center at Rensselaer Polytechnic Institute. Its own description of its constitution is that ASSIST was established by that center "as a collaboration among researchers, manufacturers, public benefit and government organizations to find solutions to the many technical and market challenges facing solid-state lighting."

What it produced is the material point. By its own account ASSIST "has developed definitions and calculation tools to evaluate light source flicker, discomfort glare, dimming, color rendering capability, and mesopic efficiency," together with application metrics for "under-cabinet, directional, decorative, parking lots, roadways, and freezer cases," published in a series titled ASSIST recommends. Its first industry recommendation, released in 2005, defined the useful life of an LED at L70 and supplied a method of estimating it, which in its own account "eventually became the basis for the IES LM-80 standard."

Two of the five light-source characteristics in that list — flicker and discomfort glare — are among the emission characteristics this comment identifies at Parts V.C.4 and V.D. The calculation tools by which they are evaluated were developed by an industry consortium organized at a private university. No federal equivalent exists.

The membership is also of record. The list printed on the consortium's own publication reads: "Amerlux; Federal Aviation Administration; Finelite; GE Current, a Daintree Company; Hubbell Lighting; New York State Energy Research & Development Authority; OSRAM; U.S. Environmental Protection Agency."

The Foundation draws a narrow point from that list and wishes to be exact about its limits. Participation in a research consortium is not regulatory authority, and the membership contradicts nothing either federal member later wrote. The Environmental Protection Agency's letter of October 7, 2022 and the Federal Aviation Administration's of November 9, 2022 addressed their authority to regulate, not their participation in research, and each agency had a program reason of its own to take part. Parts II.H.3 and II.H.7.

The point concerns the composition of the room. Two federal agencies contributed to the consortium that developed the metrics by which LED illumination is characterized, and a State energy authority contributed alongside them. The agency to which both of those federal agencies deferred on questions of health and safety was not a member, and the Foundation has located no

record of its participation in, comment upon, or correspondence with the consortium at any point in its operation.

Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from professional organizations, industry and labor associations and other organizations on present and future potential electronic product radiation. A consortium organized to define the performance of the emitting product, with federal agencies among its members and a publication record spanning two decades, is the paradigm case of what that paragraph describes. Whether the Department received information from it, and if so what became of that information, is a question only the Department can answer.

5. Industry and labor associations

The paragraph names industry, and industry and labor associations, separately. As to industry, the manufacturers of the products at issue and their trade associations hold the emission data that Part IX.F asks be disclosed: spectral power distribution, source radiance, driver switching frequency and modulation depth. That information is measured in the ordinary course of manufacture. It is not published, and no federal requirement compels its publication. Paragraph (a)(3) directs the Secretary to receive it.

As to labor, Part II.H.10 sets out the three places in which this chapter speaks of labor organizations, of which this paragraph is one. The Foundation is aware of no instance in which the agency has sought or received information from a labor association concerning occupational exposure to visible light emitted by LED products, and the occupational settings at issue are described at Part II.H.10 and Part VI.F.

6. Information received and not acted upon

The Foundation is an "other organization" within the terms of this paragraph, and the record of what it has transmitted to the agency is set out at Part IV.B: the LED Incident Reports, the petition comments, the signature totals, and the related correspondence. The agency acknowledged receipt. Part IV.B.3 reproduces the acknowledgments and Part IV.B.8 tabulates them.

Receipt is therefore not in dispute, and the Foundation does not frame this subsection as a complaint that the information failed to arrive. It arrived, and the Department's own files confirm it. Part IV.B.7.

What the Foundation cannot establish from the public record is what became of it. No evaluation of the reports has been published. No analysis of them appears in the Final Response of May 24, 2024, which addresses the published literature and not the reports. The Foundation does not assert that no evaluation occurred, because it does not know; the action described at Part IV.D.3 seeks the agency's records on precisely this question and has not yet produced them.

The distinction the Foundation asks the Department to hold onto is the one drawn in subsection 1. Paragraph (a)(3) directs that information be received. Paragraph (a)(4) directs that emissions and conditions of exposure be studied and evaluated. Receipt discharges the first. It does not discharge the second, and a program in which information arrives, is acknowledged, and is not evaluated has performed the collecting function of § 360ii without performing the evaluating one.

The Foundation accordingly asks the Department to state what was done with the material described at Part IV.B after it was received; whether any evaluation of it was undertaken and by whom; and if none was, what the agency understands paragraph (a)(3) to require of it once information has been received. Part IX.H.4.

Information published by a component of this Department

One body of information requires separate mention, because it did not have to be received from anyone. It originated inside the Department.

Environmental Health Perspectives is the peer-reviewed journal of the National Institute of Environmental Health Sciences, an institute of the National Institutes of Health, within the Department of Health and Human Services. In May 2025 that journal published a case-control study of 736 children with papillary thyroid cancer and 36,800 controls, nested in a California birth cohort, examining perinatal exposure to fine particulate matter and to outdoor artificial light at night. Appendix C.11 sets out the study. Its statement of objectives contains the following sentence:

> "Both are considered environmental carcinogens with evidence of thyroid function disruption, reported associations with thyroid cancer in adults, and concerns of distributive inequity."

The Foundation is exact about what that sentence is and is not, because the temptation to overstate it would be the quickest way to lose the point. It is a characterization in the authors' statement of rationale, describing how the two exposures are regarded in the literature they are working in. It is not a finding of the study. It is not a regulatory classification, and the Foundation does not assert that one exists. The International Agency for Research on Cancer has classified night shift work involving circadian disruption as probably carcinogenic to humans, in Group 2A; it has not classified outdoor artificial light at night, and the two are not the same exposure.

What the Foundation asks the Department to weigh is the relation between two statements, and the fact that both of them are the Department's.

- In May 2024 the Center for Devices and Radiological Health wrote that light-emitting diode products have a long history of safety with respect to the visible wavelengths being emitted, and that performance standards have historically not been considered necessary. Part I.C.
- In May 2025 a journal published by an institute of the same Department published peer-reviewed research describing outdoor artificial light at night as considered an environmental carcinogen, and reporting an association between it and pediatric papillary thyroid cancer.

The Foundation does not contend that those statements are formally inconsistent. They can be reconciled: the first addresses performance standards for electronic products under subchapter C, and the second concerns ambient outdoor light from all sources. The Foundation asks whether they have in fact been reconciled, by whom, and on what basis. A determination resting on a long history of safety is a determination about the state of knowledge, and the state of knowledge is partly constituted by what this Department itself publishes.

The same journal, fifteen years earlier

The 2025 study is not the first occasion on which this Department's journal addressed this subject, and the earlier instance bears more directly on a determination resting on a long history of safety, because it precedes that determination by fourteen years.

In December 2010 Environmental Health Perspectives published, in its news section, an item headed Light Pollution: Light at Night and Breast Cancer Risk Worldwide, at volume 118, page A525. The Foundation is precise about what that item is: it is science journalism, written by a freelance science writer, and it is not peer-reviewed research. It is not in Appendix C for that reason. What makes it material is not its authority as science but its provenance as a publication of an institute of this Department, and what it records.

It records four things.

First, the state of the field as of 2010, described in the Department's own journal as already established rather than novel. The item opens by stating that several studies over the preceding decade had suggested that exposure to artificial light at night increases cancer risk, particularly for cancers that require hormones to grow, and it recites the two findings that frame the literature:

elevated breast cancer rates among women who work night shifts, and decreased risk among blind women. Part V.G records that the hypothesis itself dates from 1987.

Second, the International Agency for Research on Cancer classification, which this comment cites elsewhere. The item identifies the source as the Agency's Monographs volume 98, Painting, Firefighting, and Shiftwork, published in 2007.

Third, a research program inside this Department, coordinated. The item quotes Les Reinlib, identified as the program director who coordinates grants of the National Institute of Environmental Health Sciences related to the health effects of light at night:

> "Light at night is likely to be one of a number of factors that contributed to the increase in breast cancer over the last few decades. … It seems to be significant, and if it is, then that's something we can control."

Fourth, practical advice to readers. Under the heading Embrace the dark, the item set out measures for reducing circadian disruption: extending the dark period to nine or ten hours, installing room-darkening shades, avoiding brief light exposures, and using a dim red light rather than ordinary lighting if one rises at night, on the stated ground that red light suppresses melatonin production less than other wavelengths.

The Foundation draws two points from this and no more.

The first concerns the coordination argument made above, which this item sharpens and partly corrects. The Foundation wrote that the support exists and the coordination does not. The item shows that as to the research itself coordination did exist, in 2010, within the National Institute of Environmental Health Sciences, with a named program director holding the portfolio. The accurate statement is therefore narrower and worse. Research on the health effects of light at night was not merely funded by this Department; it was coordinated as a program. What the Foundation has been unable to find is any connection between that coordinated program and the Center that holds the authority to prescribe a performance standard for a light-emitting product under § 360kk. The two are components of one Department.

The second concerns the wavelength statement, which the Foundation notes because of where it appears. The proposition that red light suppresses melatonin less than other wavelengths is a proposition about the spectral composition of emitted light and its biological effect. It appeared in a publication of an institute of this Department in 2010, addressed to the general reader as practical guidance. Part V.B.3 describes the absence of any federal requirement addressed to the spectral composition of a light-emitting product, and Part IV.G describes a federal efficacy standard that selects against the long-wavelength content this item advised readers to prefer.

The item also reports the caution a reviewer offered, and the Foundation reproduces it because a comment that quoted only the favorable half of a source would deserve to be discounted. The Harvard epidemiologist Eva Schernhammer is quoted agreeing that the study added evidence, while observing that as an ecological study its result, even had it been negative, would not have been strong enough to rule out the evidence from prior case-control studies. The study the item reports is at Appendix C.58, which grades it as an ecological analysis and sets out its limitations at length.

There is a further fact in this sequence, and it goes beyond publication to expenditure. In September 2024 Frontiers in Neuroscience published a study reporting an association between outdoor nighttime light intensity and the prevalence of Alzheimer's disease across the United States. The funding statement identifies two grants of the National Institutes of Health, numbered R01AG056653 and R24AA026801.

The Foundation is as careful with this study as with the last. It is an ecological analysis, which is the weakest observational design in this comment, and Appendix C.16 grades it accordingly and at

length. Nothing in this subsection depends on its finding being correct, and the Foundation does not assert that artificial light causes Alzheimer's disease.

What the Foundation asks the Department to notice is not the result but the grant. Publication in a journal of an institute of this Department shows that the Department's scientific community regards the subject as worth investigating. A grant shows that the Department allocated money to it. Those are different facts and the second is harder to answer.

It bears directly on the text of § 360ii(a)(2), which directs the Secretary to plan, conduct, coordinate, and support research to minimize the emissions of and the exposure of people to unnecessary electronic product radiation. Four verbs. A grant from the National Institutes of Health for research into the health effects of artificial light at night is the Secretary supporting research on this subject. The Foundation does not criticize that and would not have it stop. It observes that of the four verbs in the paragraph, the one being performed is the one that requires only money, and the three that require a program — planning, conducting, and above all coordinating — are the ones for which the Foundation has found no evidence as to light-emitting diode products. The support exists. The coordination does not. And because both the funding institute and the Center holding the radiation-control authority report to the same Secretary, the coordination that is absent is not interagency coordination. It is coordination within one Department.

There is a further point about paragraph (a)(3) that the Foundation puts shortly. That paragraph directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests. Where the related interest lies within the Secretary's own Department, there is no channel to establish and no other agency to persuade. Whatever difficulties attend interagency coordination, and Part II.H describes several, none of them applies here. The National Institutes of Health and the Food and Drug Administration answer to the same Secretary, and it is the Secretary on whom § 360ii places these duties.

F. § 360ii(a)(4) — Study and Evaluate Emissions of, and Conditions of Exposure to, Electronic Product Radiation

Three lines of argument in this comment converge on this paragraph, and the Foundation sets them out together because the paragraph is where the rest of Part II comes to rest. Part I.C.8 holds that the judgment committed to the Secretary by § 360kk(a)(1) operates on a record, and that this paragraph is what produces it. Part II.D.6 holds that a duty to minimize cannot be performed, or shown to have been performed, without the measurement this paragraph directs. Part II.E.6 holds that information received under paragraph (a)(3) is evaluated under this one. If paragraph (a)(4) has not been carried out as to a form of electronic product radiation, very little else in the program can be.

1. What the subsection requires

Paragraph (a)(4) directs the Secretary to:

> study and evaluate emissions of, and conditions of exposure to, electronic product radiation and intense magnetic fields

The paragraph is nineteen words long and three features of it matter.

The first is that it contains two objects, not one. The Secretary is to study and evaluate emissions, and to study and evaluate conditions of exposure. These are different subjects and they are measured differently. An emission is a property of a product and can be characterized in a laboratory: what the device radiates, at what wavelengths, at what radiance, with what temporal structure. A condition of exposure is a property of the world: who encounters the radiation, where, at what distance and angle, for how long, how often, and alongside what else. A measurement of a luminaire on a bench answers the first and is silent on the second. The paragraph requires both, and the second is the one that reaches the installed environments described at Part VI.

The second is the phrase that closes the paragraph. The subject matter is electronic product radiation "and intense magnetic fields." Those words do not appear in the definition at § 360hh(1), and they do not appear in the standard-setting provision at § 360kk. Congress named an additional subject for study that it did not name for regulation.

The consequence is structural and the Foundation asks the Department to weigh it. The duty to study is written wider than the power to prescribe. An agency may be directed to evaluate what it does not regulate, and under this section it is. It follows that a determination that a performance standard is unnecessary cannot answer paragraph (a)(4), because the two provisions were not drawn to the same scope. The letter of May 24, 2024 disposed of a request made under § 360kk. It did not reach this paragraph, and on the face of the statute it could not have.

The third is what the paragraph omits. There is no determination clause. There is no finding of necessity. There is no qualifier of the kind the government has relied on elsewhere in this section. Part I.C.5 identifies the paragraphs the Foundation claims as unqualified, and this is the central one.

2. Information bearing on conditions of exposure already in the agency's possession

The paragraph does not require the Secretary to generate every input from nothing. A substantial body of material bearing on conditions of exposure to this radiation is already in the Department's files, and most of it was placed there by the Foundation or by other federal agencies.

The LED Incident Reports transmitted to the Center for Devices and Radiological Health and acknowledged by it. Part IV.B. Each report describes a setting, a source and an effect; whatever is made of the effects, the settings and sources are descriptions of conditions of exposure, which is what this paragraph directs the Secretary to study.

The regulatory petitions, the comments filed on them, and the signature totals. Part IV.C.

The record of the federal action that produced the exposure, including the general service lamp rulemakings and the environmental determinations made in them. Part IV.G.

The congressional directives on headlamp brightness and the related legislation. Part IV.F.

The agency's own records on the subject, which remain unproduced and are sought in the action at Part IV.D.3.

The Foundation makes a narrow point with this list. Whatever is thought of the quality of any particular item, the Department is not in the position of an agency asked to begin from nothing. The evaluation this paragraph directs would begin with material the Department already holds.

3. Studies and evaluations the agency has conducted for other electronic product radiation

The agency has performed this duty before, for other electronic product radiation. The record of how it did so is relevant here because it establishes that the question in this comment is not one of institutional capability.

Each standard in subchapter J was prescribed through notice and comment rulemaking, and each therefore has a documented record behind it of what the agency examined before acting. The principal ones, by their codification:

Television receivers, 21 C.F.R. § 1020.10, promulgated at 38 Fed. Reg. 28,632 (Oct. 15, 1973), amended at 88 Fed. Reg. 3,654 (Jan. 20, 2023). Part 1020 is titled Performance Standards for Ionizing Radiation Emitting Products, and the standard addresses the x-radiation a receiver emits rather than the light it is built to produce. The Foundation notes the distinction so that no inference is drawn from it: this is not an instance of the agency regulating a display for its visible output.

Microwave ovens, § 1030.10, promulgated at 38 Fed. Reg. 28,640 (Oct. 15, 1973), amended repeatedly thereafter and most recently at 88 Fed. Reg. 3,654 (Jan. 20, 2023).

Laser products, § 1040.10, at 50 Fed. Reg. 33,688 (Aug. 20, 1985) and 50 Fed. Reg. 42,156 (Oct. 18, 1985), with a further revision at 65 Fed. Reg. 17,138 (Mar. 31, 2000) and amendments at 75 Fed. Reg. 20,917 (2010) and 83 Fed. Reg. 13,864 (2018).

Sunlamp products and ultraviolet lamps intended for use in sunlamp products, § 1040.20, at 50 Fed. Reg. 36,550 (Sept. 6, 1985), amended at 67 Fed. Reg. 9,587 (2002), 69 Fed. Reg. 18,803 (2004), 75 Fed. Reg. 20,917 (2010) and 83 Fed. Reg. 13,865 (2018).

Two things about that list bear on this subsection. The first is that the agency has repeatedly determined what an electronic product emits, in what quantity, and under what conditions people are exposed to it, and has then written a limit expressed in the units of the emission. For sunlamp products it did so in radiometric and spectrally resolved terms, as Part II.C.2 describes. The second is that subchapter J has been revisited as recently as January 2023, in the rulemaking that also revoked the ultrasonic therapy standard formerly at part 1050. The program is administered. It is not dormant.

The study described at Part II.I.4 is a further instance, conducted under § 360jj by the Bureau of Radiological Health, which is one of the two bureaus from which the Center for Devices and Radiological Health was formed. Part II.A.3.

The institutional capability therefore exists, or existed. The Foundation does not suggest that the agency lacks the expertise to characterize optical emissions or to design an evaluation of exposure conditions. It has done both, for other radiation, within this same subchapter.

4. Absence of any study or evaluation of visible light emitted by LED products

The Foundation states first what the agency did do, because the record is not empty and a comment that said it was would be inaccurate.

The Final Response of May 24, 2024 states that the agency engaged an independent, third-party organization to conduct a comprehensive literature search and systematic review to identify the current state of knowledge with regard to adverse health effects of LED light on humans. Something was therefore commissioned, and the Foundation does not assert otherwise.

But a literature search and systematic review is not what paragraph (a)(4) directs, and the difference is not a quibble about words. A literature review establishes what other people have published about effects. Paragraph (a)(4) directs the Secretary to study and evaluate emissions, and to study and evaluate conditions of exposure. A review of the published health-effects literature does neither. It does not measure what the products emit. It does not characterize the circumstances in which people encounter them. Those are the two things the paragraph names, and a search of other people's papers about outcomes is not a study of either.

What the review did find makes the point sharper rather than weaker. The Final Response reports that the overall quality of the evidence was low, that sample sizes were small, and that results were inconclusive or inconsistent. Taken at face value, that is a finding about the state of published research. Under paragraph (a)(4) such a finding is the occasion for the Secretary to conduct the study, not a reason to refrain from it. An agency directed to study and evaluate, which learns that the existing literature is too weak to support a conclusion, has been handed the case for performing its own duty. It has not been excused from it.

The Foundation is also unable to say what the review examined, because the organization has not been identified, the protocol has not been disclosed, and the review itself has not been published. Part I.C.6. The requests at Part IX.H.1 and IX.H.2 ask for each of those. Until they are answered the Foundation can describe the commissioned work only in the terms the letter uses.

What the agency has measured, and it is one thing. In 2010 four scientists of the Center for Devices and Radiological Health published a laboratory characterization of the ocular hazard presented by cutaneous transilluminators, which are hand-held devices pressed against the skin to locate a blood vessel. The authors were Sharon Miller, Robert James, Robert Landry and Joshua

Pfefer, all of the Division of Physics, Office of Science and Engineering Laboratories, Center for Devices and Radiological Health; the first author is identified in the paper as then being with the Electronic Products Branch, Division of Mammography Quality and Radiation Programs, within the same Center. The paper is Miller S, James R, Landry R, Pfefer J, Optical characterization of cutaneous transilluminators for eye safety, Biomedical Optics Express 2010;1(3):771–779, doi:10.1364/BOE.1.000771. It is open access. The Foundation sets out its contents at some length because it is the agency's own work and because it is, so far as the Foundation has been able to determine, the only measurement by the agency of the optical emission of a light-emitting diode product.

What the agency measured. Six models of transilluminator were evaluated. Two incorporated white light-emitting diodes and were the focus of the retinal assessment; one used red diodes and three used red and orange. Three units of one model, purchased at different times, were measured to establish variability between devices. Spectral irradiance and spectral radiance were determined for each. Spectral radiance was weighted by the aphakic hazard function and integrated from 380 to 700 nanometers. The aphakic function was chosen, in the authors' words, as a worst case because infants have higher transmission of ultraviolet and visible light through the lens, and because ICNIRP recommends that weighting for children under two years of age. The resulting quantity was compared against the ANSI/IESNA RP 27.1 photochemical retinal hazard limit of 100 joules per square centimeter per steradian for exposures under 10,000 seconds, yielding a time to reach the limit.

What the agency found.

- The light levels produced by all devices were below the acceptable limits relevant to eye safety. The Foundation states that first because it is the authors' own conclusion and the finding is about time, not exceedance.
- For the two white light-emitting diode devices, the time to reach the hazard limit was between 1.03 and 3.35 minutes. Across all white diodes tested the mean time was 4.0 minutes, standard deviation 1.45, with individual results from 2.06 to 6.7 minutes.
- The authors state that this is probably not a significant risk for healthy adults, since most people using these devices will not be looking directly at the diode, but that it may be a risk for neonates, who in their words may be more sensitive and may lack a developed aversion response to bright light.
- Citing published measurements, the authors record that the eyes of infants of 40 to 50 weeks post-menstrual age are significantly smaller than adult eyes, such that for a constant luminance at the cornea the retinal illuminance is approximately three times higher in the infant eye.
- On that basis they compute a worst case. If the young eye can focus images to a sharp spot on the retina, the time to reach the hazard limit would range from 21 seconds to 1.1 minutes.
- They further note that raised blood oxygen reduces the dose needed to damage the retina, and that because some neonates are kept in an enhanced-oxygen environment this may place them at higher risk.
- They observe that the white diode has peak irradiance in the region of 440 or 460 nanometers, which is the region of the spectrum most hazardous to the retina.

The authors' own summary of the paper is that transilluminators incorporating white-light diodes have emissions with the potential for producing injury to the retina, especially in patients who may have a reduced aversion response.

Four things follow and the Foundation separates them carefully, because this paper can be overstated and the Foundation does not wish to overstate it.

First, on capability. Part II.F.3 above argues that the question in this comment is not one of institutional capability. This paper closes that question. The characterization paragraph (a)(4) describes — measure the spectral radiance of a product, weight it by the applicable action spectrum, integrate it, and compare it to an exposure limit — was performed by this Center, on a light-emitting diode product, using published methods, and published in a peer-reviewed journal. It is not a method the agency would have to develop. It is a method the agency has used.

Second, on what the paper does not establish. A transilluminator is not a streetlight. It is a small, high-radiance source applied at short range for a clinical purpose, and nothing in this paper bears directly on general illumination, vehicle lamps, displays or indicator lamps. The authors found no exceedance of any limit and reported no injury. The Foundation does not cite this paper for the proposition that general lighting is hazardous and asks the Department not to read it that way.

Third, on what the paper does establish about the framework. The safety margin the authors identify for healthy adults is behavioral: people will not look directly at the diode. The risk they identify for neonates is the absence of that behavior. The protective mechanism and the vulnerability are therefore the same fact viewed from two sides, and the agency's own scientists said so in 2010. Part V.C.2 returns to this, because the international statement on which any alignment would rest relies on the same aversion response as a general assurance.

Fourth, on what did not follow. The Foundation has identified no subsequent measurement by the agency of the optical emission of any other light-emitting diode product class. It has identified no extension of this method to general service lamps, roadway luminaires, vehicle headlamps, displays or indicator lamps. It has identified no performance standard, no guidance and no recommendation issued in consequence. What the record shows is a single application of the right method to one device class in 2010, and nothing after it.

What remains absent is therefore narrower than the Foundation would otherwise have stated, and the Foundation states it narrowly. For the product classes described at Part VI — general service lamps, roadway and area lighting, vehicle lamps, displays, indicator lamps and the rest — the Foundation can identify no measurement by the agency of the emission characteristics of any of them: no spectral power distribution, no source radiance, no temporal modulation measurement, no exposure survey, no measurement of the environments described at Part VI, and no estimate of duration or frequency of exposure for any population. Nor can the Foundation identify any characterization by the agency of the conditions under which people are exposed to this radiation, or any baseline of the kind described at Part II.D.6, against which a future change could be assessed. For one clinical device class, a measurement exists, the agency made it, and it is fifteen years old.

The pattern is not confined to one product class, and the second instance is far larger. Dental light-curing units set resin restorations by photopolymerization. Modern units are blue light-emitting diodes, emitting in the region of 450 to 470 nanometers, because that is the absorption region of the photoinitiators in dental composites. The FDA classifies them at 21 C.F.R. § 872.6070 under product code EBZ, in Class II. The regulation reads in full:

> § 872.6070 Ultraviolet activator for polymerization. (a) Identification. An ultraviolet activator for polymerization is a device that produces ultraviolet radiation intended to polymerize (set) resinous dental pit and fissure sealants or restorative materials by transmission of light through a rod. (b) Classification. Class II.

The identification describes a device that produces ultraviolet radiation and delivers it through a rod. The devices in use produce blue visible light and most deliver it from a handpiece without any such rod. The Foundation asks the Department to consider the clearance record against that text. By the agency's own database, 216 premarket notifications have been cleared under this regulation. The earliest fall in 1977 and 1978. The most recent in the sample the Foundation examined was decided on May 5, 2025. The device names in the record describe the technology the regulation does not: a clearance in 1986 for a product named a visible light curing system;

clearances in 2000 and 2004 and 2006 for products named for the color blue; a clearance in 2002 for a product whose name contains the abbreviation for light-emitting diode; a clearance in 2008 for a cordless light-emitting diode curing light; and a clearance in 2025 for a product named Bluemoon.

The Foundation draws three conclusions and no others.

First, this is not an oversight in a corner of the schedule. Two hundred and sixteen clearances over forty-eight years is sustained regulatory attention. The agency has examined these devices again and again, and has done so in Class II, which carries general controls and special controls and premarket notification rather than the exemption that applies to the whitening class. Whatever else may be said, the Department cannot characterize this product class as one it has not looked at.

Second, the classification does not describe the emission. A product class whose regulatory identification says ultraviolet, and whose members have been named for blue light since at least 1986, has been cleared more than two hundred times against a definition that names the wrong waveband. The Foundation makes the same point here that it makes about the whitening class, and it is stronger here because of the scale: where this agency has engaged with optical radiation from light-emitting diode products, it has done so through descriptions that do not correspond to what the products emit. Part IV.C and Part V.C.2 describe the same defect in the measurement conventions. This is the defect in the nomenclature of the agency's own device schedule.

Third, and this is the point that returns to paragraph (a)(1): none of that attention produced an emission limit. There is no performance standard in part 1040 for either product class, for the reason given at subsection 3. Neither appears in the OPTICAL category of Table 1 to 21 C.F.R. § 1002.1, so no product report, supplemental report, abbreviated report, annual report or test record is required of their manufacturers. And the control measure that the dental literature actually relies on is protective eyewear, a shield, and adherence to recommended exposure times and distances, as the systematic review at Appendix C.52 records — none of which is specified by any federal instrument. Two product classes, cleared between them more than two hundred times, and the hazard is managed by asking the operator to look away and wear orange glasses whose optical density nobody has prescribed. Part II.G.3.

The request the Foundation makes under this paragraph is the establishment of that baseline, and it is worth being exact about what the request is and is not. It is not a request that the Department prescribe a performance standard. It is not a request that the Department find that LED products cause harm, or adopt any position on the questions Part V describes as unresolved. It is a request that the Department carry out the study and evaluation this paragraph directs: measure what these products emit, in quantities that bear on biological effect rather than on appearance; characterize the conditions under which people are exposed to them; and publish both. Granting it decides nothing about whether a standard is necessary. It supplies the record on which that question would be decided, which is the order the statute sets. Parts IX.H.3 and IX.H.7.

G. § 360ii(a)(5) — Develop, Test, and Evaluate Procedures and Techniques for Minimizing Exposure [RFI Q5.o]

Paragraph (a)(5) directs the Secretary to:

> develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation

1. What this paragraph adds to the two before it

The object of this paragraph is not the radiation. It is the procedures and techniques for minimizing exposure to the radiation, and what the Secretary is directed to evaluate is their effectiveness. The three research paragraphs of § 360ii(a) divide cleanly once that is seen. Paragraph (a)(4) directs the measurement of the emissions and of the conditions of exposure,

which is the problem. Paragraph (a)(2) directs the program of research, development, training and operational activity aimed at minimizing them. Paragraph (a)(5) directs the development and testing of the countermeasures themselves, and a determination of whether they work.

Question 5.0 of this request for information repeats the language of this paragraph almost word for word. The Foundation reads that as the Department asking what the statute already directs it to find out, and answers accordingly.

2. The agency has already asserted the conclusion this paragraph directs it to reach

The Final Response of May 24, 2024 declined to prescribe performance standards on the ground, among others, that they are not necessary "given the effectiveness of existing mitigations in addressing unnecessary radiation and alternative approaches to protect public health."

The Foundation asks the Department to read that clause against the paragraph quoted above. The agency asserted the effectiveness of mitigations. Paragraph (a)(5) directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure. The assertion in the letter is the conclusion of the evaluation this paragraph directs.

Two possibilities follow and the Foundation does not know which obtains. Either the evaluation was performed, in which case the Department holds it and should produce it, and this comment's principal complaint under this paragraph falls away. Or the conclusion was stated without the evaluation, in which case the letter asserts as established the very thing the statute directs the Secretary to determine. Part II.D.5 asks what the existing mitigations are. This subsection asks the further question: by what testing was their effectiveness established, and where is it recorded. Part IX.H.2.

3. The techniques exist; what is absent is the federal evaluation of them

The Foundation is not asking the agency to invent anything. For every product class treated in Part VI, techniques for reducing human exposure already exist and are in commercial use, developed by manufacturers, by standards bodies and by municipalities. What has not happened is the development, testing and evaluation of their effectiveness by the agency this paragraph addresses. Four examples make the pattern plain.

Vehicle headlamps. Federal Motor Vehicle Safety Standard No. 108 specifies luminous intensity in candela at defined angular test points, and includes maxima at certain angles above the horizontal that operate to limit glare. What the standard does not contain is any limit on the luminance of the emitting surface, any requirement as to spectral content, and any limit on temporal modulation; and no limit it does contain was derived from a photobiological criterion. The distinction between intensity and luminance is the substance of the point. Luminance is intensity per unit of emitting area, and two headlamps delivering identical candela to the same test point can differ by orders of magnitude in the luminance they present, according to whether the light leaves a large diffusing surface or a small intense die. Discomfort and disability glare depend on the luminance of the source and the angle it subtends at the eye, not on the total output measured at a point on the roadway. Parts V.B.2 and V.C.3. Techniques for reducing the exposure of the oncoming driver exist — beam pattern control, shielding, aim, automatic beam switching, diffusion to lower source luminance at constant output, and selection of correlated color temperature — and the Foundation can identify no federal testing or evaluation of the effectiveness of any of them for that purpose. Some will be considered in the proceeding described at Part II.H.5, by an agency that does not hold the authority conferred by § 360ii.

Indicator and status lamps in appliances, tools and electronics. These emit a trivial quantity of light and present a very high luminance, because the emitting area is minute and luminance is the quotient of intensity by area. The quantity that governs the response of the eye is the one that no specification reports. The techniques for minimizing exposure are elementary and cheap: diffusion, reduction of drive current, a defeat switch, dimming in response to ambient level, and selection of a longer-wavelength emitter. Each is already used in some products and omitted from

others, which is itself an opportunity for comparison. Nothing federal requires any of them, and none has been evaluated for effectiveness. This is the clearest case under paragraph (a)(5) in the whole of Part VI, because the countermeasures are known, inexpensive and already deployed. All that is missing is the finding of which ones work.

Roadway, area and parking lighting. The techniques here are the most thoroughly developed of any in this list, and none of the development was federal: limits on correlated color temperature, full-cutoff optics and shielding, mounting height and spacing, dimming and adaptive control, and curfews. They have been recommended by professional bodies, adopted in model ordinances, and enacted by municipalities and by States. Part II.D.3 and Part II.E.3. The agency has evaluated the effectiveness of none of them. The result is that public entities choosing among them are choosing without any federal finding as to which reduces human exposure and by how much.

Flashing warning lamps on emergency, utility and work-zone vehicles. The available techniques include reduction of intensity at night, reduction of flash rate, synchronization of phase across the lamps on a single vehicle, selection of color, and directional control to limit emission toward the eyes of passing drivers and pedestrians. Several are commercially available and fitted to some apparatus and not to others. Those exposed include the responders working alongside the apparatus at close range, which is occupational exposure of the kind Part II.H.10 describes, as well as every passing driver and pedestrian. Part VI.C. No federal evaluation of the effectiveness of any of these techniques has been identified.

The roadway entry above states that none of that development was federal. The record bears it out, and the Foundation identifies the body that did it. The metrics by which parking lot, roadway and directional lighting are evaluated were published between 2005 and 2012 by the Alliance for Solid-State Illumination Systems and Technologies, a consortium of manufacturers, research institutions and federal and State agencies organized at Rensselaer Polytechnic Institute, in a series titled ASSIST recommends. Part II.E.4 sets out its constitution and membership.

That history locates precisely what paragraph (a)(5) asks for and what is missing. The paragraph does not direct the Secretary to develop these techniques; they have been developed. It directs the Secretary to develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure. Private parties developed the procedures. The federal test and evaluation of whether they are effective at minimizing human exposure has not been performed, and until it is, a public entity choosing among them is choosing on the basis of documents prepared by the manufacturers of the products.

One of the techniques on that list has now been evaluated in the manner this paragraph describes, and the evaluation was neither American nor private. Shielding and cutoff optics on roadway luminaires were tested against an unlit control over four years at a controlled field site and then on public streets in three municipalities, by investigators funded by the German Federal Agency for Nature Conservation with resources from that country's federal environment ministry. Custom luminaires were designed and manufactured, their emission was characterized on a goniophotometer, the illuminance on the ground was matched to the fixtures they replaced, compliance with the European road lighting standard was maintained, and the effect was measured. The study is described at Appendix C.136 and taken up at Part V.I. Its endpoint was ecological rather than human, so the Foundation does not present it as the evaluation this paragraph requires of this Department. It presents it as proof that the evaluation is feasible, that it can be done on installed products without compromising a road lighting standard, and that when it is done the characteristic it isolates — where a luminaire sends its light — proves to matter more than the characteristic ordinarily offered first, which is how much light it sends. A federal agency of another government performed under its conservation statute the kind of work paragraph (a)(5) directs the Secretary to perform under this one.

One further technique belongs in this list and it is different in kind from the four above, because here the emitting product is one the FDA itself has reviewed. Blue-light dental devices, and the

orange filter. Light-accelerated tooth whitening and light-curing devices emit in the blue, at irradiances described at Part II.C.4, and the dental profession controls the resulting ocular exposure by a single technique used as a matter of routine: an orange or amber long-pass filter, as a handheld shield, a clip-on screen or eyewear worn by operator and patient. The technique is universal in practice, it is the entire control measure, and no federal instrument specifies either side of the problem it is meant to solve. There is no limit on what the device may emit, as Part II.C.4 sets out, and there is no performance requirement for the filter: no specified cut-on wavelength, no minimum optical density in the hazard band, no test method and no verification.

The required performance is calculable even though it is unspecified, which is what makes this the clearest instance in this Part of what paragraph (a)(5) directs. On the figures at Part II.C.4, reducing a blue-light-weighted irradiance of approximately 1,670 watts per square meter to the continuous-exposure limit of 1.0 watt per square meter requires attenuation by a factor of about 1,670, which is an optical density of about 3.2 across the hazard band. That is the number a federal evaluation under paragraph (a)(5) would produce and against which a filter could be tested. The Foundation does not assert that any filter in use falls short of it; it does not know, and that is the point. The Department is directed by paragraph (a)(5) to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure. Here is a technique, in daily use across a profession, protecting against the emission of a product the agency has cleared, whose required performance can be computed from published exposure limits and whose actual performance no federal program has ever measured.

4. What the Foundation asks under this paragraph

The request is narrow and it is the least burdensome in this comment. The Foundation does not ask the Department to develop new countermeasures, to prescribe any of the existing ones, or to decide any contested question about injury. It asks the Department to test the techniques that already exist, to determine which of them reduce human exposure and by how much, and to publish the result.

The Foundation draws attention to what follows from publication alone. A federal finding that a particular technique reduces exposure by a stated amount would be acted on by purchasers, specifiers, fleet operators, public works departments and accessibility officers without any regulation being issued at all. Much of the exposure described in this comment is created by procurement decisions rather than by conduct any standard would reach, and procurement responds to published evidence. Paragraph (a)(5) is the provision under which that evidence would be produced, and it has not been.

The Foundation further asks the Department to state what the existing mitigations referred to in the letter of May 24, 2024 are, as applied to visible light emitted by LED products, and by what testing their effectiveness was established. Part IX.H.2.

H. § 360ii(a)(6) — Consult and Maintain Liaison With Other Federal Departments and Agencies

1. The departments named expressly in the statute

Paragraph (a)(6) directs the Secretary to:

> consult and maintain liaison with the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor, the Atomic Energy Commission, and other appropriate Federal departments and agencies on (A) techniques, equipment, and programs for testing and evaluating electronic product radiation, and (B) the development of performance standards pursuant to section 360kk of this title to control such radiation emissions.

The grammar of the paragraph carries the weight of this subsection. Four officers are named: the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor, and the Atomic Energy Commission, whose functions have since been distributed among successor agencies. The

adjective appropriate appears once, and it modifies the residual class — other appropriate Federal departments and agencies. It does not modify the four named officers.

That distinction matters because of the position the United States has taken. As Part I.C.5 describes, the government has read the word appropriate as committing to the agency's judgment the question which additional agencies are consulted. The Foundation has accepted that the reading is available on the text. But it is available only where the text supplies the word. For the four officers Congress named, there is no qualifier to construe. The direction to consult and maintain liaison with the Secretary of Labor is not conditioned on the Secretary of Health and Human Services finding it appropriate to do so.

The subject matter of the consultation is likewise specified rather than left at large. It is techniques, equipment, and programs for testing and evaluating electronic product radiation, and the development of performance standards under § 360kk. Both subjects are engaged by this comment.

a. The Department of Commerce, which this comment treats first among the four

Of the four officers Congress named, the Department of Commerce is the one whose own bureaus bear most directly on the subject of this comment. The Foundation sets the point out at length because it is not apparent from the Department's name, and because the direction to consult it carries no qualifier to construe. Three bureaus are engaged. One realizes and maintains the national measurement scales for visible light and operates a calibration program directed specifically at light-emitting diode products. One produces the satellite measurement record of how much artificial light the United States emits at night. One sits on the interagency committee that annotates the tariff line by which a light-emitting diode product is identified to this Department at the border. None of the three is a health agency, none of them asserts authority over lighting, and the Foundation does not suggest otherwise.

b. The National Institute of Standards and Technology

The National Institute of Standards and Technology is a bureau of the Department of Commerce and is the national measurement institute of the United States. It is established within that Department by 15 U.S.C. § 272(a), which creates "a science, engineering, technology, and measurement laboratory to be known as the National Institute of Standards and Technology"; it was the National Bureau of Standards until the Omnibus Trade and Competitiveness Act of 1988 converted it, Pub. L. 100-418, title V, §§ 5111, 5112(a), 5115(c), 102 Stat. 1427. Its functions are stated in the same section. Subsection (b)(2) directs it:

> to develop, maintain, and retain custody of the national standards of measurement, and provide the means and methods for making measurements consistent with those standards

And subsection (c)(2) authorizes the Secretary of Commerce, acting through the Director, to "test, calibrate, and certify standards and standard measuring apparatus." That bureau is accordingly the body that answers, for the United States, the question what a stated quantity of light is.

What that bureau maintains, it maintains for visible light. The candela, the International System base unit of luminous intensity, is realized there by a detector-based method and is maintained on six standard photometers traceable to the bureau's Primary Optical Watt Radiometer. The lumen is realized from the candela by the absolute integrating sphere method in a sphere of two and a half meters. The photometric range the bureau states for this work is 360 to 830 nanometers, which is to say the visible band and a margin on either side of it. Calibration services are offered against those scales, in the form of lamp standards for luminous intensity, luminous flux and color temperature, together with reference photometers and reference materials.

The bureau also runs a measurement program directed at these products in particular. It provides calibration services for light-emitting diode packages and arrays, for integrated light-emitting

diode lamps and for small light-emitting diode luminaires. The quantities it states for that work are total luminous flux in lumens, radiant flux in watts, luminous efficacy in lumens per watt, luminous intensity in candelas, chromaticity coordinates, correlated color temperature, color rendering index and dominant wavelength. It operates a spectrally tunable lighting facility, it has developed a junction-temperature method for measuring high-power light-emitting diodes, it runs a measurement assurance program for solid-state lighting products, and it has carried that work into the documentary standards: it led the development of the illuminating engineering standard for the electrical and photometric measurement of solid-state lighting products, contributed to the international commission's technical report on light-emitting diode measurement and to the American national standard on solid-state lighting chromaticity, and helped establish the laboratory accreditation program on which a federal efficiency labeling program depends.

Set that beside the words of the paragraph under discussion. Subparagraph (A) directs consultation and liaison on:

> "techniques, equipment, and programs for testing and evaluating electronic product radiation"

Those are three nouns, and the bureau described above supplies all three, for these products, inside a Department this paragraph names without qualification. The Foundation does not need to argue that the bureau is an appropriate agency, because it does not sit in the residual category. It sits in the Department of Commerce.

What the Foundation has not found is the consultation. Where that bureau describes the federal agencies it works with on solid-state lighting standards, it names the Department of Energy and the Federal Aviation Administration; where it lists the stakeholders of its photometry program it names the lighting industry, the Department of Energy's lighting labeling program, the Environmental Protection Agency's efficiency labeling program, the national laboratory accreditation program and the consensus standards bodies. This Department does not appear in either list. The Foundation states the inference narrowly. A program description is not an exhaustive record of an agency's correspondence, and the Foundation does not contend that no contact has ever occurred between these two bodies. It contends that where the federal measurement authority for visible light sets out whom it works with on these products, the agency charged with the electronic product radiation control program is not among them, and that the Foundation has located no record of such consultation anywhere else. If a record exists, the Department can produce it in a sentence, and Part IX.E asks it to.

The Foundation is careful about what this establishes, because the available overstatement is obvious and would not survive scrutiny. The quantities that bureau maintains are for the most part photometric and colorimetric, and they were developed to serve energy efficiency and color quality rather than health. Luminous efficacy and the color rendering index are not health metrics and this comment does not present them as such. Radiant flux in watts is a radiometric quantity, but it is a total over the sphere rather than a spectral irradiance at the position of a person's eye, and Part V.J sets out at length why the second of those is the quantity that matters and why nobody records it. The existing services would therefore not, as they stand, measure what a standard prescribed under § 360kk would require to be measured.

What follows is narrower and is sufficient for the purpose. The instruments, the traceability chain and the institutional competence already exist within the federal government, in a Department this paragraph names, and they are already applied to these products. Adapting them to a health-relevant quantity is work, and it is the work paragraph (a)(5) directs this Department to perform: to develop, test and evaluate procedures and techniques for minimizing exposure. Part II.G sets out that no such procedure has been developed. The bureau that would be consulted in developing one is not an agency this Department would have to identify as appropriate. It is named.

Two passages elsewhere in this comment corroborate that the capability is practical rather than theoretical, and neither of them involved this Department. Part V.I describes a field study of a

rodent in which optical radiation was measured with a spectroradiometer calibrated against lamps traceable to this bureau, at the height of the animal's eye, on a field site, by conservation biologists. Part V.B describes two national metrology institutes that built instruments and compared them against one another in order to determine the angular distribution of light-emitting diode packages, the authors stating that new methods of measurement were required because these sources differ from traditional lighting sources. The national traceability chain this bureau maintains was available to a small research team studying a mouse. It has been available to this Department throughout.

c. The National Oceanic and Atmospheric Administration

The National Oceanic and Atmospheric Administration is also a bureau of the Department of Commerce, established by Reorganization Plan No. 4 of 1970, effective October 3, 1970, 35 Fed. Reg. 15,627, 84 Stat. 2090, section 2(a) of which provides that "There is hereby established in the Department of Commerce an agency which shall be known as the National Oceanic and Atmospheric Administration". The Foundation reaches it by a different route than the last, and states the route plainly: this bureau holds no authority over lighting and makes no claim to any. It is engaged because of what it measures and because of what its scientists have published, both of which this comment already relies on.

That bureau operates the instruments from which the measurement record of artificial light at night is derived, and this comment already relies on that record. Part V.I sets out the instrument history and the Foundation repeats here the feature of it that bears on this paragraph. The earlier operational line-scan system was sensitive from 450 to 1000 nanometers; the day-night band of the visible and infrared imaging radiometer suite, carried on the Suomi satellite and on the bureau's own NOAA-20, is sensitive from 480 to 920 nanometers. Neither instrument is sensitive to the band from 380 to 450 nanometers, and the sensors have been panchromatic, which is to say they record no spectral composition at all. The consequence is stated in the literature and the Foundation adopts it: the federal radiance record systematically under-measures the short-wavelength component of the emission, which is the component this comment is about, and records nothing of the spectrum. That is not a criticism of the instruments, which were built for other purposes. It is information about the limits of the federal record, and paragraph (a)(3) directs this Department to receive information of exactly that kind from agencies with related interests.

A second engagement is already set out at subsection 3 and the Foundation does not repeat it beyond a sentence. A scientist of that bureau co-authored, in 2011, a peer-reviewed proposal for numerical limits on what outdoor lamps may emit in a protected wavelength band, for the stated purpose of protecting human health and the environment. Appendix C.57. The expertise paragraph (a)(3) contemplates receiving was published, by an employee of a named Department, thirteen years before the Final Response of May 24, 2024.

The Foundation states plainly what it does not claim, because an assumption in the other direction is natural and is wrong. That bureau does not regulate lighting. Where artificial lighting is restricted for the protection of a listed species it is restricted on land, and jurisdiction over sea turtles on land does not belong to that bureau: under a memorandum of understanding of 1977 the Fish and Wildlife Service of the Department of the Interior has jurisdiction over sea turtles on land and the bureau's fisheries service has jurisdiction in the marine environment. 79 Fed. Reg. 39,856 (July 10, 2014). The sea turtle literature treated at Part V.I accordingly rests on the science and not on any assertion of authority here. What this subsection establishes about this bureau is confined to measurement and to published scientific information, which is what paragraphs (a)(3) and (a)(6) are about.

d. The Bureau of the Census, and the last two digits of a tariff number

Subsection 18 describes the one sustained liaison of record between this Department and another federal agency concerning light-emitting diode products, which is the import arrangement with

United States Customs and Border Protection, and Part VI.V sets out the mechanism in full. One element of that mechanism belongs in this subsection rather than in those, because it reaches a named officer.

A tariff number of the United States has ten digits and they are not all of one kind, as Part VI.V sets out. The first six are international. The seventh and eighth are a legal subdivision of the United States and fix the rate of duty. The ninth and tenth are a statistical suffix, and they are not set by this Department or by Customs and Border Protection. They are set by the Committee for Statistical Annotation of Tariff Schedules, authorized under section 484(f) of the Tariff Act of 1930, 19 U.S.C. § 1484(f), and commonly called the 484(f) Committee. It is chaired by the United States International Trade Commission, and its members are the Commission, United States Customs and Border Protection and the Bureau of the Census, which is continued by 13 U.S.C. § 2 "as an agency within, and under the jurisdiction of, the Department of Commerce."

The composition is not an administrative arrangement that happens to include a bureau of a named Department. The statute itself directs three officers to establish the enumeration:

> The Secretary, the Secretary of Commerce, and the United States International Trade Commission shall establish from time to time for statistical purposes an enumeration of articles in such detail as in their judgment may be necessary, comprehending all merchandise imported into the United States and exported from the United States [.]

The Secretary there is the Secretary of the Treasury, reached by the definition at 19 U.S.C. § 1401(l) rather than by name, and the Foundation states that distinction because the subsection does not say Treasury. The Secretary of Commerce it names expressly. So the direction to establish the enumeration in which these products are counted as they enter the country runs, by statute, to an officer whom paragraph 360ii(a)(6) directs this Department to consult without qualification. Separately, 13 U.S.C. § 301(a) authorizes the Secretary of Commerce to collect information from all persons importing into the United States and directs the compilation and publication of information pertaining to imports.

The tariff number named in the instruction of June 6, 2017 was a ten-digit number. The identifier on which the only routine federal identification of a light-emitting diode illumination product as a radiation-emitting electronic product depends is therefore a number maintained jointly: its first six digits are set by an international body, its seventh and eighth by the United States as law, and its ninth and tenth under a statutory direction addressed to the Secretary of Commerce among others, executed through a committee that includes the agency administering the border and a bureau of that Department.

The Foundation confines the observation, because the architecture is the point and the inference beyond it would be wrong. The statistical annotation does not affect the legal classification of goods, as the Commission states in the preface to the schedule, and the committee cannot alter the classification of goods or rates of duty. The Foundation does not suggest that this committee decides whether these products are electronic products within § 360hh(1)(A), and does not suggest that consulting it would answer any question this comment raises. The observation is that the identifier is jointly maintained, that two of its three maintainers are bodies this comment asks the Department to consult, and that one of those two sits inside a Department Congress named.

e. The three named officers treated elsewhere, and the one that no longer exists

The Foundation does not leave the other named officers without a pointer. The Secretary of Labor is treated at subsection 10, with the Occupational Safety and Health Administration and the National Institute for Occupational Safety and Health, and is the officer whose staff told the Foundation that they awaited notification from this Department. The Secretary of Defense is treated at subsection 14, with the other federal building operators. The Atomic Energy Commission no longer exists and its functions were distributed among successor bodies; nothing in this comment turns on that reference.

Bureau of the Department of Commerce	What it maintains that bears on this comment	Whether this Department appears among the federal bodies it names
National Institute of Standards and Technology	The national photometric scales for visible light, 360 to 830 nm; calibration services for LED packages, arrays, integrated lamps and small luminaires; the measurement standard for photometric testing of solid-state lighting; a laboratory accreditation program	No. It names the Department of Energy and the Federal Aviation Administration on solid-state lighting standards, and the Environmental Protection Agency among its stakeholders.
National Oceanic and Atmospheric Administration	The satellite radiance record of artificial light at night, from instruments sensitive from 480 to 920 nm and insensitive from 380 to 450 nm; a 2011 published proposal for numerical limits on outdoor lamp emission	None identified
Bureau of the Census	Membership of the committee that sets the ninth and tenth digits of the tariff line flagged for LED illumination imports, under § 484(f) of the Tariff Act of 1930	Through the import arrangement at subsection 20, which concerns admissibility and not emissions

2. "Other appropriate Federal departments and agencies" — scope of the residual category

The residual category is the one the government has relied on, and the Foundation sets out its position on it precisely rather than broadly.

The phrase is "other appropriate Federal departments and agencies." The Foundation accepts, as it accepts at Part I.C.5, that the adjective confers judgment on the Secretary as to which additional agencies are consulted. It does not accept three things that are sometimes treated as following from that.

The first is that the judgment extends to the four officers named in the paragraph. It does not, for the reason given in subsection 1: the adjective modifies the residual class and nothing else.

The second is that a judgment committed to an agency is a judgment that need not be made. The paragraph directs the Secretary to consult and maintain liaison with appropriate agencies. Identifying which are appropriate is the exercise of the judgment, and it is a step that has to be taken before the direction can be said to have been carried out. The United States has represented in litigation that no decisionmaking process has occurred with respect to these products. Part I.C.4. The Foundation takes that representation at face value and draws from it the consequence it bears here: if no decisionmaking process has occurred, then the judgment this paragraph commits to the Secretary has not been exercised, correctly or otherwise.

The third is that the breadth of the category makes it unworkable. It is broad. Electronic product radiation is emitted by nearly every product that runs on electricity, as the United States has itself observed, and the agencies with a related interest in some aspect of it are many. But breadth of this kind is ordinary in federal practice and is managed by ordering the work, not by declining it. The Foundation does not ask the Department to consult every agency about everything. It asks for consultation with the agencies whose own programs place these particular products in front of people, which is a list of manageable length and is set out in the subsections that follow.

3. Environmental Protection Agency

The Environmental Protection Agency is the most consequential of the agencies in this category, for a reason that Part II.D.3 sets out: the subject this comment calls light pollution is, in the language of § 360ii(a)(2), unnecessary electronic product radiation. Pollution is the Environmental Protection Agency's subject. Electronic product radiation is this Department's. The same emissions are described by both vocabularies, and neither agency has treated them as its own.

The Environmental Protection Agency has answered that question, and the Foundation sets out its answer because it disposes of an objection that would otherwise be made to Part II.D.3.

On October 7, 2022 the Director of the Radiation Protection Division in that agency's Office of Radiation and Indoor Air replied to a letter the Foundation had sent to the Administrator on December 7, 2021. The reply states:

> The EPA sets protective limits on the ionizing radiation in the environment that comes from human use of radioactive elements such as uranium. Congress has not granted the EPA any statutory authority to regulate visible light or non-ionizing radiation that is emitted from electrical devices, including LEDs. For that reason, the EPA does not regulate artificial light, radiation from LEDs, or other visible electromagnetic radiation, and we do not maintain experts in this field.

The letter goes on to refer the Foundation to a compilation maintained by a legislative organization of the States and municipalities that have enacted light pollution laws.

The Foundation does not dispute that answer and has no reason to. What it asks the Department to take from it is this. Part II.D.3 identifies light pollution as unnecessary electronic product radiation within the meaning of § 360ii(a)(2). The natural objection is that pollution is the Environmental Protection Agency's subject and the matter should be taken there. That agency has said, in writing and at the level of a division director, that Congress gave it no authority over visible light or non-ionizing radiation from electrical devices and that it maintains no experts in the field. The objection is therefore not available. If light that serves no purpose is to be addressed by any federal body, the authority is in this chapter.

That does not make consultation pointless. The Environmental Protection Agency holds expertise in emission inventories and in population exposure assessment that bears on the baseline described at Part II.D.6, whatever the limits of its regulatory authority, and § 360ii(a)(3) directs the Secretary to receive information from other Federal agencies without regard to whether they could regulate the subject themselves.

The Foundation raised this with the agency's attention in the comments on its petitions, which stated that the Food and Drug Administration is required to limit the exposure to and emissions of unnecessary visible light radiation from LED products, that unnecessary light is also known as light pollution, and that the Food and Drug Administration has not liaised with the Environmental Protection Agency to set limits on light pollution from LED products. Part II.D.3. The Final Response does not address the point.

What consultation would supply is concrete. The Environmental Protection Agency holds expertise in emission inventories, in exposure assessment across populations, and in the construction of environmental criteria documents. Part II.D.6 and Part II.F describe the absence of any baseline for this radiation. Building one is work of a kind that agency does routinely for other emissions, and the Foundation asks the Department to consult it on how.

a. Why that answer is correct, and when the line was drawn

The Foundation has examined the statutory history, and the agency's position is not merely defensible. It is the documented consequence of an allocation made deliberately in 1970.

Reorganization Plan No. 3 of 1970, the instrument that created the Environmental Protection Agency, transferred to it at section 2(a)(3) certain functions of the Environmental Control Administration of the Department of Health, Education, and Welfare, described as portions of the functions carried out by the Bureau of Radiological Health. The Bureau of Radiological Health is the predecessor of the Center for Devices and Radiological Health.

That transfer was deliberately incomplete. It excluded functions pertaining to the regulation of radiation from consumer products, to radiation in medical practice, and to occupational radiation exposure.

The sequence is worth stating plainly. In 1968 Congress enacted the Radiation Control for Health and Safety Act and assigned the electronic product radiation control program to the Secretary of Health, Education, and Welfare. In 1970 the Executive created an environmental agency, moved part of radiological health to it, and expressly left radiation from consumer products where Congress had placed it.

The Environmental Protection Agency therefore does not lack this authority through inadvertence, and this is not a subject that fell through a gap between statutes. The question was considered and decided. The letter of October 7, 2022 is correct, and it is correct for a reason that strengthens the Foundation's position rather than weakening it: the allocation of this subject to the Department of Health, Education, and Welfare and its successor was confirmed at the moment when the alternative was available and was declined.

Section 2(a)(7) of the same plan transferred to the agency all functions of the Federal Radiation Council, and section 2(a)(6) transferred the authority of the Atomic Energy Commission to establish generally applicable environmental standards for the protection of the general environment from radioactive material. Those are the radiation authorities the agency does hold. Neither reaches optical radiation emitted by a lamp.

b. The template Congress used for a physical agent emitted by products

Four years after the Radiation Control for Health and Safety Act, Congress legislated again on a physical agent emitted by products in commerce, and on that occasion assigned the work to the Environmental Protection Agency. The comparison is instructive and the Foundation offers it without rhetoric.

The Noise Control Act of 1972, 42 U.S.C. §§ 4901–4918, opens with a congressional finding that "the major sources of noise include transportation vehicles and equipment, machinery, appliances, and other products in commerce," and declares the policy of the United States "to promote an environment for all Americans free from noise that jeopardizes their health or welfare," to be achieved in part by authorizing "Federal noise emission standards for products distributed in commerce."

That is the architecture of subchapter C applied to a different physical agent, and the resemblance extends to the interagency provisions. Section 4903(c) directs that "The Administrator shall coordinate the programs of all Federal agencies relating to noise research and noise control," and that "Each Federal agency shall consult with the Administrator in prescribing standards or regulations respecting noise." Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research. Paragraph 360ii(a)(6) directs consultation with other departments and agencies.

Congress built one scheme and used it twice: a lead agency, a product emission standard, a research mandate, and a duty of interagency consultation. Noise went to the Environmental Protection Agency in 1972. Electronic product radiation had gone to the Secretary in 1968, and the reorganization of 1970 confirmed it.

One further feature of the noise program belongs here, because it is the nearest available picture of what an unexecuted program of this kind looks like over time. The Office of Noise Abatement and Control was defunded in 1981. The Noise Control Act was never repealed. Its standards remain in the Code of Federal Regulations and its preemptive effect on State and local regulation remains in force. The result is a federal product emission program that exists, preempts, and does nothing, and has been in that condition for more than four decades. The Foundation draws attention to it because 15 U.S.C. § 2080 produces a comparable preemptive effect in the present case. Part II.H.9.

c. A related interest, documented by federal scientists

One further matter bears on the liaison duty rather than on authority.

In 2011 scientists at the National Oceanic and Atmospheric Administration and the Cooperative Institute for Research in Environmental Sciences published a communication in Nature Geoscience on the effect of urban lighting on nocturnal atmospheric chemistry. Stark H, Brown SS, Wong KW, Stutz J, Elvidge CD, Pollack IB, Ryerson TB, Dubé WP, Wagner NL, Parrish DD. City lights and urban air. Nature Geoscience 2011;4:730–731. doi:10.1038/ngeo1300. They reported that the nitrate radical, which removes nitrogen oxides and volatile organic compounds from the atmosphere overnight, is destroyed by artificial light, and that over Los Angeles city lights reduce nitrate radical concentrations by several percent, leaving nitrogen oxide concentrations correspondingly higher the following morning.

The Foundation states the magnitude as the authors state it. The effect on next-day ozone is small, and they say so. They also observe that ozone does not respond linearly to nitrogen compounds, that their model may have underestimated the effect, and that even small changes in ozone levels may determine whether a city is above or below a regulatory threshold. They identify the cause specifically: the effect is produced by light projecting skyward, and shielded fixtures directing light downward would prevent it. Part II.D.3.d.

The Foundation does not contend that this gives the Environmental Protection Agency authority over lighting, and says so to foreclose the argument rather than to invite it. The Clean Air Act operates on emissions of air pollutants, defined at 42 U.S.C. § 7602(g) in terms of a substance or matter entering the ambient air, and it addresses ozone through ambient standards and the control of precursor emissions rather than through the physical conditions that affect reaction rates. Sunlight is the dominant driver of ozone photochemistry and is not regulated. Neither is temperature.

What the finding establishes is narrower and sufficient. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests. It does not say with regulatory authority. Federal scientists have published a finding that the design of outdoor lighting perturbs the nocturnal chemistry bearing on ozone. That is a related interest on any reading of the phrase, and it exists notwithstanding that the agency holds no authority over the emission. The letter of October 7, 2022 answers a question about authority. It does not answer the question paragraph (a)(3) asks.

One further fact about the authorship of that communication belongs here, because it bears on the same paragraph and the Foundation found it while verifying the citation. One of its authors, Christopher D. Elvidge of the National Oceanic and Atmospheric Administration, co-authored in the same year a second peer-reviewed paper on outdoor lighting, and that paper does not stop at describing an effect. It proposes numerical limits on what outdoor lamps may emit, in a protected wavelength band, for the stated purpose of protecting human health and the environment. Appendix C.57 and Part V.B.3.

The Foundation is careful about what that does and does not show. It does not show that the National Oceanic and Atmospheric Administration holds a position on lamp spectra, and it does not show that the agency has authority over lighting; a paper is the work of its authors. What it shows is that in 2011 a federal scientist, publishing in the peer-reviewed literature, set out a quantitative proposal for limiting the short-wavelength emission of outdoor lighting on health and environmental grounds. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and to receive information from other Federal departments and agencies with related interests. The expertise paragraph (a)(3) contemplates receiving was in the federal government, in print, thirteen years before the Final Response of May 24, 2024.

d. What the Foundation asks of this agency, and what it does not

The Foundation states its position on the Environmental Protection Agency explicitly, so that no part of this comment is read as asking for something it does not ask for.

It does not ask the Environmental Protection Agency to regulate light pollution. Under the law as presently written that agency has no authority to do so; its letter of October 7, 2022 says so; and the Foundation agrees, for the reasons at subsection a.

It does not ask Congress to confer such authority, and takes no position in this comment on whether it should.

What it asks is directed to this Department. The Foundation asks the Secretary to establish and maintain the liaison that paragraphs 360ii(a)(3) and (a)(6) direct; to share with the Environmental Protection Agency the results of the testing, evaluation and research that paragraphs (a)(2), (a)(4) and (a)(5) direct, once that work is undertaken; and to receive from that agency the emission inventory and population exposure assessment expertise described above.

The direction of the obligation is the point of this subsection. Nothing in it asks the Environmental Protection Agency to do anything at all. The duty is the Secretary's. It is not conditioned on a request from another agency, and it is not discharged by another agency's accurate statement that it lacks authority of its own.

4. Department of Energy — general service lamps (developed at Part IV.G)

Part IV.G sets out the history in full and this subsection states only the consequence under this paragraph. The Department of Energy determined which lighting technology would illuminate the country, through the general service lamp rulemakings and the backstop they codify. It concluded that the action produced no change in environmental effect requiring analysis. Its rulemaking records do not mention this Department, and when asked for records of communication with the Food and Drug Administration it identified three public dockets in which that agency does not appear. Part IV.G.7.

The liaison contemplated by this paragraph would have been with the agency whose standards select the emitter, on the subject of what the selected emitter emits. It is the clearest instance in this comment of a consultation that would have mattered and did not occur, and it is the one instance in which the Department of Energy has been asked directly and has answered.

5. Department of Transportation and National Highway Traffic Safety Administration — FMVSS No. 108

Federal Motor Vehicle Safety Standard No. 108 governs the photometric performance of vehicle lamps. It is the only federal standard that sets numerical limits on the output of any of the LED products this comment is concerned with, and the limits it sets are photometric: luminous intensity in candela, measured at specified test points. It contains no limit on source radiance, no spectral requirement, and no limit on temporal modulation. Part VI.B develops this.

On October 6, 2026, while this comment was in preparation, the Department of Transportation announced that it will conduct a negotiated rulemaking to modernize that standard. The notice of intent was published in the Federal Register two days later, on October 8, 2026, at 91 Fed. Reg. 64462. The proceeding is docketed as NHTSA-2026-1981. Applications for membership on the negotiating committee and comments are due by November 9, 2026. The Secretary of Transportation is to appoint up to eighteen members. The announced subjects include light-emitting diodes, dusk sensors, automatic high beams, replaceable light sources, headlamp height and aim, and — stated expressly — headlamp glare. The Administrator of the National Highway Traffic Safety Administration is quoted as saying that the agency is bringing stakeholders together to modernize the standards and "address potential causes of glare."

The Foundation brings this to the Department's attention for four reasons, and asks that the comment be read in light of the fact that the proceeding is open as of the date of filing.

First, the liaison duty is no longer a matter of hypothesis. Paragraph (a)(6) directs this Department to consult and maintain liaison with other appropriate Federal departments and

agencies on techniques and equipment for testing and evaluating electronic product radiation and on the development of performance standards. A second federal agency has announced that it will develop performance requirements governing the optical output of the highest-radiance class of LED product that ordinary people encounter, and has named glare as a subject. There is a docket, a committee, and a date. Whatever force there is in the proposition that the appropriateness of consultation is committed to the Secretary's judgment, the occasion for exercising that judgment is present and identifiable.

Second, the division of authority is the one this comment describes throughout. The National Highway Traffic Safety Administration has authority over motor vehicle equipment. It does not have the authority conferred by 21 U.S.C. § 360ii(a)(4) to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and it has never claimed it. A proceeding that will set the optical performance requirements for these lamps is about to be conducted by an agency that does not hold the radiation-health authority, while the agency that holds it has not evaluated the emissions. Part IV.G describes the same pattern in the general service lamp rulemakings. The difference is that this one has not happened yet.

Third, the categories of member the Department of Transportation has announced are vehicle lighting manufacturers, motor vehicle equipment associations, safety organizations, research institutions and engineering associations. No category is named for the persons on whom the radiation falls, and none is named for persons with the photosensitive and other conditions described at Part V and Part VIII. The Foundation makes no criticism of the agency's list, which may be expanded. It observes only that the health effects of the emission are the subject on which this Department, and no other, is directed by statute to develop expertise.

Fourth, and most practically, the timing permits action. The comment period in this proceeding closes on October 21, 2026. Applications and comments in NHTSA-2026-1981 are due on November 9, 2026. The Department can, if it chooses, communicate with the Department of Transportation about that proceeding after reading this comment and before that proceeding's record closes. The Foundation asks it to, and asks that it state on the record whether it has. Part IX.E.4.

How the Department might take part is worth setting out with some care, because the routes differ in what they require and two of them require nothing from anyone.

The first route is consultation, and it is already a duty. Paragraph (a)(3) directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests on present and future potential electronic product radiation. The National Highway Traffic Safety Administration has a related interest by any measure, and a proceeding to revise the photometric requirements for vehicle lamps concerns present and future potential electronic product radiation exactly. Paragraph (a)(6)(A) is more specific still: it directs consultation and liaison with other appropriate Federal departments and agencies on "techniques, equipment, and programs for testing and evaluating electronic product radiation." The announced subjects of the proceeding include the streamlining of test procedures. Revising how the output of a light-emitting product is measured is the subject that subparagraph names. Neither route requires the permission or the invitation of the Department of Transportation.

The second route is the docket. Comments in NHTSA-2026-1981 are due by November 9, 2026, and the docket is open to anyone. A federal agency may file in another agency's rulemaking docket as any other person may. Nothing stands between this Department and the record of that proceeding except a decision to file.

The third route is membership on the negotiating committee, and here the Foundation states a limit on what it is asking. The Negotiated Rulemaking Act provides for representation of the convening agency on the committee. It does not address participation by other federal departments, and the Foundation does not assert that this Department has any entitlement to a seat. Whether a representative of another department may be appointed is a question for the

Department of Transportation and for the committee's charter. The Foundation asks only that this Department seek whatever form of participation the proceeding permits, and that it not treat the absence of an invitation as an answer.

There is a final observation, and the Foundation makes it plainly because it bears on everything else in this comment. The obstacle to this Department contributing to a proceeding about headlamp glare is not that it lacks a route in. Two of the three routes above are open today and need no one's consent. The obstacle is that the Department has not measured what these lamps emit and has not characterized how people are exposed to them, so it has little to contribute beyond the observation that the question is open. The request that the Department take part in that proceeding and the request that it carry out § 360ii(a)(4) are therefore the same request, arriving from different directions. Part II.F.

One further fact belongs in this subsection, and the Foundation states it without characterization because none is needed. The agency that will conduct that proceeding has twice told the Foundation, in writing and in substantially the same terms, that the expertise relevant to the health questions raised by these products resides in this Department.

The first occasion was the published denial of three petitions for non-compliance orders, 87 Fed. Reg. 75,327 (Dec. 8, 2022), described at Part IV.C.3. Having set out that the Food and Drug Administration has authority to regulate certain aspects of these products as radiation-emitting devices, and that there is at present no performance standard for them in 21 C.F.R. part 1040, the agency wrote:

> "NHTSA also wants to express appreciation to the Petitioner for bringing to its attention health concerns that the Petitioner associates with LED headlamps. NHTSA takes these concerns seriously. NHTSA, as an agency focused on automotive safety, also recognizes the expertise of its sister agencies that are health-focused, such as the FDA."

The second was a letter of February 13, 2024 from the Office of the Chief Counsel, described at Part IV.C.9, answering a separate inquiry about the reach of the standard:

> "NHTSA's focus is on automotive safety, but the agency recognizes that separate expertise resides in sister agencies that are health-focused, such as the Food and Drug Administration."

The two statements were made fourteen months apart, by different offices of the same agency, in two unrelated proceedings. That agency has now announced a negotiated rulemaking to modernize Federal Motor Vehicle Safety Standard No. 108 with headlamp glare among its stated subjects, and the categories of committee member it has announced do not include the agency to which it twice said it defers.

The Foundation draws no inference about anyone's intentions from that sequence. It observes only that the agency conducting the proceeding has itself identified where the relevant expertise lies, and that this Department is therefore not an outside party seeking entry to another agency's proceeding. It is the agency that proceeding's sponsor named.

6. Federal Highway Administration — MUTCD, warning beacons, and roadway lighting

The Federal Highway Administration publishes the Manual on Uniform Traffic Control Devices, which States adopt or amend and which governs the flash rate, intensity and application of the warning devices treated at Part VI.C.2, and it issues guidance on roadway lighting design. Those documents determine the characteristics of a large class of the optical emissions people encounter in the public way.

The Manual specifies flash rates and refers to industry intensity classes. It contains no exposure criterion, no spectral requirement and no limit expressed in terms of effect on a person, and Part VIII sets out what the Foundation has established about how the accessibility consequences of these devices have been treated. A consultation under this paragraph would be addressed to the question the Manual does not reach: what the devices it specifies do to the people in front of them.

This agency has been approached twice, and it has given two answers. They are different in kind, they were given seven weeks apart, and the Foundation sets out both in the order they were received. The first came in response to a complaint submitted by Mark Baker in his individual capacity as a person affected by these devices, and it is a statement about the limits of the agency's authority. It belongs with the responses collected at subsection 21. The second came in response to a petition filed by the Foundation, and it is a deferral in time. It does not.

The response of October 19, 2022, on the health effects of rectangular rapid-flashing beacons

On June 29, 2022 Mark Baker submitted a complaint under Title II of the Americans with Disabilities Act and section 504 of the Rehabilitation Act of 1973 concerning rectangular rapid-flashing beacons installed by three municipalities. He submitted it to the Department of Justice, which transferred it to the Department of Transportation, which referred it to the Office of Civil Rights of the Federal Highway Administration. It was docketed as DOT#2022-0375. On October 19, 2022 the ADA Team Leader of that Office replied. The letter first states the allegations as the agency understood them:

> "In particular, you allege that the Cities' installation and use of Rapid Rectangular Flashing Beacons (RRFBs) discriminates against you and other individuals with disabilities by inducing disorientation, visual impairment, anxiety, fear, seizures, and/or other medical/health issues."

The agency declined to investigate. It set out the framework for that decision, citing the Department of Justice's statement in the 2010 Title II final rule that there is no statutory requirement that every Title II complaint receive a full investigation, and the factors an enforcement agency weighs in deciding whether to conduct one, among them whether a violation may have occurred and how limited resources are best spent. It then gave the following reason:

> "The allegations you have raised about the health impacts of RRFBs raise complex issues related to the regulation of all Light Emitting Diode (LED) lights, not just those used in RRFBs, that extend beyond FHWA's authority."

The Foundation asks the Department to read that sentence closely, and states first what it does not do. It is not a finding that the devices are safe, and it is not a finding that they are harmful. It is a dismissal without investigation under a discretionary framework the letter describes, and the sentence quoted is one of two grounds given. Nor does the letter identify any agency that does hold the authority. Unlike the responses of the National Highway Traffic Safety Administration, the Federal Aviation Administration, the Department of Energy, the Occupational Safety and Health Administration and the United States Access Board, all collected at subsection 21, this one names no destination. The Foundation does not supply one on the agency's behalf.

What the sentence does do is three things, and each of them bears on a question this comment puts to the Department.

- It identifies the subject as the health impacts of a flashing warning device. Of the responses collected at subsection 21, this is the only one directed to the health effects of a specific emitting product rather than to the allocation of authority in the abstract. The agency that approves the device for use on the public way was asked what it emits and what that does to people, and answered that the question is not one it can reach.
- It identifies the subject as the product class rather than the application. The agency wrote that the issues concern the regulation of "all Light Emitting Diode (LED) lights, not just those used in RRFBs." That is the same distinction this comment asks the Department to draw at Part V.C.2.k, where the point is made that instruments organized by application leave a hazard that crosses applications addressed in one domain and not another. Here a federal agency drew the distinction itself, in writing, in 2022, and placed the subject on the side of the line this Department occupies.

It records, in the agency's own paraphrase, an allegation that these devices induce seizures. Part V.E.1 sets out the thresholds that exist for flashing content presented on displays, including a federal limit of three flashes per second applied to digital content procured by government through section 508 of the Rehabilitation Act, and establishes that no federal limit of any kind applies to a flashing beacon. The complaint that produced this letter was brought under section 504 of the same Act. The Foundation draws no legal conclusion from the coincidence of statutes and does not suggest that section 508 reaches these devices. It observes that an allegation of seizures from a flashing roadway device was received by a federal agency in 2022, was not investigated, and was referred to no one.

The Foundation makes no criticism of the agency. A decision not to investigate a particular complaint is committed to the agency that receives it, the letter preserved the right to bring a private action under section 203 of the Act, and the Foundation's own view, stated at subsection 21 as to each of the other agencies, is that the authority described is described correctly. The agency that installs and approves the device said that the regulation of what it emits lies outside its authority. That statement is almost certainly right. It is also the point of this Part.

The response of December 7, 2022, on the Foundation's petition for repeal

On November 23, 2022 the Foundation petitioned for repeal of the interim approval under which rectangular rapid-flashing beacons are deployed. On December 7, 2022 an Agency Counsel in the Office of the Chief Counsel replied:

> We received the Soft Lights Foundation's petition for rulemaking regarding the interim approval of the RRFB traffic control device. As you know, FHWA issued a Notice of Proposed Amendments (NPA) to the MUTCD. The rulemaking process for the NPA has not yet concluded and, therefore, a final rule has not been issued. The Soft Lights Foundation submitted comments about the RRFB to the NPA docket. Its petition will be considered as part of the organization's March 10, 2021, comments to the NPA docket. Your letter and this response will also be submitted to the docket.

That is not a statement that the subject belongs elsewhere. It is a deferral in time: the petition was folded into a pending rulemaking rather than answered. The Foundation records it without complaint, because consolidating a petition with comments already before the agency in an open docket is ordinary practice.

The rulemaking has since concluded. What the Foundation asks the Department to notice is what the agency was able to consider when it did. The comments and the petition addressed the effect of a flashing device on the people in front of it. There is no federal measurement convention for that effect, no exposure criterion, and no study of the kind § 360ii(a)(4) directs. An agency asked to weigh those effects in a traffic control rulemaking had nothing federal to weigh them against, because the agency that holds the authority to produce it has not produced it. Part VIII sets out what followed.

What the liaison duty would have carried, and to whom

This subsection has set out two answers from the agency that publishes the Manual on Uniform Traffic Control Devices. The first says that the health effects of a flashing warning device raise issues extending beyond that agency's authority. The second folded a petition into a pending rulemaking. Neither is a finding about the device, and the Foundation has said that it regards the first as correct.

What the Foundation asks the Department to add to those two facts is a third, which is the subject of this Part. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests, and paragraph (a)(6) to consult and maintain liaison with them. The agency that sets the flash rate of every warning beacon in the United States has stated in writing that the health question is not within its

authority. The authority is here. The channel between the two is the one those paragraphs describe, and it is the Secretary's to open.

The Foundation makes the point concrete rather than abstract, because the duty is to carry information and the question is what information there is to carry. Part V of this comment collects it. A peer-reviewed neurophysiological review describes the interaction between flash rate and color and identifies red-blue alternation at fifteen hertz as the combination investigators are instructed to avoid. Appendix C and Appendix D set out what the measurement standards cover and, more to the point, the frequencies and effects they do not. Part VI.I reports the only photometric characterization of a flashing product in American service the Foundation has been able to obtain, which a private party had to pay for. None of this is secret, none of it is new, and none of it has been transmitted to the agency that sets the rates, because no one is charged with transmitting it except the Secretary.

The Foundation does not suggest that the Federal Highway Administration has failed in a duty. It has said the subject is beyond its authority and the Foundation agrees. The failure described by this Part is upstream of that answer and is the Department's own: the agency holding the electronic product radiation authority has not developed the information, and has not conveyed what exists to the agencies whose instruments decide how often a light on an American road will flash.

One qualification belongs with that argument, and the Foundation supplies it rather than waiting to be met with it. It is not the case that the federal government has never funded research into flashing warning lamps. It has. The study at Appendix D.4 was performed under contract to the United States Fire Administration, with further support from a fellowship program within the Department of Transportation, and it measured the effect of the intensity, color, modulation and flash rate of emergency vehicle lamps on drivers at night.

The Foundation asks the Department to read what that study was for. Its outcome measures were the visibility of the lamps, the discomfort glare they produced, the distance at which a driver could detect a responder, and the lateral position of the vehicle. Its stated purpose was the prevention of struck-by incidents among emergency responders. It is a study of occupational safety for the people standing beside the lamp, and a good one. It is not a study of what the emission does to the people it is pointed at, it contains no biological endpoint, and it was never meant to.

That is the shape of the gap this Part describes, and it is a more particular shape than an absence. The capacity to fund this research exists within the federal government and has been exercised. It has been pointed at the responder and not at the public, at discomfort and detection rather than at health, and by the agencies responsible for fire and transportation rather than by the agency holding the electronic product radiation authority. No part of 21 U.S.C. § 360ii was engaged in commissioning it, and the questions paragraphs (a)(2) and (a)(4) direct the Secretary to ask were not among the questions it asked.

7. Federal Aviation Administration — obstruction, airfield, and aircraft lighting

The Federal Aviation Administration specifies obstruction lighting on towers and structures, airfield lighting, and aircraft lighting, and the conversion of these to light-emitting diode sources has proceeded alongside the others described in this comment. Obstruction lighting is distinctive in that it is designed to be seen from a distance, at night, by people who are not its intended audience as well as by those who are, and it is installed in places where people live. Part VI has no subsection devoted to this product class, which is a gap rather than a decision.

The agency's specifications govern intensity, flash characteristics and color for aviation purposes. They are not written to address the exposure of persons on the ground, which is not that agency's subject, and the Foundation does not suggest it should be. It is this Department's.

a. Obstruction lighting, and the one federal lighting specification that mandates a reduction at night

The governing document is Advisory Circular 70/7460-1N, Obstruction Marking and Lighting, dated August 11, 2026, which cancels revision M of November 16, 2020. It does not itself carry the photometric values; it refers them to Advisory Circular 150/5345-43J, Specification for Obstruction Lighting Equipment, dated March 11, 2019. The Foundation sets the figures out because they are the only federal numerical specification of lamp intensity in candelas it has found outside the motor vehicle standard, and because of the one feature of them described below.

For red lights the specification gives the L-810 steady-burning lamp a minimum of 32.5 candelas at all radials through 360 degrees within a minimum vertical spread of 10 degrees; the flashing L-810(F) the same minimum average instantaneous intensity at 30 flashes per minute plus or minus 3; and the flashing red L-864 a peak of 2,000 candelas plus or minus 25 percent at 30 flashes per minute, with a minimum of 750 candelas across a minimum vertical spread of 3 degrees. For white lights the specification gives three intensities to each lamp, by time of day. The medium-intensity L-865 at 40 flashes per minute and L-866 at 60 are specified at 20,000 candelas by day, 20,000 at twilight and 2,000 at night. The high-intensity L-856 at 40 flashes per minute is specified at 270,000 candelas by day, 20,000 at twilight and 2,000 at night, and the L-857 at 60 flashes per minute at 140,000 by day with the same twilight and night values.

That last column is the reason this subsection exists. The specification does not permit the operator to reduce intensity at night; it requires the lamp to do so, as a condition of conformity, by a factor of ten for the medium-intensity lamp and of one hundred and thirty-five for the high-intensity one, with the transition controlled by a photocell at stated thresholds in foot-candles. Part IX.J asks the Department to recommend ambient sensing and a default-low condition for general illumination, and Part VI.D describes roadway and area lighting, in which no such requirement appears. The architecture that request describes is not novel and does not need to be invented. It is written into a federal specification, in candelas, with a measured trigger, and it has been in service for years.

The Foundation states what the comparison does not establish, because three overstatements are available and all three would fail. The step-down exists so that a lamp can be seen against a bright sky by day and a dark sky at night, not because anyone considered a person beneath it; neither circular addresses the exposure of persons on the ground at all. The tolerance of plus or minus 25 percent around each nominal value is a manufacturing conformance band and is not a protective ceiling; the only limits in the specification that operate as true maxima are on stray light, which must not be greater than 3 percent of the peak intensity at the same radial, and on output during the off period of a flash. And the Foundation does not suggest that aviation intensities are appropriate to general illumination, since a quarter of a million candelas directed at the sky is not a model for anything at eye level. What the comparison establishes is that a mandatory, automatic, measured reduction of lamp intensity at night is an ordinary provision of federal engineering practice, and that its absence from every instrument governing lighting that people actually live among is therefore not explained by difficulty.

b. Small unmanned aircraft: a lighting rule with a floor and no ceiling

Since 2021 the agency has permitted small unmanned aircraft to be operated at night and has required lighting to make them visible. 14 C.F.R. § 107.29, as amended by the final rule Operation of Small Unmanned Aircraft Systems Over People, 86 Fed. Reg. 4,314, 4,382 (Jan. 15, 2021), corrected at 86 Fed. Reg. 13,630, 13,631 (Mar. 10, 2021). The operative requirement, which appears in identical terms for night and for civil twilight, is this:

> The small unmanned aircraft has lighted anti-collision lighting visible for at least 3 statute miles that has a flash rate sufficient to avoid a collision. The remote pilot in command may reduce the intensity of, but may not extinguish, the anti-collision

> lighting if he or she determines that, because of operating conditions, it would be in the interest of safety to do so.

Three features of that sentence and one absence. It sets a minimum, and the minimum is a distance at which the lamp must still be seen rather than a quantity of light. It sets a flash requirement that is wholly qualitative, sufficient to avoid a collision, with no rate specified. It gives the pilot a discretionary permission to reduce intensity which is expressly not a permission to extinguish. And it sets no maximum.

The absence is not confined to the section. There is no maximum intensity, luminance or brightness anywhere in part 107. The words luminance, brightness, candela and glare do not appear in the part at all, and the word intensity appears only in the clause just quoted. No provision of part 107 limits lighting for the protection of persons on the ground; the protective provisions of the part are addressed to impact injury and to operational hazard. So the federal rule governing a new class of nighttime emitter specifies how far it must be seen and says nothing about how bright it may be, which is the same structure Part VI.C describes for emergency vehicle warning lamps and Part II.H.5 for the motor vehicle lighting standard.

The characteristics that make this class worth raising here are the ones the rule does not reach. A lamp designed to be conspicuous at three statute miles is a small source of high luminance. It is mounted on a platform that moves across the field of view rather than remaining in a fixed position. It switches rather than ramps, so the onset is effectively instantaneous. It operates at night, against a dark adapted eye. And it may be operated in numbers, which is the subject of the movement below. Part V.C.3 sets out why a small bright source at distance produces disability glare through intraocular scatter rather than through the light reaching the retinal image alone, Part V.C.5 why that effect is greater with age, astigmatism and cataract, Part V.D the response to temporal modulation, and Part V.E the photosensitive response. The Foundation asserts no quantitative finding about these aircraft, because none exists and the measurement that would supply one is the measurement Part V.J establishes nobody records. It asserts that the exposure is new, that it is unmeasured, and that the instrument governing it contains a floor and no ceiling.

There is one place where the agency has acknowledged the visual effect, and it is the most important thing in this subsection. Advisory Circular 107-2A, Small Unmanned Aircraft System, dated February 1, 2021, explains at paragraph 5.7.2.2 why the pilot is permitted to reduce intensity:

> However, the remote PIC may reduce the intensity of the light if the remote PIC determines it is in the interest of safety to do so. For example, a bright light or a bright strobe light on the small unmanned aircraft in very close proximity to the remote pilot could cause the remote pilot to lose the ability to observe the small unmanned aircraft's location, speed, attitude, or altitude with accuracy.

So the agency has recognized, in a published document, that a bright strobe on one of these aircraft can deprive a human observer of the ability to observe accurately. It is the mechanism this comment is about, stated by a federal agency about a light-emitting diode product. The Foundation notes precisely what the agency then did with the recognition. It addressed it to one observer, the remote pilot. It treated it as a matter of that pilot's performance rather than of anyone's health. And it met it with a discretionary permission rather than a limit. There is no counterpart anywhere in the rule or the circular for any other person who sees the same light. The Foundation does not say that was wrong. That agency's subject is aviation safety and the remote pilot is properly its concern. It says that the visual effect is acknowledged in a federal document, that the mechanism acknowledged is the impairment of accurate observation by a human eye, and that the question who else is standing in the light is not that agency's to answer. Part II.H.22 records that this agency told the Foundation on November 9, 2022 that it is not a regulatory agency on light-emitting diode requirements and would defer to this Department for comfort, health and safety regulations.

c. Performances flown with many aircraft at once

Operating more than one small unmanned aircraft from a single control station requires relief from 14 C.F.R. § 107.35, which permits a person to operate only one at a time. Relief is granted by certificate of waiver under § 107.200; § 107.205 is the list of regulations that may be waived and includes § 107.35. The certificates the Foundation has read waive the lighting requirements of § 107.29 in the same instrument.

The scale now authorized is the first point. A certificate issued in 2026 authorizes operations with up to 10,000 small unmanned aircraft per remote pilot in command, and one issued in 2025 authorizes up to 1,000 with one visual observer for every 250 aircraft. The Foundation states that these are ceilings written on a certificate rather than records of performances flown, and it has not established the largest number actually operated.

The second point is what the certificates condition and what they do not. They require that the lighting system be used in a manner sufficient to alert approaching aircraft, which is a performance term pointing outward to the operator's application rather than to any value. They require that the operating area be sterile, that spectators be kept out of the restricted area and that the area be monitored for intrusion. They require notice to the local flight standards district office including audience locations and the total number of aircraft. And they state that the certificate does not constitute a waiver of any state law or local ordinance. Not one of them sets a light intensity, a luminance, a candela value, a flash rate or any limit related to glare. Spectators appear in them only as an exclusion-zone problem, and persons who are not spectators are not mentioned at all. The authorization governs where a person may stand and not how bright the light may be.

The Foundation is careful about the request it makes here, and aligns it with Part VI.K. That subsection treats entertainment lighting and states that the Foundation does not ask the Department to regulate a light show, because a person who buys a ticket to a performance seeks the exposure. The Foundation does not withdraw that and does not ask for it here. What distinguishes this case from a concert is that these aircraft fly in open airspace above a city, and the federal authorization that permits them addresses the audience and is silent as to everybody else beneath them. The fifth matter at Part IX.I concerns the number of emitters a person meets at once. A performance that may place thousands of independently moving, individually addressable high-luminance emitters into a single field of view is the clearest instance of that question the Foundation has encountered, and the instrument authorizing it contains no photometric term of any kind.

d. What the Foundation asks under this subsection

Nothing that requires this agency to do anything, and nothing that depends on a finding about aviation. That the Department consult it under paragraphs (a)(3) and (a)(6) on two matters. The first is the obstruction lighting specification, which is the nearest thing in federal practice to the capability Part IX.J asks the Department to recommend, and which this Department has every reason to understand before recommending anything of the kind. The second is the lighting rule for small unmanned aircraft, where this agency has acknowledged in writing that a strobe on one of these products can impair accurate observation by a human eye, and has limited the remedy to the pilot because the rest is not its subject. And that any classification system developed under Part IX.G treat motion of the source across the field of view, and the number of sources present at once, as parameters rather than as qualifications added afterward.

8. Federal Communications Commission

a. Why this agency stands differently from the others in this Part

Every other agency treated in this Part regulates a product, a place, or a activity in which an emitting product is installed. This one shares a subject matter with this Department. Both administer frameworks addressed to non-ionizing electromagnetic radiation emitted by electronic products, and the statute that creates this Department's program defines electronic product

radiation to include radiofrequency and visible light alike. Part II.B. It is also the only federal agency with which a consultation of record about the health effects of an electronic product radiation exists at all. Subsection 18.

For that reason this subsection is organized around three things rather than one: what that Commission has said about the division of responsibility, what its rules do and do not reach in the radiofrequency emissions of light-emitting diode products, and the proceeding it has presently opened, which is the clearest occasion for the exercise of paragraph (a)(6) that has arisen in the period this comment describes.

b. The radiofrequency emissions of light-emitting diode products

The Foundation sets this out at some length and with citations, because an earlier draft of this subsection asserted both halves of it without them and one of the two assertions was imprecise.

i. What this Commission has said about who protects the public

The Office of Engineering and Technology of that Commission publishes a page of answers to questions about radiofrequency safety. It contains this:

> The Commission does not regulate exposure to emissions from these devices. Protecting the public from harmful radiation emissions from these consumer products is the responsibility of the U.S. Food and Drug Administration (FDA). Inquires [sic] should be directed to the FDA's Center for Devices and Radiological Health (CDRH), and, specifically, to the CDRH Office of Compliance …

The Foundation states the limits of that passage before stating its use, because the passage is easy to overread and an earlier draft of this comment did overread it. The page carries no date of publication or review. And the Foundation has not been able to recover the question under which the passage sits, so the class of articles to which the words these devices and these consumer products refer is not established from the page as the Foundation has read it; the surrounding discussion concerns microwave ovens. The Foundation therefore does not offer this passage as a statement that this Commission regards this Department as responsible for consumer products generally, and does not rely on it at all for the optical question this comment raises.

What the passage does establish is narrower and is still worth having. Where this Commission declines to regulate exposure to an emission from a consumer product, it identifies this Department as the agency responsible for protecting the public from that emission, and it refers the inquirer to the Center for Devices and Radiological Health by name and to one office within it. The division of responsibility is not a construction the Foundation has placed on the statute. It is the account the other agency gives of it, in its own published material.

Three further statements on the same page bear on this comment and the Foundation records them with the treatment they receive elsewhere. That the Center established a performance standard for microwave ovens in 1971, which Part II.C treats as the one exercise of the § 360kk power that reached a consumer product in general use. That the Center has not adopted performance standards for other products emitting radiofrequency energy, which is consistent with the record set out at Part II.C and Part I.C.7. And that the Food and Drug Administration is the lead federal health agency in monitoring the latest research developments, which is a statement of posture rather than of activity, and which Part II.D examines against what the Foundation has been able to establish the monitoring consists of.

ii. Which of this Commission's rules actually reach a light-emitting diode product

A light-emitting diode is a semiconductor driven by direct current and it does not use radiofrequency energy to produce light. What emits radiofrequency energy in such a product is the driver, which converts and switches at high frequency, and in a networked product the radio. The distinction matters to what a consultation would be about, so the Foundation states which part of this Commission's rules applies and which does not.

Part 18 does not reach these products. Its subject is industrial, scientific and medical equipment, which 47 C.F.R. § 18.107(c) defines as equipment "designed to generate and use locally RF energy for industrial, scientific, medical, domestic or similar purposes". The part does use the term RF lighting device, at §§ 18.213(d), 18.305(c) and 18.307(c), but it nowhere defines it; when the Commission adopted those provisions it described the class as devices which "produce light by using RF energy to stimulate gases contained inside a lamp". A light-emitting diode stimulates no gas. And § 18.107(a) defines radiofrequency energy as "Electromagnetic energy at any frequency in the radio spectrum from 9 kHz to 3 THz (3,000 GHz)", which places visible light, at roughly 430 to 750 terahertz, about two orders of magnitude above the definitional ceiling of the part. Visible light is outside part 18 by the part's own terms.

Part 15 is the part that reaches them, and it reaches them twice. A lamp or luminaire whose driver generates radiofrequency energy for use within the device but is not intended to emit it is an unintentional radiator within § 15.3(z), and the limits are the conducted limits of § 15.107 and the radiated limits of § 15.109, in subpart B. A luminaire containing a deliberate radio is in addition an intentional radiator within § 15.3(o), certified under subpart C, with the general radiated limits at § 15.209 and the band rules at §§ 15.247 and 15.407. The assembled article is a composite system, measured under § 15.31(k). So a networked luminaire carries two classifications at once, and Part VI.L treats the class.

The purpose those limits serve is the point of this movement. Part 18 states its own: its rules are promulgated under section 302 of the Communications Act of 1934 "in order to prevent harmful interference to authorized radio communication services." Part 15 conditions operation on causing no harmful interference and on accepting interference from authorized stations and other devices, §§ 15.5(b) and (c). Neither part contains a single emission limit adopted for the protection of human health. Health enters either part only by cross-reference, to the radiofrequency exposure requirements at 47 C.F.R. §§ 1.1307(b), 1.1310, 2.1091 and 2.1093, which § 18.313 imports for part 18 and which part 15 imports section by section in subpart C. Those requirements govern exposure to radiofrequency fields. No provision of part 15 or of part 18 addresses visible light, luminance, spectral composition, temporal modulation or glare in any respect.

One structural feature belongs here because it recurs throughout this comment. Every limit in both parts is a maximum. Neither part sets a floor of any kind: a device may emit less than the limit, or nothing at all, and what it may not do is exceed. That is what a limit adopted to protect something other than the emitter looks like, and Part I.C.7 records that no federal instrument imposes a limit of that shape on the optical emission of a light-emitting diode product in the general environment.

iii. What follows for consultation under this paragraph

The consultation this paragraph contemplates with this Commission has two subjects and they are not alike. On radiofrequency energy there is a framework, a proceeding presently open, and one letter of record; the movement below sets that out. On optical radiation there is nothing on this Commission's side, and the Foundation does not suggest there should be. That Commission has no authority over visible light and claims none, and nothing in this comment asks it to acquire any.

What the Foundation asks is one question that only this Department can put. These products emit in two regions of the spectrum at once, from the same housing, to the same person, under two unrelated federal regimes: an interference regime administered by that Commission which reaches the radiofrequency emission and says nothing about health, and this Department's own electronic product radiation control program which reaches the optical emission and has prescribed nothing. Part VI.L sets out the product class in which both occur. The Foundation asks the Department to ascertain and state whether the two emissions of these products have ever been considered together by anyone, and Part IX.E carries the request.

c. The proceeding now open at that Commission, and the occasion it presents

On September 17, 2026 the Office of Engineering and Technology of the Federal Communications Commission released Public Notice DA 26-997 in ET Docket No. 13-84, summarized in the Federal Register at 91 Fed. Reg. 60,128 (Sept. 22, 2026), seeking comment on the radiofrequency exposure issues remanded to that Commission in Environmental Health Trust v. Federal Communications Commission, 9 F.4th 893 (D.C. Cir. 2021). Comments are due October 22, 2026, which is the day after the comment period in this proceeding closes.

The notice records what the court directed, and the Foundation reproduces it because the three items define the scope of what is open. The Commission is to address its decision to retain its testing procedures for determining whether cell phones and other portable electronic devices comply with its guidelines; the impacts of radiofrequency radiation on children and the health implications of long-term exposure to it; and the impacts of radiofrequency radiation on the environment. The notice also records that the panel did not vacate the decision of 2019 and that it "merely directed the Commission to provide further explanation."

Two passages of that notice bear directly on this subsection. The first is an invitation:

> the Commission invites the broadest range of commenters to participate, including local, state, federal, and international health and safety agencies, science-based standard-setting organizations that are active in this area, and other interested parties.

The Foundation does not read that as an instruction to this Department and it is not one. It is an open invitation from a sister agency, placed on a public record, dated, naming federal health and safety agencies as a category of participant it wishes to hear from, in a docket whose subject is the adequacy of a federal exposure framework for a non-ionizing electronic product radiation. Paragraph (a)(6) directs the Secretary to consult and maintain liaison with other appropriate federal departments and agencies on techniques, equipment and programs for testing and evaluating electronic product radiation, and on the development of performance standards to control such emissions. Whatever view is taken of the breadth of that paragraph, an occasion for its exercise is presently open, it was created by the other agency rather than by this one, and it closes on October 22, 2026.

The second passage is the Commission's account of how it will weigh what it receives:

> Probative value will be accorded to parties who have demonstrated a capacity to interpret the biological research necessary to assess the health impact of RF emissions and determine what exposure levels are considered safe for humans, and who can do so with sufficient detail and persuasiveness to overcome the failings that the court identified when the Commission last attempted to rely on the expertise of expert agencies.

On the record set out at subsection 20, the last occasion on which that Commission relied on the expertise of an expert agency in this docket was the correspondence of April 24, 2019 from the Director of the Center for Devices and Radiological Health. The Foundation draws attention to the sentence for one reason and states the reason precisely. Subsection 19 concludes that the program's single consultation of record produced an assurance which the receiving agency relied on and which a court then held could not carry the decision that rested on it. That conclusion is the Foundation's, and a reader is entitled to discount it accordingly. This passage is the receiving agency's own account of the same events, written seven years later, and it is less favorable than the Foundation's: it describes the episode as an attempt, and it fixes the standard for present submissions as the capacity to overcome the failings the court identified in it.

The Foundation states the limits of the point, because the overstatement available here would be serious and would be wrong. The notice confines itself to record evidence that was properly before the court in that case. It is a proceeding about radiofrequency exposure and it is not a forum for the optical question this comment raises. The Foundation does not suggest that material

concerning visible light could properly be filed there, does not ask this Department to file any such material, and does not ask this Department to take any position on the radiofrequency science. Nor does the Foundation know whether this Department intends to participate; it may already have done so. What the Foundation says is narrower. Paragraph (a)(6) imposes a duty of consultation and liaison rather than a duty to reach any conclusion. The agency with which the one consultation of record exists has reopened the record on the very order that consultation supported, it has invited federal health agencies to take part, and this Department will be preparing its answer to this Request for Information in the same weeks.

One further feature of the notice is recorded as incomplete rather than relied upon. The notice asks expressly for comment on the probative value of a letter of 2014 from the Department of the Interior, which the court had faulted the Commission for not discussing. In the Federal Register summary of the notice this Department is not named. The Foundation draws no conclusion from that, because the Federal Register document is by its own terms a summary of a longer Public Notice which the Foundation has not been able to obtain, and the longer document may name it.

d. What the Foundation asks under this subsection

Four things, none of which requires this Department to adopt any position on radiofrequency energy. That it state whether it has communicated with that Commission, since the correspondence of April 24, 2019, about any of the matters remanded in Environmental Health Trust, and if so place the communications on this record. That if it has not, it treat the open docket as an occasion of the kind paragraph (a)(6) contemplates, and say what it decides. That it state whether the assessment conveyed in 2019 remains its position, which is a question Part II.D asks in another form and Part IX.B asks directly. And that it state the division of responsibility for the radiofrequency emissions of products it has itself classified as electronic products, which is the subject of the subsection above and of Part VI.L.

9. Consumer Product Safety Commission

The Consumer Product Safety Commission has jurisdiction over consumer products, which includes the flashlights, portable lamps, toys, tools and appliances that carry the emitters described at Part II.G.3 and Part VI.G. Its complaint database receives reports from the public about consumer products, and Part VII.J notes it among the channels that should be checked for reports concerning LED products.

The division of authority here is not a matter of practice or of agency preference. It is statutory, and the Commission has said so.

On November 7, 2022 Jonathan Midgett, Ph.D., the Consumer Ombudsman in that agency's Office of the Executive Director, wrote to the Foundation by electronic mail. He began by saying that the agency's staff evaluates products on an individual basis and that its jurisdiction over LED lights depends on the hazard. He then drew the division:

> CPSC may have jurisdiction over LED lights for hazards such as electrocution and fire, but CPSC does not have jurisdiction over LED lights under the CPSA if the risk is related to electronic product radiation that may be regulated by FDA.

The email then quotes the provision, which is the second sentence of section 31 of the Consumer Product Safety Act, 15 U.S.C. § 2080(a):

> The Commission shall have no authority under this chapter to regulate any risk of injury associated with electronic product radiation emitted from an electronic product (as such terms are defined by sections 355(1) and (2) of the Public Health Service Act) if such risk of injury may be subjected to regulation under subpart 3 of part F of title III of the Public Health Service Act.

The referenced provisions of the Public Health Service Act are those transferred into the Federal Food, Drug, and Cosmetic Act and now codified at 21 U.S.C. §§ 360hh and following, as Part II.A.1

describes. The Foundation does not have to supply that identification, because the Commission supplied it. Its quotation of the provision carries a bracketed note of the Commission's own, recording that the referenced sections of the Public Health Service Act were later transferred to 21 U.S.C. § 360hh. Part II.A.1 gives the renumbering provision and its public law citation and they are not repeated here. So the agency that is barred identified the statute that bars it, and the statute it identified is this one.

Two consequences follow, and the second is the one that matters.

The first is that the Commission is right. It is barred by statute, and no amount of evidence about injury would give it authority over a risk arising from electronic product radiation.

The second is in the words of the bar. It operates where the risk "may be subjected to regulation" under this chapter. It is not conditioned on the risk having been regulated, or on a performance standard existing, or on the Secretary having determined that one is necessary. The potential for regulation under this chapter is what displaces the Commission's authority. It follows that the Department's conclusion that a standard is not necessary does not return the subject to the Commission. It leaves the subject where the statute put it, with this Department, and unaddressed.

10. Department of Labor — OSHA and NIOSH

Of all the liaison relationships this Part describes, the one with the Department of Labor is the least contestable, for the textual reason given in subsection 1: the Secretary of Labor is named in the statute and is not within the category qualified by the word appropriate.

The Foundation notes the direction in which the duty runs, because it is sometimes stated the other way around. Neither the Occupational Safety and Health Administration nor the National Institute for Occupational Safety and Health bears any duty under this chapter. Chapter 9, subchapter V, part C of title 21 imposes its obligations on the Secretary of Health and Human Services. It is this Department that is directed to consult and maintain liaison with the Secretary of Labor, and the request the Foundation makes is addressed accordingly: that this Department discharge its own duty, not that another Department be directed to discharge one it does not have.

That is not a theoretical observation. The Foundation approached the Occupational Safety and Health Administration directly, over two years, and the correspondence establishes the point.

On September 7, 2022, the Assistant Secretary of Labor for Occupational Safety and Health responded to a Foundation petition for rulemaking on electromagnetic radiation from LED devices. He wrote that the topic was not on the agency's regulatory agenda and would not be added at that time, given other priorities he identified, among them heat injury, workplace violence, and occupational exposure to COVID-19. He stated that the agency's Directorate of Standards and Guidance would examine the relevant scientific literature and monitor developments. Concerns raised under the Americans with Disabilities Act were referred to the agencies that administer that statute.

The Foundation reads that letter as a decision about the allocation of rulemaking resources rather than a determination that occupational exposure to LED optical radiation is not a workplace hazard. The letter makes no finding on the latter question, and the Foundation does not suggest that it does.

On July 22, 2023, the Foundation petitioned the same Assistant Secretary, in a document titled Petition To Publish Performance Standards for the Visible Radiation Emitted by Products Using Light Emitting Diodes. It asked that the agency:

> consult and liaison with the FDA to minimize the risk of harm to all workers, especially those who are most sensitive, from LED visible radiation devices and to publish performance standards for all categories of LED products, in accordance with 29 U.S.C. 651 and 21 U.S.C. Section 360ii—

and relied on 29 U.S.C. § 651(b), the congressional declaration of purpose to assure so far as possible safe and healthful working conditions, together with § 360ii(a).

On August 15, 2024, the Director of the Directorate of Standards and Guidance replied to that petition and to a further letter of July 1, 2024. The reply states that the agency cannot violate the provision relied upon because that provision does not apply to it, and declines the requested consultation with the Food and Drug Administration on that basis.

The Occupational Safety and Health Administration is correct. Section 360ii(a)(6) imposes no duty on the Secretary of Labor and none on that agency. It imposes a duty on the Secretary of Health and Human Services. The Foundation asked the wrong department, and the department it asked said so accurately.

What the exchange establishes is therefore not a failure by the Department of Labor. It is the shape of the problem. A person seeking to have occupational exposure to this radiation evaluated is told by the Department of Labor that the liaison provision does not apply to it, which is right, and by the Food and Drug Administration that a performance standard is not necessary, which is the subject of Part I.C. The provision that connects the two — the direction to this Department to consult and maintain liaison with the Secretary of Labor — has been invoked by neither agency, and only one of the two can invoke it.

Two things in the correspondence are worth the Department's attention as it considers the request below. The first is that the agency with occupational health expertise stated in 2022 that it would examine the relevant scientific literature. Whether it did, and what it found, is precisely the kind of information § 360ii(a)(6)(A) contemplates passing between the two departments, and this Department can ask for it. The second is that the Department of Labor has now been on notice of this subject since 2022, so a consultation initiated by this Department would not be arriving unannounced.

Labor appears three times in this chapter, which is not an accident of drafting.

- Section 360ii(a)(6) names the Secretary of Labor among the four officers with whom consultation and liaison are directed.
- Section 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from, among others, "industry and labor associations" on present and future potential electronic product radiation. Part II.E.
- Section 360kk(a)(1) directs that, in developing a performance standard, the Secretary consult with interested persons "including representatives of industries and labor organizations which would be affected by such standards." Part II.C.1.

Congress wrote occupational exposure into this statute in three separate provisions, at the program level, at the information-gathering level, and within the standard-setting procedure itself.

One feature of the arrangement makes the request unusually straightforward. The National Institute for Occupational Safety and Health is not an agency of the Department of Labor. It is a component of the Centers for Disease Control and Prevention, within this Department. The Department therefore does not need to reach outside itself to obtain an occupational health evaluation of this exposure. The Institute conducts health hazard evaluations at workplaces on request, and the expertise the question requires is already inside the building.

The occupational exposures at issue are not confined to one setting. They include, at least: employees in large-format retail and grocery interiors, treated at Part VI.F, who work a full shift beneath high-density arrays designed for merchandise presentation rather than for visual comfort; warehouse and distribution center workers under high-bay lighting; roadway and utility workers in work zones among flashing warning lamps, treated at Part VI.C.3; emergency responders exposed at close range to the lamps mounted on their own apparatus, Part VI.C.1; and

commercial and transit drivers who face oncoming headlamps for the length of a shift, Part VI.B.1. What these have in common is duration. Part V.C.2 explains why duration is the variable the existing exposure limits stop accounting for.

As to what presently governs these exposures on the occupational side, the Foundation can identify no federal limit addressed to the optical characteristics at issue. The illumination provisions the Foundation is aware of prescribe minimum intensities for particular work, not maximum luminance, and no federal standard prescribes a spectral requirement, a glare limit, or a limit on temporal modulation in a workplace. The practical consequence is that an employer who wished to evaluate this exposure would find no criterion to evaluate it against, and an employee who raised it would find no standard to invoke.

The Foundation accordingly asks the Department:

- to state on the record whether consultation or liaison under § 360ii(a)(6) has occurred at any time with the Secretary of Labor with respect to visible light emitted by LED products, and if so, when and with what result;
- to initiate that consultation if it has not occurred, on the subjects the paragraph specifies — techniques, equipment and programs for testing and evaluating electronic product radiation, and the development of performance standards under § 360kk;
- to request from the Department of Labor the examination of the scientific literature that its Directorate of Standards and Guidance stated in September 2022 it would undertake, and to publish what it receives;
- to direct the National Institute for Occupational Safety and Health to evaluate full-shift occupational exposure to visible light from LED products, beginning with the settings listed above, and to publish the result;
- to receive information from labor associations under § 360ii(a)(3), which so far as the Foundation is aware has not been sought on this subject;
- and, when a performance standard is developed under § 360kk, to consult representatives of labor organizations as § 360kk(a)(1) requires.

11. United States Access Board

The Access Board writes the accessibility guidelines that public entities and places of public accommodation build to. Part VIII sets out the position in full: the guidelines contain no criterion addressed to optical radiation, and the Foundation has established that the Federal Highway Administration has treated disability access in relation to flashing devices as a matter for other authorities.

The Board has addressed this subject directly, and its answer is the most useful single document in this Part.

On June 5, 2023 the Foundation petitioned the Board for rulemaking to publish accessibility requirements for LED products pursuant to 21 U.S.C. § 360ii, asking that the Board consult and liaise with the Food and Drug Administration to develop techniques to evaluate the visible radiation emitted by LEDs and to publish performance standards minimizing exposure. On August 21, 2023 the General Counsel of the Board denied the petition. The denial reads in part:

> The Access Board must deny this petition as the Board has no authority under 21 U.S.C. §360ii either to initiate rulemaking or to require the FDA, were they to do so, to coordinate with the Access Board. This statute directs the FDA to establish and carry out an electronic product radiation control program, to include issuing performance standards for electronic products pursuant to 21 U.S.C. §360kk and to [consult and maintain liaison with the Secretary of Commerce, the Secretary of Defense, the Secretary of Labor, the Atomic Energy Commission, and other appropriate Federal departments and agencies]— The Access Board was not directed

> by Congress to participate in the development of these Standards and, as such, it is not within the Board's authority to require such a consultation.

Three things in that passage repay attention.

The first is that a federal agency other than this Department has construed § 360ii, and has construed it as directing the Food and Drug Administration to establish and carry out an electronic product radiation control program. The Board quoted paragraph (a)(6) in full in support of that reading.

The second is that the Board is right about its own position. Congress did not name it in paragraph (a)(6), and nothing in the paragraph allows the Board to compel a consultation that this Department does not initiate. The direction runs one way, as Part II.H.10 says of the Secretary of Labor and as subsection 1 explains generally.

The third is the sentence that follows, and the Foundation asks the Department to read it twice. The Board continued:

> However, the Access Board does provide technical assistance regarding accessibility issues to other federal agencies upon request. Were we to receive such a request from the FDA or another federal agency, we would provide assistance to the extent our resources and expertise allowed us to do so.

That is a standing offer, made in writing by the General Counsel of the agency that writes the accessibility guidelines public entities build to, and it has been open since August 2023. The Foundation is aware of no request having been made to the Board by the Food and Drug Administration or by any other federal agency concerning visible light emitted by LED products.

What that converts the request at Part IX.E into is worth stating plainly. The Foundation is not asking this Department to persuade a reluctant agency, to negotiate an interagency agreement, or to expend anything beyond the effort of composing a letter. The expertise exists, it is federal, it has been offered, and it has not been sought. Part VIII describes what the absence of any accessibility criterion addressed to optical radiation has meant for the people this comment concerns; the Board has said it would help to develop one if asked.

A consultation under this paragraph would be directed at the gap that produces. Accessibility guidelines can address a barrier only once the barrier has been characterized. Characterizing this one requires the measurement that § 360ii(a)(4) directs and that has not been performed, which is why Part VIII and Part II.F are the same argument in two registers.

12. Department of Education — school facilities

The Department of Education administers the programs under which school facilities are built, renovated and equipped, and school interiors are among the settings treated at Part VI.E. Children are exposed in them for the length of a school day, on a compulsory basis, in rooms whose lighting they did not choose and cannot alter.

Three features distinguish this setting from the others in this Part. The exposure is compulsory in a way that almost no other is. The exposed population includes children, whose optical media transmit short-wavelength light more freely than those of adults, as Part V.C.5 describes. And the lighting is installed through procurement decisions responsive to published federal guidance, which means that a finding of the kind Part II.G.4 describes would change installations without any regulation being issued.

13. Federal Trade Commission — labeling and advertising of LED products

The Federal Trade Commission prescribes the Lighting Facts label that appears on general service lamp packaging, which reports brightness in lumens, estimated annual energy cost, life, light appearance on a warm-to-cool scale expressed in kelvin, and wattage.

The label is the only disclosure of emission characteristics most purchasers ever see, and the quantities it reports are the quantities this comment identifies as insufficient. Lumens describe total output weighted by the photopic response. Correlated color temperature describes appearance and not spectral content, as Part V.B.3 sets out, and two lamps of identical correlated color temperature may differ substantially in short-wavelength emission. Nothing on the label reports spectral power distribution, source luminance, or temporal modulation. A purchaser seeking to avoid the characteristics described in this comment cannot do so from the information the federal government requires to be disclosed.

The disclosure requested at Part IX.F would be given effect at the point of purchase through this label or its successor, which is why this agency belongs in the consultation this paragraph directs.

14. General Services Administration, Department of Defense, and other federal building operators

This subsection differs in kind from the thirteen before it, and the Foundation says how at the outset. Those agencies regulate an emitting product, or a place in which one is installed, and each of the nine that answered said the subject was not its own. The agencies treated here regulate nothing relevant to this comment. They buy, specify, install, operate and own lighting, and they employ the people who work beneath it. The federal government appears in this subsection as an employer and a landlord rather than as a regulator.

The Foundation also records at the outset that it set out to write this subsection on an assumption which the documents refuted, and that the correction improved the argument rather than weakening it. The assumption was that federal facilities criteria specify how much light and how much power and say nothing about spectrum, flicker or glare. They say a great deal about all three.

a. Scale, and which officer the statute names

The Office of Personnel Management reported 2,289,472 federal civilian employees as of March 31, 2025, which it describes as a preliminary figure and which excludes the Postal Service and the intelligence agencies. The Department of Defense reported for 2024 an active-duty strength of 1,267,738 and a Selected Reserve and Guard strength of 754,403, a total military community of 2,022,141. The Public Buildings Service of the General Services Administration states that it maintains, builds, leases and operates more than 360 million rentable square feet of space, of which 1,699 federally owned buildings account for approximately 187 million.

The Secretary of Defense is one of the four officers paragraph (a)(6) names, and the direction to consult that officer carries no qualifier. Subsection 1. The General Services Administration falls in the residual category and the Foundation does not contend otherwise.

One precision about the scope of paragraph (a)(6) belongs here, because the Foundation would otherwise be claiming more than the text gives it. That paragraph specifies its two subjects: techniques, equipment and programs for testing and evaluating electronic product radiation, and the development of performance standards under § 360kk. It is not a general direction to advise the Secretary of Defense about the health effects of the lighting in Department of Defense buildings. The Foundation accordingly rests this subsection principally on paragraph (a)(3), which directs liaison with and receipt of information from other federal departments and agencies with related interests, and Part II.E develops that paragraph. Paragraph (a)(6)(A) is engaged too, and squarely, but for a narrower reason: what the criteria described below actually contain is testing and evaluation criteria for the emission of a lamp, which is the subject the paragraph names.

b. What the federal facilities criteria require, which is more than the Foundation expected

The Department of Defense criteria are the Unified Facilities Criteria for interior and exterior lighting systems, UFC 3-530-01, dated February 9, 2023 with Change 1 of December 15, 2023, and

the Department of Defense Building Code, UFC 1-200-01, lists it as a core criterion with which projects must comply and reproduces no lighting criteria of its own. Five provisions of the lighting criteria bear on this comment.

The first is a mandate. Paragraph 2-1.1 requires solid state lighting and light-emitting diode systems for all interior lighting, paragraph 2-2.1 requires them unless no equivalent product exists for the application, paragraph 2-2.1.3 directs that incandescent and tungsten halogen sources not be used except where specifically required for certain medical uses, and paragraphs 2-8.1 and 2-8.2 require that emergency lighting units and internally illuminated exit signs be light-emitting diode. That is the clearest instrument the Foundation has found anywhere in federal practice requiring this technology rather than permitting it.

The second is a limit on color temperature. Paragraph 2-1.4.6.1 directs: provide light sources with a correlated color temperature of no greater than 4100 K for all interior spaces, and records that the recommended value for most interior applications is 3500 K, with 2700 K recommended for residential and hospitality uses. That is a numerical ceiling on a spectral characteristic of a lamp, in a federal document, applicable across a building portfolio of the size just described.

The third is a limit on glare, and it is quantitative. Paragraph 2-1.4.1 directs that in regularly occupied spaces luminaires be used whose luminance is less than 650 candelas per square foot, or 7,000 candelas per square meter, in the zone between 45 and 90 degrees from nadir. An alternate path permits higher luminance where continuous dimming is provided and accessible to occupants. A second alternate path permits compliance by demonstrating, through software modeling, a Unified Glare Rating of less than 19. Paragraph 2-1.4.2 separately directs that disability glare caused by bright luminaire components be avoided. The Foundation asks the Department to notice what that is: a federal criterion limiting the luminance of a luminaire within a stated angular zone, which is the form of limit Part IX.I discusses and which Part I.C.7 records does not exist for any product in general use.

The fourth is flicker, and here the criteria are narrower than they first appear. The term is used at paragraph 2-2.1.2, which requires that screw-base replacements dim without flicker or dropouts across the dimming range, at paragraph 2-9.2.4 as to existing control systems, and at paragraph 2-9.2.5 as to linear retrofits. Every one of those provisions treats flicker as a performance defect at the dimming interface rather than as an exposure to be limited. There is an appendix headed Flicker which the Foundation has not read. Part V.D sets out why the distinction matters: a product that does not visibly flicker when dimmed may still modulate at a depth and frequency with physiological consequence.

The fifth is an appendix headed Lighting for Circadian Rhythms, whose sections address spectrum, timing, duration, quantity and distribution, and the spectral power distribution of circadian lighting luminaires. The Foundation has not read it and does not know whether it is mandatory criteria or advisory guidance, which is the question that matters most about it. What the Foundation can report from the main body is paragraph 2-1.4.6.2, which states that tunable white lighting is not a substitute for spectral tuning and does not provide circadian rhythm-specific lighting conditions.

The General Services Administration criteria are the Facilities Standards for the Public Buildings Service, the document known as the P100, in its edition of May 2024, with the lighting requirements at sections 6.1 through 6.3 of its electrical engineering chapter. The Foundation has not been able to read that chapter and states the requirements as they are quoted, by section, in two documents the agency itself commissioned. On that authority the P100 requires interior lighting below 4100 K and exterior lighting below 3500 K, a color rendering index greater than 80 for interior lighting, a fidelity index greater than 85 for lighting in its upper project tiers, and circadian-effective lighting in tiered projects. It restricts lighting power density further than the strictest model energy codes, by thirty percent below the space-by-space method of the governing building energy standard.

c. The mandate that drove the conversion, and the only criterion it uses

The conversion of federal building lighting to light-emitting diode sources was not a matter of taste. Two statutory provisions drive it and the Foundation identifies the operative one precisely, because the mechanism is the point.

Title 42 U.S.C. § 8253(a) requires each agency to apply energy conservation measures to its federal buildings and sets a schedule of reductions in energy consumption per gross square foot rising to thirty percent by fiscal year 2015 against a 2003 baseline. That table was put in its present form by section 431 of the Energy Independence and Security Act of 2007, which replaced the schedule originally set by section 102(a)(1) of the Energy Policy Act of 2005. Title 42 U.S.C. § 6834 separately requires new and renovated federal buildings, where life-cycle cost-effective, to be designed to consume at least thirty percent less energy than the governing standard as it stood in 2005.

The provision that actually produces retrofits is § 8253(f), added by section 432 of the Act of 2007. Each agency designates an energy manager; covered facilities must account for at least seventy-five percent of the agency's facility energy or water use; each energy manager must complete a comprehensive energy and water evaluation of roughly a quarter of covered facilities each year, so that each facility is evaluated at least every four years; and within two years of each evaluation the measures identified must be implemented where they are life-cycle cost-effective, with performance contracting used for at least half of them. That quadrennial cycle, with a two-year implementation clock, is the machinery that converts an audit finding into a lighting retrofit across a portfolio of hundreds of millions of square feet.

The criterion the machinery applies is life-cycle cost-effectiveness and there is no other. Nothing in § 8253(f) permits or requires the health of the occupant to be considered in choosing a light source. And the asymmetry in the companion section is worth stating exactly, because Congress did address the indoor environment there and confined what it addressed. Section 6834(a)(2)(C) directs that standards be developed with regard to radon and other indoor air pollutants, and § 6834(a)(3)(D)(iii)(IV)(cc) credits improved indoor environmental quality through enhanced indoor air quality. Congress legislated about the quality of the air in federal buildings and legislated nothing about the light. Part IV.G describes the same asymmetry in the general illumination standards that govern the lamps the public buys.

The Foundation adds one point of currency rather than leave a reader to a superseded instrument. The executive order on federal sustainability of December 8, 2021 was revoked on January 20, 2025, and the Foundation has identified no replacement. That does not weaken anything above. The provisions just described are statutory and remain in force, so the driver of this conversion is permanent rather than a matter of executive policy that changes hands.

d. The conflict the government has already documented, in its own commissioned words

Two documents the General Services Administration commissioned say, in substance, what Part IV.G and Part V.B of this comment say, and the Foundation quotes them because a federal agency's own contractor is a better witness than the Foundation.

The first is guidance on light-emitting diode lighting and controls prepared for that agency by a national laboratory and dated December 6, 2023. On flicker it states:

> Very low flicker can induce seizures; higher flicker can cause headaches and migraines.

It directs that the driver be high frequency and not have rectangular or complex waveforms, and then records the difficulty:

> There is currently no quick and easy way to assess the driver's waveform.

The Foundation asks the Department to read those two sentences together. A federal building operator has been told, in guidance it paid for, that the modulation of these products can induce seizures and cause headaches and migraines, and in the same guidance that there is no ready means of determining whether a given product does so. Part V.D sets out the literature on the first proposition and Part V.J the absence of any measurement regime answering the second. A measurement method is a technique for testing and evaluating electronic product radiation, which is the subject paragraph (a)(6)(A) names, and Part II.G sets out that this Department has developed none. The same guidance states that all tubular retrofit lamps can create glare problems and that they should be tested in place.

The second document is a technical report prepared for that agency by a research center of a medical school, dated March 14, 2025, on codes and standards that can conflict with circadian-effective lighting in the agency's buildings. Its finding is that the agency's own lighting power limits are in tension with the health-based lighting the agency's own standard requires: that the limit could make it extremely challenging to provide circadian-effective lighting, and that a particular setpoint would very likely result in inadequate circadian-effective light levels. The report inventories the instruments that bear on the question — the agency's own facilities standard, the building energy standard, the model energy code, a state energy code, an illuminating engineering recommended practice, a green building rating system and a design standard for circadian lighting — and it names no instrument of this Department, because there is none to name.

e. The meeting this Department was not at

On November 9, 2022 the Solid-State Lighting Program of the Department of Energy and the National Institutes of Health convened a research and development meeting on human physiological responses to light. The participants included that Program and the Building Technologies Office of the Department of Energy; the National Institutes of Health as co-host, with two conveners named; the National Aeronautics and Space Administration, represented by the head of its Fatigue Countermeasures Laboratory; and the Department of Defense, represented by a Commander of the United States Navy serving as Director of the Military Operational Medicine Research Program. The Centers for Disease Control and Prevention appear in the report only as a source of statistics.

Neither the Food and Drug Administration nor the Center for Devices and Radiological Health appears in that document. The Foundation states the finding at the level the record supports: it has read the published account of the meeting and this Department is not in it, and it does not assert that no official of this Department was aware of the meeting or has ever spoken to anyone who attended.

What the meeting establishes is the proposition this Part is about, in the cleanest form the Foundation has found. The federal government convened a meeting on the physiological effects of light on human beings. The health agency charged with research on human health was there. The space agency was there. The military medical research program was there. The energy agency that drove the technology convened it. The agency holding the statutory duty to study emissions of, and conditions of exposure to, electronic product radiation, and to develop criteria to minimize exposure to unnecessary radiation, was not among them. Paragraph (a)(3) directs this Department to maintain liaison with and to receive information from other federal departments and agencies with related interests. A convened interagency meeting on the physiological effects of light is the paradigm case of a related interest, and the Foundation has not identified any record of this Department receiving anything from it.

f. The same question was asked in 1974, by a component of this Department

The Foundation closes this subsection with a comparison that is to this Department's credit in its earlier form, and it offers the comparison for that reason rather than against the Department.

In 1974 the National Institute for Occupational Safety and Health, a component of this Department, convened a symposium on the occupational safety and health effects of reduced illumination, and the General Services Administration participated in it. The published proceedings of March 1, 1975 carry a paper by an official of that agency on its approach to energy conservation in lighting. The proceedings record a need for more information on the impact of low levels of lighting at the workplace, and address the role of color and contrast in health and safety.

So the sequence is this, and the Foundation states it as a sequence of facts. Fifty-one years ago, when the federal government changed the lighting in its own buildings for reasons of energy, a component of this Department convened a public inquiry into what that would do to the people working under it, and the building operator came and presented. The federal government has since changed the lighting in its own buildings again, on a far larger scale, under a statutory mandate whose only criterion is cost-effectiveness, to a technology whose spectral and temporal characteristics differ from what it replaced in the respects Part V.B describes. The Foundation has identified no comparable inquiry, and no participation by the component of this Department that holds the electronic product radiation authority.

g. What the Foundation asks under this subsection

Four things, and three of them require the agreement of no one.

First, that the Department state whether it has at any time advised, consulted or corresponded with the General Services Administration, the Department of Defense or any other federal building operator concerning the health effects of artificial light, and produce what it holds. Part IX.E.

Second, that it obtain from those agencies the criteria described at subsection b and say, on the record, whether it agrees with them. The Foundation asks that without suggesting the answer. These are procurement specifications for the government's own buildings rather than regulations; they bind nobody outside the government, they were written by facilities engineers rather than by a health agency, and the Foundation does not present them as health standards or contend that their numbers are the right numbers. What they show is narrower and is enough. Numerical criteria for the color temperature and the luminance of a lamp have already been written down by federal agencies, for buildings housing millions of people, without waiting for the settled criterion of necessity whose absence is advanced as a reason that no standard can be developed.

Third, and this is the request the Foundation makes nowhere else in this comment, that the study paragraph (a)(4) directs be performed in the federal portfolio. Part II.F sets out that no study of the emissions of, or the conditions of exposure to, visible light from these products exists. Part V.J sets out what such a study would have to measure and why nobody has measured it: the quantity is the spectral irradiance at the position of a person's eye under the conditions in which the person actually is, and obtaining it requires access to installed lighting in occupied space with the agreement of the owner and the occupants. The federal government owns or leases that space and employs the occupants. No access negotiation is required, no private consent, no manufacturer's cooperation, no new authority and no rulemaking. The lighting was installed to the government's own specifications, under the government's own mandate, in the government's own buildings, for the government's own employees. The Foundation does not assert that federal buildings are harming federal employees and has measured nothing. The argument is about availability and not about harm: whatever is thought of the difficulty of studying conditions of exposure generally, it is not difficult here, and Part IX.C carries the request.

Fourth, that the position of the federal workplace be addressed expressly. Subsection 10 records that staff of the Occupational Safety and Health Administration told the Foundation that the subject was not on that agency's regulatory agenda and that they awaited notification from this Department concerning light-emitting diode hazards in the workplace. Federal workplaces are not outside that program. Section 19 of the Occupational Safety and Health Act, 29 U.S.C. § 668, assigns responsibility for occupational safety and health programs to the head of each agency, and

the implementing regulations adopted under Executive Order 12196 of February 26, 1980 provide at 29 C.F.R. § 1960.8(b) that the head of each agency shall comply with the standards of that Administration applicable to the agency. So the standard that would govern the exposure of two and a quarter million federal civilian employees to the lighting in buildings their employer owns does not exist, and the agency that would write it has said it is waiting to hear from this Department. Part VI.E treats the product class and the exposed populations, and Part VIII the position of employees with the conditions described at Part V.C.5.

15. United States Customs and Border Protection

This agency is established in the Department of Homeland Security by 6 U.S.C. § 211(a), which provides that "There is established in the Department an agency to be known as U.S. Customs and Border Protection." The customs revenue functions that preceded the transfer were retained by the Secretary of the Treasury rather than moved, 6 U.S.C. § 212, and the definition of a customs revenue function at § 215 includes the compiling of import statistics. It is not a health agency and it regulates nothing that emits.

It is in this Part for a reason none of the preceding subsections supplies. Every agency at subsections 4 through 14 is an agency whose own program places an emitting product in front of people and which has told the Foundation in writing that the subject belongs to this Department. This agency has told the Foundation nothing. What it has done is relay this Department's own position to the regulated trade, in an operative instruction, in these words:

> LED products emit visible optical radiation, which qualifies them to be radiation-emitting electronic products

That is CSMS 17-000330 of June 6, 2017, a message of this agency relaying an update from this Department, and the Foundation is careful to describe it as what it is rather than as a statement of this Department. Subsection 18 sets out the whole of the arrangement: a final rule of November 29, 2016, a shared operational system, an instruction to importers and nine years of practice. Part VI.V sets out the tariff mechanism, and the two questions of fact the Foundation asks about its present condition.

The liaison of record with this agency is the most extensive this Department has with any federal agency concerning light-emitting diode products, and its subject is admissibility rather than emission. The Foundation does not criticize that. Nothing in paragraph (a)(6) required the liaison to be about anything other than what it was about, and this agency is not equipped to be asked about spectral composition or retinal exposure. The comparison the Foundation asks the Department to draw is set out at subsection 21.

16. United States International Trade Commission

An independent agency, created by the act of September 8, 1916, 39 Stat. 795, as the United States Tariff Commission, renamed by section 171 of the Trade Act of 1974, 19 U.S.C. § 2231, and organized under 19 U.S.C. § 1330. It maintains and publishes the Harmonized Tariff Schedule of the United States, is directed by 19 U.S.C. § 3005 to keep the schedule under continuous review and to recommend modifications and by § 3007 to publish it, and chairs the interagency committee that annotates the statistical digits of a tariff number under section 484(f) of the Tariff Act of 1930. Subsection 1.d; Part VI.V.

This agency regulates no product, operates no program that places a lamp in front of anyone, and holds no health responsibility of any kind. The Foundation includes it in this list for one reason and states the reason narrowly. The identifier on which this Department's only routine identification of a light-emitting diode product as a radiation-emitting electronic product depends is this agency's publication, and the question Part VI.V asks about the present state of that identifier is a question this agency and Customs and Border Protection can answer between them and nobody else can.

No consultation of record between this Department and this agency has been identified. The Foundation does not suggest that consulting it would answer any health question, because it would not. It would answer a question of fact.

17. United States Fire Administration

This subsection is longer than the two before it, because this agency has done, for one class of light-emitting diode product, a version of what paragraphs (a)(2), (a)(4) and (a)(5) direct this Department to do, and it did so without any health mandate and without any authority over electronic product radiation.

a. What it is, and the Department it was placed in

It was established by the Federal Fire Prevention and Control Act of 1974, Pub. L. 93-498, approved October 29, 1974, 88 Stat. 1535, as the National Fire Prevention and Control Administration. Section 5(a) of that Act provided that "There is hereby established in the Department of Commerce an agency which shall be known as the National Fire Prevention and Control Administration", and the Act defined the Secretary to whom the Administrator reported as the Secretary of Commerce. The codified provision, 15 U.S.C. § 2204(a), still reads that the agency is established "in the Department of Commerce"; those words were never struck. The present placement is carried by the definitions at 15 U.S.C. § 2203 and by the reorganization instruments: the functions were transferred to the Director of the Federal Emergency Management Agency by Reorganization Plan No. 3 of 1978, §§ 201 and 301, 43 F.R. 41,944, 92 Stat. 3788, effective April 1, 1979 under Executive Order 12127, and the functions of that Agency passed to the Secretary of Homeland Security under the Homeland Security Act of 2002.

b. The research function that was deliberately left behind in the Department of Commerce

Section 201 of the Reorganization Plan did not transfer everything, and what it kept back belongs in this Part. It transferred the functions under the 1974 Act "exclusive of the functions set forth at Sections 18 and 23 of the Federal Fire Prevention and Control Act (15 U.S.C. 278(f) and 1511)." Section 18 of that Act is codified at 15 U.S.C. § 278f, and it provides:

> There is hereby established within the Department of Commerce a Fire Research Center

So when the fire administration function went to the Federal Emergency Management Agency, the fire research function was expressly withheld and left with the Secretary of Commerce, and it remains in the chapter of title 15 that governs the National Institute of Standards and Technology, because section 18 was enacted as an amendment to that bureau's own organic act. Subsection 1.b. The content and priorities of the program are to be determined in consultation with the Administrator, and one of the three subjects the section specifies is this:

> research into the biological, physiological, and psychological factors affecting human victims of fire

The Foundation records that for a single and limited purpose. It is not an argument about fire. It is an instance, in the Department this paragraph names first, of a statutory research program directed at the physiological effects of a physical hazard on human beings, with a duty of dissemination running to the Secretary, administered in the same bureau that maintains the national measurement scales for visible light. The bureau presently conducts that work through a Fire Research Division within its Engineering Laboratory. The objection that research of this kind lies outside the competence of the Department of Commerce is answered by a statute of 1974 that put it there and a reorganization of 1978 that declined to move it.

c. What the Administrator is directed to do about warning devices

Title 15 U.S.C. § 2207(a) directs the Administrator to:

> conduct a continuing program of development, testing, and evaluation of equipment for use by the Nation's fire, rescue, and civil defense services, with the aim of making available improved suppression, protective, auxiliary, and warning devices incorporating the latest technology

The Foundation draws attention to the words warning devices, and to the verbs. Development, testing and evaluation of a warning device, with the latest technology in view, is the same activity paragraph 360ii(a)(5) directs this Department to perform with respect to procedures and techniques for minimizing exposure, and Part II.G sets out that it has not been performed. One agency has that duty as to the equipment and has acted on it. The other has it as to the radiation and has not.

d. What it has actually done about emergency vehicle warning lights

Three things, of which the first is relied on throughout this comment. This agency contracted for the controlled experiment described at Appendix D.4.5, which measured the effect of the intensity, color, modulation and flash rate of emergency vehicle warning lamps on drivers at night. That study found that higher intensity lamps were judged consistently more glaring while being only marginally more visible, that discomfort glare is related to short-wavelength content, that blue lamps at high intensity elicit high levels of discomfort glare, and that using lower intensities at night would reduce discomfort glare without reducing visibility. It is relied on at Part II.H.6, Part VI.C.1, Part VI.I and Part V.L, and it is the only federally funded assessment of discomfort glare from flashing lamps the Foundation has found. The Foundation records, because it matters to how the report should be cited, that the study was produced under contract to this agency but is published by the Emergency Responder Safety Institute and not by this agency, and that the Foundation has found no copy of it on any federal site.

Second, this agency has published the conclusions in its own voice. Its report FA-336 of February 2014 describes the research program as concerning "the disorientation of motorists caused by the daytime and nighttime use of emergency warning lights" and as having "documented the resulting desirable (conspicuity) and undesirable (glare) effects", and states, in discussing the minimization of emergency vehicle lighting, that "excessive lighting has been proven to increase the risk of secondary crashes". And a notice published by this agency on March 7, 2024 states two findings in a single line each:

> Blue and red lights are rated most visible; blue and white lights are most glaring.
>
> Reducing light intensity at night will maintain alerting but allow responders to be seen more accurately.

Third, and this is the comparison the Foundation asks the Department to hold onto. A federal agency with no health mandate, no authority over electronic product radiation and no power to prescribe a performance standard for a lamp has paid for research into the discomfort glare and the spectral content of a class of light-emitting diode product, has published the findings, and has told its own constituency to use less light at night. It did so because the product was impairing the vision of the people it is responsible for. Parts II.D through II.G set out that this Department, which holds the duty to study emissions and conditions of exposure and to develop and evaluate techniques for minimizing them, has done none of it for this radiation.

e. The incident reporting comparison, and the limit the Foundation places on it

Section 9 of the 1974 Act, 15 U.S.C. § 2208(a), directs the Administrator to operate "an integrated, comprehensive National Fire Data Center for the selection, analysis, publication, and dissemination of information related to the prevention, occurrence, control, and results of fires of all types", and specifies among the subjects "information on the number of injuries and deaths resulting from fires". The Administrator implemented that direction as the National Fire Incident Reporting System, which this agency describes as a voluntary reporting standard and as the world's largest national annual database of fire incident information. For 2024 this agency reports

that 22,582 fire departments submitted data, and it states that the system captures about seventy percent of fire incidents annually and is not a complete census. The system was retired on January 31, 2026 and is being replaced by the National Emergency Response Information System.

The Foundation states exactly what that comparison establishes, because the loose version of it would be wrong in three ways. It does not suggest that fires and optical radiation are alike as hazards. It does not suggest that § 2208 is a model for a provision this Department lacks, because the statute neither names the reporting system nor obliges any state or locality to report; its lever is to encourage and assist. And it does not treat a system that captures about seventy percent of incidents on a voluntary basis as complete. What the comparison establishes is that a national voluntary incident reporting system for a category of injury is an ordinary thing for the federal government to operate, that Congress directed one in another domain in 1974 and an agency built it and ran it for decades at the scale just described, and that the objection that such a system would be impracticable for optical radiation is answered by the existence of one for fire. Part VII.J sets out that for optical radiation there is no such system at all, and Part IX.D asks for one.

f. What the Foundation does not claim about this agency

No consultation of record between this Department and this agency has been identified, in either direction. This agency has not written to the Foundation and is not among the agencies collected at subsection 21. It maintains three published position statements, on home smoke alarms, on residential fire sprinklers and on fire service ethics, and none of them concerns lighting. The Foundation has not established that it holds any view about light-emitting diode products in general, as distinct from emergency vehicle warning lamps, and does not attribute one to it. And the Foundation does not suggest that this agency should regulate anything; it could not, and has not asked to.

18. Department of Justice

This Department's own rules are not the only federal rules that determine whether an emission denies a person access to a public service. The Department of Justice issues the regulations under Title II and Title III of the Americans with Disabilities Act and adopts the standards made under them, and Part VIII sets out the framework in full. If a criterion is ever written stating when an optical emission denies access, it is written under that authority or the Access Board's.

The Foundation addresses the question of fit before the record, because paragraph (a)(6) is confined to two subjects and this agency does not test electronic products. The Foundation's position is that the Department of Justice falls within the residual category as to the second subject the paragraph names, the development of performance standards under § 360kk, because a criterion stating when an emission denies access would have to be expressed in the quantities such a standard bounds, and because the Access Board at subsection 11 is in this Part on the same footing and its own denial quoted the paragraph at length in explaining why. Where the connection is to information rather than to standards, paragraph (a)(3) is the broader provision and Part II.E treats it.

What the record shows is set out at subsection 6 and the Foundation restates the sequence here because the agency is the subject of this subsection rather than a step in another's story. A complaint under section 504 of the Rehabilitation Act, concerning rectangular rapid-flashing beacons installed by three municipalities, was submitted to the Department of Justice. That Department transferred it to the Department of Transportation. That Department referred it to the Office of Civil Rights of the Federal Highway Administration. That office declined to investigate, and the ground it gave was the Department of Justice's own statement in the 2010 Title II final rule that there is no statutory requirement that every Title II complaint receive investigation, together with the provision at 28 C.F.R. § 35.172(d).

Two observations follow and the Foundation separates them, because only the first is about this Department. The first is that this Department's name appears nowhere in that sequence. A complaint about the optical characteristics of a federally approved device travelled through three

federal bodies, and the agency holding the radiation-health authority over the emission was not one of them and so far as the Foundation can establish was never notified. The second is that the Foundation does not contend that any of the three acted improperly. The transfer and the referral were each within the receiving body's ordinary practice, and the declination rested on a published regulation rather than on an ad hoc view.

The Foundation has identified no communication between this Department and the Department of Justice concerning the visible light emitted by light-emitting diode products, and asks the Department to state whether any has occurred. It asks that this agency be among those to which the written invitation at Part IX.E.5 is sent, and it notes the particular reason for doing so here: of all the agencies in this Part, this is the one whose rules would have to carry any accessibility criterion that a performance standard made it possible to write.

19. Equal Employment Opportunity Commission

The Commission administers Title I of the Americans with Disabilities Act, which reaches employment. The workplace is the one place of exposure a person cannot leave for the duration of a shift, which Part VIII.B.6 develops and which Part VI.E treats as a setting in its own right.

The Foundation explains why this is a separate agency from the one at subsection 10 rather than a duplication of it. Subsection 10 concerns the Department of Labor, whose occupational safety provisions operate through standards of general application, and records that agency's position that the liaison provision of this subchapter imposes nothing on it, which the Foundation accepts as correct. Title I operates differently. It proceeds through individual charges of discrimination and through the duty to provide reasonable accommodation, so an employee affected by the lighting of their workplace has a route that does not depend on any occupational safety standard existing. That route runs through this Commission, and it is open now.

What the record shows is slight and the Foundation states it as such. On February 26, 2023 the Foundation wrote to the Chair of the Commission; the letter is at Appendix E.20 and Part VIII.B.6 sets it out. That subsection also records the feature of the letter that limits what can be drawn from the silence that followed: the Foundation's own letter stated no request for action. The Foundation treats that as a limitation of its own document rather than of the Commission's conduct, and no reply is recorded.

The Foundation states what it does not claim, which is most of what might be claimed. It has not established that the Commission has received any charge concerning lighting. It has not surveyed the Commission's determinations, its guidance or its litigation releases. It does not assert that the Commission has failed in any duty, and it repeats the point made at subsection 10 about the direction in which these duties run: this subchapter imposes obligations on the Secretary of Health and Human Services, and the Commission bears none under it.

What the Foundation asks is accordingly narrow. That this agency be among those to which the written invitation at Part IX.E.5 is sent, and that the Department state whether any communication with it has occurred. And that the consultation, if it occurs, seek the one thing the Commission holds and this Department does not: whatever charges, determinations or guidance it has concerning lighting as a subject of reasonable accommodation. That is precisely the kind of information paragraph (a)(3) contemplates passing between agencies, and this Department can ask for it.

20. The documented instances of consultation and liaison with another federal agency

The one consultation of record, and what a court made of it

The Foundation sets this out as body text rather than leaving it to a note, because it is the whole of the program's documented practice on this subject and because what happened to it afterward is a matter of published judicial record.

On April 24, 2019 Jeffrey Shuren, then Director of the Center for Devices and Radiological Health, wrote to Julius Knapp, then Chief of the Office of Engineering and Technology of the Federal Communications Commission. The Foundation has obtained the letter and describes it from the document.

It is a reply, and it is a reply to two requests rather than one. The Commission had written on March 22, 2019 requesting the Center's guidance on standards as new technologies such as 5G were introduced. It had written earlier, on February 4, 2014, requesting guidance on the exposure principles under which the Commission should consider wireless power transfer devices operating at frequencies for which its rules specified no exposure limits, and asking the Center to identify any risk of interference with medical devices. The April 2019 letter answers both. Whether the Center replied to the 2014 request when it was made is not shown by the document, which refers to it only as a request previously made.

The Foundation therefore states its position more precisely than it was able to before. This is the only letter from this Department to another federal agency about the health effects of an electronic product radiation that the Foundation has been able to identify. It is not a single event. It is one side of a correspondence in which the other agency asked twice, five years apart, and it establishes that the channel for consultation existed, was known to both agencies, and was used.

The Commission relied on it. In its 2019 order declining to revise its radiofrequency exposure limits, the Commission cited this Department's assessment as support for its conclusion.

That order was reviewed. In Environmental Health Trust v. Federal Communications Commission, 9 F.4th 893 (D.C. Cir. Aug. 13, 2021), the Court of Appeals for the District of Columbia Circuit granted the petitions in part and remanded. It held the order arbitrary and capricious in its failure to respond to record evidence, and in its complete failure to respond to comments, as to effects other than cancer. It observed that the Commission said nothing at all in its order about any specific health effects unrelated to cancer. And as to the material the Commission had relied on, including this Department's statements, the court held that conclusory assertions cannot substitute for a reasoned explanation. It upheld the Commission's reasoning on cancer, and it took no position in the scientific debate.

What the Foundation takes from that, and what it does not

It does not say that the 2019 letter was wrong, and it takes no position on the radiofrequency science or on the merits of that litigation. The holding was about the Commission's obligation to explain its own decision, not about this Department's conduct, and the Foundation does not characterize this Department's conduct here or anywhere in this comment in the vocabulary of judicial review. Part I.C.10 explains why.

Two narrower propositions survive those limits, and the Foundation relies only on them.

The first is about the program. The single documented instance of this Department consulting another federal agency about the health effects of an electronic product radiation produced an assurance which the agency that received it relied on, and which a court of appeals then held could not carry the decision that rested on it. The Foundation offers that without comment on who was at fault. It offers it because the instance is the program's only one, and because a program whose sole consultation of record ended that way is a program whose consultation practice has not been tested and found adequate. It has been tested once, in the only forum that tests such things, and the result is reported above.

The second is about what an agency owes a record, and it is the proposition this comment is ultimately addressed to. A federal court of appeals has held that an agency administering an exposure framework for one form of non-ionizing radiation, presented with a record of evidence on health effects, must respond to that evidence and must give a reasoned explanation for the conclusion it reaches, and that saying nothing at all about a category of effect will not do. The court required no particular outcome. It required that the agency explain.

That is what this comment asks for, and the Foundation states the request in those terms because it is the request the Department can grant without conceding anything. Parts V and VII place a record before the Department: the peer-reviewed literature appraised at Appendix C, and 593 reports of harm at Appendix A, every one of which was transmitted to the Food and Drug Administration before this Request for Information issued. Part IV.B. The Foundation does not ask the Department to agree with any conclusion it draws from that record. It asks the Department to respond to it, and to say why it reaches whatever conclusion it reaches, including as to the consultation this subsection describes and the nine federal bodies whose answers are collected at subsection 22.

What the Center recommended in that letter, which is the most important thing in it for this comment

The passage above concerns the part of the letter about cell phones, because that is the part the Commission relied on and the part the litigation concerned. Most of the letter is about something else, and the Foundation sets that part out at length, because it is the closest thing in the record to this Center doing what this comment asks of it.

The Commission had asked about wireless power transfer devices operating at frequencies for which its rules set no human exposure limit. On that subject the Center did not confine itself to assessing whether harm had been established. It recommended that limits be set:

> "We agree that with the increase in technology that uses frequencies below 300 kHz and even below 100 kHz, setting human exposure limits below 300 kHz and 100 kHz would better ensure the protection of the general public."

It then explained the physical basis for the recommendation, that at the lower end of that range nerve stimulation and induced currents predominate while at the upper end heating does, and drew the regulatory consequence that the long averaging times associated with thermal limits are not appropriate to a rapid biological response. It named two existing consensus standards as adequate models for the Commission to adopt.

On interference with implanted and body-worn medical devices, it recommended reduction of the emission itself as the remedy:

> "Therefore, the most effective mitigation against EMI to active medical devices from the emissions of WPT devices is to reduce the WPT emissions and thus medical device exposure."

And it specified four means:

> "The methods to reduce exposure should include limits on the WPT output power, designing the WPT with safety interlocks (i.e., designing the WPT source so that it can detect the presence of humans or animals and shut off or greatly reduce power output), creating exclusion zones, and recommending separation distances between the WPT emitter and any active medical devices."

The two halves of the letter are not alike, and the difference can be tabulated

The Foundation asks the Department to read the halves of this document against each other. The Center answered two inquiries in one letter. In the half where it recommended action it was specific, and in the half where it declined to recommend action it was not. The difference is visible on the face of the document and does not depend on any characterization by the Foundation.

As to cell phones, the Center reviewed the then recently published rodent study of the National Toxicology Program in the context of all available scientific information, including epidemiological studies, and concluded that no changes to the current standards were warranted at that time, that the experimental findings should not be applied to human cell phone usage, and that the available scientific evidence to date did not support adverse health effects in humans at or

under the current limits. It described this as part of its ongoing monitoring activities and stated that it continues its review of the many sources of scientific literature on the topic.

	Wireless power transfer: no limit existed	Cell phones: limits already existed
What the Center did	Recommended that human exposure limits be set below 300 kHz and 100 kHz	Concluded that no changes to the current standards were warranted at this time
Operative verbs	Reduce emissions; limits on output power; shut off or greatly reduce power output	Collect and analyze; review; monitor
Existing standards named	Two, each identified by designation and year, either adequate as a model	None
Mitigation methods specified	Four: a cap on output power, a sensing interlock, exclusion zones, separation distances	None
Where the letter's footnotes go	All three, at footnotes 1 to 3	None
Forward commitment	A recommendation the receiving agency could act on	Continued review, of unstated scope and on no stated schedule

Every source the letter cites supports the half in which the Center recommended action. The half in which it declined to recommend anything refers to the rodent study and to epidemiological studies in its text and cites none of them. The Foundation draws attention to that distribution because the letter demonstrates, within its own four corners, that this Center knows how to support a conclusion about an electronic product radiation with named standards, specified methods and cited literature. Where it did not do so, the omission cannot be attributed to the state of the art or to the conventions of the genre.

The Foundation also observes what the word monitoring does not disclose. It does not name a study, a program, a measurement, a criterion, a trigger, or a date. The Department is the body charged with the program, and a reader cannot tell from the letter what the program did. Part II.D and Part VI.M.3 return to this, because the Final Response of May 24, 2024 answered the Foundation's petition in the same register, and because a statement that an agency continues to review a subject is a statement about posture rather than about anything the agency has done or will do. Environmental Health Trust holds that conclusory assertions of that kind cannot substitute for a reasoned explanation. Part II.H.20.

The letter recites this Department's function without its purpose

One sentence of the letter requires separate attention, because it states the Department's own responsibility and states it incompletely:

> "As you are aware, FDA is responsible for the collection and analysis of scientific information that may relate to the safety of cellphones and other electronic products."

Section 360ii(a)(1) does direct the Secretary to collect and analyze data. But the collection and the analysis are instrumental, and the provision that states what they are for is paragraph (a)(2), which directs the development of criteria to minimize exposures to and emissions of unnecessary electronic product radiation. The letter recites the instrument and omits the purpose, and in place of the purpose it supplies the word safety. The word minimize does not appear anywhere in the letter. Part I.B.3 and Part II.B set out the difference between the two frames and why it decides this proceeding.

The Foundation does not suggest that the omission was deliberate, and nothing in its argument turns on whether it was. What matters is that the same letter which left the minimizing purpose out of its account of the Department's function then applied that purpose, in substance and

without naming it, to the other radiation it was asked about. The letter recommended reducing an emission in order to reduce exposure. That is paragraph (a)(2) being performed, in the half of the letter where no limit existed, by an author who had just described this Department's responsibility as one of collection, analysis and safety.

The word unnecessary appears in the letter once, and in the same half:

> "Adoption of higher emissions levels may expose patients to unnecessary risk."

The Foundation states precisely what that sentence does and does not supply. It is unnecessary risk and not unnecessary radiation, so it is not a construction of the statutory term and the Foundation does not offer it as one. What it shows is narrower and still useful. The Center was willing to identify an exposure as unnecessary, and to recommend limits on that footing, without a quantified reference for necessity, without a dose-response relationship for the harm it was concerned about, and on a record of potential rather than demonstrated injury. The concern the letter describes is a potential for interference inferred from the known susceptibility of implanted devices and from the absence of immunity testing below 150 kHz. It recommended limits anyway.

That matters here because the absence of a settled criterion of necessity is advanced as a reason that no optical standard can be developed. Part VI.M. This letter shows the Center proceeding without one.

What follows for this proceeding, and what does not

Visible light emitted by light-emitting diode products is, on the single question of whether a limit already exists, in the position of wireless power transfer and not in the position of cell phones. No federal limit exists on the radiance, the irradiance, the luminance or the spectral distribution of a visible-light emitter in the general environment. Part I.C.7. The Final Response of May 24, 2024 answered that absence in the safety frame, concluding that a standard was not necessary given a long history of safety with respect to the visible wavelengths emitted. The April 2019 letter shows that this Center has, for another radiation, answered the absence of a limit in the other frame, and did so on a thinner record of harm than the one Parts V and VII place before the Department now.

Three of the four methods the letter recommends are methods this comment asks for, and the Foundation had reached them before obtaining the letter. A cap on output is the performance standard at Part IX.I. A source that detects a person and shuts off or greatly reduces its output is, in the optical case, the ambient-sensing and default-low capability at Part IX.J. Exclusion zones and separation distances are statements about geometry, which is the subject of the fifth matter at Part IX.I concerning the number of emitters a person meets at once, and the Foundation notes that the Center reached for geometry as a remedy in a case where a single emitter was at issue.

The Foundation confines the argument to this. It does not contend that recommendations made for a radiofrequency emission translate to an optical one without work, and the mechanisms, the exposed population and the cost of the remedies all differ. It does not contend that the Center was wrong about cell phones. It contends that the choice between the minimizing frame and the safety frame is a choice this Center has made both ways within one document, that the variable which separated them was the presence or absence of an existing limit rather than the strength of the evidence of harm, and that optical radiation sits on the side of that line where the Center recommended action.

A second instance, of an entirely different character, and the Foundation is careful about what it shows

The correspondence described above is the only exchange between this Department and another federal agency about the health effects of an electronic product radiation that the Foundation has been able to identify. It is not, however, the only liaison of record between this Department and another federal agency about light-emitting diode products. There is a second, and it is sustained, codified and operational.

On November 29, 2016 the Department published a final rule, Submission of Food and Drug Administration Import Data in the Automated Commercial Environment, 81 Fed. Reg. 85,854, effective December 29, 2016, Docket FDA-2016-N-1487, RIN 0910-AH41. The rule added subpart D to 21 C.F.R. part 1 and requires that certain data elements, among them the complete FDA Product Code, be transmitted at the time of entry in the Automated Commercial Environment, which is the system operated by United States Customs and Border Protection. The rule identifies section 536 of the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. § 360mm, as its authority in respect of radiation-emitting electronic products. In the rulemaking the Department described the relationship in its own words: "The discharge of this joint responsibility has involved close coordination and cooperation."

Five months after that rule took effect, on June 6, 2017, Customs and Border Protection published a message to the trade, numbered CSMS 17-000330 and headed Light-Emitting Diode (LED) Reporting to FDA, relaying an update from this Department. It stated that "LED products emit visible optical radiation, which qualifies them to be radiation-emitting electronic products" and instructed that entry data was expected for light-emitting diodes used for general or local area illumination, such as lamps and lightbulbs, under a stated tariff heading. Part VI.V sets out the tariff mechanism and Part II.B.6 the classification that sits behind it.

A third federal body is engaged in the same arrangement without being a party to it. The tariff headings to which this Department attaches its import flags are not written by this Department or by Customs and Border Protection. They are the Harmonized Tariff Schedule of the United States, which is the tariff law of the United States at 19 U.S.C. § 1202 and is maintained and published by the United States International Trade Commission, an independent agency, under 19 U.S.C. § 3005. The classification of these products at the border therefore runs through three federal bodies, of which this Department is one.

One of those three reaches a named officer, and the Foundation records it here because the consequence belongs to this subsection rather than to Part VI.V. The tariff number in the instruction of June 6, 2017 was a ten-digit number, and the ninth and tenth digits of such a number are set by the Committee for Statistical Annotation of Tariff Schedules under section 484(f) of the Tariff Act of 1930, 19 U.S.C. § 1484(f). That subsection directs the Secretary of the Treasury, the Secretary of Commerce and the United States International Trade Commission to establish the statistical enumeration, naming the Secretary of Commerce expressly, and the committee through which they do it comprises the Commission, Customs and Border Protection and the Bureau of the Census. The Secretary of Commerce is one of the four officers paragraph (a)(6) names without the qualifier appropriate. Subsection 1.d. So the arrangement this subsection describes as the program's one sustained liaison already touches, at its mechanical core, an officer the statute directs this Department to consult unconditionally — on a matter of admissibility, and on nothing else.

The Foundation is careful about what that establishes and what it does not, because the distinction is the whole of its value. It establishes that this Department is capable of sustained liaison with another federal agency about light-emitting diode products, that it has conducted such liaison through notice-and-comment rulemaking, that it maintains a shared operational system with that agency, that it has issued instructions to the regulated trade through it, and that it characterized the relationship as a joint responsibility discharged by close coordination and cooperation. Paragraph 360ii(a)(6) directs the Secretary to consult and maintain liaison with other federal departments and agencies, and this is what the Department does when it decides to.

What it does not establish is any consultation about what these products emit or what exposure they produce. The subject of that liaison is admissibility: whether an article may lawfully enter the United States, and what data must accompany it. Nothing in the rule, in the system or in the instruction to the trade concerns the spectral composition of the emission, its luminance, its temporal modulation, or any effect on any person. The Foundation does not criticize that.

Customs and Border Protection is not a health agency, and nothing in paragraph 360ii(a)(6) required the liaison to be about anything other than what it was about.

The comparison the Foundation asks the Department to draw is therefore not between a good instance and a bad one. It is between two kinds of silence. With the agency that inspects these products at the border, this Department has a rule, a shared system, an operative instruction and nine years of practice. With the agencies that put these products on the roadway, in the police vehicle, at the pedestrian crossing, in the classroom and on the appliance — the agencies set out at subsections 4 through 14, each of which has told the Foundation in writing that the subject belongs to this Department — there is one letter, on radiofrequency energy, to one of them, in 2019. The capacity is demonstrated. It has not been directed at the question this comment is about.

21. What those instances show about the program as a whole

There is a second pattern in the record, and the Foundation regards it as the most significant single finding in this Part. It is not that the other agencies have ignored the subject. Several of them have addressed it directly, and have said that it belongs to the Food and Drug Administration.

The clearest instance is in writing. On November 9, 2022 the Manager of the Airport Engineering Division in the Office of Airport Safety and Standards of the Federal Aviation Administration wrote to the Foundation:

> To be more clear, the FAA provides standards and guidance for certain types of airport and obstruction lighting and is not a regulatory agency on LED requirements. The agency defers to other agencies, depending on the issue at hand. We would defer to the FDA for comfort, health, and safety regulations and to OSHA for specific topics like cockpit lighting, in regard to LED products.

It is not an isolated answer. Between March 2022 and August 2023 nine federal bodies told the Foundation, in writing, that this subject was not theirs, and the first of them did so before any of the Foundation's petitions to this Department had been decided. The complaint in the action described at Part IV.D.1 collects eight of them, and the Foundation has read the underlying letters for five.

The Federal Highway Administration, through the ADA Team Leader of its Office of Civil Rights, on October 19, 2022, that allegations about the health impacts of rectangular rapid-flashing beacons raise complex issues related to the regulation of "all Light Emitting Diode (LED) lights, not just those used in RRFBs," that extend beyond that agency's authority. Alone among the responses in this list, it names no agency that does hold the authority. Subsection 6.

The National Highway Traffic Safety Administration, twice: in the published denial of three petitions for non-compliance orders, 87 Fed. Reg. 75,327 (Dec. 8, 2022), that it recognizes the expertise of its sister agencies that are health-focused, such as the Food and Drug Administration; and again by letter of February 13, 2024 from its Office of the Chief Counsel, that separate expertise resides in sister agencies that are health-focused, such as the Food and Drug Administration. Subsection 5; Part IV.C.3; Part IV.C.9.

The Department of Energy, in its published denial of the Foundation's petition for repeal at 88 Fed. Reg. 16,869 (Mar. 21, 2023), that the Food and Drug Administration has authority to regulate certain aspects of LED products. Subsection 4 and Part IV.G.

And the Occupational Safety and Health Administration, through staff of its Directorate of Standards and Guidance, that it awaited notification from the Food and Drug Administration concerning LED hazards in the workplace. Subsection 10.

The National Transportation Safety Board, on March 23, 2022, through the Chief of its Executive Secretariat, who wrote: "We encourage you to pursue your concerns with the

National Highway Traffic Safety Administration or with one of the non-government safety organizations, such as the Insurance Institute for Highway Safety, which may be able to conduct the study you desire. This will be our final reply to you on this issue." That Board investigates and recommends; it does not regulate, and the Foundation does not suggest that it should have acted. The Foundation records the reply because of what it proposes. The study it suggested might be conducted by a private organization is the study that 21 U.S.C. § 360ii(a)(4) directs the Secretary of Health and Human Services to conduct.

The Environmental Protection Agency, on October 7, 2022, that Congress has granted it no statutory authority to regulate visible light or non-ionizing radiation emitted from electrical devices including LEDs, and that it maintains no experts in the field. Subsection 3.

The Consumer Product Safety Commission, on November 7, 2022, that it is barred by 15 U.S.C. § 2080 from regulating a risk of injury from electronic product radiation where that risk may be subjected to regulation under this chapter. Subsection 9.

The Federal Aviation Administration, on November 9, 2022, in the terms quoted above.

The United States Access Board, on August 21, 2023, that it has no authority under 21 U.S.C. § 360ii either to initiate rulemaking or to require this Department to coordinate with it, and that the statute directs the Food and Drug Administration to establish and carry out the program. Subsection 11.

The Access Board answer differs from the rest in a way that matters. The other agencies said the subject was not theirs. The Board said the subject was not within its authority and added that it would provide technical assistance to the Food and Drug Administration on request. It is the only one of the nine that offered to be consulted.

The Foundation sets out the whole of that record for a reason that goes beyond its volume, and states the accounting exactly, because a count of this kind is the first thing a skeptical reader will test. Nine federal bodies, over seventeen months, addressed the question of who is responsible for the health effects of visible light emitted by light-emitting diode products. Not one of them claimed the subject. Six of the nine identified this Department: five named the agency, and the sixth named the chapter of the United States Code this comment concerns and said it was barred from acting where that chapter may reach. Two disclaimed their own authority without identifying any other agency. The ninth pointed to the National Highway Traffic Safety Administration, which has itself twice pointed here. Of the six that identified this Department, one said it was awaiting notification from it and one offered it technical assistance on request.

The Foundation does not say that any of those agencies was wrong. It has examined each of their positions in the subsections above and finds them, so far as it can tell, correct. That is what makes the record worth the Department's attention. This is not a case of a subject falling between agencies because each supposed another was handling it. It is a case of a subject that Congress assigned to one agency, that every other agency asked about has correctly said belongs to that agency, and that the agency has answered by stating that a performance standard is not necessary.

The significance is not that any of those agencies was wrong. On the contrary, the Federal Aviation Administration's answer appears to the Foundation to be correct. That agency sets standards for obstruction and airfield lighting for aviation purposes. It holds no authority to evaluate the health effects of optical radiation, and it said so. Each of the other agencies is in a similar position, for the reasons given in the subsections above.

The significance is where the deferral points. Each agency that has addressed the question has identified the same destination. The destination is this Department, and this Department has answered that a performance standard is not necessary. The result is that a subject several federal agencies have expressly assigned to one agency has not been taken up by that agency, and the agencies that pointed to it have no occasion to revisit the matter, because they were right to point.

The Foundation asks the Department to weigh that pattern when it considers the breadth objection discussed at subsection 2. The objection is that the category of appropriate agencies is unmanageably large. The record suggests a different difficulty. The other agencies have not been reluctant to engage; several have engaged and have identified the agency with the authority. What is missing is the response from the agency they identified.

What the record does to the judgment the statute confers

The Foundation returns to the one textual point the government has pressed, because the record in this subsection bears on it directly and the Foundation does not think the point survives contact with that record in the form the government gives it.

Paragraph (a)(6) directs consultation and liaison with four named officers and with other appropriate Federal departments and agencies. Part I.C.5 concedes, and the Foundation concedes again here, that the word appropriate confers judgment over which additional agencies are consulted. The concession is real and the Foundation does not withdraw it.

But judgment over which agencies are appropriate is not judgment over whether any are. And the nine answers set out above bear on the first question in a particular way, because appropriateness is not a quality this Department assesses in the abstract. It is a relation between two agencies. Each of the nine was asked whether this subject was within its authority, and each answered in writing. Six of them identified this Department. One of those six said it was awaiting notification from this Department. Another offered this Department technical assistance on request. Not one said that consultation with it would be unwelcome, unnecessary, or outside its competence to receive.

The Foundation puts the consequence narrowly. An agency that has told the Foundation in writing that this subject belongs to this Department, and in one case that it is waiting to hear from this Department, has answered the appropriateness question as to itself. Whatever judgment paragraph (a)(6) commits to the Secretary about which additional agencies are appropriate, it is difficult to see how that judgment could be exercised against an agency in that position, and the Foundation is aware of no reason it has been.

That last clause is the point of this movement, and the Foundation states it as an absence rather than as a characterization. The Foundation has not found, in the Final Response of May 24, 2024, in any other agency document it has obtained, or in the litigation record, any statement of the Department's reasons for not consulting these agencies. The Final Response addressed the request for a performance standard under § 360kk. Part II.M.3 sets out that it is the only one of the six duties in § 360ii(a) whose mechanism carries a condition of necessity, and the only one that letter addressed; the letter does not discuss paragraphs (a)(2) through (a)(6).

The government's own position in the pending litigation is to the same effect, and the Foundation relies on it rather than on any inference of its own. Opposing an arbitrary-and-capricious claim for want of final agency action, the United States stated that there has been no decisionmaking process, much less a consummation of the agency's decisionmaking process, as to consultation with the National Highway Traffic Safety Administration on testing and evaluating visible light from light-emitting diode vehicle headlamps. Part I.C.4 quotes it.

The Foundation takes that representation at face value and draws the consequence that follows for this proceeding rather than for the case. If no decisionmaking process has occurred, then there is no exercise of the judgment paragraph (a)(6) confers. A discretion that has not been exercised has not been exercised wrongly, and the Foundation makes no such claim; Part I.C.10 sets out why it declines to characterize the Department's position in the vocabulary of judicial review, and that reasoning holds here. What it asks for is the thing an unexercised discretion lacks and a court could not supply. It asks the Department to exercise it, and to say what it decides and why.

That request costs the Department nothing it is defending. A statement of reasons for consulting these agencies, or for not consulting them, takes no position in the pending case, reopens no

determination, and concedes no proposition in this Part. It is also, so far as the Foundation can tell, the only thing that would allow anyone outside the Department to understand why a subject that nine federal bodies have placed here has not moved. Part IX.E.4 states the request.

22. Summary table: agency, emitting products regulated, FDA consultation of record

The subsections above set out each agency in turn. The table collects them, so that the pattern can be seen rather than followed. The last column is the one the Foundation asks the Department to read first.

Agency	Emitting products or activities it regulates	What it said about this subject, and when	Consultation of record
United States Customs and Border Protection	Admissibility of imported articles; operates the entry system through which this Department's product codes are filed. Regulates no emission.	June 6, 2017: relayed this Department's position to the regulated trade, that "LED products emit visible optical radiation, which qualifies them to be radiation-emitting electronic products".	Yes, and sustained. Final rule of November 29, 2016, a shared entry system, an operative instruction to importers, and nine years of practice — on admissibility, not on emissions or exposure. Subsections 15 and 18.
Federal Communications Commission	Radiofrequency emissions of devices under 47 C.F.R. parts 15 and 18, and human exposure to radiofrequency fields. No authority over visible light.	Undated page: where it does not regulate exposure to emissions from a consumer product, protecting the public from them is the responsibility of the FDA, and inquiries are directed to CDRH; the class of products meant is not established. September 17, 2026: reopened ET Docket No. 13-84 on the Environmental Health Trust remand, inviting federal health and safety agencies to comment by October 22, 2026.	Yes. The letter of April 24, 2019 from the Director of CDRH, on radiofrequency energy. The only consultation of record on the health effects of any electronic product radiation. Subsection 18. None identified as to optical radiation.
National Transportation Safety Board	Investigates and recommends; does not regulate	March 23, 2022: encouraged the Foundation to pursue the matter with NHTSA or a non-government safety organization; final reply.	None identified
Environmental Protection Agency	Ionizing radiation; no authority over visible light	October 7, 2022: Congress has granted it no statutory authority to regulate visible light or non-ionizing radiation from electrical devices; maintains no experts in the field.	None identified
Federal Highway Administration	Manual on Uniform Traffic Control Devices; interim approvals for roadway devices	October 19, 2022: the health impacts of these beacons raise complex issues related to the regulation of all LED lights, not just those used in beacons, extending beyond its authority. Names no agency that holds it.	None identified
Consumer Product Safety Commission	Consumer products, including lamps, flashlights, toys, tools and appliances	November 7, 2022: barred by 15 U.S.C. § 2080(a) from regulating a risk of injury from electronic product radiation where that risk may be subjected to regulation under this chapter.	Referral of electronic product radiation complaints from that Commission to this Department, described by the Center in 2019 as routine. Not consultation about emissions or exposure. Subsection 9.

Agency	Emitting products or activities it regulates	What it said about this subject, and when	Consultation of record
Federal Aviation Administration	Airport and obstruction lighting for aviation purposes	November 9, 2022: not a regulatory agency on LED requirements; would defer to the FDA for comfort, health, and safety regulations.	None identified
National Highway Traffic Safety Administration	Motor vehicle lighting under FMVSS No. 108	December 8, 2022 and February 13, 2024: recognizes that separate expertise resides in sister agencies that are health-focused, such as the FDA.	None identified
Department of Energy	Lamp efficiency standards for general service lamps	March 21, 2023: the FDA has authority to regulate certain aspects of LED products.	None identified
Occupational Safety and Health Administration	Workplace health and safety; named in § 360ii(a)(6)(A)	September 7, 2022 and subsequently: the topic is not on its regulatory agenda; staff awaited notification from the FDA concerning LED hazards in the workplace.	None identified
United States Access Board	Accessibility guidelines for the built environment and public rights-of-way	August 21, 2023: no authority under 21 U.S.C. § 360ii to initiate rulemaking or to require this Department to coordinate; the statute directs the FDA to establish and carry out the program; would provide technical assistance to the FDA on request.	None identified

The last column does not read the same way in every row, and the Foundation asks the Department to read the three exceptions before the eight. Each of the three is a real instance of liaison. None of the three is about what these products emit.

With the agency that inspects these products at the border the liaison is sustained, codified and operational, and its subject is whether an article may lawfully enter. With the Commission there is one letter, written in 2019, about a different radiation; the agency that received it has since reopened the record on the order that relied on it, and has invited federal health agencies to take part. With the Consumer Product Safety Commission there is a standing arrangement for routing complaints, which the Center described in 2019 as routine. Subsections 9, 15 and 18 set out each one.

So the table shows two kinds of silence rather than one, and subsection 21 develops the distinction. Where liaison exists, its subject is admissibility, or another radiation, or the routing of complaints. As to what light-emitting diode products emit and what exposure they produce, the Foundation has identified no record of consultation between this Department and any agency in this table.

That is a statement about what the Foundation has found and not about what exists. It does not mean that no such consultation occurred. The Foundation cannot prove a negative of that kind, and states every assertion of absence in this comment as a statement of what it has found rather than of what exists. What it can say is that it asked. The request under the Freedom of Information Act described at Appendix E.48 sought, as its fifteenth item, all documents relating to 21 U.S.C. § 360ii(a)(6)(A) for ten named federal agencies, among them every one of the nine agencies that answered the Foundation. Whether that request reached the Commission or the border agency the Foundation has not established and does not assert. No record has been produced, and the United States has admitted in the action at Appendix E.50 that as of the filing

of that complaint no determination had been made, no responsive record produced, and no exemption asserted. Part IV.D.3.

Four agencies treated in this Part are absent from the table, and the Foundation says why rather than leave the omission to be noticed. The Equal Employment Opportunity Commission has made no statement about this subject that the Foundation has found, and no consultation with it has been identified, so a row for it would be empty in both of the last two columns; subsection 19 sets out why it is in this Part. The Department of Justice has acted on this subject matter, in that it received and transferred a complaint concerning flashing devices and its own rule supplied the ground on which another agency declined to investigate, but it has said nothing about this Department and nothing about what these products emit; subsection 18 sets that out. The United States International Trade Commission has made no statement about this subject and no consultation with it has been identified, so a row for it would be empty in both of the last two columns; subsection 16 explains why it is in this Part at all. The United States Fire Administration has made statements bearing directly on this subject, and they are set out at subsection 17, but it has said nothing about this Department and no communication between the two has been identified. What that agency contributes to this comment is research it funded and findings it published, which a table of this shape cannot hold and which subsection 17 holds instead.

I. § 360jj — Studies by the Secretary and Reports to Congress

1. The text

Section 360jj(a) provides:

> *"The Secretary shall conduct the following studies, and shall make a report or reports of the results of such studies to the Congress on or before January 1, 1970, and from time to time thereafter as he may find necessary, together with such recommendations for legislation as he may deem appropriate"*

The second of the enumerated studies is:

> *"A study to determine the necessity for the development of standards for the use of nonmedical electronic products for commercial and industrial purposes."*

LED vehicle headlamps, LED streetlights, LED flashing warning beacons, and LED general service lamps are nonmedical electronic products used for commercial and industrial purposes. Nothing in the paragraph excludes them.

2. What is qualified in this provision, and what is not

The distinction matters and the comment should draw it precisely. The direction to conduct the studies carries no qualifier: the Secretary shall conduct them. The first report carried a date certain, January 1, 1970. Only two things in the provision are committed to judgment: whether further reports are made from time to time thereafter, which turns on what the Secretary finds necessary, and what legislative recommendations accompany them, which turns on what he deems appropriate.

3. How the United States has characterized § 360jj

In the liaison litigation described at Part IV.D.2, both the government and the magistrate judge cited § 360jj as the contrasting example of a provision that does direct the agency to specific subject matter. The findings reason that because § 360jj(a)(1)(C) requires the FDA to study used electronic products and particularly antiquated X-ray equipment, Congress "directed regulation of specific products when it so intended," and therefore did not create product-specific requirements in § 360ii(a)(6).

4. Whether the § 360jj(a)(2) study has ever been conducted as to LED products

The Foundation does not contend that the Secretary never conducted the study the provision directs. It contends something narrower and, on the face of the chronology, unanswerable: whatever study was conducted in or about 1969 cannot have examined LED products, because the products did not exist. High-brightness white light-emitting diodes suitable for general illumination were not commercially available until the late 1990s. The product class that now accounts for most human exposure to artificial optical radiation postdates the only performance of the duty the record may show.

a. The study was performed once, in 1969, and its scope was stated on its face

The predecessor of § 360jj was section 357 of the Radiation Control for Health and Safety Act of 1968, Public Law 90-602, whose text is materially identical. The Secretary performed the duty. The Bureau of Radiological Health of the Department of Health, Education, and Welfare transmitted the 1969 Annual Report to Congress on the Administration of the Radiation Control for Health and Safety Act of 1968 on April 1, 1970, incorporating the Report to the Congress on Studies Conducted Pursuant to Section 357. That report was prepared from a series of eight Bureau staff documents.

The staff document performing the second study is BRH/DEP 70-30, A Study to Determine the Necessity for the Development of Standards for the Use of Selected Nonmedical Electronic Products for Commercial and Industrial Purposes, issued by the Division of Electronic Products of the Bureau of Radiological Health. Its preface states:

> *"The Radiation Control for Health and Safety Act of 1968 requires the Secretary of Health, Education, and Welfare to conduct "a study to determine the necessity for the development of standards for the use of nonmedical electronic products for commercial and industrial purposes." The required study was performed during 1969 and was limited to three classes of products: industrial radiographic and fluoroscopic x-ray units, particle accelerators, and analytical x-ray equipment. The findings are presented in this report."*

The introduction states the same limitation: the study "was confined to the following three classes of products: industrial radiographic and fluoroscopic X-ray units; particle accelerators, and analytical X-ray equipment."

b. All three classes are sources of ionizing radiation

Industrial radiographic and fluoroscopic X-ray units, particle accelerators, and analytical X-ray equipment emit ionizing radiation. Not one of the three is a source of visible light or of any other non-ionizing optical emission. The statutory definition at § 360hh(1)(A) reaches "any ionizing or non-ionizing electromagnetic or particulate radiation." The study as performed addressed the first branch of that definition and not the second.

c. What the study concluded for the products it did examine

The study did not conclude that standards were unnecessary. As to particle accelerators it states: "It is the conclusion of this study, therefore, that standards including instrumentation for the safe use of accelerators are needed." The second study, where performed, found a need for standards.

d. The consequence

The duty in § 360jj(a)(2) has been performed once, for three classes of ionizing radiation sources, in 1969. It has never been performed for any product emitting visible light. That is not a conclusion the Foundation asks the Department to draw from silence. It is what the agency's own report says about its own scope, in its preface and in its first paragraph.

e. The separate annual reporting requirement, and its repeal

Part C originally carried two reporting obligations. One was the studies and reports provision now codified at § 360jj. The other was a standing requirement that the Secretary report annually to Congress on the administration of the program, codified at 21 U.S.C. § 360qq. Annual reports were transmitted under that provision for approximately three decades. Section 360qq was repealed by Public Law 105-362, title VI, § 601(a)(2)(A), on November 10, 1998. Section 360jj was not repealed and remains in force.

f. Participation of other agencies in the studies

Section 357 of the 1968 Act also directed the Secretary to invite the participation of other agencies and organizations in conducting the studies. That direction survives, at § 360jj(b) and (c), and it is a second interagency requirement, independent of § 360ii and attached to the studies rather than to the program generally. Subsection (b) provides that, in carrying out these studies, the Secretary shall invite the participation of other Federal departments and agencies having related responsibilities and interests, State governments, and interested professional, labor, and industrial organizations; and that on request the Secretary shall keep interested congressional committees currently informed of the progress of the studies and permit them to send observers to meetings of the study groups. Subsection (c) provides that the Secretary or his designee shall organize the studies and the participation of the invited participants, and that a participant's dissent from the Secretary's findings and recommendations shall be included in the report if the dissenter so requests.

Two consequences follow for this comment. The first is that the participation duty is not satisfied by the liaison duty of § 360ii(a)(3), and the absence of either is not excused by the presence of the other; they are separate provisions with separate triggers. Part II.H. The second is that subsection (c) supplies the verb this comment has otherwise had to supply for itself. The Secretary is to organize the studies and the participation of the invited participants. Part IV.G.12 describes federally funded research on this subject which no one has organized, received or evaluated. That is the condition § 360jj(b) and (c) were enacted to prevent.

5. The petition of December 30, 2025

On December 30, 2025 the Soft Lights Foundation and Mark Baker petitioned the Commissioner under 21 C.F.R. §§ 10.25 and 10.30 to comply with § 360jj(a)(2) and submit a report to Congress on the health hazards of LED products, the measures necessary to address them, and the cooperation required with other federal agencies. Part IV.C.2 sets out the petition and the agency's response.

a. What the petition asks

The petition is titled Petition to Report to Congress on the Impacts of Light Emitting Diode Products on Human Health. It was submitted jointly by the Soft Lights Foundation and by Mr. Baker, which Part IV.A.2 notes, and it is addressed to the Commissioner of Food and Drugs under 21 C.F.R. §§ 10.25 and 10.30, invoking 21 U.S.C. § 360jj(a)(2) and § 360ii.

It asks the Secretary to conduct the study that § 360jj(a)(2) directs and to submit a report to Congress addressing three matters:

> the photobiological, neurological, psychological, hormonal and other health hazards of light-emitting diode products;
>
> the measures necessary to ensure the comfort, health, safety and civil rights of the public with respect to exposure to visible light radiation emitted by those products;
>
> and the cooperation required between the Food and Drug Administration and other federal agencies in order to operate a functional radiation control program as to those products.

The Foundation draws attention to what the petition does not ask. It does not ask for a performance standard. It does not ask the agency to find that these products injure anyone. It asks

the Secretary to perform a study the statute directs and to tell Congress what the study found. That is the same posture this comment takes throughout, and for the same reason: the question whether anything further is warranted cannot be answered until the work the statute directs has been done.

b. The procedural history, stated without characterization

The petition was received on December 30, 2025. Under 21 C.F.R. § 10.30(e)(2) the Commissioner is to furnish a response within 180 days of receipt, and the regulation provides four permitted dispositions, of which one is a tentative response indicating why the agency has been unable to reach a decision.

On June 18, 2026, the one hundred and seventieth day, the agency issued a response of that fourth kind, stating that the petition raises issues requiring further review and analysis by agency officials. The 180 days expired on June 28, 2026. As of the closing date of this request for information the petition has been pending for 295 days.

The Foundation does not contend that the regulation was contravened. A tentative response is expressly permitted, and the agency gave one within the period. The chronology is set out because the subject of the petition is the subject of this request for information, and because the Department is now being asked by its own notice for information on a question that one of its components has had before it, under a statutory duty, since December 2025.

c. Why the petition bears on this comment

The petition and Part II.F of this comment ask for the same work. Paragraph 360ii(a)(4) directs the study and evaluation of emissions and conditions of exposure. Section 360jj(a)(2) directs a study to determine the necessity for the development of standards for the use of nonmedical electronic products, and a report to Congress of the result. What differs is where the output goes, not what the work is.

That difference is worth something, and the Foundation says why. Congress has acted on the adjacent subject already, as Part IV.F sets out. A report under § 360jj(a)(2) would therefore arrive to a body that has demonstrated an interest in it, and would place before that body a federal account of what these products emit and how people are exposed to them — which does not presently exist in any form, as Part II.F.4 describes.

The second thing worth noting is the one established at subsection 2 above. The direction to conduct the studies carries no qualifier. Whatever is said about the judgment conferred elsewhere in this part of the Act, the petition asks for something the statute directs without condition.

6. A duty performed once is not a duty discharged

The structure of § 360jj is continuing. The Secretary conducts the studies and reports on or before a date certain and from time to time thereafter. A provision drafted that way contemplates that the subject matter will change and that the obligation will be revisited when it does. It is the same architecture as the self-evaluation duty that 28 C.F.R. § 35.105 places on public entities, discussed at Part VIII: an evaluation completed once, as to the facilities and programs then existing, is not an evaluation of what the entity operates now.

The text settles the question. The Secretary is to make a report or reports of the results of such studies to the Congress "on or before January 1, 1970, and from time to time thereafter." A date certain for the first report is not a terminus for the duty. The words that follow it contemplate further studies and further reports, and a provision drafted in those terms is not discharged by one performance in 1969.

The subject matter of the second study makes the point independently. Paragraph (a)(2) directs a study to determine the necessity for the development of standards. Necessity is not a fixed fact. It depends on what products exist, what they emit, how many of them there are, and what is known

about their effects, and every one of those variables has changed beyond recognition since 1969. A study that answered the question of necessity for three classes of ionizing-radiation sources in that year does not answer it for a class of products that did not then exist in any comparable form and that now reaches substantially the whole population. Part II.D.6.

The 1970 document's own method confirms the reading. Its title describes a study of selected nonmedical electronic products. Selection presupposes a larger field from which the three classes were drawn, and presupposes that what was not selected remained unexamined. Subsection 4 sets out the scope the document states on its face. The Bureau chose three classes, examined them, and said so. It did not purport to have exhausted the statutory question.

The Foundation states the limit of this argument. It does not contend that § 360jj requires a study of every product class, or any study at any particular interval, and the phrase from time to time confers latitude as to timing which the Foundation does not dispute. What it contends is narrower: that a study confined by its own terms to three classes of ionizing-radiation sources, performed in 1969 and reported in 1970, has not answered the statutory question for light-emitting diode products in 2026; that the question is therefore open; and that the latitude conferred by from time to time is latitude as to when the duty is performed and not as to whether it is.

7. Comparison: judicial treatment of an abandoned statutory program

One judicial treatment of a comparable statutory program is worth setting beside this record, and the Foundation states it as a comparison rather than as authority.

In July 2026 the United States District Court for the District of Columbia held that the Environmental Protection Agency had unreasonably delayed in carrying out duties under the Noise Control Act of 1972, a statute of the same era and of comparable structure, the agency having almost entirely stopped implementing it more than four decades earlier. The duties at issue included informing the public of the health consequences of the exposure, identifying major sources of it, and setting emission standards.

The Foundation draws attention to the branch of review on which that case proceeded, because it differs from the branch on which this record has so far been litigated. Section 706(1) of title 5 reaches agency action unlawfully withheld or unreasonably delayed. The liaison claim described at Part IV.D.2 was litigated on the first of those. A duty to conduct a study and to report, unperformed as to a product class for more than twenty-five years, sits more naturally on the second. The Foundation makes no prediction about any proceeding and asks nothing of this Department on this ground; it notes the comparison because an agency that has stopped implementing a program of this kind has been held to account for the delay rather than for a decision.

8. The repealed annual report to Congress, and the premise on which it was repealed

Section 360jj is not the only reporting provision this Part has to account for. Until 1998 the Secretary was also required to report to Congress every year on the administration of the whole program. That requirement no longer exists, and the circumstances of its removal bear directly on the subject of this comment.

What was repealed

Section 540 of the Federal Food, Drug, and Cosmetic Act, codified at 21 U.S.C. § 360qq, required an annual report to Congress on the administration of the Radiation Control for Health and Safety Act of 1968. It began life as section 360D of the Public Health Service Act and came into the Food, Drug, and Cosmetic Act by the same transfer described at Part II.A.1. It was repealed by section 601(a)(2)(A) of Public Law 105-362, enacted November 10, 1998, 112 Stat. 3285.

The Foundation describes the repealing statute before drawing anything from it, because the statute will not bear a reading that the repeal was aimed at this program and the Foundation does

not advance one. Public Law 105-362 is the Federal Reports Elimination Act of 1998, whose long title is to eliminate unnecessary and wasteful Federal reports. It contains no findings and no statement of purpose. It runs to fifteen titles covering Agriculture, the National Oceanic and Atmospheric Administration, Education, Energy, the Environmental Protection Agency, Health and Human Services, Housing and Urban Development, Indian Affairs, Interior, Justice, the National Aeronautics and Space Administration, the Nuclear Regulatory Commission, the Office of Management and Budget and the Office of Personnel Management, trade, and Transportation, and it makes on the order of one hundred and thirty amendments.

Within this Department alone it eliminated some twenty-five reports. In the same subsection as the radiation report it repealed reporting requirements concerning a tribal direct-billing demonstration program, a Public Health Service report under a statute of 1970, and the effect of an Indian Health Service eligibility rule. Elsewhere in the same section it eliminated reports on organ transplantation, the biennial report of the Director of the National Institutes of Health, sudden infant death syndrome research, the National Vaccine Program, chronic fatigue syndrome research, end-stage renal disease, and the annual reports of the interagency committees on diabetes and on arthritis. The radiation report was swept up in a general exercise and the Foundation says no more about the repeal than that.

The Department recommended the repeal, and gave its reason

What the Foundation does rely on is why the requirement was given up, because the reason was the Department's own and it was stated in writing.

The annual report for calendar year 1994, transmitted to Congress on March 27, 1996, recommended the repeal of section 540. The annual report for calendar year 1995, transmitted on April 8, 1997, recommended it again. The ground given was that the same information already reached Congress, and reached it more quickly, through other channels: the technical reports of the Center for Devices and Radiological Health, the Radiological Health Bulletin, the Center's web page, and other public sources. The second of those transmittals adds the practical reason:

> Agency resources devoted to the preparation of this report should be put to other, better uses.

The Foundation states the provenance of that account precisely. It describes these recommendations from the Presidential messages transmitting the two reports to Congress, and not from the reports themselves, which it has not obtained. The recommendation is therefore attributed on the authority of the transmittals.

The justification was a substitution premise, and nothing provided for it to be revisited

The Foundation asks the Department to notice the form of that reasoning, because it is a form that recurs throughout this subject. The obligation was not given up on the ground that the information did not matter. It was given up on the ground that the information would continue to reach Congress by other means. That is a substitution premise, and the Foundation does not suggest it was unreasonable when it was made.

But a substitution premise is a statement of fact about the world, and a statement of fact can stop being true. A repeal founded on one is sound only for as long as the substitute performs, and nothing in the Act of 1998 provided for anybody to check. Twenty-eight years have passed. The Foundation accordingly asks the Department to test the premise now, on the subject of this comment, by answering four questions. Each concerns the Department's own records and publications, none requires any scientific determination, and the Foundation is not in a position to answer any of them.

> First, and most important: where has this Department informed Congress about visible light emitted by light-emitting diode products? The Foundation asks for the document and its date. The products at issue include motor vehicle headlamps, flashing and warning lamps,

roadway and area lighting, and interior lighting, and the matters at issue include the reports described at Part VII and the petitions described at Part IV. If the information has reached Congress by some channel other than a report of this kind, the Foundation asks the Department to identify it.

Second, as to the Radiological Health Bulletin, the Foundation has looked and records what it found. The Center maintains a page listing the newsletters it presently publishes. Five are listed: a newsletter of the Digital Health Center of Excellence, an educational newsletter of the Division of Industry and Consumer Education, the MedSun newsletter, a newsletter of the Office of Science and Engineering Laboratories, and a standards newsletter. The Radiological Health Bulletin is not among them, and none of the five is dedicated to radiation-emitting products, although the description of the educational newsletter names them among the subjects it covers.

The Foundation therefore does not ask whether the Bulletin still exists. It asks the Department to state when it ceased publication, and to say which of the three channels named in 1996 and 1997 as the substitute for the annual report is still operating. The Foundation has not been able to establish the date on which the Bulletin ceased and does not assert one. What it records is that the publication named to Congress as part of the reason the annual report was unnecessary is not among the publications the Center lists today.

Third: do the technical reports of the Center continue as a series, and has any of them addressed non-coherent light sources since 1979? The year is not chosen by the Foundation. It is the year the Center itself identified, in the paper it put before its own statutory committee in October 2016, as the last in which the agency developed a performance standard for any lamp. Part II.K.5.

Fourth, as to the Center's web page, the Foundation has looked and records what it found. The page describing the Radiological Health Program states the mission as protecting the public from hazardous or unnecessary radiation exposure from radiation-emitting electronic products, and offers links to the electronic product radiation control program, radiation safety, recent scientific publications, and other program pages. It does not mention light-emitting diodes, lamps, non-coherent light sources, or visible light anywhere. It does not mention an annual report, a bulletin, or any report to Congress.

The Foundation has since found the one page on that site which does mention these products, and records it here because it bears on the same question. The page is about laser products, and it mentions light-emitting diodes once, to say that they are different from laser diodes and not subject to the laser performance standard. It says nothing else about them and directs the reader nowhere. Part IX.A.5 sets it out. So the position as to this channel is that the program page does not mention these products and the one page that does mentions them only to state what does not apply. Whatever the substitution premise of 1996 and 1997 assumed the web page would carry, it does not carry this.

What survived the repeal

Congress repealed the report and nothing else. Section 360ii remains, with every paragraph this Part has examined. Section 360jj remains, including the study and report provisions discussed in the subsections above. Section 360kk remains, and so does the committee provision at subsection (f). The duties were left exactly where they were. What was removed was the single recurring, unconditional occasion on which the Department had to say what it had done about them.

The Foundation sets out four dates and draws no causal connection between them, because it cannot and does not need to. In 1979 the agency developed the last performance standard it has ever made for a lamp, on its own account. Part II.K.5. In 1998 the annual report was repealed, on the Department's recommendation. In October 2016 the statutory committee met for the last time the Foundation has been able to identify, with light-emitting diodes on its agenda. Part II.K.5. In May 2024 the Department answered the Foundation's petition by concluding that a performance standard was not necessary given a long history of safety with respect to the visible wavelengths emitted. Part I.C.7.

Why this bears on the petition of December 30, 2025, and on this comment

The petition described at Part II.I.5 asked the Secretary to conduct a study of light-emitting diode products and to report to Congress under § 360jj(a)(2). The Department responded that it was unable to reach a decision on it. What that petition sought is substantially what section 540 once compelled every year without anybody having to ask. The Foundation did not frame the petition as a request to restore a repealed obligation and does not frame it so now. It observes only that the mechanism which would have produced the information automatically was given up in 1998, and that the mechanism which remains requires a petition and has so far produced no decision.

The Foundation has also attempted to obtain the underlying records directly, by request under the Freedom of Information Act, and the course of that attempt is described at Part IV.D. It states here only what is necessary to the present point: the records sought concerned this Center's treatment of visible light from light-emitting diode products, no records were produced in response, and proceedings followed which remain pending. The Foundation offers no characterization of a matter that is before a court.

The general point is the one the Foundation asks the Department to carry away from this subsection, and it is not confined to this program. Where a reporting duty is given up because the information is said to be available elsewhere, and the elsewhere does not in fact carry it, the saving is not of paperwork. What disappears is the subject. There is no document the Department is obliged to produce in which the absence of any standard, any study, any committee proceeding, or any consultation about this radiation would become visible on a fixed schedule, and the Foundation has been unable to find one produced voluntarily.

That is the reason this comment takes the form it does. The Foundation is submitting 593 first-hand reports, a petition record, a chronology, and an account of the program's own documents, to a request for information, because it has not found a federal document that states these things and can point the Department to none. If the Department can point to one, the Foundation asks that it do so in response to this comment, and it will stand corrected.

J. Related Duties Within the Same Part

1. § 360ll — Notification of defects and repair, replacement, or refund

a. The duty, and the thing about it that matters most

Section 360ll(a)(1) provides, so far as relevant:

> Every manufacturer of electronic products who discovers that an electronic product produced, assembled, or imported by him has a defect which relates to the safety of use of such product by reason of the emission of electronic product radiation, or that an electronic product produced, assembled, or imported by him on or after the effective date of an applicable standard prescribed pursuant to section 360kk of this title fails to comply with such standard, shall immediately notify the Secretary of such defect or failure to comply—

The sentence contains two triggers joined by the word or, and the Foundation asks the Department to attend to the first of them. One trigger is failure to comply with a standard prescribed under § 360kk. That trigger depends on a standard existing. The other is the discovery of "a defect which relates to the safety of use of such product by reason of the emission of electronic product radiation." That trigger does not.

The consequence is the most important structural point in this Part. The entire ground of the Final Response of May 24, 2024 is that performance standards are not necessary. Whatever is made of that ground as to § 360kk, it has no bearing on the first trigger of § 360ll(a)(1). A manufacturer who discovers that its product has a defect relating to safety of use by reason of radiation emission must notify the Secretary immediately, and must notify purchasers, dealers

and distributors, whether or not any standard has ever been prescribed for that product. The absence of a standard is not a defense to the defect duty. It is irrelevant to it.

b. What follows notification

Subsection (b) directs how notice reaches first purchasers, subsequent transferees, dealers and distributors. Subsection (c) requires the notice to describe the defect, evaluate the hazard, and state the measures to be taken. Subsection (d) requires the manufacturer to furnish the Secretary copies of its communications on the subject. Subsection (f) requires the manufacturer, without charge, to repair the product, to replace it with a like product that has no defect, or to refund the purchase price, and to reimburse transportation costs. That is a recall remedy, and it exists in this chapter already.

Subsection (e) is the provision the Foundation asks the Department to notice particularly. It authorizes the Secretary, upon determining that a product has such a defect, to direct the manufacturer to furnish the notification. The determination is the Secretary's to make. It requires no rulemaking, no performance standard, and no action by any other agency.

Because the provision is the one on which this subsection turns, the Foundation sets it out rather than describing it. Section 360ll(e) provides:

> If through testing, inspection, investigation, or research carried out pursuant to this part, or examination of reports submitted pursuant to section 360nn of this title, or otherwise, the Secretary determines that any electronic product—(1) does not comply with an applicable standard prescribed pursuant to section 360kk of this title; or (2) contains a defect which relates to the safety of use of such product by reason of the emission of electronic product radiation; he shall immediately notify the manufacturer of such product of such defect or failure to comply. The notice shall contain the findings of the Secretary and shall include all information upon which the findings are based. The Secretary shall afford such manufacturer an opportunity to present his views and evidence in support thereof, to establish that there is no failure of compliance or that the alleged defect does not exist or does not relate to safety of use of the product by reason of the emission of such radiation hazard.

Three features of that text bear on what follows. The determination may be reached "through testing, inspection, investigation, or research carried out pursuant to this part, or examination of reports submitted pursuant to section 360nn of this title, or otherwise." The words or otherwise are not decorative: the statute contemplates that the Secretary may come to the determination on information from any source, including information supplied from outside the agency. Once the determination is made, notification to the manufacturer is mandatory and immediate. And the manufacturer is then given an opportunity to answer, which is to say that the provision contains its own procedural protection and does not require the Secretary to be certain before beginning.

c. The notice of December 1, 2025

The Foundation has invoked this provision. On December 1, 2025 it wrote jointly to the Commissioner of Food and Drugs and to the Administrator of the National Highway Traffic Safety Administration, under the heading Notice of Defective Technology — LED Vehicle Headlamps. The letter transmitted three compilations for entry into the record keeping systems of both agencies and for public release: the LED Incident Reports covering April 21, 2024 to November 27, 2025; the comments on the Ban Blinding Headlights petition covering November 17, 2016 to November 30, 2025; and the signatures on that petition. It recited that the petition had reached 75,000 signatures on November 28, 2025 and that the comments exceeded 4,700.

The letter quoted 49 U.S.C. § 30118(a) and 21 U.S.C. § 360ll(e) and asked both agencies to comply with their duties under those provisions by notifying the manufacturers that LED vehicle headlamp technology is defective, and by requiring each manufacturer to open an investigation and submit detailed reports.

The Foundation states what that letter accomplished and what it did not. It did not establish a defect; no private party can. What it did was supply the Secretary with information, which is the circumstance the words or otherwise in § 360ll(e) describe. The Foundation is aware of no response to it, and no determination under § 360ll(e) has been communicated to the Foundation or published.

c. What the Foundation contends, and what it does not

The Foundation contends that light-emitting diode headlamps have a defect which relates to the safety of their use by reason of the emission of electronic product radiation, and that the same is true of light-emitting diode roadway lighting. The grounds are set out at Part V and Part VII: the source radiance and short-wavelength content described at Part V.B, the disability and discomfort glare described at Part V.C.3 and V.C.4, and the reports of seizure, migraine, visual impairment and other neurological effect described at Part VII.

The Foundation does not contend that the Department should accept that conclusion on this comment. A defect determination under § 360ll(e) is a finding of fact about particular products, and it would be improper to ask for it on a record the Department has not built. What the Foundation asks is the step before: that the Department conduct the testing and evaluation § 360ii(a)(4) directs, which is what would permit a determination under § 360ll(e) to be made either way. Part II.F. The defect provision is another route by which the absence of that work prevents the statute from operating.

d. The parallel provision at the Department of Transportation, and the gap beside it

A corresponding mechanism exists for motor vehicles. Under 49 U.S.C. § 30118 a manufacturer who learns that a vehicle or item of motor vehicle equipment contains a defect related to motor vehicle safety must notify the Secretary of Transportation and the owners, and the Secretary may make that decision independently after notice and an opportunity for a hearing. The Foundation has invoked that provision. On June 30, 2025 it submitted a petition to the National Highway Traffic Safety Administration under § 30118(e) requesting a hearing on LED headlights, following its petition of March 1, 2024 to limit headlamp intensity and its petition of May 15, 2024 to limit correlated color temperature. Part IV.C.

The procedures by which that agency opens and conducts a defect investigation are prescribed at 49 C.F.R. part 554. The Foundation notes the existence of those procedures for a reason that bears on this Part: there is no counterpart to them under this chapter. Section 360ll confers the authority described above, and the Foundation has identified no regulation in subchapter J establishing how the Secretary determines that a defect exists, how a determination is initiated, or what a person outside the agency may do to seek one. The power at § 360ll(e) exists without any stated procedure for invoking it.

The request to the Department of Transportation has not been the Foundation's alone. In December 2025 the Foundation published a form of letter and invited members of the public to send it to the Administrator, asking that a hearing be held under § 30118(e) to determine whether manufacturers have met the notification requirements of § 30118 for LED vehicle headlamps. Letters were sent. The public petition those letters refer to carries more than 75,000 signatures and more than 4,700 comments describing the hazard, and Part VII.G addresses what that material does and does not establish.

The Foundation sets that beside § 360ll in order to make a point about scope rather than about either agency. Section 30118 reaches motor vehicles and motor vehicle equipment, and nothing else. Section 360ll reaches every electronic product that emits electronic product radiation.

Roadway and area lighting is the case that shows what that difference means. A streetlight is not motor vehicle equipment. No provision of title 49 reaches it. The Consumer Product Safety Commission's authority runs to consumer products, and a luminaire installed on a municipal pole

is not one. The Department of Energy regulates its efficacy and not its emission, as Part IV.G sets out. For a light-emitting diode streetlight alleged to have a defect relating to safety of use by reason of its emission, § 360ll is not merely the best route. So far as the Foundation can determine, it is the only one in federal law.

That is the answer to a question the Department may fairly ask of this comment: why bring this subject here rather than to the agencies that regulate the products. For headlamps there is another agency, and the Foundation has gone to it. For street and area lighting, for indicator lamps, for the retail interiors described at Part VI.F, and for most of the product classes in Part VI, there is no other agency. There is this chapter, and the duties it imposes on this Department.

2. § 360nn — Inspection, records, and reports

Section 360nn is the inspection, records and reports provision of the same part. It authorizes officers designated by the Secretary to enter and inspect premises where electronic products are manufactured or held, and it directs that manufacturers and dealers establish and maintain such records and make such reports as the Secretary may reasonably require.

The Foundation brings it into this Part for one reason, which is its relation to the provision at subsection 1. Part II.J.1 sets out § 360ll(e), and the text quoted there provides that the Secretary may reach a determination of defect through testing, inspection, investigation or research carried out pursuant to this part, or examination of reports submitted pursuant to section 360nn, or otherwise. So § 360nn is named in the defect provision as one of the routes by which the Secretary may come to know what a product does.

What follows is a matter of sequence rather than of argument. The records and reports this provision authorizes the Secretary to require are the records that would answer several of the questions this comment asks: what the products in commerce emit, which Part IX.C asks be characterized, and what manufacturers themselves know about it, which Part IX.F asks be disclosed. The authority to require them does not depend on a performance standard existing, and the Foundation has identified no instance in which it has been exercised as to the visible light emitted by a light-emitting diode product.

The Foundation asks nothing under this head beyond what Part IX.C and Part IX.F ask. It records the provision because a comment that asks the Department to find out what these products emit should identify the provisions that already let it ask.

K. § 360kk(f) — The Technical Electronic Product Radiation Safety Standards Committee

1. What the statute requires

Establishment and composition. The Committee consists of fifteen members: five selected from government, five from the affected industries and five from the general public, of whom at least one is to represent organized labor.

Qualification. Each member is to be technically qualified by training and experience in a field applicable to electronic product radiation safety.

Consultation before a standard. The Secretary shall consult the Committee before prescribing any standard under § 360kk. This is the operative requirement, and it is the reason a functioning Committee is a precondition to the relief requested at Part IX rather than an afterthought to it.

The Committee's own power to propose. The Committee may itself propose radiation safety standards for the Secretary's consideration. It is therefore not merely reactive, and a functioning Committee is a route to a standard that does not depend on the agency acting first.

The record of proceedings. All proceedings of the Committee shall be recorded and the record shall be available for public inspection.

2. The implementing regulations — 21 C.F.R. part 14, subpart G

a. § 14.120 — establishment

The regulation establishes the Committee in the agency's own rules and fixes its size, providing for the Technical Electronic Product Radiation Safety Standards Committee, consisting of fifteen members, to advise the Commissioner before any performance standard for an electronic product is prescribed. The Committee is therefore not a body the agency may constitute or not as it chooses. It exists by statute, and the agency has given it a regulation of its own.

b. § 14.122 — functions

This is the provision on which the Foundation places most weight, and it is set out in full because its structure is the answer to the position described at subsection 6. Section 14.122 provides:

> (a) In performing its function of advising the Commissioner, TEPRSSC—
>
> (1) May propose electronic product radiation safety standards to the Commissioner for consideration;
>
> (2) Provides consultation to the Commissioner on all performance standards proposed for consideration under 21 U.S.C. 360kk; and
>
> (3) May make recommendations to the Commissioner on any other matters it deems necessary or appropriate in fulfilling the purposes of the act.
>
> (b) Responsibility for action on performance standards under 21 U.S.C. 360kk rests with the Commissioner, after receiving the advice of TEPRSSC.

Three functions are conferred, and only one of them is triggered by anything the Commissioner does. Paragraph (a)(2) is the consultation that attaches to standards proposed for consideration. Paragraphs (a)(1) and (a)(3) are the Committee's own, and paragraph (a)(3) is not confined to standards at all. Its subject is any other matter, and the judgment as to which matters qualify is placed with the Committee by the words it deems necessary or appropriate.

The Foundation draws the consequence at subsection 6. It states here only what the text provides. A Committee that does not convene cannot exercise paragraph (a)(1) or paragraph (a)(3) at any time, whether or not a standard is under consideration, because both are functions it performs on its own motion and neither waits on the Commissioner.

c. § 14.125 — procedures, including submission of a proposed standard to the Committee before publication in the Federal Register

Paragraph (a) is the provision the Department has invoked in explaining the Committee's inactivity, and the Foundation quotes it in full so that the reader may measure the explanation against the text:

> When the Commissioner is considering promulgation of a performance standard for an electronic product, or an amendment of an existing standard, before issuing a proposed regulation in the Federal Register the Commissioner will submit to TEPRSSC the proposed standard or amendment under consideration, together with other relevant information to aid TEPRSSC in its deliberations.

Three further paragraphs of the same section matter and are less often noticed.

- Paragraph (c) fixes the quorum at ten members, of which at least three shall be from each of the government, industry and general public categories. The Foundation draws attention to the source. The quorum is not merely a term of the Committee's charter, which an agency may revise; it is in the Code of Federal Regulations.
- Paragraph (d) provides that the Chairperson of TEPRSSC will ordinarily submit a report to the Commissioner within sixty days, extendable by thirty. The consultation contemplated by paragraph (a) is therefore completed by a report, and the report is the Chairperson's to make.

> Paragraph (b) provides for materials to reach members at least two weeks before a meeting where possible.

Paragraph (d) has a practical consequence that bears directly on the relief sought in Part IX.H. If the office of Chairperson is vacant, the consultation required by paragraph (a) cannot be completed as the regulation contemplates, because the officer who is to report does not exist. A position that the Committee will be reconstituted if and when a standard comes under consideration accordingly assumes that reconstitution can be accomplished within the period the regulation allows for the report. The Foundation does not assert that it cannot. It asks the Department to say how long the reconstitution would take, because the regulation measures the consultation in days.

d. § 14.127 — membership and terms

The Commissioner appoints five members from government, five from the affected industries and five from the general public. Terms are three years, members may not serve two consecutive full terms, and the conflict of interest provisions of part 14 apply. The limitation on consecutive terms is worth noting for a reason that is not adverse to the Department: a committee of this kind requires continuous replenishment by design, so vacancies are the expected condition and filling them is a recurring administrative task rather than an extraordinary one.

e. § 14.130 — conduct of meetings and availability of records

All proceedings of the Committee are to be recorded and the record is to be available for public inspection, and proceedings are open except where the Commissioner closes a portion of a meeting under § 14.27. Taken with the notice requirements of the Federal Advisory Committee Act, this provision has an evidentiary consequence that subsection 5 relies on and that the Foundation states here. A meeting of this Committee cannot occur without public notice and cannot occur without a record. The absence of notice and of a record is therefore not merely a failure of the Foundation's search. It is the form in which the absence of a meeting would be expected to appear.

3. Chartering history

The Foundation has obtained the operative charter. It was approved on December 18, 2024 by the Director of the Advisory Committee Oversight and Management Staff, and its stated filing date is December 24, 2024. The charters are renewed on a two-year cycle and are filed on December 24; the Foundation has also seen the charters filed on that date in 2014 and in 2016, and a renewal notice published on January 24, 2023, 88 FR 4190, extending the then charter to December 24, 2024.

The charter describes the Committee as a permanent statutory committee established pursuant to the Radiation Control for Health and Safety Act of 1968, 21 U.S.C. § 360kk(f), governed also by the Federal Advisory Committee Act as amended, 5 U.S.C. 1001 et seq. Management and support services are assigned to the Center for Devices and Radiological Health. The duration is stated as Continuing.

The charter states its own objectives in terms the Foundation relies on at Part II.K.7 and at Part IX.H, because they are the agency's description of what this body is for:

> This Act creates the Technical Electronic Product Radiation Safety Standards Committee (TEPRSSC) and requires the Commissioner to consult with the Committee before prescribing standards for radiation emissions from electronic products. The TEPRSSC advises FDA regarding proposed performance standards for electronic products which emit radiation.

Its statement of duties is to the same effect, and adds the Committee's own power of initiative:

> This Committee provides advice and consultation to the Commissioner of Food and Drugs on the technical feasibility, reasonableness, and practicability of performance standards for

electronic products to control the emission of radiation from such products and may recommend electronic product radiation safety standards to the Commissioner for consideration.

The termination date, which falls within weeks of this comment

The charter provides that unless renewed by appropriate action before it expires, it will expire two years from the date it is filed. Filed December 24, 2024, it expires December 24, 2026.

Three provisions of that charter bear on the subsections that follow, and the Foundation quotes them because they are the agency's own undertakings rather than the Foundation's characterizations.

On frequency: "Meetings shall be held approximately once every other year." Meetings are to be open to the public except as the Commissioner determines otherwise, and notice of all meetings is to be given to the public.

On membership: fifteen voting members including the Chair, selected by the Commissioner or designee from among authorities knowledgeable in the fields of science or engineering applicable to electronic product radiation safety, and invited to serve for overlapping terms of up to four years. The fifteen comprise five from governmental agencies including State and Federal Governments, five from the affected industries after consultation with industry representatives, and five from the general public of whom at least one shall be a representative of organized labor.

The charter's four-year term resolves a discrepancy this comment flagged at Part II.K.2, where 21 C.F.R. § 14.127 gives terms of three years. The three members shown on the roster held terms running from April 11, 2022 to December 31, 2025, which is three years and rather more than eight months. The Foundation therefore takes the charter to govern and does not rely on the three-year figure. It notes the point because a reader comparing the regulation with the roster would otherwise find an inconsistency the Foundation had not addressed.

On quorum: "A quorum shall consist of 10 members, of which at least 3 shall be from the general public, 3 from the government agencies, and 3 from the affected industries." The same quorum is prescribed by regulation at 21 C.F.R. § 14.125(c), and the Foundation cites the regulation in preference to the charter wherever the two agree.

A fourth provision should be added to those three, because it forecloses an answer that might otherwise be given. The charter assigns to the Designated Federal Officer the duty to attend each Committee meeting, to approve and prepare all meeting agendas, and to call all the Committee and subcommittee meetings. The officer who convenes this Committee is therefore not the Chair, and the roster at Part II.K.4 shows that office to be filled. The Committee's inability to meet is accordingly not for want of anyone empowered to call a meeting. It is for want of members to attend one.

The same provision assigns the Designated Federal Officer the duty to maintain information on committee activities and to provide it to the public as applicable, including as required by 5 U.S.C. § 1009(b). The charter's recordkeeping provision adds that Committee records will be available for public inspection and copying subject to the Freedom of Information Act. Part II.K.5 and Part VII.I return to the consequence of those undertakings for the meeting record.

The charter also states the cost of operating the Committee, and the Foundation gives both components because the smaller one alone would understate it. The estimated annual cost of operating the Committee, including compensation and travel expenses for members but excluding staff support, is $29,333. The estimated staff support is 0.50 person years, at an estimated annual cost of $100,937. The two together are approximately $130,000 a year.

The Foundation notes those figures for one reason only, and it is not a complaint about expense. Whatever has prevented this Committee from functioning, the cost of convening it is not a substantial obstacle for a Department whose annual appropriation is measured in billions. The

Foundation makes no suggestion that cost has been the reason, and the Department has never given it as one.

4. Membership status

The Department publishes a roster of this Committee, and it answers the question this subsection previously had to leave open. The Foundation sets out what the roster states, as reviewed in October 2026, and then the arithmetic that follows from it.

The roster describes the Committee's purpose by reference to the statute, in terms worth quoting because they are the agency's own account of what the body is for:

> Advises on technical feasibility, reasonableness, and practicability of performance standards for electronic products to control the emission of radiation under 21 U.S.C. 360kk(f)(1).

It then states a figure for vacancies, against the fifteen seats the statute and the charter provide:

> Current Number of Vacancies: 12

Twelve vacancies against fifteen seats leaves three. The roster lists three members, each with the same term, and distributes them among the statutory categories as follows.

> Government representatives: two. One is the Chief of the Electronic Products Branch, Division of Nuclear Safety, at a State emergency management agency, whose expertise the roster gives as nuclear safety health physics. The other is a Surveillance Section Director in the Consumer Protection Division of a State health department, whose expertise the roster gives as regulatory radiation control.
>
> General public representatives: one. A professor of radiology at a university school of medicine, whose expertise the roster gives as medical physics.
>
> Industry representatives: none. The roster defines the category in its own legend, as Industry Representative, and lists no person in it.

The roster shows the office of Chairperson as vacant, in terms. It names a Designated Federal Officer in the Office of Management of the Center for Devices and Radiological Health, who is not a member of the Committee.

All three members were appointed on the same day, April 11, 2022, and all three terms ended on the same day, December 31, 2025. No person shown on the roster holds a term that has not run out.

The Foundation states three qualifications before drawing any conclusion, because each is capable of being raised against it. The roster carries its own caveat, which the Foundation quotes rather than paraphrases: one or more vacancies may be in the nomination process or a final appointment may have been made. The page bears no date of last revision, so the Foundation cannot establish how current it is. And the Foundation does not assert that the Committee has no members at all. An expired term is not the same thing as a vacant seat. The roster lists these three as members while showing their terms as ended, and it counts twelve vacancies rather than fifteen, so the Department evidently does not treat the three as having left. Whether a member may continue to serve pending replacement is a question of the charter, the Federal Advisory Committee Act and the instruments of appointment, which the Foundation does not resolve and does not need to resolve.

The arithmetic against the quorum the regulation requires

Section 14.125(c) of title 21 of the Code of Federal Regulations fixes the quorum of this Committee at ten members, of whom at least three must be drawn from each of the government, industry and general public categories. The charter provides the same. Measured against the roster, every element of that requirement fails, and three of the four fail by a margin.

> Ten members are required. Three are listed.

Three government representatives are required. Two are listed.

Three general public representatives are required. One is listed.

Three industry representatives are required. None is listed.

The Foundation asks the Department to notice how little that conclusion depends on anything capable of dispute. It does not turn on whether the roster is current, because the shortfall is twelve appointments. It does not turn on whether a member whose term has expired may continue to serve, because if all three continue to serve the number is still three. It does not turn on the identity or the diligence of any member, none of whom is responsible for a vacancy. And it does not turn on the headcount at all, because the industry category is empty and no quorum of this Committee can be constituted without three members drawn from it. That element fails on its own and would fail if every other seat were filled.

The position as to the Chair is separate and equally concrete. Section 14.125(d) provides that the Chairperson of the Committee ordinarily submits the report of its consultation to the Commissioner within sixty days, and that report is the act by which the consultation required by § 360kk(f) is completed. The roster shows the office as vacant.

The nomination record, which is now background rather than inference

The Foundation previously had to reason about membership from the agency's requests for nominations. Those remain relevant as history rather than as evidence of the present position. On January 10, 2025 the agency published a request for nominations for five general public representatives and five government representatives, for current and upcoming vacancies effective January 1, 2025, with first consideration for nominations received by March 11, 2025. That was a request to fill ten of the fifteen seats, and it is now nineteen months old.

It was not the first. The Foundation has identified four requests for nominations to this Committee, published on November 30, 2021, February 16, 2022, December 1, 2022 and January 10, 2025, together with a renewal of the charter published on January 24, 2023. In the same period it has identified no notice of any meeting. The roster page itself carries a standing invitation, stating that the agency is requesting nominations for members to serve on its advisory committees as part of its ongoing efforts to recruit qualified experts with minimal conflicts of interest.

The Foundation offers that sequence without characterizing it. An agency that publishes four requests for nominations and maintains a standing invitation is an agency attempting to seat the Committee, and the Foundation does not suggest neglect. What the sequence and the roster together establish is that the difficulty is of long standing, that the agency has been aware of it for at least five years, that four nomination requests have not remedied it, and that as matters stand the Committee has three members, no Chair, no industry representative, and not one member whose term is current.

5. Meeting record

The Foundation has obtained the materials from that proceeding and sets out what they show, because they are the agency's own words to its own statutory committee.

The meeting was noticed in the Federal Register on September 22, 2016 and was held on October 25 and 26, 2016 at Gaithersburg, Maryland. The notice states the purpose of the first day in terms the Foundation quotes exactly, because the whole of the argument that follows is built on them:

> "On October 25, 2016, the committee will discuss and make recommendations regarding possible FDA performance standards" for, among other subjects:
>
> "Radiofrequency (RF) radiation products, such as microwave ovens and wireless power transfer"; and
>
> "non-coherent light sources (e.g., LEDs and UVC lamps) including new initiatives."

> "Radiofrequency (RF) radiation products, such as microwave ovens and wireless power transfer"; and
>
> "non-coherent light sources (e.g., LEDs and UVC lamps) including new initiatives."

The Foundation asks the Department to notice three things about that notice, each of which is a fact about the agency's own practice rather than an argument.

First, light-emitting diodes and radiofrequency radiation were before this Committee together, in one sitting, as candidate subjects for performance standards. The present request for information concerns electromagnetic radiation, and the Department has already had both halves of that subject before the committee the statute gave it for exactly this purpose.

Second, wireless power transfer was among the radiofrequency subjects on that agenda. Part II.H.20 sets out the letter of April 24, 2019 in which the Center recommended to the Federal Communications Commission that human exposure limits be set for wireless power transfer below 300 kHz and 100 kHz, and recommended four methods of reducing the emission. The sequence is therefore that a subject came before the statutory committee in October 2016, and that two and a half years later the Center recommended limits on it to another agency. The Foundation does not know what the Committee said about it in 2016.

Third, and this is the observation the Foundation asks the Department to weigh most carefully in the whole of this Part, the notice is itself evidence of what the agency was doing. A notice stating that the Committee will discuss and make recommendations regarding possible FDA performance standards for non-coherent light sources, LEDs among them, is a published statement that performance standards for those products were a subject the agency was taking to its statutory committee for recommendations. The phrase including new initiatives points the same way.

That bears directly on § 14.125(a), the provision quoted at subsection 2, whose trigger is the Commissioner considering promulgation of a performance standard for an electronic product. The Foundation does not need to resolve what degree of settled intention the word considering requires, and declines to try. It is enough to put the Department to an election, because the two available answers lead to the same place.

> If performance standards for light-emitting diode products were under consideration in October 2016, then § 14.125(a) was engaged, the Committee was consulted as the regulation contemplates, and the question for the Department is what became of that consideration. No proposed regulation followed. The Foundation has identified no published document in which the agency recorded a decision not to proceed, no notice withdrawing the subject, and no statement that the consideration had concluded. A consideration begun and neither completed nor abandoned on the record is the condition this comment describes throughout: not a decision against a standard, but no decision at all. Part II.D and Part II.I.
>
> If performance standards for those products were not under consideration in October 2016, then the Committee was convened, and spent a day discussing possible performance standards across seven subject areas, at a time when nothing was under consideration. On that view the agency's own practice in 2016 is inconsistent with the position that this Committee need meet only when a standard is under consideration, and the explanation for nine years of inactivity cannot rest on § 14.125(a).

The Foundation does not know which answer is correct and says so. It asks the Department to supply it: to state whether performance standards for non-coherent light sources were under consideration in or after October 2016, and if they were, to state when and by what document that consideration ended. That is a question about the Department's own records, it requires no scientific determination of any kind, and the Foundation is not in a position to answer it.

One further matter should be stated so that it is not mistaken for an answer. The Final Response of May 24, 2024 concluded that a performance standard was not necessary, and a reader might take that as the disposition of whatever began in 2016. The Foundation asks the Department not to treat it so without saying so expressly. That document responded to the Foundation's petition of

2022, it was issued eight years after the proceeding described here, and so far as the Foundation can determine it does not mention the proceeding of October 25, 2016, the paper presented there, or the Committee's recommendations. If it is the disposition of the 2016 consideration, the Department should say so and should explain how a petition response discharges a consideration that preceded the petition by six years. Part I.C.7 and Part VI.M.

At the Committee meeting of October 25, 2016, the Center for Devices and Radiological Health presented a paper titled Non-Coherent Light Sources, prepared by Sharon Miller, Ph.D., of the Office of In Vitro Diagnostics and Radiological Health and delivered by William Calhoun, Ph.D. The paper treats light-emitting diodes as non-coherent light sources, which it describes as electronic products that emit light, commonly known as lamps. Its stated agenda was what a non-coherent light source is, how the agency regulates light-emitting diodes and ultraviolet-C lamps, the agency's concerns as to each, and questions for the Committee.

On the regulatory history the paper states that in 1979 the agency developed performance standards for two types of non-coherent light source emitting ultraviolet radiation, sunlamp products and high-intensity mercury vapor lamps, and that "since that time, FDA has not developed any new Performance Standards for lamps."

Under the heading Safety Concerns the paper identifies, as to light-emitting diodes:

- the blue light hazard, stating that blue light is hazardous to the retina "especially due to reduced pupillary constriction compared to white light," that the peak of the hazard is at 440 nanometers, and that there is "high luminance or hot spots due to small source size";
- glare from increased scatter due to shorter wavelengths, and afterimages;
- circadian rhythm disruption, with fatigue, sub-optimal performance and "effects on long-term health";
- and "uncertainty regarding chronic effects of low doses on eye damage," giving age-related macular degeneration as the example, with the further statements that there are "no studies with appropriate animal models," that a 2012 study found subthreshold retinal damage at doses below published thresholds, and that military personnel after months in desert conditions have retinal lesions resembling solar retinitis.

The paper also sets out the risk group classification of the photobiological safety standard, describing the four groups as based on "potential acute hazard" and giving the exempt group as presenting no risk for up to 10,000 seconds. Part V.C.2 explains why that figure, and the word acute, matter to the whole of this comment.

The Foundation states carefully what this document is and is not. It is a staff presentation. It is not a finding by the agency, it is not a determination of harm, and the Foundation does not offer it as one. What it establishes is narrower and is not open to dispute.

- The subject of this comment was before the agency, and before the Committee the statute created, in October 2016.
- The particular characteristics this comment identifies at Part V — short-wavelength peak, high luminance arising from small source size, scatter and glare, circadian effect — are the characteristics the agency itself identified.
- The agency itself described the state of the evidence on chronic low-dose effects as uncertain and noted the absence of appropriate animal studies.
- And the agency itself stated that it had developed no new performance standard for any lamp since 1979.

6. Consequence: the standard-setting mechanism is not presently operable

Three things follow, and the Foundation states them in the order of how firmly the record supports them.

The first is a matter of the agency's own charter. That document provides that meetings shall be held approximately once every other year. That provision is not conditioned on a standard being under consideration. If the last proceeding was in October 2016, the interval since is not approximately two years.

That observation gains force from the way the charter is maintained. This charter is not a document settled once and left. It expires two years after filing unless renewed, and the Department renews it. The renewal published on January 24, 2023 extended it for two further years, and the Department has described the Committee in that notice as a non-discretionary Federal advisory committee established to provide advice and consultation to the Commissioner. The meeting provision is a term of the instrument that is renewed.

The Foundation therefore puts the point in the form the record supports. In successive charters the Department has undertaken that meetings of this Committee shall be held approximately once every other year. The undertaking has been renewed in the period during which no meeting was held. And the undertaking is not conditioned on anything: it does not refer to a standard, to a proposal, to a petition, or to the Commissioner considering anything. Whatever may be said about § 14.125(a), it cannot explain an interval of nine years in the performance of a provision to which § 14.125(a) is irrelevant.

The Foundation states two qualifications, because it would rather state them itself than have them supplied. The provision says approximately once every other year, and the word approximately plainly admits of some latitude; the Foundation's point does not depend on precision, because nine years is not an approximation of two. And a charter provision of this kind is an administrative undertaking rather than a legislative rule, so the Foundation does not characterize the interval as a violation of law and does not ask the Department to treat it as one. It asks something narrower and harder to answer. The Department has said, repeatedly and in a document it renews, that this Committee shall meet approximately every other year. The Foundation asks the Department to state why it has not, and to state that reason in terms that do not depend on § 14.125(a), since the undertaking does not.

The renewal that falls due in December 2026

One further matter is placed before the Department because of its timing, and the Foundation raises it as a question rather than as a charge. The operative charter expires on December 24, 2026. Part II.K.3. That is approximately two months after the closing date for comments in this proceeding, which means the Department will decide whether to renew this charter within weeks of reading this comment.

If the charter is renewed in the ordinary way, the Department will re-adopt, for a further two years, an instrument providing that meetings of this Committee shall be held approximately once every other year, that its quorum is ten members including three from the affected industries, and that it exists to advise the Commissioner on the technical feasibility, reasonableness and practicability of performance standards. It will do so in respect of a Committee that, on the Department's own roster, has three members, no Chair, nobody at all in the industry category, and no meeting since October 2016.

The Foundation does not suggest that the charter should not be renewed. It should. The Committee is a creature of statute and its existence is not discretionary. What the Foundation asks is that the renewal not be the only thing that happens: that the Department treat the occasion as the natural moment to fill the seats, appoint a Chair and set a meeting, and that it say in response to this comment whether it will. A renewal unaccompanied by appointments would commit the

Department on paper, for the sixth consecutive two-year period, to a meeting frequency it has not observed since 2016.

The second concerns capacity to act, and on this the Foundation is able to be definite where earlier drafts of this comment were not. Section 360kk(f) makes consultation with the Committee a precondition to prescribing any standard under that section. The quorum is fixed by regulation at ten members with at least three from each of the three categories, 21 C.F.R. § 14.125(c), and by the charter in the same terms. The Department's published roster lists three members, no Chair, and no industry representative. Subsection 4 sets out the arithmetic and the qualifications that do not disturb it. A quorum cannot be constituted from that membership.

The Foundation is careful about what that does and does not mean. It does not mean the Committee has been dissolved; it has not, and Part II.K.3 records the renewals. It does not mean the Committee has no members; the roster lists three and counts twelve vacancies rather than fifteen. It does not mean the condition is permanent; it is an appointments problem and the Department can remedy it without resolving anything else. And it rests on no inference about the statute, which contains no express quorum requirement, but on the regulation the agency wrote for itself and the roster the agency publishes.

Formal existence and functional capacity are different questions

The Foundation separates two propositions that are easily run together, because the distinction is the whole of its position and because the Department is entitled to know which one it is being asked to answer.

The first is whether the Committee exists. It does. It is a permanent statutory committee, its charter has been renewed, and the Department publishes both its roster and its purpose. The Foundation asserts nothing to the contrary and would be wrong to.

The second is whether the Committee can presently do the thing the statute requires of it before a standard is prescribed. It cannot, because a quorum cannot be constituted from three members where the regulation requires ten including three drawn from a category that is empty, and because the officer who completes the consultation is not in office.

A body may exist and be unable to act, and it is the second proposition that bears on this proceeding. The Foundation does not ask the Department to accept any characterization of the Committee's condition, and advances none. It asks the Department to apply its own regulation to its own roster. The relief sought follows from the second proposition alone and requires no view about the first: fill the seats, appoint a Chair, and convene the Committee. Part IX.H.

The third is the one the Foundation asks the Department to weigh most carefully, because it is about the structure of the reasoning rather than about any fact in dispute. The explanation given for the Committee's inactivity is that the agency is not considering new performance standards. But consultation with the Committee is what the statute requires before a standard may be prescribed. So the position is that no standard is contemplated, therefore the Committee need not function; and the Committee not functioning is among the reasons no standard can be prescribed. Each proposition rests on the other, and neither is examined.

There is a textual answer to that reasoning and it does not depend on anything the Foundation contends about LED products. Section 360kk(f)(1)(B) provides that the Committee may propose electronic product radiation safety standards to the Secretary for his consideration. The Committee is not solely a body that reviews what the agency brings to it. Congress gave it an independent power to put standards before the Secretary that the Secretary has not proposed. A committee holding that power cannot be stood down on the ground that the agency is not contemplating a standard, because identifying standards the agency has not contemplated is part of what Congress created it to do.

The same answer in the agency's own regulation, which is where it is clearest

The reasoning described above has been supported by reference to § 14.125(a), quoted at subsection 2. The Foundation accepts that provision entirely and relies on it. Its submission is that the provision does not bear the weight placed on it, for a reason that is structural rather than interpretive.

Section 14.125(a) imposes a duty on the Commissioner. It is a duty of submission: when he is considering a standard or an amendment, he must give the Committee the proposal and the relevant information before he publishes. The provision governs what the Commissioner must hand over, and when. It does not confer the Committee's functions, it does not state when the Committee shall meet, and it does not purport to condition the Committee's existence or activity on anything.

The Committee's functions are conferred by § 14.122(a), and there are three of them. Section 14.125(a) feeds only the second. Paragraph (a)(2) is the consultation on standards proposed for consideration, and it is that function, and that function alone, which waits on the Commissioner. Paragraph (a)(1) permits the Committee to propose standards to the Commissioner on its own motion. Paragraph (a)(3) permits it to make recommendations on any other matters it deems necessary or appropriate in fulfilling the purposes of the act.

Paragraph (a)(3) is the provision the Foundation asks the Department to weigh. Its subject is not standards. Its subject is any other matter within the purposes of the Act, and the purposes of the Act include the minimizing purpose set out at Part I.B.3 and Part II.B. And the clause that identifies which matters qualify is it deems necessary or appropriate, which places that judgment with the Committee and not with the Commissioner.

The consequence is that an explanation framed in terms of § 14.125(a) answers a different question from the one asked. Whether the Commissioner is presently considering a standard determines whether the duty of submission under § 14.125(a) has arisen. It does not determine whether the Committee may propose a standard under § 14.122(a)(1) or recommend on any other matter under § 14.122(a)(3), because neither of those functions is triggered by the Commissioner at all. A Committee that cannot convene cannot exercise either of them, and that disability does not wait on a standard coming under consideration. It is present now.

The Foundation makes one observation about the terms of § 14.125(a) and then leaves the point, because it does not need it. The provision does not define what it is to be considering promulgation of a standard, and it does not say how long before publication the submission must be made. Those are genuine indeterminacies and a reader may make of them what the reader will. The Foundation does not rest anything on them. Its argument is that § 14.125(a) is the wrong provision for the purpose, not that it is an unclear one.

Nor does the Foundation contend that reconstituting the Committee would be a sufficient response to this comment. It would not be, and the Foundation says so plainly because others have made the opposite case. In a petition to this Department of December 20, 2021, petitioners urging action on radiofrequency radiation objected that reconstituting a dormant advisory committee was a minor step and was not a rulemaking compliant with the Administrative Procedure Act. On that narrow proposition the Foundation agrees with them. Reconstituting the Committee is not a standard, it is not a rulemaking, and it would not by itself minimize anyone's exposure to anything. The Foundation asks for it on different grounds: not as the remedy, but because it is the precondition the statute imposes on the remedy, and because two of the Committee's three functions are presently incapable of being exercised at all.

7. Relationship to this request for information

The Foundation puts this narrowly, and declines the broader form of the argument that is available to it.

It does not contend that the Committee is required to review the comments submitted in response to this request for information. This is not a proceeding under § 360kk, no standard is before the Department, and the Committee's statutory function is addressed to standards. A comment that claimed otherwise would be wrong and would deserve to be corrected.

What the Foundation observes is this. The Department has issued a request for information seeking scientific and technical material on the health effects of electromagnetic radiation. Congress has provided the Department with a standing committee of fifteen people, each required to be technically qualified by training and experience in a field of science or engineering applicable to electronic product radiation safety, drawn in equal parts from government, industry and the public, meeting in public, with its proceedings recorded and available for inspection, and empowered to propose standards on its own initiative. That committee last met, so far as the Foundation can determine, in October 2016, at a meeting where the Center presented its concerns about light-emitting diodes.

The Foundation asks the Department to reconstitute the Committee and to convene it. Part IX.H. The request is independent of everything else in this comment. It requires no view about whether light emitted by LED products injures anyone, no determination that a standard is necessary, and no finding of any kind. It requires the Department to fill the seats and hold the meeting its own charter says shall be held approximately once every other year, at a stated cost of approximately one hundred and thirty thousand dollars a year including staff support. Until that is done, the mechanism Congress built for deciding questions of this kind is not available to the Department, whatever the Department may conclude about the questions.

L. Reporting of Accidental Radiation Occurrences — 21 CFR 1000.3(a), 1002.20

1. The definition and the reporting duty

The regulation defines the term broadly. 21 C.F.R. § 1000.3(a) provides:

> Accidental radiation occurrence means a single accidental event or series of accidental events that has/have resulted in injurious or potentially injurious exposure of any person to electronic product radiation as a result of the manufacturing, testing, or use of an electronic product.

Two features of that definition are favorable to the Foundation and one is not, and the Foundation sets out all three.

The exposure need only be "potentially injurious." Demonstrated injury is not required by the text.

The occurrence may arise from the "use" of an electronic product. It is not confined to malfunction, misuse or breakage.

But the events must be accidental, and that word is doing work. A headlamp or luminaire emitting exactly as it was designed to emit is not obviously the subject of an accident. The Foundation does not pretend the point is free from difficulty.

The reporting duty is at 21 C.F.R. § 1002.20, and the first thing to notice about it is who bears it. The section provides that "manufacturers of electronic products shall, where reasonable grounds for suspecting that such an incident has occurred, report to the Director." Incidents associated with a death or serious injury are to be reported immediately; others may be compiled and submitted quarterly.

2. What the Foundation has submitted, and what it is

The Foundation has transmitted to the Center for Devices and Radiological Health the LED Incident Reports and the compilation of reports concerning vehicle headlamps described at Part VII, most recently by the letter of December 1, 2025 described at Part II.J.1.c, which transmitted

them expressly for entry into the agency's record keeping systems. It has also submitted at least one individual radiation report, concerning light-emitting diode lamps on an emergency vehicle, which the agency numbered COR22000194 on October 14, 2022. Part VII.I.2. Receipt of the transmittals is documented at Part IV.B.

The Foundation states plainly what those submissions are not. Section 1002.20 imposes its duty on manufacturers. A report from a member of the public, or from an organization, is not a report under § 1002.20 and does not discharge any manufacturer's obligation. The Foundation has supplied the agency with information. It has not performed, and could not perform, the statutory reporting function.

3. The question that follows, which is for the Department

That allocation of the duty is what makes this subsection worth the Department's attention, and it produces a question the Foundation cannot answer and the Department can.

If exposures of the kind described in Part VII are accidental radiation occurrences, then the manufacturers of the products concerned were required by § 1002.20 to report them, upon reasonable grounds for suspecting that such an incident had occurred. The Foundation accordingly asks the Department to state how many reports under § 1002.20 it has received from any manufacturer concerning visible light emitted by light-emitting diode products, and in what years. The Foundation does not know the answer. If the answer is none, that is a fact about compliance with an existing regulation, and it is a fact the Department is in a position to establish without conducting any study at all.

If the answer is none, a second question follows. The Foundation has placed before the agency several hundred first-hand accounts of exposure to these products, and has done so in writing and with acknowledgment. Whether those accounts give a manufacturer reasonable grounds for suspecting that such an incident has occurred is a matter the Department can address, and § 360ll(e) supplies the mechanism for addressing it. Part II.J.1.

4. The structural point, which does not depend on the definition

Whatever view is taken of the word accidental, this is the only incident reporting provision in subchapter J, and it runs in one direction only. It obliges manufacturers to report what they have reasonable grounds to suspect. It establishes no channel through which an exposed person may report anything, and the Department has not created one; Part VII.J.1 describes the request made to a component of this Department on March 3, 2023 that such a channel be established, and the fact that it was not.

The consequence is the one Part I.C.7 identifies. A regulatory scheme in which the only reports come from manufacturers, about their own products, upon their own suspicion, and in which no route exists for the people exposed, will produce few reports whatever is happening to the people exposed. An absence of reports in such a scheme is not evidence about the products. It is a description of the scheme.

M. Summary: Which Duties Have Been Discharged and Which Have Not

This Part has examined each duty in turn. The accounting is set out here in one place, stated as findings about the record rather than as argument, so that the Department can see what the Foundation says is unperformed and test each item against its own files.

1. The duties of 21 U.S.C. § 360ii(a)

Paragraph (a)(1), performance standards. Discharged as to twelve product categories, by the standards collected at 21 C.F.R. parts 1020 through 1040. Not discharged as to visible light emitted by LED products, as to which the agency declined on the ground that a standard is not necessary. Part II.C.

Paragraph (a)(2), research and operational activity to minimize emissions and exposure. The Foundation has identified no research, development, training or operational activity directed to this radiation, and no baseline against which any minimization could be measured. Part II.D.

Paragraph (a)(3), liaison with and receipt of information from other agencies, States, standards bodies, industry and labor. Information has been received and acknowledged; no evaluation of it has been published. The Foundation has identified no liaison with any State agency, any professional or standards body as to incoherent optical radiation, or any labor association on this subject. Part II.E.

Paragraph (a)(4), study and evaluation of emissions and of conditions of exposure. A literature search and systematic review was commissioned and has not been published. No measurement of emissions and no characterization of exposure conditions has been identified. Part II.F.

Paragraph (a)(5), development, testing and evaluation of the effectiveness of techniques for minimizing exposure. The effectiveness of existing mitigations has been asserted; no evaluation establishing it has been identified, and the mitigations themselves have not been identified. Part II.G.

Paragraph (a)(6), consultation and liaison with the named officers and other appropriate departments. One documented instance exists in the whole program, concerning radiofrequency energy, in 2019. None has been identified for optical radiation with any agency, including the Secretary of Labor, who is named in the paragraph. Part II.H.

2. The related provisions

Section 360jj, studies and reports to Congress. Performed once, in 1969, for three classes of ionizing radiation source, and reported in 1970. Never performed for any product emitting visible light. A petition seeking performance has been pending since December 30, 2025. Part II.I.

Section 360kk(f), the Technical Electronic Product Radiation Safety Standards Committee. Chartered and continuing. Last met, so far as the Foundation can determine, in October 2016, at a meeting where the Center presented its concerns about light-emitting diodes. In January 2025 nominations were sought for ten of the fifteen seats. Part II.K.

Section 360ll, notification of defects. Available, and not conditioned on the existence of a performance standard. Invoked by the Foundation by notice of December 1, 2025. No determination under § 360ll(e) has been communicated or published. Part II.J.1.

Section 1002.20, reporting of accidental radiation occurrences. The only incident reporting provision in subchapter J. It runs from manufacturers only. The Foundation does not know whether any manufacturer has ever reported under it as to these products. Part II.L.

3. What the pattern shows

The Foundation draws one inference from that accounting and no more.

Of the six duties in § 360ii(a), exactly one operates through a mechanism that conditions action on a determination by the Secretary: paragraph (a)(1), which runs through § 360kk and its finding of necessity. That is the one duty the Final Response of May 24, 2024 addressed. The other five carry no such condition, and the letter does not discuss them.

The Foundation does not suggest that this was a stratagem. The more likely explanation is the ordinary one: the petitions asked for a performance standard, and the agency answered the question it was asked. But the consequence is the same either way. A disposition of the only conditional duty has been treated, in effect, as a disposition of the program, and the five unconditional duties have gone unaddressed by anyone.

That is what this comment asks the Department to correct, and the requests at Part IX are framed accordingly. They are not requests for a performance standard. They are requests that the duties which carry no condition be carried out: that the emissions and the conditions of exposure be measured and published, that the techniques for minimizing exposure be tested, that the agencies the statute names be consulted, that the Committee be reconstituted, and that the study Congress directed be conducted and reported. Whether a standard is necessary is a question that comes after those things, and on a record they would produce.

III. MINIMIZING EMISSIONS AND EXPOSURE

A. What This Part Does, and the Two Questions It Asks of Each Characteristic [RFI Q5, Q7, Q8]

Part II establishes that the Secretary is directed to "plan, conduct, coordinate, and support research, development, training, and operational activities to minimize the emissions of and the exposure of people to, unnecessary electronic product radiation," 21 U.S.C. § 360ii(a)(2), and to "develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation," § 360ii(a)(5). It establishes that neither paragraph has been performed as to the visible light emitted by light-emitting diode products. Part II.D and Part II.G set out each. What Part II does not do is say what performing them would consist of. This Part does.

A direction to minimize is empty until the dimensions in which minimization is to occur have been identified. Radiation is not a single quantity that can be turned down. An emission has a spectrum, a geometry and a time course, and a person receives it at a place, for a duration, from some number of sources at once, at an hour of the day, with eyes of a particular age. A program directed to minimize emissions and exposure has to say which of those it proposes to bound, and in what dimension each boundary runs. Sixteen characteristics are identified below. The Foundation does not represent the list as exhaustive, and identifies at subsection H the two it regards as most likely to require addition.

Of each characteristic this Part asks two questions and keeps them separate, because they have different answers and different evidentiary requirements.

The first is the boundary question. In what dimension, and of what shape, must a limit be drawn if emission or exposure in this characteristic is to be minimized? That question is about the form of a criterion and can often be answered now, from the physics and from the structure of the existing instruments, even where no number can be supplied.

The second is the necessity question. What makes emission in this dimension unnecessary? That question has an answer already settled in this comment, and it is not the answer the word carries in energy policy. Part II.D.2.a distinguishes the two senses. In energy policy the question is whether a component of the emission serves the purpose of the lamp, which is measured in lumens delivered for each watt consumed. In paragraph 360ii(a)(2) the question is whether it serves any purpose for the person exposed to it, in a subchapter whose stated purpose is to protect the public health and safety from electronic product radiation. Those two senses can point in opposite directions, and Part II.D.2.a describes a spectral region in which they appear to have done so. The second sense is the test applied throughout this Part.

One further feature of paragraph (a)(2) governs the whole of this Part and is easy to lose. Minimization is a direction of travel and not a ceiling. Part II.D.2 sets out the contrast with § 360kk, which authorizes standards to control emission and conditions their prescription on a determination of necessity; a ceiling is satisfied by remaining beneath it, and once a product is beneath it nothing further is required. Paragraph (a)(2) attaches no such condition and states no such threshold. The consequence for this Part is that a boundary responsive to paragraph (a)(2) need not be a maximum permitted value, and in several of the dimensions below it cannot be.

What this Part is not. It is not a proposed performance standard. The single standard the Foundation asks the Secretary to consider prescribing is at Part IX.I, it addresses one characteristic of the sixteen, and the reasons for asking for one rather than sixteen are stated there. This Part is not the scientific literature, which is Part V, and it does not restate it; each subsection below cites the subsection of Part V that carries the evidence. It is not the product landscape, which is Part VI. It is not the terminology and unit conventions, which are at the front matter, subsection G, where every quantity named below is defined with its unit and its counterpart in the vocabulary of this request for information. This Part is the statement of which characteristics a program discharging paragraphs (a)(2), (a)(4) and (a)(5) would have to reach, and of what the Foundation can and cannot presently say of each.

A statement about the state of the record, made once here rather than sixteen times below. For most of these characteristics the Foundation cannot state the number at which a boundary should be set. That is not a concession extracted from it; it is the premise of the request. The research paragraph (a)(2) directs and the evaluation paragraph (a)(4) directs are what produce such numbers, and neither has been conducted as to this radiation. Where a value can be stated, it is stated below with its source. Where it cannot, the subsection says so and identifies what would have to be done to obtain it. A table of sixteen characteristics with a number against each would make a stronger-looking submission and a less honest one, and the Department would be entitled to discount the whole of it on discovering the first invented figure.

B. The Three Families, the Shapes a Boundary Can Take, and Two Items That Are Not Characteristics of the Emission

a. The three families, and why the sixteen are grouped rather than listed

The front matter, subsection G, groups the quantities in which optical emission is specified into three families, and states that this comment uses that grouping throughout. Spectral characteristics describe what wavelengths are emitted and in what proportion. Spatial characteristics describe the geometry of the emission: the radiance of the emitting surface, its apparent size and the angle it subtends at the eye, the directionality of the beam, the uniformity of output across the surface, and the number, separation and arrangement of emitters within the field of view. Temporal characteristics describe how the output varies in time: modulation depth and waveform, drive and flash frequency, duty cycle, rise and fall times, the duration of a single exposure, and exposure accumulated across repetitions.

That grouping is load-bearing elsewhere. Part V organizes the literature by it. Part VI describes each product class by it. Part IX.G proposes it as the structure of the classification system Question 5 of this request for information asks about. The sixteen characteristics are therefore presented below within the three families rather than as a flat list, so that this Part and those three can be read against one another without translation.

The grouping also carries a substantive point that a flat list would obscure, and the front matter states it: a criterion that limits one family while leaving the others unconstrained does not protect against the effects described in Part VII. A limit on luminous output that permits any spectrum and any flash rate, or a limit on spectrum that permits any radiance, leaves the mechanism of injury untouched. Several of the characteristics below are individually unbounded in federal law while a neighboring characteristic of the same product is bounded precisely, and Part VI.U records which.

b. The shapes a boundary can take, of which a maximum is only one

An objection available against this Part is that the Foundation asks for numbers it cannot supply. In several of these dimensions the objection misdescribes what is being asked for, and the Foundation sets out the available shapes so that the request in each subsection can be read against the right one. Four recur.

A ceiling: a maximum permitted value of a quantity, which is the shape most federal optical criteria take where they exist at all. Part VI.U collects them.

A floor: a minimum permitted value, which is the shape required where the characteristic complained of is that a quantity is too small or too fast rather than too large. The transition time of a flashing lamp is the clearest instance, and subsection E.2 sets it out: the defect is that the transition is abrupt, so the boundary needed is a minimum duration. The angular size of the emitting surface is another, where the defect is concentration of a given output into a smaller source.

A required relationship between two quantities: a criterion that cannot be stated as a single number because the acceptable value of one quantity depends on another. Permitted luminance as a function of the angle from which the luminaire is seen, or as a function of the adaptation level of the surrounding field, is of this kind. So is permitted output as a function of the hour. A boundary of this shape is not less rigorous than a ceiling and is harder to evade, because it cannot be satisfied by relocating the emission into an unregulated variable.

A required measurement and disclosure: where no value can presently be set, the characteristic can still be required to be measured by a specified method and reported. That is not a limit and the Foundation does not present it as one. It is the step that makes the later setting of a limit possible, and in several dimensions below it is the most the present record supports. Part V.J.4 describes what is lost when a characteristic is reported only photometrically, and Part IX.C asks the Department to express its own measurements radiometrically.

c. Two of the sixteen are not characteristics of the emission, and the Foundation says so rather than absorbing them

Fourteen of the sixteen items are properties of the radiation or of the conditions under which it is received. Two are not, and placing them in a family would misdescribe them.

Special populations is a property of the person exposed rather than of the radiation. It does not take a boundary of its own. It determines, for every other boundary in this Part, the population against which that boundary must be set, and the question it raises is whose response a criterion is calibrated to. It is treated at subsection F for that reason, and Part V.C.5 and Part V.E supply the evidence that the relevant responses differ by age and by condition.

Luminaire shielding, diffusion, and a user control by which a person can extinguish a device's own indicator light are techniques for minimizing exposure rather than characteristics to be bounded. Techniques for minimizing exposure are the subject of paragraph 360ii(a)(5), which directs the Secretary to develop, test and evaluate their effectiveness, and evaluating the effectiveness of a technique is a different exercise from setting a limit on a quantity. Part II.G.3 records that the techniques exist and that what is absent is the federal evaluation of them. It is treated at subsection G.

The Foundation makes the distinction expressly because the two paragraphs of the statute are differently worded and a comment that ran them together would invite the answer that it had not read either with care. Both items belong in this Part. Neither belongs in a family.

C. Spectral Characteristics

One characteristic of the sixteen falls in this family. It is also the one on which the most federal activity has already occurred, in a program directed to a different end, and the one where the two senses of unnecessary described at Part II.D.2.a diverge most sharply.

1. Spectral distribution

The quantity, and the quantity it is not

The characteristic is spectral power distribution: radiant power as a function of wavelength across the emitted band, reported as spectral irradiance in watts per square meter per nanometer where

the measurement is taken at the exposed surface. The front matter, subsection G, defines it and gives its counterpart in the vocabulary of this request for information, which is emission spectrum together with operating frequency and bandwidth.

The quantity is not correlated color temperature. A single number describing the appearance of a source by reference to a blackbody radiator does not describe its spectral content, and two sources of identical correlated color temperature may differ substantially in short-wavelength output. Part V.B.3 sets out the limits of the descriptor and the quantities that do describe spectral content. The Foundation states this against its own customary vocabulary and against much public advocacy on this subject, including some of its own earlier advocacy, because a boundary written in correlated color temperature would be satisfiable without changing the emission that matters. Part II.H.14 records a federal facilities criterion presently written in that descriptor.

Why a boundary is needed in this dimension

Phosphor-converted white light-emitting diodes produce white light by exciting a phosphor with a short-wavelength emitter, and the resulting distribution carries a pronounced peak in the blue region together with a trough at the wavelengths the phosphor converts least efficiently. Part V.B.1 sets out the distribution and the respects in which it departs from the thermal and discharge sources the photometric conventions grew up around. Part V.B.5 sets out the sources under which human visual and circadian physiology developed.

Two of the four weighting functions that matter to this comment are greatest in the region where that peak sits. The blue-light hazard function, which describes the wavelength dependence of photochemical injury to the retina, and the melanopic action spectrum, which peaks at approximately 480 nanometers, both assign their highest weights there. The photopic luminous efficiency function does not; it is normalized to unity at 555 nanometers and falls steeply toward the short-wavelength end. The front matter, subsection G, sets out the consequence, which is that a photometric specification discounts by arithmetic the part of the spectrum this comment is concerned with. Part V.C.2 sets out the hazard assessment framework and where it stops. Part V.F sets out the circadian and neuroendocrine evidence.

The necessity test applied to this characteristic, and the answer the Foundation gives

Applying the test at Part II.D.2.a: does the short-wavelength content of this emission serve a purpose for the person exposed to it? The honest answer is that it does, in part and in some circumstances. Short wavelengths contribute to luminous output, they contribute disproportionately to the alerting and phase-setting response during the day, and a source with the short-wavelength component removed is not white. This is therefore not a dimension in which the Foundation contends the emission is unnecessary at every level. It is a dimension in which a part of the emission is unnecessary, and the part is identified by the purpose it serves for the person rather than by the lumens it contributes to the lamp.

Two components answer that description on the present record. The first is short-wavelength output in excess of what the visual task requires, which is a quantity that depends on the task and the adaptation level and not on the lamp. The second is short-wavelength output at hours when the alerting and phase-setting response is not wanted, which is a function of the clock rather than of the emission, and which subsection E.4 treats as a characteristic in its own right. Neither is a maximum permitted value. Both are boundaries of the relationship shape described at subsection B.

A consequence the Foundation reports against its own position

A spectral boundary expressed solely as a cap on short-wavelength content would be incomplete, and may be wrong in one respect. Part V.B.6 sets out published work, several studies by Jeffery and colleagues and one of them funded by the Department of Energy, reporting a physiological function in human subjects for the long-wavelength component that the federal efficacy standards described at Part IV.G removed from American general illumination. If that work is sound, the dimension

requires a floor on long-wavelength content as well as a boundary on short-wavelength content, and the one federal program that has addressed the spectral composition of American lighting removed the part that may have been necessary and retained the part that may be unnecessary in the sense this subchapter uses. The Foundation does not assert that this is settled. Part V.A.3 places it among the open questions. It states the consequence here because a request for a cap alone, if that work is sound, would ask the Department for half of a criterion.

What can be specified now, and what cannot

The Foundation cannot state the numerical limit. What it can state is that limits of this kind are writable, because they have been written. Part V.B.3.e sets out a regional instrument that regulates a named spectral index and states its limits as plain numbers by zone. And the precedent for a radiometric lighting criterion exists inside this subchapter: 21 C.F.R. § 1040.30, within part 1040, titled Performance Standards for Light-Emitting Products, prescribes a standard for high-intensity mercury vapor discharge lamps that is not written in photometric terms at all, and addresses shortwave ultraviolet emission instead. The Department has already written a lighting standard around a radiometric quantity that luminous output does not describe.

What the Foundation asks in this dimension is accordingly the measurement-and-disclosure boundary first and the relationship boundary when the research supports it: that spectral power distribution be measured by a specified method and reported with the spectral data from which any weighted quantity is derived, which is the request at Part IX.C, and that no criterion intended to control a response other than daytime visual response be written in a quantity weighted for daytime visual response.

D. Spatial Characteristics

Nine of the sixteen characteristics fall in this family. Five of the nine are the quantities in which optical emission is conventionally specified and regulated, and the Foundation treats them separately because they are separately named in the request for information and because the relationship among them is the single most important structural fact in this Part. It is set out first, before the individual subsections, because each of them depends on it.

The five quantities are not independent, and a boundary on one does not constrain the others

The front matter, subsection G, defines each quantity with its unit. Taken together they divide along two axes. Radiance and luminance are referred to the emitting surface: power, or photometrically weighted power, per unit area of source per unit solid angle. Irradiance and illuminance are referred to the exposed surface: power, or weighted power, arriving per unit area. Luminous intensity is referred to direction: weighted power emitted per unit solid angle, without reference to the area it came from or the area it lands on. And within each pair the distinction is the photopic weighting: luminance is radiance weighted by the photopic luminous efficiency function, and illuminance is irradiance weighted by the same function.

The consequence is arithmetic and it is the reason this comment exists. Luminous intensity is luminance multiplied by the apparent area of the emitting surface. A limit expressed in candela is therefore satisfied by any combination of luminance and emitting area whose product falls beneath it. Hold the candela figure constant and reduce the area, and luminance rises without limit, because nothing in the criterion mentions area. The emission a person actually receives at the retina is governed by the luminance of the source and the angle it subtends, not by the total output per solid angle, and Part V.B.2 sets out the optics and the point at which the governing regime changes.

That is not a hypothetical evasion. It is what happened. Federal Motor Vehicle Safety Standard No. 108 specifies lamp output in candela, as roadway lighting practice is expressed in lux and in candela per square meter. Those conventions were written when the available sources were incandescent filaments and gas discharges, whose emitting surfaces were large and diffuse, and for such sources a

candela limit implied a bounded luminance because the area could not be reduced much. The light-emitting diode removed that implication. It emits from a small, flat, highly directional surface, so for a given luminous output the source is smaller and the emission more concentrated, and the radiance at the source and the irradiance at the retina can be far higher at equal measured lumens. The front matter, subsection G, states this as a limitation of photometric specification. Stated as a regulatory fact it is sharper: a technology change moved the emission into a variable that the existing criteria do not mention, and the criteria were not revised.

The Foundation draws one conclusion and declines a second. The conclusion is that a boundary in this family must reach luminance or radiance, and that a criterion expressed only in luminous intensity or only in illuminance cannot do the work, whatever number is chosen. The conclusion it declines to draw is that the existing criteria were evaded deliberately. Nothing in the record before the Foundation supports that and it is unnecessary to the argument. A criterion written for one source geometry does not constrain a different one, and that is true whether or not anyone intended it.

Where federal law speaks to these quantities at all, it overwhelmingly speaks in minima

The Foundation examined the federal instruments that state numerical values for the optical output of the product classes at Part VI. The pattern is consistent and, so far as the Foundation is aware, has not previously been collected. Part VI.U tabulates it by class.

Locomotive lighting is specified at 49 C.F.R. § 229.125. A headlight must produce a figure of at least 200,000 candela and illuminate a person at 800 feet; auxiliary lights must each produce at least 200,000 candela, or meet stated minima off axis. The section states no maximum for any of these quantities. Part VI.Q sets out the provision and the rulemaking in which a maximum was raised and not adopted.

Marine navigation lights are specified at 33 C.F.R. § 84.14, which gives a formula for minimum luminous intensity as a function of required visibility range and a table of the resulting values: 0.9 candela for one nautical mile, rising to 94 candela for six. These are minima. The international instrument from which the domestic rule derives contains, in a note to its annex, the statement that the maximum luminous intensity of navigation lights should be limited to avoid undue glare. That statement names no number, is hortatory in form, and was not carried into § 84.14. Part VI.Q sets out the comparison and the four qualifications the Foundation attaches to it.

Lighting on bicycles, scooters and personal mobility devices is the extreme case. The federal regulation for bicycles, 16 C.F.R. § 1512.16, requires reflective devices and does not require a lamp at all. No photometric limit of any kind appears in the part. Part VI.N sets out the position.

The Foundation states the counter-example because it is the strongest evidence available that a boundary of this kind is writable, and it comes from a federal agency rather than from this commenter. Aviation obstruction lighting is specified in Federal Aviation Administration Advisory Circular 150/5345-43J, which states intensities as nominal values with tolerance bands rather than as floors: the L-864 red flashing beacon at a peak of 2,000 candela with a tolerance of twenty-five percent and a minimum of 750, and the L-865 and L-866 white beacons at 20,000 candela by day, 20,000 at twilight and 2,000 at night. More to the present point, the same document limits stray light to a maximum of three percent of peak intensity, which is a boundary on spatial distribution and not merely on magnitude. Part VI.O sets out the specifications and the respects in which an advisory circular differs from a regulation, which the Foundation does not elide.

Two observations follow, and the Foundation separates them because the first is a fact and the second is an inference. The fact is that the federal numbers governing the optical output of these product classes are, with the aviation exception, minima: they establish that a lamp is bright enough and are silent as to whether it is too bright. The inference is that this is what one would expect of instruments written to secure conspicuity and visibility, by agencies whose statutory missions are

transportation safety, at a time when the available sources made excess difficult to achieve. The agency with the radiation-health authority, whose criterion would have run the other way, has prescribed nothing. Part II.C.3 records the absence and Part IV sets out what the agency was told.

1. Spatial distribution of the emission

The quantity

The characteristic is the distribution of emitted power across direction and across the emitting surface: the directionality of the beam, the uniformity of output across the aperture, the angle the source subtends at the eye of a person at a stated position, and the proportion of output emitted into directions the application does not require. Part V.B.8 sets out the characteristic and Part V.B.2 the optics of non-uniform emission from a small aperture.

Why a boundary is needed in this dimension

Spatial distribution is the dimension in which the greatest part of the emission from these products is, on the Foundation's reading of the statute, unnecessary in the fullest sense available: emitted into directions where it performs no function for anyone and reaches people who are not the intended beneficiaries of the installation. Light emitted above the horizontal from a roadway luminaire illuminates no roadway. Light emitted into a bedroom window from a parking area illuminates no parking area. Part II.D.3 establishes that radiation of this kind is unnecessary electronic product radiation within paragraph (a)(2), that it does not leave, and that it reaches people. Part VI.P treats light trespass as a product class characteristic.

The second reason is that spatial distribution determines what the other eight characteristics in this family amount to in practice. The same luminous intensity delivered as a wide diffuse field and as a narrow collimated beam produce different retinal irradiance, different disability glare and different discomfort, and Part V.C.3 and Part V.C.4 set out the two glare mechanisms and their measurement.

The necessity test applied

Applying the test at Part II.D.2.a: does emission in this direction serve a purpose for the person who receives it? In this dimension the test is unusually tractable, because the answer can often be determined from the geometry of the installation without any physiological evidence at all. Output directed away from the surface or task the installation exists to serve is, by the terms of the installation, serving no purpose for anyone; whether it also injures the person it reaches is the separate question that paragraph (a)(2) does not ask. This is the clearest instance in the Part of radiation that is unnecessary without any demonstration of hazard.

The shape of the boundary, and what can be specified now

The boundary in this dimension is not a magnitude at all. It is a distribution: the proportion of emitted output permitted above a stated angle, or outside a stated solid angle referred to the installation geometry. Criteria of exactly this form exist in lighting practice and in state and local instruments, and the aviation stray light provision described above is a federal instance. The Foundation does not supply the numerical proportion. It identifies the form, states that the form is in use, and asks that the characteristic be measured and reported, which is the disclosure boundary described at subsection B.

The Foundation notes one limit of its own position. A distribution criterion constrains where output goes and not how concentrated it is at the source, so it does not reach the luminance problem described in the family introduction. The two boundaries are complements rather than alternatives, and a program that adopted either alone would leave the other mechanism untouched.

2. Radiance

The quantity

Radiance is radiant power per unit area of source per unit solid angle, in watts per square meter per steradian. The front matter, subsection G, defines it and records that it is the physical basis of what is perceived as brightness, and that it has no single counterpart in the vocabulary of this request for information; the nearest equivalent is power density referred to the emitting aperture rather than to the exposed surface.

Why this is the quantity the Foundation would bound first

Radiance is conserved along a ray through a lossless optical system. The consequence for exposure is that the radiance of the image formed on the retina is determined by the radiance of the source, and is not reduced by moving away from it. Distance reduces the angle the source subtends, and therefore the retinal area over which the energy is deposited, but it does not reduce the irradiance at that area. Part V.B.2 sets out the optics. Part VI.J.3 applies it to a product class and states the consequence that distance does not resolve the problem.

That is why a boundary on radiance does work that no boundary on a surface-referred quantity can do. Illuminance and irradiance at a receiving plane fall with the square of distance, so a criterion written in those quantities is satisfied by separation. Radiance is not, and a criterion written in radiance therefore constrains the source itself.

The necessity test applied, and the one weighted form that matters most

Applying the test: does radiance in excess of some value serve a purpose for the person exposed? Beyond the level required to make the source and the task visible at the adaptation level obtaining, the Foundation is aware of no purpose it serves for that person, and Part V.C.3 and Part V.C.4 set out two mechanisms by which it works against the purpose of the installation: disability glare, which reduces what the person can see, and discomfort glare, which does not.

The weighted form of this quantity is the one in which the hazard literature is written. Blue-light hazard weighted radiance, in the same unit, weights radiance by the function describing the wavelength dependence of photochemical retinal injury, and the front matter, subsection G, records that it stands to radiance as specific absorption rate stands to incident power density in the radiofrequency case. Part V.C.2 sets out the assessment framework built on it and the point at which that framework stops, which is an exposure duration of ten thousand seconds. A boundary on weighted radiance is the one criterion in this Part for which an internationally used quantity, a measurement method and a weighting function all already exist.

What can be specified now, and what cannot

The Foundation cannot state the value. It states three things that bear on the Department's ability to arrive at one. The quantity is measurable with instruments presently available, which Part V.J.1 describes. The weighted form is already the subject of a consensus assessment framework and of a federal classification practice for other emitting products. And the existing framework was built for occupational and short-duration exposure, so the question the Department would have to answer is not how to measure the quantity but what value is appropriate for involuntary, repeated, lifelong exposure of a general population including the groups at subsection F. That question is the research paragraph (a)(2) directs.

3. Luminance

The quantity, and its relation to the one before it

Luminance is radiance weighted by the photopic luminous efficiency function, in candela per square meter. The front matter, subsection G, records that it is a biologically weighted exposure quantity standing to radiance as specific absorption rate stands to incident power density. It is the quantity in

which brightness is conventionally specified and procured, and the quantity in which most of the literature at Part V and most of the Foundation's own advocacy is expressed.

Why the Foundation treats it separately, and the concession it makes in doing so

The Foundation treats luminance as a characteristic requiring a boundary notwithstanding that it has just explained why the photopic weighting is the wrong instrument for several of the effects at issue. The reason is practical and it is stated rather than concealed. Luminance is the quantity in which existing criteria are written, in which products are specified and purchased, in which public entities conducting the self-evaluation described at Part VIII.C would have to work, and in which the only federal facilities criterion the Foundation has located expresses a limit at all. A boundary in luminance is therefore immediately usable in a way that a boundary in weighted radiance is not, and the Foundation would rather have a usable criterion in an imperfect quantity than an exact criterion that no procurement officer can apply.

The concession that accompanies that position is set out at the front matter, subsection G, and the Foundation repeats it here so that this subsection is not read as abandoning it: two sources of identical measured luminance may differ substantially in short-wavelength radiance, and a luminance criterion cannot distinguish them. A luminance boundary is a necessary component of a criterion in this family and not a sufficient one.

The one federal numerical luminance limit the Foundation has located, and what it governs

Unified Facilities Criteria 3-530-01, which governs interior and exterior lighting design for Department of Defense facilities, states a luminance limit for luminaires in the zone from 45 to 90 degrees from nadir, expressed in candela per square foot, together with a limit on the Unified Glare Rating. Part II.H.14 sets out the document, the criterion, and the respects in which a facilities design criterion differs from a performance standard binding a manufacturer. The Foundation draws attention to its form rather than its value: it is an angle-dependent luminance limit, which is the relationship shape described at subsection B, and it was written by a federal department for its own buildings. The Department of Health and Human Services has written no such criterion for anyone.

What can be specified now, and what cannot

The Foundation cannot state the general value, and states one reason it cannot that is specific to this quantity. The luminance at which a source becomes uncomfortable or disabling is not a constant; it depends on the adaptation state of the observer, which depends on the luminance of the surrounding field. The same luminaire that is unremarkable at midday is disabling on an unlit road at night. A single number cannot express that, which is why the boundary in this dimension takes the relationship shape, and why subsection E.4 treats the hour of use as a characteristic in its own right. Part V.C.3 sets out the mechanism through which adaptation operates.

4. Luminous intensity

The quantity

Luminous intensity is luminous power emitted per unit solid angle in a given direction, in candela. The front matter, subsection G, gives its counterpart in the vocabulary of this request for information as effective isotropic radiated power together with antenna gain and beamforming, both describing concentration of emission into a direction rather than total output.

Why it is nonetheless the quantity most federal instruments use

This is the quantity in which the federal instruments collected at Part VI.U are predominantly written. Federal Motor Vehicle Safety Standard No. 108 specifies lamp output in candela. The locomotive provision at 49 C.F.R. § 229.125 is written in candela. The marine table at 33 C.F.R. § 84.14 is written in candela. The aviation obstruction lighting intensities are written in candela. If a

single quantity can be said to be the regulatory currency of optical emission in the United States, it is this one.

The Foundation accordingly does not ask the Department to abandon it, and repeats that it does not ask for existing standards to be re-specified; the front matter, subsection G, states that position. What it asks is that the limitation of the quantity be recognized where a criterion is intended to control something other than total directional output, because the arithmetic set out in the family introduction means that a candela limit alone leaves luminance unconstrained.

The necessity test applied, and the direction in which the existing numbers run

Applying the test: the honest answer in this dimension is that luminous intensity sufficient for the application serves a purpose for the person exposed, because conspicuity is itself a safety function, and the Foundation has never contended otherwise. Part VI.C treats the class in which that function is strongest. What the Foundation contends is that intensity in excess of the amount the application requires serves no such purpose, and that the federal instruments establish the floor of that range and not the ceiling. A locomotive auxiliary light producing at least 200,000 candela complies with the regulation at 200,000 and complies equally at any larger figure.

The Foundation adds a qualification against itself. It has not established, for any product class, the intensity at which the application's own requirement is satisfied, and so cannot say by how much any particular installation exceeds it. Establishing that for a class is an exercise in the evaluation of techniques and conditions that paragraphs (a)(4) and (a)(5) direct, and Part IX.C asks for it.

What can be specified now

In this dimension, more than in any other in this family, the boundary the Foundation asks for is the pairing rather than the number: that wherever a criterion states a minimum luminous intensity for a safety function, the instrument also state a maximum, and that the two be set by reference to the same application requirement. The Foundation is aware of one federal instrument in which an upper bound of this kind is expressed, at Advisory Circular 150/5345-43J, and of one hortatory international statement to the same effect in the marine annex described above. Both are described at Part VI.O and Part VI.Q. Neither was written by this Department.

5. Illuminance

The quantity

Illuminance is irradiance weighted by the photopic luminous efficiency function, in lux: light arriving at a surface as the daytime visual system responds to it. The front matter, subsection G, gives its counterpart in the vocabulary of this request for information as power density adjusted for biological response.

Why a boundary is needed, and the respect in which this quantity is the weakest in the family

Illuminance is the quantity in which lighting is specified for the surfaces it is meant to serve, and in which nearly every minimum lighting requirement in American practice is written: roadway lighting levels, workplace lighting levels, and the illuminance provisions of the accessibility framework. Part VIII.D.4 sets out the one place in which that framework states an optical number.

The Foundation states plainly that this is the weakest of the five quantities for its purposes, and says why rather than leaving the Department to notice it. Illuminance is referred to the receiving surface, so it falls with the square of distance from the source, and a criterion written in it is satisfied by separation without any change to the emitting product. It also discards, by the arithmetic the front matter sets out, the spectral information that the photochemical and circadian questions require. A person standing beneath a luminaire receives an illuminance at the pavement that is unrelated to the luminance of the aperture they are looking at, and it is the latter that produces the glare described at Part V.C.3 and Part V.C.4.

The one dimension in which it is the right quantity

There is a dimension in which illuminance is the correct quantity and the Foundation identifies it: light trespass, where the question is precisely how much light is arriving at a surface that nobody intended to illuminate. Vertical illuminance measured at a property boundary is a direct measure of that, it is the quantity in which such criteria are in fact written, and the criteria are maxima rather than minima. Part VI.P treats the class. The Foundation records that the instruments expressing those maxima are municipal and state rather than federal, which is the condition Part VIII.E.2 and Part VIII.E.3 describe as producing inconsistent determinations and duplicated cost across thousands of public entities.

What can be specified now

The Foundation asks for no new federal illuminance maximum of general application and does not contend the record supports one. It asks that where this Department or any other states a minimum illuminance for a task, the instrument state the condition it assumes about the luminance of the sources used to achieve it, because the same illuminance at a surface can be produced by a diffuse installation and by a small number of intense apertures, and the two are not equivalent for the person in the space. That is the condition-stating request made at Part IX.I in the temporal dimension, applied here.

6. Irradiance

The quantity, and the fact about it that is most consequential for this proceeding [RFI Q5]

Irradiance is radiant power arriving per unit area at a surface, in watts per square meter. The front matter, subsection G, states its counterpart in the vocabulary of this request for information, and the statement is not an analogy: irradiance and power density are the same quantity, in the same unit, differing only in the part of the spectrum measured.

The Foundation regards that identity as the single most important structural fact it can place before this Department in this proceeding, and sets out the reason at the length it deserves. This request for information is addressed principally to radiofrequency and electromagnetic field exposure. Radiofrequency exposure limits in the United States are expressed in power density, in watts per square meter or milliwatts per square centimeter. Optical exposure can be expressed in the identical quantity and unit. The two subject matters are therefore not analogous, not comparable, and not parallel. They are continuous. A program that measured radiofrequency exposure in watts per square meter and declined to measure optical exposure at all is not drawing a line between two different kinds of thing; it is measuring one part of a single quantity and not the other, within a statutory definition at § 360hh(1)(A) that Part II.B establishes reaches both.

Part V.J.5 develops the consequence for the presentation of evidence, and Part IX.C asks the Department to express its own studies in radiometric terms, which would render them directly comparable with the radiofrequency exposure literature this request is principally addressed to.

Why a boundary is needed in this dimension

Irradiance at the cornea, and the retinal irradiance that follows from it once the eye's optics are accounted for, is the quantity in which photochemical and thermal injury thresholds are expressed. Part V.C.1 sets out the injury and how it is recognized, and Part V.C.2 the assessment framework. It is also the quantity in which the Department has already written performance standards for other electronic products emitting optical radiation, which Part II.C.2 collects.

The necessity test applied

Applying the test: irradiance in excess of what the visual task requires at the adaptation level obtaining serves no purpose for the person exposed, and the Foundation is aware of no contention to the contrary. The difficulty in this dimension is not the test but the measurement position.

Irradiance is referred to a surface, so the value depends entirely on where the surface is placed, and a criterion is uninterpretable without a stated measurement geometry. Part V.J.2 sets out the difference between laboratory measurement and real-world exposure conditions.

What can be specified now, and what cannot

The Foundation cannot state the value. It states that the quantity is the one in which the Department's existing optical performance standards are written, that it is the same quantity in which the radiofrequency limits this request for information concerns are written, and that the measurement geometry is the question that would have to be settled first. It asks for the measurement and disclosure boundary described at subsection B: that optical emission be reported in this quantity, at a stated geometry, with the spectral distribution from which any weighted figure is derived.

7. Glare rating

Two mechanisms, which require separate treatment and are routinely run together

Glare is not one phenomenon and the distinction matters to what a boundary can be written against. Disability glare is a reduction in visual performance produced by light scattered within the eye, which lays a veiling luminance over the retinal image and reduces contrast. It is measurable, it has an established physical model, and it does not depend on what the observer reports. Part V.C.3 sets out the mechanism, veiling luminance, and intraocular straylight. Discomfort glare is the sensation of aversion, pain or unwillingness to look, and it can occur at levels that produce no measurable loss of visual performance at all. Part V.C.4 sets it out and Part V.C.4 also sets out its measurement.

The Foundation emphasizes that the second is not a lesser form of the first. A criterion that bounded only disability glare would permit sources that are painful to look at provided they do not measurably degrade acuity, and the reports at Part VII describe aversion, pain and flight far more often than they describe loss of acuity.

The metric in federal use, and the objection to it that the Foundation must state

The metric for discomfort glare in general use is the Unified Glare Rating, and it is in federal use: Unified Facilities Criteria 3-530-01 states a limit on it for Department of Defense facilities, as Part II.H.14 records. The existence of that limit is useful to the Foundation's argument, because it shows a federal department bounding discomfort glare by number in its own buildings.

The objection, which the Foundation states because the comment is stronger for meeting it, is that the metric's own validity conditions may exclude the sources at issue. Part V.C.4 sets out the validity domain and the respects in which it fails for this technology, which concern small, high-luminance, non-uniform apertures of the kind described at Part V.B.2. A rating formula derived from and validated against large diffuse luminaires is being applied to sources that are neither. The Foundation does not contend the metric is useless. It contends that a federal criterion that adopted it without addressing its validity domain for these sources would be adopting a number whose applicability has not been established, and that establishing it is work paragraph (a)(4) directs.

The necessity test applied

Applying the test to this characteristic produces the clearest answer in the Part. Glare, in both senses, is by definition emission that works against the purpose of the installation: disability glare reduces what the person can see, which is the opposite of what lighting is for, and discomfort glare imposes a cost on the person while delivering them no benefit. There is no construction on which glare serves a purpose for the person who receives it. It is unnecessary electronic product radiation in the fullest sense the term carries at Part II.D.2.

What can be specified now, and what cannot

The Foundation cannot state a numerical rating limit of general application, and identifies the two steps that would have to precede one: establishing the validity of an existing discomfort metric for small high-luminance sources, or developing one that is valid for them; and determining the value appropriate to a general population including the groups at subsection F, rather than to the healthy adult observers from whom the existing formulas were derived. Part V.C.5 sets out the ocular modifiers that make the second step necessary.

8. Number of emitters present during a single exposure [RFI Q15]

The characteristic, and why the Foundation places it first in importance

The characteristic is how many separate sources are present in the field of view at one time, their angular separation, whether their outputs are synchronized, and the composite waveform and summed irradiance they produce at the eye. The front matter, subsection G, defines it and records that Question 15 of this request for information asks for evidence on exactly these characteristics in the wireless context: antenna density, cumulative neighborhood exposure, and simultaneous exposure to multiple sources.

Part IX.I.3.b states this as the matter the Foundation puts first in importance among those a performance standard would have to settle, and this subsection states why it is a characteristic requiring a boundary and not merely a measurement problem. Every other characteristic in this Part is a property of one product. This one is a property of the environment a person stands in, and no amount of care about individual products reaches it.

The statutory hook, which is in the text of the paragraph itself

The Foundation rests this characteristic on a feature of paragraph (a)(2) that is easy to read past. The paragraph directs activities to minimize "the emissions of and the exposure of people to" unnecessary electronic product radiation. It names two objects, not one. Emissions are a property of products. Exposure is a property of people. A paragraph that named only emissions could be answered product by product; a paragraph that names exposure separately cannot, because the exposure of a person standing in a street is the sum of what reaches them from every source in it.

That distinction also marks the limit of what a performance standard can do, and the Foundation states the limit rather than overclaiming. A standard prescribed under 21 U.S.C. § 360kk bounds what a product emits. It does not bound how many compliant products a person encounters at once. Paragraph (a)(2) is not so confined, which is why the request the Foundation makes in this dimension is addressed to the research, evaluation and liaison paragraphs rather than to the standard-setting one. Part IX.I.3.e sets out the three things it asks and the limit of what it can ask.

Why the existing literature cannot answer it

Part V.J.3 establishes the position: the experimental literature on optical exposure is, with very few exceptions, built on single-emitter designs, in which one source is presented to one observer under controlled conditions. That design is appropriate to the questions it was built for and it cannot answer this one. The scientific committee of the European Commission has identified the same gap, and Part V.J.3 records what it said.

A consequence the Foundation reports against its own proposals

The Foundation recommends a radiance boundary at subsection D.2 and in several places in this comment. It records here that a radiance boundary does not aggregate in any simple way across sources, because what matters at the retina when many small sources are present is the summed irradiance and the geometry of their arrangement rather than the radiance of any one of them. Part IX.I.3.d states the same consequence against the same proposal. A criterion that bounded every individual product correctly could still permit an environment that no one would defend, and the Foundation does not know how to write a product standard that prevents that.

What can be specified now

Nothing numerical. What can be specified is the condition and the research: that any criterion stated for an individual product state on its face the assumption it makes about the number of such products in the field of view, so that the assumption is visible rather than implicit; and that the research directed by paragraph (a)(2) and the evaluation directed by paragraph (a)(4) include the aggregate case rather than the single-source case alone. Part IX.I.3.e states both requests in the form in which the Foundation makes them.

9. Movement of the source through space

The characteristic, and the reason it belongs in this family rather than the next

The characteristic is relative motion between the source and the observer: a headlamp approaching on a curve, a beacon rotating, a beam sweeping, an aircraft or an unmanned aircraft crossing the field of view, a vehicle-mounted lamp passing at speed. The Foundation places it in the spatial family because the quantity that changes is a geometric one, the angular position of the source relative to the line of sight, and because the rate at which it changes is determined by the installation and the encounter rather than by the driver circuit.

The analytical point, which is that movement converts a spatial characteristic into a temporal one at the retina

A source that moves across the field of view deposits its energy on successive regions of the retina, and any given region therefore receives a rising and falling irradiance even though the output of the source is perfectly steady. Movement is in that sense a mechanism for generating temporal modulation at the retina out of a spatially non-uniform but temporally constant emission. The converse holds and the comment already relies on it: Part V.D.2 sets out the phantom-array effect, in which movement of the eye across a temporally modulated source produces a spatial pattern. The two are the same coupling observed from the two ends.

The consequence for a criterion is that neither family can be bounded in isolation. A boundary on modulation that assumed a stationary source and a stationary eye would not reach the retinal modulation produced by relative motion, and a boundary on spatial non-uniformity that assumed a static encounter would not reach what that non-uniformity does when it crosses a retina at speed. This is the clearest instance in the Part of the point made at subsection B: a criterion addressing one family while leaving another unconstrained does not reach the mechanism.

The necessity test applied, and the product classes in which the question is live

Applying the test: motion itself is not emission and cannot be unnecessary. What the test reaches is emission whose characteristics were chosen without regard to the motion under which it will be encountered, and the Foundation identifies three classes in which that is presently the case. Part VI.B treats motor vehicle lighting, where the encounter is by definition in relative motion and where Part II.H.5 records the proceeding now open at the Department of Transportation. Part VI.O treats aircraft, drone and obstruction lighting. Part VI.K treats entertainment lighting.

The unmanned aircraft case is the one in which the gap is widest, and Part II.H.7 sets it out: high luminance, instantaneous transitions, motion, and large numbers of independently moving emitters in open airspace above a populated area, under a federal authorization that addresses the audience of the performance and is silent as to everybody else beneath it. Part VI.O records what the federal position is.

What can be specified now

The Foundation cannot state a limit on angular velocity and does not ask for one; the rate at which a source crosses a field of view is not a property of the product that any manufacturer controls. What it asks is that the condition be stated: that where a criterion is set for a lamp intended to be encountered in relative motion, the instrument state the encounter geometry and speed it assumes,

and that the evaluation directed by paragraph (a)(4) be conducted under the conditions of motion in which the product is actually met rather than under static laboratory presentation. Part V.J.2 sets out the distinction between the two.

E. Temporal Characteristics

Four of the sixteen characteristics fall in this family. It differs from the other two in a way that governs everything below and that Part IX.I.2 sets out at length: this is the one family in which the quantities are settled, a consensus body has already written numerical criteria in mandatory language, the effects are documented in human beings at frequencies human beings cannot perceive, and the Department has prescribed a standard for an optical emission characteristic before. It is for that reason the only family in which the Foundation asks the Secretary to consider prescribing a performance standard now, and the request is at Part IX.I rather than here.

One general finding applies across the family and the Foundation states it here rather than four times below, because it is the most useful thing it has to say about the time domain. Every federal instrument the Foundation has examined that addresses the temporal behavior of an optical emission specifies a schedule and none specifies a shape. Schedule means how often and for how long: flash rate, duty cycle, period. Shape means how the output gets from one state to the other: rise time, decay time, waveform. Subsection 2 sets out the evidence for that finding and the single apparent exception, which runs the opposite way from what would be needed.

1. Temporal characteristics of the output

The quantities

The front matter, subsection G, defines five. Percent flicker, or modulation depth, is the difference between maximum and minimum output over a cycle as a proportion of their sum. Flicker index is the proportion of the waveform lying above its own mean, and is sensitive to waveform shape as percent flicker is not. Pulse-width modulation frequency is the repetition rate at which a driver switches the emitter on and off. Duty cycle is the proportion of each period during which the emitter is on. Waveform is the shape of the output over the period, of which the transition times treated at subsection 2 are one aspect. Part V.D.1 sets out pulse-width modulation, modulation depth and frequency as the literature treats them.

Why a boundary is needed in this dimension

Light-emitting diodes do not dim by reducing current in the way a filament dims by cooling. They are predominantly dimmed and regulated by being switched on and off rapidly, so modulation is not an incidental defect of particular products but a consequence of the ordinary method of driving the technology. Part V.B.7 sets out the temporal characteristics of the emission and Part V.D the literature on effect.

The effects are documented at frequencies above those at which modulation is visible as flicker, which is the feature of this dimension that distinguishes it from the others in this Part. Part V.D.2 sets out the stroboscopic and phantom-array effects, Part V.D.4 flicker in vehicle lamps, warning beacons and displays, Part V.D.5 interference with clinical measurement, and Part V.E.1 photosensitive epilepsy and flash-rate thresholds. A person cannot avoid an exposure they cannot perceive, which is the respect in which this characteristic most resembles the radiofrequency exposures this request for information is principally addressed to.

The necessity test applied

Applying the test at Part II.D.2.a: does modulation serve a purpose for the person exposed? In the general case it does not. Modulation is a property of the driver circuit, adopted for reasons of cost, efficiency and dimming control, and the person exposed receives no benefit from the output being delivered in pulses rather than continuously. The Foundation identifies the exception rather than waiting to be shown it: where modulation is the signal, as in a flashing warning lamp or a

communication function, the modulation serves a purpose, and subsection 2 and Part VI.C treat that case.

What can be specified now, and the standing of the instrument that would supply it

This is the one dimension in this Part in which numerical criteria already exist in mandatory language from a recognized body. IEEE Std 1789-2015 states them. Part V.D.3 sets out what they are and the Foundation relies on them in this comment in a substantial number of places.

The Foundation states the objection to that reliance in its strongest form before answering it, and Part V.D.3 does the same. IEEE Std 1789-2015 is a recommended practice rather than a standard, which is a distinction the issuing body itself draws. Its status is recorded as inactive-reserved, with an inactivation date in March 2026. A commenter who asked a federal agency to adopt the numerical content of an inactive recommended practice without saying so would be concealing something material.

The answer the Foundation gives is set out at Part V.D.3 and at Part IX.I.2 and is not repeated here beyond its substance: the criteria were derived from the published human-response literature rather than from the standing of the document that collects them, the derivation does not expire when a document is reclassified, and the appropriate federal response to the lapse of the only numerical guidance in existence is not to treat the question as settled but to supply what the lapse leaves absent. The Foundation asks the Department to search for a successor instrument and to state whether one exists, which is a question it is better placed than the Foundation to answer.

2. Rise and decay times of flashing lamps

The characteristic, stated precisely, because the general word flicker does not reach it

The characteristic is the time the output takes to travel between its off state and its on state, and back: the rise time and the decay time of a single transition. It is a property of the shape of the waveform and not of its schedule. Two lamps flashing at the same rate, with the same duty cycle and the same peak intensity, can differ entirely in this characteristic, and no quantity in the preceding subsection distinguishes them. Percent flicker is computed from maximum and minimum output and is indifferent to how the output travels between them. Flicker index is sensitive to waveform and is the nearest available quantity, and it is not a measure of transition time either.

Why this characteristic is the one most clearly lost in the conversion, and what was lost with it

An incandescent lamp has thermal mass. Its filament takes time to heat and time to cool, so its output rises and falls along a curve whose duration is a physical property of the filament and cannot be designed out. A light-emitting diode has no thermal mass in the optical path and switches in microseconds. When a flashing or switched application was converted from one source to the other, the schedule was preserved because the schedule was specified, and the transition was not, because it had never needed to be specified. It had been supplied by the physics of the source.

That is the general form of a structural precedent this comment establishes elsewhere, and the Foundation draws the comparison because it is exact rather than rhetorical. Part VI.R.4 sets out a federal report concerning traffic signals in which the property lost in the conversion was heat at the lens: incandescent signals melted accumulated snow, light-emitting diode signals do not, and the specifications did not address the question because nothing had ever required them to. The agency identified the loss after the conversion. Transition time is a property of the same kind, lost in the same way, and the Foundation submits it has not yet been identified by anyone with authority over the products.

The evidence for the finding that no federal instrument specifies transition time

The Foundation examined the instruments governing the product classes in which flashing is prescribed, and Part VI.R sets out the examination for traffic signals in detail. The results are these. The Manual on Uniform Traffic Control Devices, incorporated by reference at 23 C.F.R. § 655.601, contains in its Part 4 no provision addressing rise time, decay time, turn-on time, turn-off time, waveform, modulation or duty cycle expressed in time units. The pedestrian signal provision specifies a flash rate and the proportion of the cycle during which the indication is displayed, which is a schedule and a duty cycle. The locomotive provision at 49 C.F.R. § 229.125(e) permits auxiliary lights to flash and states a permitted band of flashes per minute, which is a schedule. The aviation specifications state flash rates in flashes per minute, which is a schedule. In none of them does the shape of the transition appear.

One further instrument belongs in that list and is treated separately because the Foundation asks something different about it. The accessibility specification for a visible alarm appliance, set out at Part VIII.D.4, bounds the flash rate in both directions, the pulse duration and the duty cycle, and does not bound the transition. It is the one place in federal practice where the schedule of a deliberate flash is specified closely and its shape not at all, and Part IX.I.5 sets out the question that follows: whether the abruptness is necessary to the notification function, which is a question for paragraph 360ii(a)(5) rather than for a performance standard.

The single apparent exception is instructive and the Foundation sets it out because it runs the opposite way from what would be needed. A state department of transportation specification for light-emitting diode signal modules states a transition-time requirement in milliseconds. It is expressed as a ceiling: the turn-on and turn-off time must be less than the stated figure. A ceiling on transition time forbids slowness. It is a requirement that the lamp switch quickly, which is the opposite of a requirement that it switch gently, and a lamp that switched instantaneously would satisfy it perfectly. Part VI.R sets out the provision, its source, and the reason the Foundation does not attribute it to the consensus document the Manual references.

The one federal document that raised the question, and what became of it

The Foundation has located one place in which the question was put. A federally funded lighting research report of 1999 observed that the faster rise time of a light-emitting diode signal may have an effect on reaction time and missed signals. Part VI.R.5 sets out the observation and what followed it, which so far as the Foundation can establish is nothing. A question identified in a federally funded report in 1999, concerning a characteristic of a product class that has since been converted in its entirety, has not been studied in the twenty-seven years since.

A finding that runs against the Foundation, stated here and not only where it is developed

The one government comparison of incandescent and light-emitting diode signal switching the Foundation has located did not measure transition time photometrically. It inferred it from video recorded at thirty frames per second and examined frame by frame, which bounds its resolution at about thirty-three milliseconds. On its own figures one light-emitting diode product had the longest fade-out time of any lens tested for the solid green indication, which is the opposite of the direction the Foundation's argument runs. Part VI.R.5 sets out the study, its method, and that finding. The Foundation reports it here because a reader who met it first in Part VI would be entitled to conclude that this Part had been written without it.

What can be specified now, and the shape the boundary must take

The boundary in this dimension is a floor and not a ceiling, which is the clearest illustration of the point made at subsection B. What is complained of is that transitions are too abrupt, so what is needed is a minimum transition duration, or equivalently a maximum rate of change of output. The Foundation cannot state the value. It states that the value is the sort of quantity the research directed by paragraph (a)(2) would establish, that the measurement is straightforward with a

photometric detector of adequate bandwidth, and that no such measurement of the converted product classes appears to exist.

The Foundation also records what it has deliberately declined to do. Figures exist for the rise and decay characteristics of low-voltage incandescent vehicle brake lamps from a study of the early nineteen nineties. They are not transferable to line-voltage signal and illumination products, the operating conditions differ in voltage, thermal mass and duty, and this comment does not use them. Part VI.R records the exclusion and the reason for it.

3. Cumulative exposure

The quantity

Cumulative exposure is total dose accrued across repeated exposures over time. The front matter, subsection G, defines it and records that Question 5 of this request for information names cumulative exposure over time among the characteristics a classification system should account for.

Why a boundary is needed, and the respect in which the existing framework already concedes the principle

The principle that optical exposure accumulates is not contested and is not the Foundation's invention. Part V.C.2 sets out the international assessment framework for the blue-light hazard and records that its exposure metric is a dose rather than an instantaneous value. Part V.C.2 also sets out an established cumulative-dose framework for one waveband, which the Foundation relies on as demonstrating that regulators have been willing to express an optical limit as accumulated dose where the evidence supported it.

The gap is one of duration rather than of principle, and it is specific and citable. The framework's dose limit is stated over an exposure of ten thousand seconds, which is under three hours. Part V.C.2 sets out where the framework stops. The exposure this comment concerns is involuntary, daily, and lifelong: street lighting encountered every night for decades, workplace lighting for a working life, vehicle headlamps on every drive. A framework that bounds a three-hour occupational exposure has not addressed that, and does not claim to.

The necessity test applied

Applying the test in this dimension requires care, and the Foundation states the difficulty rather than glossing it. Cumulative exposure is not a characteristic of an emission at all; it is an integral of exposure over time, and the same product can produce very different cumulative doses depending on how long a person is near it. The test therefore does not ask whether cumulative exposure is unnecessary. It asks whether the component of the accumulated dose contributed by emission that served no purpose for the person is unnecessary, which it is by the same reasoning as applies to each component characteristic. The practical consequence is that this characteristic does not take a boundary independent of the others; it takes an accounting method.

What can be specified now

Not a number. Two things of a different kind. First, that any criterion the Department states for an optical emission identify whether it is an instantaneous limit or a dose limit, and if a dose limit, over what integration period, because the existing framework's three-hour period is a limitation that is easy to overlook when the figure is quoted without it. Second, that the evaluation directed by paragraph (a)(4), which is directed to conditions of exposure and not only to emissions, address the duration and repetition structure of exposure to these products, which Part II.F.2 records that the Department already holds information bearing on.

4. Time of day and time of night at which the product is used

The characteristic, and why it is a characteristic of exposure rather than of the product

The characteristic is the hour at which the emission reaches the person. It is not a property of the product and the Foundation does not present it as one. It is a condition of exposure, and paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, which is the authority under which it belongs in this Part. Part II.F sets out that paragraph.

Why a boundary is needed in this dimension

Two independent mechanisms make the same emission a different exposure at a different hour, and they point the same way.

The first is adaptation. The visual effect of a source depends on the adaptation state of the observer, which depends on the luminance of the surrounding field. Subsection D.3 sets out the consequence: the luminaire that is unremarkable at midday is disabling on an unlit road at night, and the difference is a property of the hour rather than of the lamp. Part V.C.3 sets out the mechanism.

The second is the non-visual photoreceptive pathway. Short-wavelength light suppresses melatonin and shifts circadian phase, and the magnitude and direction of that response depend on the time at which the light is received relative to the person's own circadian phase. The same exposure that is benign or beneficial in the morning is disruptive at night. Part V.F sets out the evidence.

The necessity test applied, which in this dimension gives the sharpest available answer

Applying the test: does emission at this hour serve a purpose for the person exposed? In this dimension the test discriminates with unusual force, because the purpose of an installation is frequently satisfied for part of the night and not the rest of it. Lighting installed to serve pedestrian or vehicle traffic serves no one at an hour when there is no pedestrian or vehicle traffic, and the emission it continues to produce at that hour is unnecessary in the fullest sense the term carries at Part II.D.2, without any need to establish that it harms anybody. Part II.D.5 records the existing mitigations, which include controls of exactly this kind.

What can be specified now, and the one dimension in which the Foundation believes a federal criterion is nearly writable

The boundary in this dimension is a relationship: permitted output as a function of the hour, or permitted output conditioned on the presence of the use the installation exists to serve. The Foundation submits this is the dimension in which a federal criterion is closest to writable on the present record, for three reasons. The technique is established and in wide use; Part II.G.3 records that the techniques exist and that what is absent is the federal evaluation of them. The capability is already built into the products, since adaptive and scheduled control is a standard feature of light-emitting diode drivers. And paragraph (a)(5) directs the Secretary to develop, test and evaluate the effectiveness of exactly this kind of procedure, which makes it the characteristic in this Part most squarely within a paragraph the Department has not performed.

The Foundation accordingly asks, in this dimension, for the evaluation rather than for a limit: that the ambient-sensing and default-low capability described at Part IX.J be evaluated for effectiveness under paragraph (a)(5), and that the Department state whether any such evaluation has been performed. It also records one federal document that bears directly on the question and that it has not yet been able to read, which is the circadian lighting appendix to the Department of Defense facilities criteria described at Part II.H.14.

F. The Exposed Person: Special Populations [RFI Q11]

This is the first of the two items that are not characteristics of the emission, and subsection B states why it is nonetheless in this Part. It does not take a boundary of its own. It determines, for every boundary in the three families above, the population against which that boundary is set, and the question it puts to each of them is the same: whose response is this number calibrated to?

a. The statutory basis for asking the question

Paragraph 360ii(a)(2) directs the minimization of the exposure of people to unnecessary electronic product radiation. It does not say the average person, the typical person, or the healthy adult. Paragraph (a)(4) directs the study and evaluation of conditions of exposure, and the condition that a person's eye transmits more short-wavelength light than another's, or that their nervous system responds to modulation that another's does not, is a condition of exposure.

Two further sources of duty apply to this Department specifically and are set out at Part VIII.B. Section 504 of the Rehabilitation Act reaches the Department's own programs, and the Department is a designated agency under Title II of the Americans with Disabilities Act for a class of public entities. Part VIII.B.2 and Part VIII.B.3 set out each. A criterion written to the comfort of an unimpaired observer, adopted by a Department carrying those duties, would be a criterion that excluded by construction the people the duties exist to reach.

b. The groups the record identifies, and where the evidence sits

The Foundation does not present a list of protected categories. It identifies the groups for which the published literature or its own record shows a different response to one or more of the sixteen characteristics, which is a narrower and more useful claim.

Children. The crystalline lens yellows with age, and a younger lens transmits more short-wavelength light to the retina. The consequence is that for the same incident exposure a child receives a larger retinal dose in precisely the waveband in which the hazard function is greatest. Part V.C.2 sets out the age-dependent ocular transmission figures and the question of who actually receives the dose. Part VI.M treats products intended for or used by children, and records that the federal standard governing toys in the United States does limit an optical quantity, which makes the absence of any limit for the general case harder to account for.

Older adults. The same yellowing reduces short-wavelength transmission, but intraocular scatter increases with age and with cataract, and scattered light is the mechanism of disability glare. Part V.C.5 sets out age, astigmatism, cataract and intraocular lenses as modifiers, and Part V.C.3 the straylight mechanism. The direction of effect differs between the photochemical and the glare questions, and the Foundation states that rather than asserting that older adults are uniformly more affected.

People with photosensitive epilepsy, migraine or photophobia. Part V.E.1 sets out photosensitive epilepsy and flash-rate thresholds and Part V.E.2 migraine and photophobia. These are the groups for which the temporal family at subsection E matters most, and for whom the relevant thresholds are already partly quantified.

Autistic people and people with sensory processing differences. Part V.E.3 sets out the literature. Part VII.A.4 records the self-identified condition categories in the Foundation's incident report database.

People who have had intraocular lenses implanted. Part V.C.5 sets out the position. The Foundation notes the feature of this group that makes it distinctive: the implanted lens does not carry the natural lens' short-wavelength absorption unless it was specified to, so the exposure of these eyes was altered by a medical intervention this Department regulates.

c. What the Foundation asks in respect of this item

Two things, neither of which is a number. First, that any criterion the Department states for an optical emission identify on its face the population whose response it is calibrated to, which is the condition-stating request made in the temporal dimension at Part IX.I applied to the receiving population. A criterion calibrated to unimpaired adult observers is not thereby wrong, but it is a different criterion from one calibrated to the population that actually encounters street lighting, and the difference should be visible rather than implicit. Second, that the research directed by paragraph (a)(2) and the evaluation directed by paragraph (a)(4) include these groups rather than treating them as a source of variance to be controlled for.

G. Techniques of Minimization [RFI Q5.o]

This is the second item that is not a characteristic of the emission. It is a technique for minimizing exposure, and techniques for minimizing exposure are the subject of a paragraph of their own: paragraph 360ii(a)(5) directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation. The Foundation therefore asks for something different in respect of this item than in respect of the fourteen characteristics: not a boundary, but the evaluation the statute already directs.

1. Luminaire shielding and diffusion

a. What the two techniques do, in terms of the characteristics above

Shielding operates on spatial distribution. A shield, a cut-off optic or a house-side reflector removes output from directions in which it serves no function, which is the dimension treated at subsection D.1 and the dimension in which the Foundation submits the emission is most clearly unnecessary.

Diffusion operates on luminance, and it does so by the only mechanism available. Luminance is luminous intensity divided by apparent emitting area, so for a fixed luminous output the way to reduce luminance is to increase the area over which the output appears to originate. That is what a diffuser does. The Foundation draws attention to the consequence: diffusion is the technique that acts directly on the variable which, as the introduction to subsection D establishes, the existing candela-based criteria leave entirely unconstrained. It is the specific remedy for the specific gap this Part identifies.

b. The trade-offs, which the Foundation states because an evaluation that ignored them would be worthless

Neither technique is free and the Foundation does not present either as costless. Diffusion scatters output in all directions from a larger apparent source, so a diffuser applied without shielding increases light trespass and skyglow even as it reduces luminance; the two techniques are complements and applying one alone can worsen the dimension the other addresses. Both reduce the proportion of generated light that reaches the intended surface, which raises the energy consumed per unit of delivered illuminance and therefore engages the efficacy metric described at Part IV.G.4, under which both techniques register as loss. And a diffuser is a component that ages, discolors and is sometimes removed in maintenance, so the technique's effectiveness in service is not its effectiveness when new.

Those trade-offs are precisely why the statute directs an evaluation of effectiveness rather than an endorsement. The Foundation is not in a position to quantify any of them, and says so.

c. The state of the record, and what the Foundation asks

Part II.G.3 records the position: the techniques exist, they are in commercial use, and what is absent is the federal evaluation of them. Part II.D.5 records the existing mitigations. Part II.G.2 records that the Final Response of May 24, 2024 asserted the effectiveness of existing mitigations, which is the conclusion of the evaluation paragraph (a)(5) directs the Secretary to perform.

The Foundation accordingly asks the Department to state whether the evaluation underlying that assertion exists, and if it does, to produce it, in which case the Foundation's complaint under this paragraph as to these two techniques falls away. If it does not, the Foundation asks that shielding and diffusion be among the first techniques evaluated under paragraph (a)(5), for the reason given above: diffusion acts on the one quantity that the existing federal criteria do not reach at all.

2. User control of the indicator light on a mains-powered device

a. The technique, and the one respect in which it differs from everything else in this Part

The technique is a control: a switch, a button, or a setting by which the person who lives with a device can extinguish or dim the indicator light on it, at their own discretion, without disabling the device. The products are those at Part VI.G.1, which sets the class out by naming it: the indicators on appliances, tools, chargers, outlets, alarms and routers, together with televisions and other equipment that continue to indicate while in standby.

Every other technique in this subsection, and every boundary in the three families above, reduces a quantity. This one removes the emission altogether, and it does so at the election of the person exposed rather than by the judgment of a regulator about what level is acceptable. The Foundation draws attention to that difference because it is the reason the technique is worth separate treatment: it is the only proposal in this Part whose operation requires nobody to determine a number.

b. Which characteristics it acts on, and which it leaves untouched

A control of this kind acts on two of the sixteen. It acts on the hour of use at subsection E.4, by allowing the person to remove the emission at the hours when the non-visual photoreceptive pathway is most sensitive and when the surrounding field is darkest; Part V.F sets out the circadian evidence and subsection D.3 the adaptation point. And it acts on cumulative exposure at subsection E.3, by reducing the duty of the emission to zero rather than reducing its instantaneous magnitude, which is the only mechanism in this Part that bears on an accumulated dose without requiring a dose limit to have been established.

The Foundation states what it does not act on, so that the technique is not mistaken for a substitute for a boundary. A control does not change the spectral distribution of the emission, its source luminance, or its beam angle. A device whose indicator has been switched off emits nothing, so those characteristics do not arise; but a device whose indicator is merely dimmed retains all three, and Part VI.G.2 sets out why the beam angle of an indicator is the characteristic nobody who meets the appliance can obtain. A control is a remedy available to the person in the room. It is not a remedy for the product.

c. Why the necessity test is satisfied more cleanly here than anywhere else in this Part

An indicator light communicates a state. Once the person has read the state, continued emission conveys nothing further to them. A router that reports, continuously and through the night, that it has power, to a person who knows it has power and cannot turn the report off, is emitting to no purpose for that person.

Applying the test at Part II.D.2.a: does the emission serve a purpose for the person exposed to it? For an indication the person does not wish to receive, in a room they are trying to sleep in, the answer is no on the face of it, and no finding about hazard is needed to reach it. Part II.D.2 establishes that unnecessary and hazardous are separate categories under this paragraph and that the duty to minimize attaches to the first without waiting on the second. This is the cleanest application of that distinction in the comment, and the Foundation says so plainly: it is the one place where the statutory test is satisfied by the election of the person exposed rather than by evidence the Foundation would have to supply.

d. The state of the record, and what this subsection adds to what the comment already asks

The Department has already been asked for this, in a different form and under a different authority, and the Foundation identifies the overlap rather than presenting the point twice as though it were two. Part IX.J.2 asks the Secretary to recommend, under § 360ii(b)(1), that an indicator lamp on a household appliance be capable of being dimmed or extinguished by the user, and records why that recommendation is available now: it asserts nothing about whether the lamp is harmful, it requires no finding about anyone's health, and it costs the manufacturer very little.

What this subsection adds is the paragraph (a)(5) character of the same thing. A user control is a procedure or technique for minimizing exposure to electronic product radiation, and paragraph 360ii(a)(5) directs the Secretary to develop, test and evaluate the effectiveness of such techniques. That duty does not depend on whether the Secretary chooses to recommend the technique under § 360ii(b)(1), and it is not discharged by declining to. The technique is in commercial use: products in several of the classes at Part VI already provide a control of this kind, which is the general position Part II.G.3 records, that the techniques exist and what is absent is the federal evaluation of them.

e. Two strengths of the same technique, which are not the same ask

The technique admits of two forms and the Foundation separates them because they differ in what they require of a manufacturer and in how defensible each is.

The weaker form is a control that permits the user to extinguish an indicator that is illuminated by default. This is the form Part IX.J.2 presently asks the Secretary to recommend. It is close to costless, it defeats no expectation, and the Foundation is aware of no argument against it.

The stronger form is an indicator that is dark by default and is illuminated only when the user elects to have it illuminated. It is the form that actually delivers what a person seeking relief from these emissions wants, because it does not require them to discover and operate a control on every device they own, and because the default is what the great majority of devices will be left at. The Foundation states the objection to it as well: a person who cannot tell at a glance whether a device is powered may be worse off in some circumstances, and the Foundation has not established for which product classes that matters. It does not ask the Department to resolve that here. It asks that both forms be within the technique whose effectiveness paragraph (a)(5) directs be evaluated, because the evaluation is what would settle which products can bear the stronger form.

f. The limit, which the Foundation states because a control that defeated a safety function would be worse than the emission

The technique does not extend to an indication that is itself a safety function required by another authority. A smoke alarm or a carbon monoxide alarm that indicates its own operating condition is the obvious case, and the Foundation does not ask that any such indication be capable of being defeated. Part IX.J.2 states the same limit and records that the Foundation has not established which household products carry such a requirement. Part IX.J.2 also records a federal instance in which a visible notification quantity is specified, which establishes that the government does specify quantities of this kind when it chooses to.

Nor does it extend to an indication the user wants. Nothing in this subsection asks that any indicator be removed, or that any person be deprived of one. The whole of the request is that the person in the room be given the choice, and the Foundation puts it in the terms its correspondents use: a person should be able to be free of the light in their own home without unplugging the device or covering it with tape. Part VII.B.5 sets out the reported sleep disruption and Part VII.D what reporters describe themselves doing about it.

g. What the Foundation asks in respect of this technique

That a user control over an indicator light be among the first techniques evaluated for effectiveness under paragraph 360ii(a)(5), for the reason given at item a: it is the only technique in this Part that

reduces an exposure to zero at the election of the person exposed, and the only one that requires no number to have been determined first. And that the Department state whether any evaluation of this technique has been performed, which is the question Part IX.G asks of the mitigations generally.

3. Substitution of the source technology

a. The technique, and the characteristic it acts on

The third technique is to replace the source with one whose spectral distribution differs, rather than to treat the emission of the existing source optically. It acts on the spectral characteristic at subsection C.1, where the two techniques above act on geometry and on duty, and it is the only one of the three that changes what is emitted rather than where it goes or when.

b. One documented instance, stated with its provenance first

The Foundation sets out the provenance before the instance, because the provenance bears on the weight. On April 3, 2026 the city of Ketchikan, Alaska enabled three low-pressure sodium streetlights in place of cool-white light-emitting diode streetlights. The account the Foundation relies on is published by the company that supplied the lamps, ballasts and components, and that sells them. The account describes the installation as a community-led pilot supported by the Soft Lights Foundation. The Foundation is therefore citing a supplier's published account of a project the Foundation supported, and it says so here rather than leaving the Department to discover it. The Foundation states, for completeness, that it has no financial relationship of any kind with that supplier and received and provided nothing of value in connection with the project.

The published account does not record why the substitution was made, and the Foundation supplies that from its own knowledge rather than from the source. Its account is that a resident whose dwelling overlooks the street requested an accommodation under the Americans with Disabilities Act, on the basis that the blue-rich light-emitting diode installation was producing adverse reactions in them, and that the city provided the accommodation requested by replacing those sources with the amber low-pressure sodium sources. The Foundation treats that resident's account of their own reactions exactly as it treats the 593 accounts at Appendix A, which Part VII.A.5 governs: it is that person's statement of their own experience and belief, it is not a finding, and the Foundation does not advance it as one. Applying a lower standard to this account because the Foundation knows of it directly would be noticed, and the Foundation does not. The Foundation does not identify the requester and does not state the interval between the request and the response, because it has not documented it.

The Foundation is exact about the standing of that account, because the distinction matters to how much weight the Department can give it. It is a statement of fact within the knowledge of the Foundation's president, offered as the Foundation's own statement and not as a citation to a document. No record of the request, of the city's response to it, or of any municipal determination has been obtained, and the published account of the installation does not mention a request at all. A commenter may state facts within its own knowledge and the Foundation does so here. It does not represent the account as independently documented. It also separates two characterizations that a reader would otherwise run together. The word pilot is the supplier's. It appears in the supplier's published account and it is the word of a party describing an installation of its own products. It is not the city's word, and the Foundation is not aware of any public characterization by the city of what it did or why. So the position is this: the Foundation states that the city provided an accommodation that had been requested; the supplier states that there was a community pilot; the city has said nothing the Foundation has found; and all three statements concern the same three luminaires.

With that said, the instance carries more than the availability point stated above. It is the only instance known to the Foundation in which a request under a disability provision produced a change in the optical characteristics of a public lighting installation, and Part VIII.A and Part VIII.F.5 set out what follows from it for the disability argument.

What the instance establishes is narrow and the Foundation claims no more. A substitution of this kind is procurable, and it has been performed by a municipality in the United States. That is a fact about availability rather than about effect, and it bears on two things in this comment: the technical achievability and practicability criterion of § 360kk(a)(2), which Part IX.I.4 addresses, and the evaluation of techniques that § 360ii(a)(5) directs.

What it does not establish is a longer list. No measurement of any optical quantity was made or reported, before or after. There is no independent evaluation, and none by the municipality. The account contains no statement from the city, names no official and names no authorizing body. The resident response it reports is qualitative and anonymous. The number of luminaires is three. And the account does not record that the substitution was requested as a disability accommodation; Part VIII.A states the consequence of that for the disability argument, which is that the instance cannot carry it.

c. Why the substitution is nonetheless the right kind of thing to evaluate

Low-pressure sodium is a narrow-band source at a long wavelength. Part V.B.3 sets out the difference between a narrow-band source and a warm white one, which is a distinction this comment insists on elsewhere because low correlated color temperature is not the same thing as low short-wavelength content. Part V.B.6 reports published work, some of it funded by the Department of Energy, on a physiological function for long-wavelength content in human subjects. A substitution of this kind therefore moves the emission in the direction the necessity test at Part II.D.2.a points. That is a reason to evaluate it. It is not a finding that it works.

d. The qualification, which the Foundation states because the technique is not costless

A near-monochromatic source renders color poorly, and color discrimination has uses on a roadway that the Foundation does not dismiss. Part V.B.3 sets out the spectral position of low-pressure sodium among common sources and Part V.M treats the safety benefits claimed for outdoor lighting, including a study that reports fewer incidents under low-pressure sodium at a significance the Foundation states rather than rounds. The Foundation does not assert that substitution is costless and does not propose it as a general remedy for any product class. It asks that it be among the techniques whose effectiveness paragraph (a)(5) directs the Secretary to evaluate, alongside shielding, diffusion and user control, and it notes that an evaluation would have to weigh the loss as well as the benefit.

H. Summary: The Sixteen Characteristics, the Shape of the Boundary Each Requires, and What Can Presently Be Stated

The table collects the Part. The third column states the form a criterion would have to take, which the Foundation asserts. The fourth states what the Foundation is presently able to supply, which in most rows is not a number, and the reason it is not is the same in every such row: the research paragraph (a)(2) directs and the evaluation paragraph (a)(4) directs have not been conducted as to this radiation.

Characteristic	Family	Shape of boundary required	What the Foundation can presently state
1. Spatial distribution	Spatial	Distribution: proportion of output permitted outside a stated solid angle referred to installation geometry	Form is in use, including in a federal aviation specification limiting stray light to 3% of peak. No proportion supplied. Asks measurement and disclosure.
2. Spectral distribution	Spectral	Relationship: short-wavelength content referred to task requirement and to hour; possibly a floor on long-wavelength content	Numerical spectral limits exist in a regional instrument, and 21 C.F.R. 1040.30 is a radiometric lighting standard. No value supplied. Not CCT.

Characteristic	Family	Shape of boundary required	What the Foundation can presently state
3. Temporal characteristics	Temporal	Ceiling on modulation depth as a function of frequency	The only dimension in which numerical criteria already exist from a recognized body, in mandatory language. Standing of that instrument stated at Part V.D.3.
4. Rise and decay times	Temporal	Floor: minimum transition duration, or maximum rate of change of output	No federal instrument specifies it. The one apparent exception is a ceiling, forbidding slowness. No value supplied.
5. Luminance	Spatial	Relationship: permitted luminance as a function of viewing angle and of adaptation level	One federal numerical instance located, in Department of Defense facilities criteria, in angle-dependent form. No general value supplied.
6. Radiance	Spatial	Ceiling, in the blue-light-hazard weighted form for the photochemical question	Quantity, measurement method and weighting function all already exist. Existing framework is bounded at an exposure of 10,000 seconds. No value supplied.
7. Luminous intensity	Spatial	Ceiling, paired with every existing minimum	The regulatory currency of optical emission in the United States, and almost everywhere expressed as a minimum only. Asks that minima be paired with maxima.
8. Illuminance	Spatial	Maximum at a boundary, for light trespass only; otherwise a stated condition	The weakest of the five quantities for these purposes, and the Foundation says why. Trespass maxima exist, but municipally rather than federally.
9. Irradiance	Spatial	Ceiling at a stated measurement geometry	The same quantity and unit as radiofrequency power density. The quantity in which the Department has written optical standards before. Geometry unsettled.
10. Glare rating	Spatial	Ceiling, on separate metrics for disability and for discomfort glare	A metric is in federal use in facilities criteria. Its validity domain may exclude these sources, which the Foundation states against itself.
11. Cumulative exposure	Temporal	An accounting method rather than an independent boundary: stated integration period	Dose-based optical limits exist for one waveband, so the principle is conceded. The existing period is under three hours; the exposure is lifelong.
12. Number of emitters	Spatial	A stated assumption on each product criterion, plus research reaching the aggregate	Rests on paragraph (a)(2) naming exposure separately from emissions. Outside what a product standard can reach, and the Foundation says so.
13. Movement through space	Spatial	A stated encounter geometry and speed, not a limit on motion	Converts a spatial characteristic into a temporal one at the retina. The only characteristic here with no federal numerical criterion in either direction.
14. Special populations	Not a characteristic of the emission	No boundary of its own: fixes the population every other boundary is set against	Groups identified with the evidence for each. Asks that each criterion name the population it is calibrated to.
15. Techniques of minimization: shielding, diffusion, and user control of indicator lights	Not a characteristic of the emission	Not a boundary: techniques, whose effectiveness paragraph (a)(5) directs be evaluated	Diffusion acts on luminance, which existing federal criteria do not reach. A user control over an indicator light is the only technique here that reduces an exposure to zero at the election of the person exposed. Asks for the evaluation, not a limit.
16. Time of day or night	Temporal	Relationship: permitted output as a function of hour or of the presence of the use served	The dimension closest to writable: technique established, capability already in the products, and squarely within paragraph (a)(5).

Two characteristics the Foundation expects will have to be added, identified now rather than defended later

Subsection A states that the list is not represented as exhaustive. The Foundation identifies the two omissions it regards as most likely to matter, so that the list is not later described as having been presented as complete.

The luminance ratio between a source and its immediate surround. Every discomfort glare formulation the Foundation is aware of depends on the luminance of the background against which the source is seen, and no characteristic in the list above captures that relationship. The same luminaire against a bright ceiling and against a night sky is two different exposures, and the quantity that distinguishes them is a ratio rather than either luminance alone. It is adjacent to the hour of use at subsection E.4 and to the adaptation point at subsection D.3 but is not the same as either, because the relevant surround is the immediate field rather than the general ambient level.

The phase relationship among wavelength channels. Products that generate white or tunable light from separate colored emitters, and displays that illuminate color channels in sequence, can modulate their channels out of phase with one another. The result is a modulation in chromaticity as well as in magnitude, and a product can present a modest modulation depth in luminance while modulating strongly in color. None of the temporal quantities at subsection E.1 is computed per wavelength channel, so a criterion written in them would not reach it. Part VI.H treats displays, screens and personal devices, and Part VI.K treats the entertainment class in which color-changing products are common.

IV. LITIGATION, REGULATORY PETITIONS, AND CONGRESSIONAL ACTION

A. Purpose and Scope of This Part [RFI Q5, Q18]

1. Why the administrative and judicial record is responsive to this RFI

Most of what a request for information of this kind receives is scientific literature. The Foundation supplies that too, at Part V. This Part supplies something a literature search cannot produce: the record of what has been asked of the federal government about this radiation, by whom, when, and what was answered.

That record is responsive for three reasons.

It is evidence about the state of federal knowledge and activity, which is what a request for information on a regulatory question is for. The Department is asking what is known. Part of the answer is what the government has been told, what it has been asked, and what it has said in reply.

Much of it is already in the Department's possession. The Foundation is not asking the Department to accept its account of these events. It is identifying documents in the Department's own files and in those of other agencies, by date and where possible by control number, so that each can be retrieved and read.

And it bears on questions the Department has asked directly, including those concerning surveillance and reporting, the characterization of exposure, and coordination among federal agencies.

There is a further reason, and it is the one the Foundation thinks explains why the record looks as it does.

Visible light is electronic product radiation within the meaning of § 360hh(1)(A), as Part II.B sets out, and the Foundation has met no serious argument to the contrary. But it is not generally thought of that way. A lamp is treated as a household object, a headlamp as part of a car, a streetlight as municipal infrastructure. Each is in law an electronic product emitting electronic product radiation, and almost no one outside this program describes them in those terms. The consequence shows in the correspondence collected at Part II.H.21: agency after agency, asked about LED products, answered in terms of lighting and of its own subject matter rather than in terms of radiation, and each correctly concluded that radiation from electronic products is not its responsibility.

That conceptual habit was not costly while the sources in ordinary use were large, diffuse and limited in output. It has become costly because the characteristics of the emitters changed. Part V.B describes the change: emission concentrated in a small area, at high radiance, with a narrow short-wavelength peak and a switched temporal structure. Those are properties that the vocabulary of lighting does not capture and the vocabulary of radiation does. The Foundation submits this record so that the Department can see how a question framed in the wrong vocabulary came to be addressed by no one.

2. Capacities: filings by the Soft Lights Foundation and filings by Mark Baker individually

This comment is submitted by the Soft Lights Foundation. The filings described in this Part were not all made by the Foundation, and the comment identifies the capacity in each instance, because the two are not interchangeable and the distinction has consequences that bear on what the Department is being asked to do.

The following were made by the Foundation:

- the regulatory petitions to the Food and Drug Administration under the electronic product radiation control program, and the petition of December 30, 2025 for a report to Congress under 21 U.S.C. § 360jj(a)(2). Part IV.C;
- the petitions to the National Highway Traffic Safety Administration, the filings before the Federal Communications Commission, and the petitions and correspondence addressed to the Occupational Safety and Health Administration between 2022 and 2024. Part IV.C and Part II.H.10;
- the request of May 30, 2023 that the Department of Energy comply with 21 U.S.C. § 360ii and establish a liaison with the Food and Drug Administration; the appeal of July 10, 2022 to that Department's Office of Hearings and Appeals; the petition to repeal the general service lamp rules decided at 88 Fed. Reg. 16,869; and the two requests under the Freedom of Information Act of January 24 and January 25, 2025. Part IV.G.7;
- the transmittal of the LED Incident Reports and the related correspondence with agencies and manufacturers. Part IV.B.

The following were brought by Mark Baker individually:

- the three federal actions described in Part IV.D, including the action under the Freedom of Information Act for records of the Center for Devices and Radiological Health.

One request was made in both capacities. The Freedom of Information Act request that became FDA Control No. 2025-3046 was submitted by Mr. Baker individually as a consumer requester and, in the accompanying cover letter, by him as President of the Foundation. Part IV.D.3.

The reason the comment is careful about this is not formality. Two different bodies of standing doctrine apply to the two capacities, and they do not overlap.

The claims that rest on exposure — the discrimination and access claims, and the claims of injury from electronic product radiation — rest on Mr. Baker's own physiological response to the

radiation at issue. They have been brought individually, because that injury is his and not the Foundation's.

The claims that rest on a request for records run the other way. Under the Freedom of Information Act the person who may sue to compel a determination is the person who made the request. The requests to the Department of Energy were made by the Foundation, and any action to compel a determination on them would be the Foundation's to bring; Mr. Baker could not bring it individually, not having been the requester. The request for the records of the Center for Devices and Radiological Health was made in both capacities, which is why the action at Part IV.D.3 could be and was brought individually.

The practical consequence for this request for information is narrow and worth stating. The Department will find in Part IV a record of requests made to several agencies by two different requesters over several years. Whether any particular one of them could be enforced in court, and by whom, is a question about remedies. It is not a question about whether the agency received the information, and the Foundation does not offer the record for the former purpose. Every filing described in this Part reached the agency it was addressed to, and the Department's own files will confirm it.

3. Sources and availability of the underlying documents

Every document described in this Part belongs to one of four categories, and the Foundation states them so that the Department can judge what it would take to verify any particular item.

- Filings in public agency dockets, including the petitions to this Department and the comments on them, which are retrievable by docket number.
- Documents on public court dockets, retrievable by case number through the federal and state electronic filing systems.
- Correspondence between the Foundation, or Mr. Baker, and a federal or state agency. Where an agency assigned a control, case or reference number, this comment gives it.
- Documents issued by this Department or by the Food and Drug Administration, which are in the Department's own files whether or not they have been published.

The Foundation holds copies of all of them. Those cited in this comment are submitted as exhibits, and the exhibit list at the end identifies each by the Part that cites it.

Two practical notes about the exhibits. They are submitted as separate files rather than appended to this document, because of the file size limit applicable to submissions in this docket. And where a document is already in the possession of this Department or of another federal agency, the Foundation has said so in the text, so that the Department may verify it against its own records rather than relying on the copy submitted here.

Where the Foundation relies on a document it has not been able to obtain, or on a description of a document rather than the document itself, this comment says so at that point. Where it has been unable to establish something it would have liked to establish, it says that too.

B. Notice to the Agencies: Transmittal of Reports of Harm and Acknowledgment of Receipt

1. The LED Incident Report submission form and the Foundation's transmittal practice

The Foundation maintains a reporting form through which members of the public describe their experience of exposure to light emitted by light-emitting diode products. Part VII.A.1 describes the form, what it asks, and the limits of data collected that way. This subsection is concerned with a narrower question: what the Foundation did with the reports after receiving them.

The practice has been to compile the reports periodically and transmit the compilation to the Food and Drug Administration, and in some periods to the National Highway Traffic Safety Administration as well. The compilations are prepared by period rather than by incident, and alongside the incident reports the Foundation has transmitted compilations of the comments filed on a public petition concerning vehicle headlamps and, in some periods, material drawn from public discussion forums.

The Foundation does not characterize these transmittals as reports under 21 C.F.R. § 1002.20. That section imposes its duty on manufacturers, and Part II.L explains why a submission from an organization is not and cannot be a report under it. What the transmittals accomplish is simpler and is not in dispute: they put the material in front of the agency.

2. Transmittal to the Food and Drug Administration at RadHealthCustomerService@fda.hhs.gov

Transmittals to the Food and Drug Administration have been made to the customer service address of the Center for Devices and Radiological Health. Each of the compilations listed below was transmitted to that address. They cover the following periods, which the Foundation lists so that the Department can locate the corresponding material in its own records

2024: April; April to May; July; August; September; October; November; December.

2025: January; February; March; April; May; June to July; August to September; October to November; and a consolidated transmittal dated December 1, 2025.

2026: December 2025 to February 2026; March to July 2026.

The compilations fall into four categories: the LED Incident Reports submitted through the Foundation's form; the comments filed on the public petition concerning vehicle headlamps; material drawn from two public discussion forums hosted on a social media platform, one of them an online community concerning vehicle headlamps, transmitted in some periods between October 2024 and September 2025; and, for the period August to September 2025, a compilation described as LED Radiation Reports.

The Foundation distinguishes that last category from the others and invites the Department to do the same. The LED Incident Reports were submitted to the Foundation through a form that asks particular questions, and Part VII.A describes what the form asks and what the resulting data can and cannot support. The forum material was not submitted to anyone. It consists of posts written by members of the public to each other, collected by the Foundation and forwarded. It is anonymous, unverified, written without any question having been put, and drawn from a community constituted around a grievance.

The Foundation offers it for one purpose and no other: as part of the record of what was placed before the agency during the period in question. It is not offered as evidence of the prevalence, the severity, or the cause of any effect, and the Foundation does not rely on it anywhere in this comment for any of those purposes.

Separately from the periodic compilations, the Foundation has submitted individual radiation reports on the agency's own form. One concerning light-emitting diode lamps on an emergency vehicle was assigned case number COR22000194 in October 2022, and is described at Part VII.I.2.

3. The FDA's acknowledgments of receipt

Acknowledgment matters here for a particular reason. The Foundation does not need the Department to agree with anything in the reports. It needs only to establish that the material arrived, because Part II.E.6 turns on the distinction between information received under § 360ii(a)(3) and information evaluated under § 360ii(a)(4), and that distinction presupposes receipt.

The acknowledgment returned from the Center for Devices and Radiological Health reads, in full:

> *"Thank you for your email. We will process your request as soon as possible."*
>
> *"Rad Health Customer Service"*
>
> *"FDA Center for Devices and Radiological Health"*

4. Transmittal to the National Highway Traffic Safety Administration

The letter of December 1, 2025 described at Part II.J.1.c was addressed jointly to the Commissioner of Food and Drugs and to the Administrator of the National Highway Traffic Safety Administration, and transmitted the same three compilations to both. The Foundation has also corresponded with that agency separately, as Part IV.C describes.

5. Transmittal of the petition comments and signature totals

A distinction has to be drawn here, because two different bodies of comment are easily conflated and the comment should not conflate them.

The first is the comments filed on the Foundation's citizen petitions to this Department, which appear on the public dockets at regulations.gov under the docket numbers given at Part IV.C.1. Those are already in the Department's possession as a matter of course, because they were filed with it.

The second, and the subject of this subsection, is the comments left on a public petition hosted on a commercial petition platform and addressed to the Department of Transportation, concerning the brightness of vehicle headlamps. Those comments are not filed with any agency by the people who write them. The Foundation has compiled them and transmitted them to this Department repeatedly since 2022, most recently as part of the periodic transmittals described at subsection 2 and in the consolidated letter of December 1, 2025, which covered comments from November 17, 2016 through November 30, 2025 and recorded that the petition had reached 75,000 signatures on November 28, 2025 and that the comments exceeded 4,700.

The Foundation states the limits of that material here rather than leaving them to Part VII. Signatures on a public petition establish that a number of people were willing to sign it. Comments on such a petition establish that those who wrote them described what they describe. Neither is a sample of anything, neither was collected under any protocol, and neither establishes the prevalence or the cause of any effect. Part VII.A.5 and Part VII.G set out what the Foundation does and does not claim from self-reported data.

What the material is offered for in this Part is narrower. It is evidence of what has been placed before the agency. A body of several thousand first-hand accounts, transmitted periodically over more than two years to the agency holding the authority at § 360ii(a)(4), is a fact about the agency's information position whatever is made of the accounts themselves.

6. Correspondence to other agencies and to manufacturers

The Foundation has corresponded with other federal agencies and with manufacturers and operators on the same subject. Part II.H.21 and Part IV.C describe the correspondence with agencies. Two sequences belong in this subsection because they concern the transmittal of information rather than requests for action.

The first is a document titled Notice of Dangerous Condition, sent in late June 2024 to a number of federal agencies including the Environmental Protection Agency, the Consumer Product Safety Commission, the Federal Aviation Administration, the Federal Highway Administration, the Access Board, the Department of Labor and the Food and Drug Administration.

The second is a document titled Compliance with 21 U.S.C. § 360ii, sent to the same agencies and to others in late June and early July 2024, in the weeks following the Final Response of May 24, 2024.

The Foundation has also written to utilities, to municipalities and to manufacturers concerning particular installations and products. Part IV.C and Part IV.E describe those where they bear on the matters in this comment.

7. Consequence: the reports are records within the Department's own possession

The consequence is the one this Part exists to establish, and the Foundation states it without embellishment.

The material described above is in the Department's own records. It was not published and then pointed to; it was sent to the agency, periodically, over a period exceeding two years, at an address the agency maintains for the purpose. The Department does not have to accept the Foundation's account of what the reports say in order to verify that they were received, and it does not have to accept the reports themselves in order to answer the question this comment asks about them.

That question is not whether the reports prove anything. It is what was done with them. Section 360ii(a)(3) directs the Secretary to receive information from organizations on present and future potential electronic product radiation. Section 360ii(a)(4) directs the study and evaluation of emissions and of conditions of exposure. The first of those appears to have been satisfied. The Foundation has found no evidence that the second was, and Part II.F explains why a literature review of published health effects is not it.

The Foundation accordingly asks the Department to state what was done with the material after it was received: whether any evaluation of it was undertaken, by whom, and with what result; and if none was, what the Department understands § 360ii(a)(3) to require once information has been received. Part IX.H.4.

8. Summary table: date, material transmitted, recipient, form of acknowledgment

The table is to be built from the transmittal record described in subsections 2 through 6, with one row for each transmittal.

C. Regulatory Petitions Submitted by the Soft Lights Foundation

1. Petitions to the FDA under the Electronic Product Radiation Control Program

Four citizen petitions were submitted to this Department under 21 C.F.R. § 10.30, each concerning a different class of light-emitting diode product, and all four were disposed of in a single letter.

Docket No. FDA-2022-P-1151, submitted June 13, 2022, seeking regulation of LED products generally. An interim response issued November 7, 2022. The Foundation filed an update to the petition in October 2022 and a further update in 2023.

Docket No. FDA-2023-P-0233, submitted January 22, 2023, concerning LED strobe and flashing lights. An interim response issued June 30, 2023.

Docket No. FDA-2023-P-3828, concerning LED vehicle lights, published on the docket September 7, 2023, with an acknowledgment letter of the same period. An interim response issued in early 2024.

Docket No. FDA-2023-P-3879, concerning LED street lights, published on the docket September 11, 2023. An interim response issued in early 2024.

The Final Response of May 24, 2024 denied all four. It is examined at Part I.C and its stated grounds are tested throughout Part II.

2. Petition to report to Congress under 21 U.S.C. § 360jj(a)(2), submitted December 30, 2025

The fifth petition to this Department is described in full at Part II.I.5, and is summarized here only so that this list is complete. Submitted December 30, 2025 by the Foundation and by Mr. Baker jointly, under 21 C.F.R. §§ 10.25 and 10.30, it asks the Secretary to conduct the study directed by

21 U.S.C. § 360jj(a)(2) and to report to Congress. It was acknowledged on January 2, 2026, a tentative response issued June 18, 2026, and it remains pending.

a. Relief requested

The petition states its request in these terms:

> "Petitioner requests that the Health and Human Services (HHS) Secretary comply with 21 U.S.C. 360jj(a)(2), which directs HHS and its implementing agency, the Food and Drug Administration (FDA), to conduct '[a] study to determine the necessity for the development of standards for the use of nonmedical electronic products for commercial and industrial purposes' and provide a report to Congress."

The report sought is one addressing the photobiological, neurological, psychological, hormonal and other hazards of LED products; the measures necessary to protect the public; and the cooperation required with other federal agencies. The petition also invokes 21 U.S.C. § 360ii(a)(6)(A), under which the Secretary is to establish and maintain liaison with other federal agencies having related radiation control programs, and it asks that the report be provided within 365 days of submission.

b. Docket number and filing date

The petition is dated December 30, 2025 and was submitted by the Soft Lights Foundation and Mark Baker that day.

The Food and Drug Administration acknowledged it by letter of January 2, 2026, signed by Dynna Bigby, Lead Administrative Proceedings Specialist, Office of Operations, Office of Management and Enterprise Services. The letter states that "Your petition dated 12/30/2025 was received by this office on 12/30/2025" and assigns Docket No. FDA-2026-P-0028. It adds that "the acceptance of this petition for filing is a procedural matter and in no way reflects the Agency's decision on the substantive merits."

That letter fixes the date from which the response period runs. Under 21 C.F.R. § 10.30(e)(2) the Commissioner is to furnish a response to each petitioner within 180 days of receipt of the petition. Receipt was December 30, 2025. The response date was therefore June 28, 2026.

c. The interim response of June 18, 2026

The agency responded on June 18, 2026, by letter from Ellen J. Flannery, J.D., Deputy Center Director for Policy and Director of the Office of Policy, Center for Devices and Radiological Health. The operative paragraph reads in full:

> *"FDA has been unable to reach a decision on your petition because it raises issues requiring further review and analysis by agency officials. This interim response is provided in accordance with FDA regulations on citizen's petitions (21 CFR 10.30(e)(2)). We will respond to your petition as soon as we have reached a decision on your request."*

d. What the interim response establishes, and what it does not

The response was furnished on the one hundred and seventieth day of the one hundred and eighty available, and it is the fourth of the four dispositions 21 C.F.R. § 10.30(e)(2) permits: a tentative response. The Foundation does not contend that the agency missed the deadline or departed from the regulation in furnishing an interim response rather than a decision.

What the regulation asks of a tentative response is that it indicate "why the agency has been unable to reach a decision on the petition, e.g., because of the existence of other agency priorities, or a need for additional information." The reason given is that the petition raises issues requiring further review and analysis by agency officials. The regulation further provides that a tentative response may indicate the likely ultimate agency response and may specify when a final response may be furnished. The letter does neither.

3. Petitions to NHTSA for non-compliance orders — 49 U.S.C. § 30162, 49 CFR part 552

The Foundation has also petitioned the National Highway Traffic Safety Administration, under that agency's rulemaking and defect petition procedures at 49 C.F.R. part 552 and under 49 U.S.C. § 30162. Its filings there fall into three groups: petitions concerning individual vehicle models, petitions seeking generally applicable limits, and the defect notifications treated at subsection 6.

The model-specific petitions, filed during 2022 and 2023, concerned the headlamps of particular vehicles then on the market. The Foundation lists them here for completeness rather than because this comment relies on them, and they are of limited relevance to a Department whose authority runs to the emission rather than to the vehicle.

Three of those petitions were decided together, and the Foundation treats them here at some length for a reason that has nothing to do with their outcome. They were denied. The denial was published in the Federal Register, and in the course of explaining it the agency made four statements about the reach of federal law over light-emitting diode products that bear directly on the questions this Request for Information asks. The Foundation relies on those statements and not on the disposition.

The petitions were filed under 49 U.S.C. § 30162(a)(2) and 49 C.F.R. part 552 on August 5, 2022, as to a model year 2021 Ford Bronco; on August 11, 2022, as to a model year 2021 Tesla Model 3; and on September 9, 2022, as to a model year 2022 Rivian R1T. Each asserted that the vehicle did not conform to Federal Motor Vehicle Safety Standard No. 108, and each asked the agency to issue an order of non-compliance. They were denied together in Soft Lights Foundation, Denial of Petition for Decision of Non-Compliance Order, 87 Fed. Reg. 75,327 (Dec. 8, 2022), Docket No. NHTSA-2022-0109, signed by the Associate Administrator for Enforcement.

First: the agency placed the authority with this Department, and stated that it has not been exercised

The published analysis opens with the question of who regulates the emission, and answers it in two sentences that the Foundation asks the Department to read as the statement of a sister agency rather than as the argument of a petitioner. The first:

> "First, the FDA has authority to regulate certain aspects of LED products as radiation-emitting devices. 21 U.S.C. 360kk states that the Secretary of Health and Human Services shall by regulation prescribe performance standards for electronic products to control the emission of electronic product radiation from such products if the Secretary determines that such standards are necessary for the protection of the public health and safety."

The second, after noting that the Food and Drug Administration issued part 1040 pursuant to that authority:

> "Currently, there is no FDA performance standard for LED products in Part 1040."

That is the proposition this comment advances, stated by the Department of Transportation in a published decision document four years before this Request for Information issued. The Foundation does not characterize it further. It observes only that the sentence is not contested anywhere in the record this comment describes, and that the agency which wrote it was at the time declining to act on the ground that the subject belonged elsewhere.

Second: the agency rejected the proposition that the standard is confined to point sources

The Foundation records the adverse holding in full, because Part V.B.8 advances a related proposition and the Department is entitled to see the answer the responsible agency gave to it. The petitions asserted that only vehicles using spherical or point light sources can comply with Federal Motor Vehicle Safety Standard No. 108. The agency disagreed:

> "FMVSS No. 108 is not limited to 'spherical/point light sources.' Specifically, regardless of the light sources used in headlamps, headlamps all have an area from which they emit light and they all emit different intensities of light in different directions. A key to understanding this topic is that the integral beam photometry requirements are for the lamp, not the light source."

The Foundation accepts that this is the agency's position and does not ask this Department to disturb it. It asks the Department to notice what the position concedes. Photometry of the complete lamp, in candelas at specified test points, is a measurement of what leaves the assembly in a given direction. It is not a measurement of the luminance of the emitting surface within the assembly, and the same agency said so in writing fourteen months later in the terms set out at subsection 9. The two statements are not inconsistent. Taken together they establish that the only federal instrument setting numerical limits on the output of these products limits a quantity which is not the quantity at issue in Part V.B.8, and that the agency administering it knows this.

Third: the agency disposed of flicker in one sentence, by assertion

The petitions raised square wave flicker. The published answer, in full, is this:

> "With respect to flicker, FMVSS No. 108 requires that 'modulating light from the lamp [must be] perceived to be steady burning.' LED integral beam headlamp systems can meet this requirement."

The Foundation makes three observations and no accusation. The first is that the requirement is quoted from an interpretation letter of November 5, 2005 rather than from the text of the standard, which is the point developed at Part VI.C.1. The second is that the test stated is one of perception. Part V.D establishes, from the published literature and from the specifications of the instruments built to measure the quantity, that modulation at the frequencies at which these products operate is by design not perceived as flicker by a stationary observer, while remaining detectable by the moving eye and resolvable by the retina. A criterion of perception is therefore satisfied by precisely the modulation that the literature identifies as the concern. The third is that the second sentence is an assertion of fact, unaccompanied by any measurement method, any threshold, any frequency range or any citation. Part V.D.1 establishes that no standardized field measurement method for these quantities exists, that the commercially available instruments are specified to five kilohertz, and that they require on the order of one hundred lux to resolve a modulation signal at all.

Fourth: the agency held that a federal qualification scheme has no category into which a light-emitting diode fits

The last holding is narrow in its application and broad in what it demonstrates. It concerns replaceable bulb headlamps, which are qualified through a submission under 49 C.F.R. part 564:

> "The design information that must be submitted is set out in part 564 and includes information regarding the filament or discharge arc and the filament capsule. Because an LED light source lacks these components, an LED light source may not be submitted for inclusion in the Part 564 docket; and, because it cannot be submitted to the part 564 docket, a replaceable bulb headlamp may not use an LED replaceable light source."

The Foundation asks the Department to read that passage as a worked example rather than as a vehicle lighting rule. A federal scheme for qualifying a light source was written around the physical features of the sources then in use: a filament, a discharge arc, a capsule enclosing them. A source lacking those features cannot be described in the terms the scheme requires, and therefore cannot enter it at all. The agency did not treat this as a defect to be corrected. It treated it as the operation of the rule. The same structural problem is what this comment describes at Part I.B and Part II.B in relation to part 1040, where the classes of light-emitting product are defined by the characteristics of the sources that existed when the sections were written.

What the Foundation does not claim from this document

Three limits, stated so that the Department is not left to find them. The agency recorded that its Office of Vehicle Safety Compliance has found evidence that light-emitting diode headlamp assemblies can meet the current requirements of the standard, and cited two compliance test reports. The Foundation does not dispute that finding, which is a finding about conformity with photometric limits and not about effect on a person. The agency also stated that it believes the current research supports that the standard contains the appropriate requirements to address glare, non-uniform luminance, peak luminance and flicker; the Foundation disagrees but records that the agency said it. And the decision is expressly confined to integral beam headlamps using light-emitting diode technology.

One feature of the glare answer is worth stating precisely, because it is easy to read it as addressing more than it does. The agency relied on a 2007 report to Congress for the propositions that beyond approximately one hundred feet the size of a headlamp has little impact on discomfort, and that no research has identified any impact of oncoming headlamp size on the visibility of the person experiencing glare. Both propositions concern the apparent size of the lamp. Neither concerns the luminance of the emitting surface or its spatial non-uniformity, which are the quantities Part V.B.8 is about, and the second is a statement that research has not been done rather than a statement of what research has found.

4. Petition to NHTSA to limit vehicle headlamp intensity

On March 1, 2024 the Foundation petitioned that agency to set an overall limit on the intensity of vehicle headlamps. Notice of the petition was published in April 2024. The Foundation wrote again in October 2024 concerning the absence of a decision.

The relevance of that petition to this comment is set out at Part II.G.3 and Part VI.B.1. The limit sought was expressed in the units Federal Motor Vehicle Safety Standard No. 108 uses, which are photometric. Nothing in that petition, and nothing that agency could have granted, would have addressed the luminance of the emitting surface, the spectral content of the emission, or its temporal structure, because that agency's standard does not speak in those terms and it holds no authority to evaluate the biological effects that would justify limits expressed in them.

5. Petition to NHTSA to limit correlated color temperature of vehicle headlamps

On May 15, 2024 the Foundation petitioned the same agency to limit the correlated color temperature of vehicle headlamps. That petition is the closest any filing by the Foundation has come to asking a transportation agency to regulate a spectral characteristic, and the difficulty with it illustrates the point this comment makes about measurement conventions.

Correlated color temperature is a descriptor of the appearance of a source and not of its spectral content, as Part V.B.3 sets out. Two lamps of identical correlated color temperature may differ substantially in the short-wavelength emission that bears on the effects described at Part V.C. The Foundation petitioned in those terms because they are the terms in which the industry and the regulator describe a lamp. A petition framed in terms of spectral power distribution would have asked an agency with no photobiological authority to adopt a criterion no federal body has published. That gap is what Part IX.C asks this Department to close.

6. Petitions and notifications under 49 U.S.C. § 30118

Three filings invoke the defect provisions of 49 U.S.C. § 30118, and they are described at Part II.J.1.d because their significance for this comment lies in the comparison with 21 U.S.C. § 360ll.

November 16, 2024: notification to a vehicle manufacturer, copied to the agency, of non-compliance under § 30118.

June 30, 2025: a petition under § 30118(e) requesting that the agency hold a hearing to determine whether manufacturers have reasonably met the notification requirements of § 30118 for LED vehicle headlamps.

December 1, 2025: the Notice of Defective Technology addressed jointly to the Commissioner of Food and Drugs and to the Administrator, described at Part II.J.1.c.

In December 2025 the Foundation also published a form of letter and invited members of the public to send it to the Administrator seeking a hearing under § 30118(e). Part II.J.1.d.

7. Filings before the Federal Communications Commission

The Foundation sets out what this comment establishes about that Commission and states expressly what it does not reproduce here.

What the record establishes. Part II.H.8 identifies the Commission among the federal agencies with which this Department is directed to consult and maintain liaison, and sets out its public request for comment. Part II.H.20 sets out the one documented instance of consultation between this Department and that Commission in the history of the program, which was a letter of April 24, 2019 from the Director of the Center for Devices and Radiological Health to the Chief of that Commission's Office of Engineering and Technology, and which concerned radiofrequency energy rather than optical radiation. Part VI.L treats the product class that emits both.

What is open now. Part IX.E.4.b sets out Public Notice DA 26-997, released on September 17, 2026 in ET Docket No. 13-84, and the request the Foundation makes of this Department in respect of it. That request is the operative one and it is addressed to this Department rather than to the Commission.

What this subsection does not contain. The Foundation's own filings before that Commission, if any, are not reproduced in this comment. The reason is one of scope rather than of reticence: the subject of that docket is radiofrequency energy, the subject of this comment is visible light, and Part IX.E.4.b states both that the Foundation recognizes the difference and why it regards the Department's participation in that proceeding as material notwithstanding. A reader who wishes to know what the Foundation itself has filed with that Commission should not infer it from this Part, which documents what was asked of federal agencies about these products and what resulted.

8. Petitions and proceedings before state regulatory bodies

The Foundation has petitioned a substantial number of State bodies, and this comment does not describe them individually. Three categories are relevant to a federal department and are summarized here.

Public utility commissions, concerning the conversion of street lighting. Proceedings include a matter before the New York State Public Service Commission and a petition before the Idaho Public Utilities Commission, which was denied by final order.

State emergency medical services boards and departments of motor vehicles, concerning the lamps on emergency and public-safety vehicles. Petitions were filed in a number of States during 2023 and 2024 and were denied, several on the ground that the body had no authority over the subject.

The California Highway Patrol, concerning auxiliary and flashing lamps, in a sequence of petitions and appeals running through 2024 and 2025.

The Foundation includes this category for a reason connected to Part II.E.3. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from State departments and agencies. These proceedings are where the question has in fact been litigated at the State level, and the records of them are in the hands of the State bodies this Department is directed to receive information from.

9. Requests for agency interpretation and the interpretations issued

One interpretation has been obtained and read in full, and it is the most useful single document the Foundation holds from this agency. On February 13, 2024 the Acting Chief Counsel of the

National Highway Traffic Safety Administration replied to a letter of June 27, 2021 and an email of October 31, 2021 from Mark Baker, which had asked whether Federal Motor Vehicle Safety Standard No. 108 regulates peak luminance, absolute spectral power distribution or flicker, and what the agency's position is on the safety of light-emitting diode light sources in headlamps.

The Foundation sets out what the reply states, in four parts.

The standard contains no performance requirement for the light source at all

> "The standard does not contain performance requirements for a light source that is part of an integral beam headlamp, but instead specifies performance requirements for the complete headlamp. These include (among other things) photometry, through minimum and maximum candela at specified test points, color, which must remain within specified boundaries, and that the headlamp be steady burning."

Read with the passage from the Federal Register denial quoted at subsection 3, this establishes the position without ambiguity. There is no federal performance requirement for a light-emitting diode used as the light source in a vehicle headlamp. There are requirements for the assembly that contains it. The source itself is governed by no federal emission standard under the transportation authority, and, by the same agency's account of part 1040, by none under this Department's authority either.

The two quantities at issue in this comment are expressly outside the standard

> "FMVSS No. 108 does not directly regulate what you describe as peak luminance as measured in nits or the spectral power distribution of the headlamp light source. However, this is indirectly regulated through the headlamp performance requirements, such as the photometry and chromaticity requirements. Additionally, flicker is regulated through the requirement that lower beam headlamps be steady burning."

The Foundation quotes the qualification as well as the admission, because the qualification is where the disagreement lies and the Department should see both. The agency's position is that peak luminance and spectral power distribution are regulated indirectly, through photometry and chromaticity. Part V.B.2 and Part V.B.8 set out why the Foundation regards that as unsound: luminous intensity integrated over a lamp aperture does not constrain the luminance of a small bright region within it, and chromaticity, being a two-coordinate summary of appearance, does not constrain the spectral power distribution that produces it. Two sources of identical chromaticity can differ substantially in short-wavelength content. That is the whole of the Foundation's objection, and it is an objection to a stated agency position rather than to a silence.

The flicker sentence should be read narrowly. What it asserts is that flicker is regulated through the requirement that lower beam headlamps be steady burning. It is confined to the lower beam, it is a requirement of operation rather than a limit on a measured quantity, and the meaning the agency gives to it is set out next.

What steady burning means, in the agency's own words

The letter defines the term in a footnote, locating the requirement in Tables I-a and I-c of the standard, and the Foundation regards this as the single most useful sentence it has obtained from the agency:

> "NHTSA has stated that 'steady burning' means 'light that is essentially unvarying in intensity.'"

That definition is attributed to a letter of the Chief Counsel dated February 9, 1982. The footnote adds two glosses. A device may fail to meet the requirement where the driver would not see a signal that was consistent or reliable in its meaning, from a letter of September 7, 1990 applied in a tail lamp context. And, in the context of a modulating motorcycle headlamp, the agency has stated that there is no failure to conform if the modulating light from the lamp is perceived to be a steady beam, from a letter of March 10, 1994.

The Foundation asks the Department to hold the definition and the gloss side by side, because the two are not the same test and the difference is the subject of Part V.D. Light that is essentially unvarying in intensity is a statement about the light. Light that is perceived to be a steady beam is a statement about an observer. A lamp driven by pulse-width modulation at a few hundred hertz, which Part V.D.1 establishes is the ordinary arrangement in these products and which by the definition of the technique extinguishes completely between pulses, is not light that is essentially unvarying in intensity. It is light that is perceived by a stationary observer to be steady. Under the 1982 definition it would not qualify. Under the 1994 gloss it does.

The provenance of the gloss is worth stating. It was given about a motorcycle headlamp modulator, a device deliberately designed to vary its output at a few hertz so as to be conspicuous, where the question was whether deliberate conspicuity modulation defeated the steady burning requirement. It is that interpretation which the agency applied in 2022, in the Federal Register, to dispose of flicker in light-emitting diode headlamps operating three orders of magnitude higher in frequency. The Foundation does not suggest the extension was made in bad faith. It observes that a perception test devised for a low-frequency conspicuity device, where perception was the hazard, has been carried over to a high-frequency modulation where the absence of perception is the reason the modulation is used, and that no one appears to have examined whether the test still measures anything.

The deferral, and an acknowledgment of the subject matter

The letter closes on the health questions put to the agency:

> "We are aware of concerns raised about possible adverse effects of certain LED devices, particularly as used in street lighting that emits excess blue light. NHTSA's focus is on automotive safety, but the agency recognizes that separate expertise resides in sister agencies that are health-focused, such as the Food and Drug Administration."

The first sentence is supported in the letter by a citation to the guidance adopted by the American Medical Association on June 14, 2016 to reduce harm from high intensity street lights. The Foundation notes the citation because it is an instance of a federal agency, in correspondence, identifying a health concern about this product class by reference to the position of a national medical body, and because the Department is asked at Part II.E to receive information of exactly that kind.

The second sentence is the second of the two deferrals set out at Part II.H.5. It was given fourteen months after the first, by the Office of the Chief Counsel rather than by the Office of Enforcement, in response to a different inquiry, and in substantially the same terms.

One further concession, on color

A footnote to the same letter addresses the white boundary, quoting an interpretation of July 4, 2000 to the effect that it is possible to design a headlamp that emits a light that approaches the blue boundary and is perceived as having a blue tint but which nevertheless remains within the boundaries that define white, and that such headlamps would comply with the color requirements of the standard. The letter states the same point in its own voice: although the standard requires that the light emitted by headlamps be white, the permissible boundary of white includes colors that may be perceived by the human eye as white with a yellow tint and white with a blue tint. Part V.B.3 and Part V.F rely on that concession. A chromaticity boundary wide enough to admit a visibly blue headlamp is not a constraint on short-wavelength content, and the agency has said so.

D. Litigation Brought by Mark Baker Individually Against the FDA

1. Baker v. FDA, No. 2:24-cv-00278-DC-SCR (E.D. Cal.) — filed January 22, 2024; voluntarily dismissed September 26, 2024

The action sought to compel the Food and Drug Administration to publish performance standards for light-emitting diode products under § 360ii(a). It was dismissed voluntarily after the hearing on the motion to dismiss and before any adjudication on the merits.

The Foundation records one point of disagreement on the record rather than resolving it. The findings in the later action treat the two proceedings as substantively related. The objection filed in that action disputes that characterization. Both characterizations are in the record and the Foundation does not ask this Department to prefer either.

2. Baker v. FDA and NHTSA, No. 2:24-cv-02558-DC-SCR (E.D. Cal.) — the § 360ii(a)(6)(A) liaison duty; pending

Filed September 23, 2024. Findings and recommendations recommending dismissal issued September 16, 2025; objections were filed September 23, 2025; the matter is pending before the district judge.

Two holdings in the findings and recommendations bear on this comment and they cut in different directions, so the Foundation states both. On the liaison claim the court found standing, including redressability, and found the claim insufficient under Rule 12(b)(6). On the claim concerning the Safety Committee the court found no standing, for want of redressability.

The Foundation draws from the first of those only what it says: that a claim resting on the liaison duties of § 360ii was held to be one a court could redress. Part I.C sets out the positions the United States has taken on this record and Part II.M sets out what the Foundation makes of them.

3. Baker v. FDA, No. 2:26-cv-02776-DJC-CSK (E.D. Cal.) — FOIA action for CDRH records on LED visible light products

The chronology of the Request

The Foundation sets the sequence out as a chronology. What the Request sought is described in the preceding paragraphs of this subsection.

Capacity in which it was submitted. Request No. 2025-3046 was submitted by Mr. Baker individually as a consumer requester and, in the accompanying cover letter, by him as President of the Foundation. Two signature blocks appear on it, which the agency admits.

Acknowledgment. The Request was acknowledged and assigned FOIA Control No. 2025-3046.

Expedited processing was denied on April 4, 2025.

No determination was made on the fee waiver request.

A status communication followed on July 16, 2025.

A complaint was filed on August 12, 2026, pleading three counts: three counts under 5 U.S.C. §§ 552(a)(6)(A), 552(a)(3), and 552(a)(6)(E).

The Answer of September 14, 2026, and the admission at paragraph 32

Paragraph 32 of the Complaint alleges:

> *"As of the filing of this Complaint, Defendant has not made a determination on the Request, has not produced any records responsive to the Request, and has not asserted any FOIA exemption with respect to any responsive record."*

The Answer responds, in full:

"Defendant admits the allegations of this paragraph."

Affirmative defenses were asserted in the Answer.

Status. No record has been produced and no search has been described.

Capacity. The litigation is Mr. Baker's individually. The Foundation is not a party to it, and Part IV.A.2 records the distinction between the two capacities.

4. What the agency has and has not made available

Records produced in response to Request No. 2025-3046 to date: none. No search declaration has been filed, and the agency has not described the scope or the method of any search it has conducted.

The Foundation states why that bears on this comment rather than on the litigation. A sworn account of what the agency searched and what it holds would go directly to the subsections of Part II concerning the duty to study and evaluate: Part II.F establishes that the Foundation has identified no study or evaluation of the optical emissions of these products, and that is a statement about what the Foundation has been able to find. An account from the agency of what it holds would either confirm it or displace it, and no other document available to any member of the public would.

E. Related Litigation and Administrative Proceedings Concerning LED Exposure

1. Federal actions concerning flashing LED devices in public rights-of-way

The proceedings in this subsection concern rectangular rapid-flashing beacons at pedestrian crossings and auxiliary flashing warning lamps on municipal vehicles. They are brought by Mr. Baker in his individual capacity, as Part IV.A.2 explains, and the Foundation's role in them is limited to the publications and the correspondence identified below.

Baker v. City of Woodland, No. 2:26-cv-00091-DAD-AC (E.D. Cal.), before District Judge Dale A. Drozd and Magistrate Judge Allison Claire. A Title II action concerning auxiliary flashing warning lamps on City vehicles. The operative pleading is a Second Amended Complaint organized around the self-evaluation obligation of 28 C.F.R. § 35.105. Part VIII.

A Title II action against the City of Davis concerning the City's rectangular rapid-flashing beacons, in preparation as of the date of this comment. A government claim was presented to the City on August 21, 2026 concerning an incident of August 20, 2026.

Administrative requests to the City of Davis, each submitted individually: a request for reasonable modification and effective communication under Title II dated September 20, 2026; a request that the City evaluate its use of flashing lights under 28 C.F.R. § 35.105 dated October 3, 2026; and a request under the California Disabled Persons Act, Civil Code §§ 54 and 54.1, dated October 4, 2026.

A request to the City of Elk Grove under Civil Code §§ 54 and 54.1, modeled on the Davis request, concerning the flashing lamps the City operates in the public way.

Correspondence in the Foundation's capacity to the city attorneys of Davis, Woodland, Winters and West Sacramento, to Yolo County Counsel and to the Yolo County Public Agency Risk Management Insurance Authority, dated August 28, 2026, and to the League of California Cities. The Foundation has also furnished its papers to individuals pursuing accommodation requests in their own names in other States, including a matter before the City of Sanford, Florida.

The determination of the Minnesota Department of Human Rights, June 15, 2023

One document in this Part is not a filing by the Foundation or by Mr. Baker. It is a determination by a State civil rights enforcement agency, issued after investigation into the charge of a private

individual for whom the Soft Lights Foundation acted as an advocate. The Foundation discloses that role at the outset and places the determination here because of what it decided and what it declined to treat as an answer.

On June 15, 2023 the Minnesota Department of Human Rights issued a memorandum in its file REF: 74059. The charging party is a woman whose disability-related symptoms are triggered by high-luminance strobing LED light. The respondent is a Minnesota city of approximately 10,500 residents, which installed a rectangular rapid-flashing beacon system at a crosswalk near her home. The memorandum opens:

> The Commissioner determines: 1. There is PROBABLE CAUSE to find that Respondent discriminated against Charging Party because of her disability.

And concludes, at page 6:

> THEREFORE, MDHR finds that there is PROBABLE CAUSE to find that Respondent discriminated against Charging Party, in violation of the MHRA.

The Foundation is precise about what that is and is not. A probable cause determination under the Minnesota Human Rights Act is a threshold finding by an enforcement agency that a charge warrants proceeding. It is not an adjudication of liability, it was not made under federal law, and it is not a finding that LED light is hazardous to the general population. It concerns one person, one installation and one city. The Foundation does not present it as more than that.

What makes it material to this request for information is the reasoning. The city defended on the ground that its beacon complied with the applicable federal criterion. The Department addressed that defense at page 4:

> Respondent's contention that the RRFB's "flash rate" was consistent with federal guidelines is irrelevant to the determination of whether providing an accommodation would have imposed an undue hardship.

That sentence describes the condition this comment is addressed to. A federal criterion existed and the city invoked it. The criterion governed flash rate. It said nothing about the luminance of the emitting surface, nothing about the spectral content of the emission, and nothing about the characteristics that produced the symptoms at issue, because no federal criterion addresses those characteristics for this class of product. Parts II.C.3 and V.J.

The consequences fell where the absence of a standard places them. The memorandum records that on February 8, 2022 a vendor quoted $8,616.45 to replace the existing beacon lights, that the quote was never formally evaluated, and that the city's director concluded the city would "stick with what we have," explaining that further exploration of alternatives appeared unnecessary because the city "still get[s] a lot of good comments on [the existing module] and the person causing all of the trouble hasn't sent anything in a while." The memorandum also records that the charging party's symptoms on one occasion "continued into the next day, and Charging Party was unable to go to work."

The Foundation draws three propositions from this determination.

- A State enforcement agency, applying a State civil rights statute after investigation, found probable cause that the operation of an LED flashing beacon in the public way discriminated against a person with a disability. Whatever the eventual disposition of that charge, the determination is of record.
- Compliance with the one federal criterion available to the respondent was held irrelevant to the question the agency had to decide. A party in that position has nothing else federal to point to, and a charging party has nothing else federal to cite.
- The city was left to evaluate an $8,616.45 equipment change with no federal measurement, no criterion of acceptable exposure and no federal evaluation of whether the alternative would

have reduced exposure at all. Paragraph 360ii(a)(5) directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure. Part II.G.

The Foundation identifies neither the charging party nor the respondent city beyond what the published memorandum itself discloses, consistent with Part I.F.

The Foundation states these matters because they establish where this question is presently being decided, not because it asks the Department to take any view of them. Part IV.E.4.

2. Proceedings concerning LED streetlights and area lighting

The proceedings in this subsection concern the conversion of street lighting to light-emitting diodes. They were brought before State utility regulators and addressed to utilities, and they are the clearest illustration in this comment of a question arriving in a forum that cannot answer it.

a. New York State Public Service Commission, Case 23-E-0727

On December 13, 2021, fifty-two residents and customers of the Village of Cambridge, Washington County, New York, filed a complaint concerning National Grid's conversion of the Village's streetlights to light-emitting diodes. The complaint invoked New York Public Service Law § 71, which provides that upon the written complaint of a village's trustees, or upon the written complaint of not less than twenty-five customers or purchasers, "the commission shall investigate as to the cause for such complaint."

The Commission issued its Order Denying Petition on November 14, 2025, three years and eleven months after the complaint was filed. The ground of the denial was that the petitioners were not the utility's customers. The Order states, at pages 7 and 13:

> "Here, National Grid's customer is the Village. The Village can choose the service it wants to receive from National Grid within the confines of National Grid's tariff."

On November 23, 2025 the Foundation wrote to the Attorney General of New York concerning that interpretation. On November 30, 2025 the Foundation and Mr. Baker as its President filed a Petition for Rehearing under 16 N.Y.C.R.R. §§ 3.7 and 3.8. The petition is directed to the construction of § 71 and not to the photobiology, because the construction of § 71 is what the Commission decided.

The Foundation offers this proceeding for a single proposition, and it is not a criticism of the Commission. A State public service commission determines what service a tariff permits a utility to supply and to whom. Nothing in its jurisdiction equips it to determine the photobiological effect of a spectral power distribution, and nothing in the record before it supplied a federal criterion by which such an effect could have been assessed. The question that fifty-two people raised in 2021 was resolved in 2025 on the identity of the customer.

b. Oregon Public Utility Commission

The Foundation filed materials with the Oregon Public Utility Commission in June 2022 and submitted public comments in September 2022. On September 12, 2022 Administrative Law Judge Nolan Moser wrote to the Foundation as follows:

> "Staff have seriously reviewed your materials and determined that they will not open an investigation at this time, but will instead monitor the investigations in other jurisdictions and the reviews conducted in other agencies. Additionally, they welcome the submission of any new completed medical study material that may be completed, and will review that if it is submitted to them. In short, Staff is willing to review materials in the future, but does not see the need for an Oregon-specific investigation at this time."

The Foundation draws attention to the second clause. The Commission did not conclude that the materials were without substance; it concluded that it would await the investigations of other

jurisdictions and the reviews of other agencies. That is the pattern Part II.H documents at the federal level, appearing here at the State level, and paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from State departments and agencies. Part II.E.3.

On October 22, 2024 the Foundation renewed the request, addressed jointly to the Commission and to the Oregon Health Authority, on the express ground that new material had become available. The material it submitted was the report described at Part V.C.2.f. The Commission had invited the submission of new study material and the Foundation supplied it.

c. Other State utility regulators and correspondence with utilities

The Foundation has filed with or written to utility regulators in a number of other States, and in July and August 2023 it wrote to the operators of street lighting systems directly, including Pacific Gas and Electric, Southern California Edison, Sempra, Duke Energy Carolinas, FirstEnergy and Chelan County Public Utility District. Those letters stated that the Food and Drug Administration has published no performance standard governing the visible light emitted by LED street lighting and asked the recipients to account for operating the products in the absence of one.

The Foundation also brought a complaint against Duke Energy Progress before the utility regulator in North Carolina in 2022, in which discovery was taken and a hearing was requested and refused.

3. Proceedings concerning high-intensity LED deterrent lighting

Two actions concern high-intensity blue-rich LED units installed for deterrent and surveillance purposes on commercial property. Both are brought by Mr. Baker individually.

Baker v. Regency Centers Corporation and LiveView Technologies, Inc., No. 2:26-cv-00017-TLN-JDP (E.D. Cal.), before District Judge Troy L. Nunley and Magistrate Judge Jeremy D. Peterson. Commenced in the Superior Court of California, County of Yolo, and removed. The property at issue is Oakshade Town Center in Davis. The first cause of action arises under Title III of the Americans with Disabilities Act; the remaining causes of action arise under the Unruh Civil Rights Act, the Disabled Persons Act, and the law of public nuisance. On August 31, 2026 the Magistrate Judge issued revised findings and recommendations recommending dismissal of the federal claim for lack of standing and remand of the State claims.

Baker v. LiveView Technologies, Inc., No. CU25-06372 (Super. Ct. Cal., Solano County), arising from a blue LED deterrent lighting installation at a shopping center in Vacaville. Three other defendants have settled and LiveView Technologies remains. Mediation is set for December 2026.

One item in the record of those proceedings bears on Part V.J rather than on the litigation. The Foundation commissioned an independent measurement report on the units from Ken Walczak of Night/Light Consulting, LLC. The Foundation commissioned it because no federal measurement convention existed to which a complaint could refer, and because no federal body measures these products. A private party had to pay for the measurement that Part II.F asks the Department to perform.

4. Relevance of these proceedings to the Department's inquiry

The Foundation does not ask the Department to intervene in any of these proceedings, to take a view of their merits, or to treat their outcomes as findings. Most of them have been unsuccessful, and the Foundation states that plainly because it is the point rather than a concession.

What the proceedings have in common is the forum's inability to reach the question. Each tribunal has jurisdiction over something adjacent to the emission and over nothing that would resolve it.

A State public service commission can determine what service a tariff permits and who the customer is. It cannot determine whether a spectral power distribution is hazardous.

A federal court hearing a Title II claim can determine whether a public entity evaluated its services and programs as 28 C.F.R. § 35.105 requires. It cannot prescribe an emission limit, and it has no criterion by which to assess one.

A State court in nuisance can determine whether a particular installation is unreasonable as against a particular neighbor. It cannot establish a criterion of general application, and the next installation is unaffected by its judgment.

A utility, asked to account for operating a product, can answer that no federal requirement governs its optical output. That answer is accurate.

In every one of these matters the tribunal had to proceed without a federal performance standard, without a federal measurement convention, without a federal evaluation of emissions or conditions of exposure, and without any federal determination of what level of optical exposure is acceptable. The absence of those things is not a grievance about the proceedings. It is a description of the material a tribunal would need and does not have, and 21 U.S.C. § 360ii assigns the production of that material to the Secretary.

Two of the proceedings add a further element. The Oregon Public Utility Commission stated in terms that it would await the reviews conducted in other agencies. The New York Commission took three years and eleven months and then decided the matter on the identity of the customer. Neither disposition reflects a judgment that the underlying question is unimportant, and neither could have been a judgment on the underlying question, because the material on which such a judgment would rest does not exist.

That is the whole of what the Foundation asks the Department to take from this Part. Not that any of these tribunals erred, but that the question has been put to a State utility regulator, to federal and State courts, to a State civil rights agency, and to the operators of the systems themselves, and that it cannot be answered in any of those places until the Department does the work 21 U.S.C. § 360ii directs. Part IX.

F. Congressional Action [RFI Q5.n, Q17]

1. The FY2026 appropriations directive on low beam headlamp brightness

The directive, as carried in H. Rept. 119-212, reads:

> *Headlight brightness.–The Committee urges the Secretary of Transportation to report to Congress on what gaps may exist related to the impact of the brightness of low beam headlamps on the vision and safety of drivers, pedestrians, and other road users, including the effect of varied terrain, including hills and curves.*

2. Why the enacted directive matters to the Department

Congress has directed a report on the vision and safety effects of light emitted by an electronic product. The Foundation asks the Department to attend to the measurand Congress named. Brightness is a property of optical radiation, and optical radiation emitted from an electronic product as a result of the operation of an electronic circuit is electronic product radiation within § 360hh(1)(A), which Part II.B establishes.

The consequence is a liaison consequence rather than a jurisdictional complaint. The subject matter Congress assigned for study in that directive is this Department's subject matter under § 360ii, and the agency directed to perform the study holds no authority over the emission. Part II.H.5 sets out that agency's own statements that the expertise relevant to the health questions resides in this Department. Part IX.E.4.a asks this Department to consult it, and identifies the proceeding in which the question is live.

3. The April 2026 House amendment directing study of LED headlamps

A House amendment directing study of light-emitting diode headlamps is recorded in the Foundation's correspondence file. The Foundation does not state its date, vehicle or citation in this comment, because it has not established them to the standard the rest of this Part observes, and a congressional action stated with the wrong vehicle or date is worse for this record than one not stated at all.

What the Foundation does record is that the enacted directive at Part IV.F.4 and the correspondence at Part IV.F.5 are the items in this Part on which it relies, and that neither depends on this one. Part IV.F.6 sets out the implementation question.

4. H.R. 7772, the LIGHT Safety Act, 119th Congress

S. 1568 and H.R. 3341, the LIT Act of 2025

A bill now before the Senate would repeal the rules examined at Part IV.G. The Liberating Incandescent Technology Act of 2025, S. 1568, was introduced on May 1, 2025 by Senator Mike Lee, with Senators Justice, Cotton, Schmitt, Curtis and Hagerty as cosponsors. Its long title is "To amend the Energy Policy and Conservation Act to modify standards for general service lamps, and for other purposes." It was referred to the Committee on Energy and Natural Resources and reported favorably by that Committee on September 30, 2026. A House companion, H.R. 3341, has not advanced.

The bill would strike section 325(i) of the Energy Policy and Conservation Act, the general service lamp efficiency provision, and would terminate three Department of Energy rules: those published at 87 Fed. Reg. 27,439 and 87 Fed. Reg. 27,461, both of May 9, 2022, and 89 Fed. Reg. 28,856 of 2024. Those are the same three rules described at Part IV.G.2 and whose environmental determinations are examined at Part IV.G.7.

The Soft Lights Foundation supports S. 1568. Its ground is narrow, and it is the ground of this comment rather than of the debate surrounding the bill.

The rules the bill would terminate had the practical effect of replacing the incandescent lamp with the light-emitting diode in American homes, schools and workplaces. Before they took effect, no federal body determined whether the replacement emission was safe for the people who would live under it. The consultation directed by 21 U.S.C. § 360ii(a)(6) — between this Department and other appropriate Federal departments and agencies, on techniques, equipment and programs for testing and evaluating electronic product radiation and on the development of performance standards — did not take place. The Foundation has sought records of any such consultation, including by request under the Freedom of Information Act, and none have been produced. Parts II.H.4, IV.D.3 and IV.G.6.

The Foundation is careful about where it places that failure, and its position here is the same as the one it takes at Part IV.G.6. The Energy Policy and Conservation Act imposes no duty on the Secretary of Energy to consult this Department. The duty runs the other way: § 360ii places it on the Secretary of Health and Human Services. The Foundation does not contend that the Department of Energy acted improperly. It contends that a federal measure which determined in practice what technology would illuminate the country took effect without the evaluation Congress assigned to this Department, and that the measure ought not to remain in force while that evaluation remains undone. The specific defect is set out at Part IV.G.4.d. The standard imposes a single parameter, lumens per watt, and no other, with the consequence that every emission characteristic bearing on human response was left to the manufacturer, unconstrained by any federal requirement.

Two things follow from the narrowness of that ground, and the Foundation states both so that its position is not mistaken for a larger one. It takes no view on the energy, cost, manufacturing or trade questions that occupy the remainder of the debate. And it does not contend that repeal

would answer the health question. Repeal would not produce the study. Only this Department can produce the study, and Part IX asks it to.

The legislative record shows something further, which is the terms on which the question is being argued, and they bear on this request for information independently of the bill's merits. The case made for the bill is consumer choice and the proper limits of federal energy policy. The case made against it, by the National Electrical Manufacturers Association and others, is product quality, household energy cost and foreign competition. Neither side's argument reaches the question whether the transition those rules produced had any effect on human health, because no federal evaluation of that question exists to be cited.

That is the condition this comment describes, appearing in a third place. Congress is now considering whether to repeal the measures that produced a nationwide change in the spectral composition of artificial light. Whichever way it decides, it will decide without any federal study of what that change did to the people exposed to it, because 21 U.S.C. § 360ii(a)(2) and (a)(4) have not been carried out as to this radiation. Part IV.G.5.

5. Congressional correspondence and requests for inquiry

Two items of congressional correspondence bear directly on this Department, and both precede the determination of May 24, 2024.

a. Representative Mike Thompson to Commissioner Califf, July 28, 2023

On July 28, 2023 Representative Mike Thompson of the Fourth District of California, Ranking Member of the Subcommittee on Health of the Committee on Ways and Means, wrote to Robert M. Califf, Commissioner of Food and Drugs. After describing constituent concern about excessively bright automotive headlights, the letter stated:

> The Radiation Control provisions of the Food, Drug, and Cosmetic Act (FDCA), under 21 USC 360ii(a) direct the Secretary of FDA to establish an electronic product radiation control program by, among other things, promulgating performance standards for electronic products. Under 21 USC 360kk(a) the Secretary of the FDA "shall by regulation prescribe performance standards for electronic products to control the emission of electronic product radiation from such products if he determines that such standards are necessary for the protection of the public health and safety."

The letter closed:

> I ask you to provide full and fair consideration to prescribing performance standards for automobile LED headlights that would address the health and safety issues related to excessively bright headlights.

The Foundation notes what the letter demonstrates and nothing beyond it. A Member of Congress identified this Department as the authority over the emission, identified the statutory provisions by section, and asked the Commissioner to consider prescribing a standard. He did so ten months before the Final Response issued. Whatever weight a single letter carries, the proposition that the subject had not been drawn to the agency's attention is not available.

b. The agency's representation relayed through Senator Maria Cantwell, March 21, 2023

On February 16, 2023 Senator Maria Cantwell inquired of the Food and Drug Administration on behalf of a constituent as to the status of citizen petition FDA-2022-P-1151. On March 21, 2023 the Senator's office relayed the agency's reply, which read in part:

> FDA provided an interim response to the citizen petition (FDA-2022-P-1151) on November 7, 2022, in accordance with the regulations at 21 CFR 10.30(e)(2)(iv). Our interim response informed the petitioner that FDA has been unable to reach a decision on the petition because it raises issues requiring further review and analysis by agency officials. Please be assured that we

> are working diligently and considering carefully the scientific and other information that was submitted in the citizen petition, as well as information submitted to the public docket by interested persons. After FDA has considered the available scientific data and other information, we intend to issue a response to the citizen petition.

The Foundation does not suggest that the representation was inaccurate. The agency did consider the petition and did issue a response. The Foundation relies on the representation for a narrower purpose, and it is the ground of the request made at Part IX.H.2.

The agency told a Member of the Senate that its decision would follow its consideration of the available scientific data. The decision, when it came, rested in part on a literature search and systematic review performed by an organization the agency has not named, under a protocol it has not published, reaching a conclusion about the quality of the evidence that no reader can evaluate. A representation to Congress that a determination will rest on the scientific record carries with it, in the Foundation's submission, a reason to publish the record the determination rested on. That is all the Foundation asks under this head.

6. Implementation status: whether NHTSA has begun the directed report

Congress has directed the Secretary of Transportation to examine low beam brightness. The Foundation has not established whether that examination has begun, and states the question rather than an answer.

The point it does press is the one at Part IV.F.2. The emission to be examined is optical radiation from an electronic product, which is this Department's statutory subject matter under § 360ii, and the examination is directed to a Department that holds no authority over it. That is the circumstance in which the liaison duties at § 360ii(a)(3) and (a)(6) operate, and Part II.H.5 sets out the record of consultation between the two Departments on vehicle lighting. Part IX.E.4.a asks that the consultation be established and that the Department state on the record whether any has occurred.

G. Department of Energy Actions and the Federal Lamp Efficiency Framework

1. EISA 2007 and the statutory 45 lumens-per-watt backstop — 42 U.S.C. 6295(i)(6)

Section 321 of the Energy Independence and Security Act of 2007, Pub. L. 110-140, added what is now 42 U.S.C. § 6295(i)(6)(A). Clauses (i) through (iv) directed the Secretary of Energy to conduct rulemakings on standards for general service lamps. Clause (v) supplied the consequence of not doing so. As the Department of Energy later described it, if that Department fails to complete a rulemaking in accordance with clauses (i) through (iv), or if the final rule from the first rulemaking cycle does not produce savings greater than or equal to the savings from a minimum efficacy standard of 45 lumens per watt, the statute requires that Department to prohibit the sale of general service lamps that do not meet a minimum efficacy of 45 lumens per watt, effective beginning January 1, 2020.

The Foundation states two things about that provision at the outset, because the rest of this Part depends on the distinction.

> Congress chose the figure and the metric. Forty-five lumens per watt is a statutory number, and lumens per watt is the unit Congress wrote into the United States Code. Nothing in this comment asks the Department of Health and Human Services to question the authority of Congress to set an efficiency standard for lamps, and nothing in it asks that the figure be revisited as a matter of energy policy.
>
> The Department of Energy chose the rest. Which lamps fall within the definitions to which the standard applies, when the backstop was triggered, and what levels would succeed it were determined by agency action across the rulemakings set out in the next subsection.

The Foundation also accepts, without reservation, that lumens per watt is a well-constructed measure of what the Energy Policy and Conservation Act is concerned with. That Act is an energy conservation statute, the quantity it seeks to conserve is electrical power, and the quantity it seeks to deliver is useful light. A ratio of the second to the first is the natural expression of that purpose. The criticism in subsection 4 is not that Congress chose the wrong metric for energy conservation. It is that a measure framed in that metric functioned in practice as a determination of which technology would illuminate the country, and that the consequences of that determination outside energy were evaluated by no one.

2. DOE general service lamp definition and standards rulemakings, 2017–2024

The administration of that provision took seven years and reversed direction twice. The sequence is set out below because it establishes both how many opportunities for the consultation described at subsection 6 arose, and what each proceeding was about.

January 19, 2017. Two final rules, 82 Fed. Reg. 7,276 and 82 Fed. Reg. 7,322, amended the definitions of general service lamp and general service incandescent lamp so as to bring within them categories of lamps that had been excluded by statute.

September 5, 2019. 84 Fed. Reg. 46,661 withdrew those definitions and restored the statutory definitions.

December 27, 2019. 84 Fed. Reg. 71,626 determined that, because the Department of Energy had decided not to amend standards for general service incandescent lamps, it had been under no obligation to issue a final rule by January 1, 2017, and the backstop requirement had therefore not been triggered.

May 9, 2022. Two final rules reversed that position. 87 Fed. Reg. 27,461 restored the broader definitions, and 87 Fed. Reg. 27,439, RIN 1904-AF09 in docket EERE-2021-BT-STD-0005, effective July 25, 2022, gave effect to the 45 lumens-per-watt backstop. These are the two rules the Foundation challenged, as Part IV.G.7 describes.

April 19, 2024. 89 Fed. Reg. 28,856, RIN 1904-AF43, effective July 3, 2024, adopted higher efficacy standards for general service lamps, with compliance required for products manufactured in or imported into the United States beginning July 25, 2028.

Each of those proceedings was conducted as an energy conservation proceeding, and properly so, because that is the authority under which the Department of Energy acts. The point of listing them is not that any was wrongly decided. It is that between January 2017 and April 2024 the federal government conducted five rulemakings that determined which lighting technology would be lawful to sell for general illumination in the United States, and that the question of what the surviving technology emits was not before the agency in any of them.

3. Effect: nationwide displacement of incandescent and halogen lamps by LED products

The effect of the framework was the removal of the alternative. A standard expressed as a minimum efficacy does not name a technology, but incandescent and halogen lamps for general service do not meet 45 lumens per watt and cannot be made to. The practical consequence of the backstop was therefore that the general service incandescent lamp ceased to be lawfully sold, and that the lamp available to replace it, in substantially every socket in the country, was the light-emitting diode.

The Foundation is careful not to overstate the causal claim. Price, service life and consumer preference moved the market toward light-emitting diodes independently of any federal requirement, and a large share of the conversion would have occurred without it. What the federal framework did was different in kind and is not a matter of degree: it removed the choice. A person who prefers an incandescent lamp for general illumination, including a person whose reason for preferring it is a response to the emission of the alternative, cannot obtain one.

That distinction matters to this Department rather than to the Department of Energy. Where a technology prevails in a market, a person adversely affected by its emission retains the ordinary remedy of not buying it. Where the alternative has been removed by federal operation, that remedy is gone, and the question whether the mandated emission is safe for the people exposed to it is no longer answerable by individual choice. Part VII describes who those people are.

4. Lamp efficacy in lumens per watt is silent as to what the selected technology emits

This subsection states the technical proposition on which much of this comment depends, and the Foundation asks that it be read carefully, because it is not an argument about policy. It is an argument about what a unit of measurement contains.

a. What a lumen is

The lumen is not a unit of radiation. It is a unit of radiation after weighting. Radiant flux, measured in watts, is multiplied wavelength by wavelength by V(λ), the photopic luminous efficiency function standardized by the International Commission on Illumination in 1924, and the result is scaled so that one watt at the peak of that function corresponds to 683 lumens. V(λ) describes the relative sensitivity of foveal cone vision for brightness matching at moderate luminance in a standard observer. It peaks at 555 nanometers.

Lumens per watt therefore expresses how efficiently a source produces a visual brightness response, in one standard observer, per unit of electrical power consumed. For the purpose of conserving electricity while delivering usable illumination, it is the correct quantity. The Foundation says so without qualification.

b. What the metric does not contain

A figure in lumens per watt is silent as to the spectral power distribution of the emission, the peak luminance of the emitting surface, the apparent size and geometry of the source, and the temporal structure of the output. Two lamps of identical efficacy may differ in every one of those respects. Parts V.B.1, V.B.2 and V.B.7 set out why each of them bears on human response.

It is also silent as to every biological response other than the one V(λ) was constructed to describe. Visual brightness matching is not the only response of the human organism to optical radiation. Light is the principal entraining stimulus of the human circadian system, acting through intrinsically photosensitive retinal ganglion cells and the photopigment melanopsin by a pathway distinct from the cone pathway V(λ) describes. Photochemical injury to the retina proceeds by a third mechanism with a weighting function of its own. Part V.C and Part V.F.

c. The weighting functions do not coincide, and the divergence runs the wrong way

The decisive point is not that lumens per watt omits these responses. It is that the function from which the metric is built assigns its lowest weights in the region where those responses are strongest.

V(λ), which defines the lumen, peaks at 555 nanometers and falls steeply toward the short-wavelength end of the visible band.

The blue light hazard function B(λ) of IEC 62471, which defines the photochemical retinal hazard, reaches its maximum at 445 nanometers, on the guidelines of the International Commission on Non-Ionizing Radiation Protection of 2013.

The melanopic action spectrum, which governs the non-image-forming responses including the suppression of nocturnal melatonin, peaks at approximately 490 nanometers.

At 440 nanometers, the wavelength of maximum photochemical hazard, V(λ) stands at roughly two percent of its own maximum. One watt of radiant power delivered at that wavelength therefore contributes on the order of fifteen lumens, against 683 lumens for the same watt

delivered at 555 nanometers. The same watt contributes the maximum possible value of the hazard-weighted quantity. Radiation that is nearly invisible to the metric is maximal to the hazard function.

There is a further relationship, and the Foundation states it with appropriate caution because it is the strongest form of the argument and must not be overstated. In phosphor-converted white light-emitting diodes, light is produced by a short-wavelength emitter and converted in part by a phosphor, and the conversion is lossy. Devices of higher correlated color temperature convert a smaller proportion of the emitter output and incur smaller conversion losses, and they generally achieve higher luminous efficacy as a result. If that relationship holds as generally as the Foundation understands it to, then a design change that increases the short-wavelength content of the emission can improve the figure the federal standard measures.

d. The standard imposes one parameter and no other

The preceding point concerns what the metric can register. This one concerns what the regulation requires, and it is the more consequential of the two.

A manufacturer placing a general service lamp on the United States market must meet a minimum efficacy expressed in lumens per watt. That is the requirement. Federal law imposes no requirement as to the spectral power distribution of the lamp, the luminance of its emitting surface, the apparent size of that surface, the modulation depth or frequency of its output, or its behavior when dimmed. The standard has one parameter.

Every other characteristic of the emission is therefore determined by the manufacturer, on commercial criteria, unconstrained by any federal requirement. Flicker is whatever the driver circuit produces at the price point. Spectral content is whatever the emitter and phosphor combination yields. Source luminance is whatever follows from the package geometry chosen. None of these is a lapse by any manufacturer. They are the predictable result of a regulatory instrument that specifies one quantity and is silent as to the rest, and the single quantity it specifies exerts design pressure of its own.

The design pressure runs in a particular direction, and on one point it runs directly against the characteristic described at Part V.B.6. Radiation outside the band the eye uses reduces lumens per watt by definition: it consumes power and contributes no lumens. A lamp that emits appreciable long-wavelength content is, by the federal metric, a less efficient lamp.

The efficacy standard therefore does not merely fail to require the long-wavelength content whose physiological function is described at Part V.B.6. It affirmatively selects against it. A manufacturer who added that content to a general service lamp would move the lamp toward noncompliance, and in the limit out of the market.

The Foundation states the consequence carefully. This is not an allegation that the Department of Energy acted improperly; the metric is the one Congress wrote and the loss is real in energy terms. It is an observation that two federal interests are in tension on this point, that the tension is not a matter of opinion but follows from the definition of the metric, and that it was never identified in any federal proceeding because the agency holding the health authority was not in the room. Subsection 6.

There is a further fact about that tension, and the Foundation offers it without any suggestion of impropriety, because there is none. The experiment described at Part V.B.6, which measured the physiological and emotional effects of adding near-infrared radiation to indoor lighting, was paid for by the Department of Energy. The funding statement reads:

> “This work was supported by the U.S. Department of Energy’s Lighting R&D Program, part of the Building Technologies Office within the Office of Energy Efficiency and Renewable Energy (EERE).”

The Office of Energy Efficiency and Renewable Energy is the office that promulgated the general service lamp rules described at subsection 2. One of the authors is a researcher at Pacific Northwest National Laboratory, a Department of Energy laboratory, and the study protocol was approved by that laboratory's institutional review board. The Department's lighting research program funded an investigation into the human consequences of a characteristic that the Department's lighting standards select against.

The Foundation draws two conclusions from this, both narrow. The first is that a research office and a standards office may properly do different things, and the Foundation does not contend otherwise. The second is that the subject matter cannot have been unknown. Whatever else may be said about the absence of the consultation that § 360ii(a)(6) directs, it cannot be said that no one in the federal government was aware that the spectral consequences of the efficacy standard were a live question. The Department of Energy was paying to investigate them.

The investigators themselves draw the line between the regulation and the research question. Writing of the implications of their findings for architectural lighting, they observe that, given the recent implementation of energy efficiency regulations that have effectively banned incandescent and halogen lamps, such lighting presently provides little if any radiation in the near-infrared or far-red regions; that this constitutes a substantial change in the indoor environment; and that the long-term consequences of the removal of near-infrared and far-red are unknown. They conclude that it will be important to determine the extent of the physiological and psychological responses, to establish dose-response relationships, and then to make decisions about how energy should be used in buildings.

The Foundation adopts that sequence and observes only that Congress has already assigned the first two steps in it. Determining the extent of physiological response to an emission, and establishing dose-response relationships for it, is what § 360ii(a)(2) and (a)(4) direct the Secretary to do. The researchers funded by one Department have identified the work that a different Department's statute assigns. What is missing is not the recognition of the question. It is the program.

This is the condition that paragraph 360ii(a)(6) exists to prevent, and the Foundation states the mechanism precisely because it is often misunderstood. The complaint is not that the Department of Energy should have regulated spectral content or flicker. That Department has no authority to do so and no expertise with which to do it. The two authorities are complementary and were always meant to be: the Energy Policy and Conservation Act governs how much power a lamp may draw for the light it delivers, and 21 U.S.C. § 360kk governs what the lamp may emit. A general service lamp sold in the United States was always going to be subject to the first. It was never made subject to the second.

The result is not a conflict between two federal programs. It is half a framework. A mandatory federal floor was built on the energy side and nothing was built on the emission side, and the consultation directed by § 360ii(a)(6)(B), which concerns in terms the development of performance standards pursuant to § 360kk, is the mechanism by which this Department would have learned that the first half was being built. Subsection 6.

e. What the Foundation asserts and what it does not

The Foundation does not assert that the efficacy standards caused injury to any person. It has not established that and does not claim it. What it asserts is narrower and is a matter of arithmetic rather than of evidence.

The quantity the federal standard selects on is orthogonal to the quantities that bear on the biological responses described in Part V, and in the short-wavelength region is inversely related to them.

A regulatory instrument that selects on such a quantity will therefore produce a change in those other quantities as a byproduct, and will produce it invisibly, because the instrument contains nothing that would register the change.

Whether that byproduct matters is an empirical question. It is the question 21 U.S.C. § 360ii(a)(4) directs the Secretary to study and evaluate, and no federal body has asked it.

That is the whole of the proposition. The lumen is a good unit for measuring light as the eye sees it, and a federal measure built on it is a reasonable instrument of energy policy. It is simply not an instrument that can detect what this comment is about, and nothing in the Energy Policy and Conservation Act asked it to be.

5. No biological or health evaluation accompanied the transition

Across the five proceedings listed at subsection 2, the Foundation has identified no evaluation of the photobiological effect of the emission of the technology the standards selected. The records are energy conservation records. They address projected energy savings, net present value, consumer purchase cost and lifetime operating cost, manufacturer impacts, and product availability. Those are the matters the Energy Policy and Conservation Act directs that Department to consider, and the Foundation does not suggest the records should have contained anything else.

The nearest the federal record comes to the question is the set of environmental determinations examined at subsection 7, and what those determinations said is set out there.

The Foundation has also sought the records of this Department bearing on the question, by request under the Freedom of Information Act, and none have been produced. Part IV.D.3.

6. The liaison duty under § 360ii(a)(3) and (a)(6) was triggered and not discharged

The Foundation is precise about where the omission lies, and its position may be narrower than a reader expects.

The Energy Policy and Conservation Act imposes no duty on the Secretary of Energy to consult this Department about anything. That Department conducted the rulemakings it was directed to conduct, on the criteria it was directed to apply. The Foundation makes no criticism of it in this subsection.

The duty runs in the other direction, and it is unconditional. Paragraph 360ii(a)(3) directs the Secretary of Health and Human Services to maintain liaison with and receive information from other Federal departments and agencies with related interests on present and future potential electronic product radiation. Paragraph 360ii(a)(6) directs the Secretary to consult and maintain liaison with the Secretaries of Commerce, Defense and Labor, the Atomic Energy Commission, and other appropriate Federal departments and agencies on techniques, equipment and programs for testing and evaluating electronic product radiation and on the development of performance standards. Neither paragraph requires the other agency to initiate. Neither is conditioned on a request. Part II.E and Part II.H.

A Department of Energy rulemaking that would determine which light-emitting technology may lawfully be sold for general illumination in the United States is a related interest within paragraph (a)(3) on any reading of that phrase, and that Department is an appropriate Federal department within paragraph (a)(6) on any reading of that one. The subject matter of the rulemakings was the emission of electronic product radiation from electronic products, which is the subject matter of this subchapter.

Five such proceedings were conducted between January 2017 and April 2024. The Foundation has found no record that the liaison or the consultation those paragraphs direct occurred as to any of them, and its requests for such records have produced none. The effect is the one described at subsection 4: a federal instrument selected a lighting technology on a quantity that cannot register

what that technology emits, and the agency holding the authority to evaluate the emission was not in the proceeding.

This is the ground on which the Foundation states its position on S. 1568 at Part IV.F, and it is the ground of the requests at Parts IX.H.3 and IX.H.5.

7. DOE's NEPA determinations for the lamp rulemakings

The rulemakings described in subsections 2 and 3 produced a nationwide change in the spectral composition of artificial light. No federal agency evaluated that change. The Department of Energy determined, four times, that no evaluation was required under the National Environmental Policy Act. The Foundation set out to learn why, and the account that follows is drawn from the documents that effort produced.

a. The four determinations

Two classes of categorical exclusion were applied to the general service lamp rulemakings.

Class A5, in appendix A to subpart D of 10 C.F.R. part 1021, "Categorical Exclusions Applicable to General Agency Actions," covers:

> A5 Interpretive rulemakings with no change in environmental effect. Rulemakings interpreting or amending an existing rule or regulation that does not change the environmental effect of the rule or regulation being amended.

That class was applied in 2022 to both of the rules published on May 9 of that year: to the rule codifying the 45 lumens-per-watt backstop, RIN 1904-AF09, 87 Fed. Reg. 27,439, Docket No. EERE-2021-BT-STD-0005, by determination CX-026079, signed April 4, 2022 by the NEPA Compliance Officer for the Building Technologies Program of the Office of Energy Efficiency and Renewable Energy; and to the rule defining general service lamps, RIN 1904-AF22, 87 Fed. Reg. 27,461, Docket No. EERE-2021-BT-STD-0012, by determination CX-026078.

Class B5.1, in appendix B, covers actions to conserve energy or water. That class was applied to the 2017 definitions rule by determination CX-100797, and to the 2024 energy conservation standards for general service lamps, which raised the minimum to 120 lumens per watt, by determination CX-030319. The 2024 determination records an affirmative finding that none of the exceptions in B5.1 applies and that no extraordinary circumstances exist requiring further environmental analysis.

b. How the Department of Energy explained the 2022 determinations

The Foundation challenged the 2022 rules three times, and the Department of Energy's reasoning on the environmental question emerged only at the end of that sequence.

On July 10, 2022, the Foundation filed an "Appeal of Final Rules for General Service Lamps EERE-2021-BT-STD-0005 and EERE-2021-BT-STD-0012" with the Department of Energy's Office of Hearings and Appeals. On August 22, 2022, the Director of that office dismissed it with prejudice for want of jurisdiction, Case No. EXC-22-0003. The office explained that its authority runs to "an adjustment from a DOE rule, regulation or order" under 42 U.S.C. § 7194, available where necessary to prevent "special hardship, inequity, or unfair distribution of burdens," and that it does not "possess authority to review or make changes to a regulation that would apply to all regulated parties." The requests to remove LEDs from the general service lamp classification and to rescind the 45 lumens-per-watt requirement sought exactly such a generally applicable change; the remaining requests, including "conducting additional studies," did not concern the adjustment of a rule at all. The letter states that the dismissal is final agency action.

The Foundation then petitioned for repeal of the two rules. The Department of Energy denied the petition in a notice published at 88 Fed. Reg. 16,869 (Mar. 21, 2023), Docket No. EERE-2023-BT-PET-0003, on the ground that repeal would contradict the statute. That published denial does not mention the National Environmental Policy Act and does not mention the categorical exclusions.

The Foundation then wrote to the NEPA Compliance Officer directly. On August 3, 2023, the NEPA Division Director for the Golden Field Office of the Office of Energy Efficiency and Renewable Energy replied. That reply is, so far as the Foundation is aware, the only statement the Department of Energy has made of its environmental reasoning for these rules. It states, in relevant part:

> Concerning the application of a categorical exclusion for the final rule on efficiency standards, the minimum 45 lm/W standard was set by statute, not by DOE. DOE's action was to codify a standard that was already set by Congress. DOE interpreted the statute to determine the backstop action was required. Any environmental effects of the standard already existed when the statute became effective. DOE did not cause a change to the environmental effects; it only codified the 45 lm/W standard that had been already set in the statute. Therefore, the appropriate action under NEPA was to apply DOE's categorical exclusion "A5" for rulemakings that interpret or amend existing rules that do not change the environmental effect of the rule, and as such, are categorically excluded from further NEPA review.
>
> DOE did not have discretion with respect to the minimum 45 lm/W standard. Congress set the minimum standard and mandated that DOE adopt it under the backstop provision of the statutes. See 40 C.F.R. § 1501.1(a)(5).

The same letter states that "there are no remedies under the law that are available to you through further contacting of DOE employees directly," and closes: "DOE considers this matter closed."

c. What a categorical exclusion determination establishes, and what it does not

A categorical exclusion determination records a conclusion that the action belongs to a class of actions not expected to have a significant effect on the human environment. It is not an evaluation. None of the four determinations produced an analysis of the emission characteristics of the technology the rules selected, and none purports to. That is the whole of the point the Foundation makes here.

The 2022 reasoning is worth stating precisely, because it shows where the analysis went. If any environmental effects "already existed when the statute became effective," they are attributed to the Energy Independence and Security Act of 2007. Congress does not prepare environmental analyses of its own enactments, and nothing requires it to. The consequence is not that anyone acted improperly. The consequence is that the effects of the nationwide lamp transition were analyzed by no one — not because a federal body considered them and found them insignificant, but because the analysis fell between the enactment and the implementation of it.

d. The extraordinary-circumstances requirement — 10 C.F.R. § 1021.410(b)

A categorical exclusion may be applied only upon a determination under 10 C.F.R. § 1021.410(b) that the proposal fits a listed class, that it has not been segmented, and that:

> There are no extraordinary circumstances related to the proposal that may affect the significance of the environmental effects of the proposal. Extraordinary circumstances are unique situations presented by specific proposals, including, but not limited to, scientific controversy about the environmental effects of the proposal; uncertain effects or effects involving unique or unknown risks; and unresolved conflicts concerning alternative uses of available resources…

10 C.F.R. § 1021.410(b)(2). The first two enumerated examples describe the present subject. Whether the spectral and temporal characteristics of LED emission have effects on human health is scientifically contested, as Part V sets out, and the effects of long-term exposure at the levels now prevailing are to a material degree unknown — which is the premise of the Department's own request for information.

There is also a statutory marker for the proposition that environmental effect was always part of this program. In the Energy Policy Act of 2005, Congress set the objectives of the Next Generation

Lighting Initiative as the development of solid-state lighting technologies that, compared with incandescent and fluorescent lighting technologies, are "longer lasting, are more energy-efficient and cost-competitive, and have less environmental impact." Pub. L. No. 109-58, § 912(c). Less environmental impact is a criterion Congress wrote into the initiative at the outset. The Foundation's request of January 25, 2025 asked the Department of Energy for the materials by which it defines that term. Subsection f describes what has been produced.

e. The 2024 determination is the one that carries the argument

The Foundation directs the Department's attention to CX-030319, and not to the 2022 determinations, for three reasons.

The first is discretion. Whatever is said of the 45 lumens-per-watt backstop, the 2024 energy conservation standards were the Department of Energy's to set. The reasoning quoted in subsection b — that Congress fixed the level and the agency merely codified it — is unavailable as to that rule.

The second is the class applied. B5.1 is addressed to actions to conserve energy or water. It is framed by the conservation purpose of the action. It says nothing about what the conserving technology emits, and it was not written to answer that question.

The third is notice. On May 30, 2023 the Foundation submitted a request to the Department of Energy to comply with 21 U.S.C. § 360ii and to establish and maintain a liaison with the Food and Drug Administration for the purpose of publishing performance standards for LED products. The Department of Energy did not respond to it. By the time the 2024 determination was signed, the Department of Energy had also received the Foundation's appeal of July 10, 2022, its petition for repeal decided at 88 Fed. Reg. 16,869, and its correspondence with the NEPA Compliance Officer answered on August 3, 2023, each raising the health effects of the technology the rules selected. The determination nonetheless records an affirmative finding that no extraordinary circumstances exist. A finding that there is no scientific controversy about the environmental effects of an action is harder to sustain once the controversy has been put to the agency in writing four times.

f. The Foundation asked the Department of Energy for the records, and was directed to three public dockets

The Foundation submitted two requests to the Department of Energy under the Freedom of Information Act on consecutive days, and the Department of Energy answered one of them.

The request of January 24, 2025, headed "FOIA Request — General Service Lamp Energy Efficiency," sought documents from 2005 through 2024 relating to LED general service lamps, in eight items. The request of January 25, 2025 is directed to the environmental determinations: it seeks materials concerning the categorical exclusion decision for the 45 lumens-per-watt rule and for the 120 lumens-per-watt rule, communications between the Department of Energy and the Environmental Protection Agency regarding the environmental impacts of artificial light and light pollution, and the materials by which the Department of Energy defines the terms significant, less environmental impact, cumulative impact to human health, and cumulative impact to environment.

The third item of the January 24 request is the one that matters here. It asked for:

> All documents involving the FDA and LED products, including documents related to the decision by the DOE to liaison or not liaison with the FDA on setting performance standards for LED products.

The Department of Energy issued a final response to that request on April 16, 2025, assigned number HQ-2025-02044-F and signed by the FOIA Officer of the Office of Public Information. It states:

> Your request was assigned to DOE's Office of General Counsel (GC) to locate records responsive to your request. On April 15, 2025, GC confirmed that requested information is publicly available on the sites below:

The letter then lists three dockets on regulations.gov: EERE-2021-BT-STD-0005, EERE-2022-BT-STD-0022, and EERE-2023-BT-PET-0003. It identifies no records beyond those dockets, withholds nothing, and reports that the Department of Energy's processing costs did not exceed fifteen dollars, the minimum at which it assesses fees.

The Foundation asks the Department to read that response against the request it answered. The request asked, in terms, for the documents relating to the Department of Energy's decision to liaison or not to liaison with the Food and Drug Administration on setting performance standards for LED products. The answer was that the responsive information is publicly available in three rulemaking dockets. As subsection h sets out, the rules in those dockets do not mention the Food and Drug Administration, the Department of Health and Human Services, or the electronic product radiation control program at all.

The Foundation states the limits of what that establishes rather than leaving them to be raised. The letter does not certify that no other responsive records exist, and a requester cannot determine from it what search was performed or where. The Foundation does not assert that no communication between the two Departments has ever occurred. What the record permits is narrower and is enough: asked directly for its records concerning the Food and Drug Administration and LED products, including its decision whether to liaise at all, the Department of Energy identified three public dockets in which the Food and Drug Administration does not appear, and nothing else.

The significance for this comment is not what it shows about the Department of Energy. The liaison duty does not run from the Secretary of Energy. It runs from the Secretary of Health and Human Services, under 21 U.S.C. § 360ii(a)(3) and (a)(6). The Department can establish from within the Executive Branch, and without a Freedom of Information Act request, whether the consultation those paragraphs direct took place while federal policy was selecting the technology now in general use. The Foundation asks it to do so and to state the result.

g. The limits of this line of argument

The Foundation states these rather than leave them to be raised against the comment. The National Environmental Policy Act does not apply to acts of Congress, so the statutory backstop itself is not reviewable on this ground. Where an agency lacks discretion, environmental review of the constrained action serves no purpose, and the Foundation does not suggest otherwise as to the 2022 backstop rule. The Act was amended in 2023, the Council on Environmental Quality has rescinded its implementing regulations, and recent Supreme Court authority narrows the scope of review that is required. Limitations periods bar challenge to the older determinations. The Foundation is not asking the Department to reopen any of them.

h. Why this history is before the Department of Health and Human Services

The Department of Energy answered a question about causation: whether its rules changed an environmental effect. It did not answer, and was not asked to answer, what the replacement technology emits or how people are exposed to it. Neither the backstop rule at 87 Fed. Reg. 27,439 nor the definitions rule at 87 Fed. Reg. 27,461 mentions the Food and Drug Administration, the Department of Health and Human Services, or the electronic product radiation control program. Neither discusses spectral power distribution, source luminance, short-wavelength content, or temporal light modulation. The rulemakings measured the technology in lumens per watt and were silent as to what it emits. Part IV.G.4.

Nothing in this comment depends on the Department of Energy having been wrong. Take its position as entirely correct, and accept every limit stated in the preceding subsection. The emissions of the selected technology, and the conditions under which people are exposed to them,

remain unevaluated. That evaluation is not assigned to the Secretary of Energy. It is assigned to the Secretary of Health and Human Services by 21 U.S.C. § 360ii(a)(4), and the duty to consult with the Department of Energy about it is assigned by § 360ii(a)(3) and (a)(6). Subsection 6 states the consequence.

The sequence, stated plainly, is this. The Foundation asked the Department of Energy to study the health effects of the technology its rules selected, and was told that the office it petitioned had no jurisdiction to order studies, that repeal would contradict the statute, that no environmental analysis was required because Congress had set the standard, and that the matter was closed. It asked the Food and Drug Administration to exercise the authority that does reach the emissions, and was told on May 24, 2024 that a performance standard was not necessary. Each answer was addressed to the authority of the agency giving it. Neither answer reached the question.

8. Whether spectral and photometric characteristics are "performance characteristics" under 42 U.S.C. 6295(o)(4)

The Energy Policy and Conservation Act bars the Department of Energy from prescribing an efficiency standard shown to result in the unavailability of performance characteristics, features, sizes, capacities and volumes substantially the same as those generally available. The Foundation raises a question about that phrase and does not answer it.

The question is whether the emission characteristics of a light source fall within "performance characteristics" as that provision uses the term. If they do, then an efficiency standard that displaces one emitting technology in favor of another with materially different spectral content engages a statutory constraint on the agency setting it. If they do not, then the emission characteristics of a light source are outside the only constraint of that kind in the statute, and Part IV.G.4 establishes that the measure the standard does use is silent as to what the selected technology emits.

The Foundation states the question as open. It has not located authority construing the phrase as applied to an optical emission, and it does not assert the answer in either direction. It raises the question because both answers lead to the same place for this Department's purposes: on either reading, no body evaluated the emission, and Part IV.G.5 establishes that no biological or health evaluation accompanied the transition.

9. DOE testimony before the Senate Committee on Energy and Natural Resources, September 16, 2026

An Associate Deputy Secretary of the Department of Energy testified before the Senate Committee on Energy and Natural Resources in support of reversing the general service lamp standard, on grounds of consumer choice.

The Foundation records the testimony as part of the chronology and takes no position on the ground advanced in it. Part IV.G.11 sets out the two distinct grounds on which the lamp standards may be reconsidered and states which of them this comment adopts.

10. S. 1568 and H.R. 3341, the Liberating Incandescent Technology Act of 2025

S. 1568 was introduced on May 1, 2025 by Senator Lee, chair of the Senate Committee on Energy and Natural Resources, with five cosponsors, and was referred to that committee. A House companion, H.R. 3341, was introduced by Representative Goldman.

The bills would amend the Energy Policy and Conservation Act to remove general service lamps from the covered products at 42 U.S.C. 6292(a), and would nullify three rules of the Department of Energy published in 2022 and 2024.

The Foundation records the bills because they are part of the chronology of the federal lamp framework described in this subsection, and takes no position on them. Its own position on reconsideration of the lamp standards is confined to the ground stated at Part IV.G.11.

11. Two rationales for reconsidering the lamp standards, and which this comment adopts

There are two distinct grounds on which the general service lamp rules may be revisited, and the Foundation states both and adopts one, because a reader is otherwise entitled to assume it adopts the other.

The first is consumer choice and the limits of federal standard-setting. That is the ground occupied by the testimony at Part IV.G.9 and by the bills at Part IV.G.10. This comment does not adopt it.

The second is procedural. The rules selected an emitting technology without any evaluation of its emissions, by any agency, under either the National Environmental Policy Act or the electronic product radiation control program. Part IV.G.5 establishes the absence of any biological or health evaluation and Part IV.H treats the environmental review. This comment adopts the second ground and not the first.

The distinction matters to the relief this comment seeks, and the Foundation sets it out rather than leaving it to be inferred. Part IX asks this Department to exercise federal standard-setting authority under § 360kk. A comment resting on the proposition that federal standard-setting is itself objectionable could not coherently ask for that. The Foundation's objection is not to a federal standard having been set. It is that the standard which was set measured efficiency and nothing else, and that no part of the federal government evaluated what the technology it selected emits.

12. The Department of Energy's lighting research program, and the loop that was supposed to close

Part IV.G.4 records that the experiment described at Part V.B.6 was paid for by the Office of Energy Efficiency and Renewable Energy. This subsection sets out what the Foundation does and does not draw from that, because the obvious inference is the wrong one and the Department should not have to guess which the Foundation intends.

a. The Department of Energy had authority to fund this research, and the Foundation does not question it

Section 912 of the Energy Policy Act of 2005, 42 U.S.C. § 16192, directs the Secretary of Energy to carry out a Next Generation Lighting Initiative of research, development, demonstration and commercial application activities related to advanced solid-state lighting. The purposes the section states are lighting that is longer lasting, more energy-efficient and cost competitive, and of less environmental impact than incandescent and fluorescent lighting. The section does not mention human health, and it does not mention the spectral composition of what the technology emits.

That silence is not a defect and the Foundation does not treat it as one. An agency may fund research useful to its mission without a statute naming the subject of the research; the authority to study is permissive and broad, and it is the authority to regulate that must be conferred specifically. The Foundation states plainly, so that the point cannot be mistaken, that the Department of Energy did not exceed its authority in funding this work, and asks this Department to proceed on that footing.

b. Why an energy agency studies human response to light

The reason is adoption. Efficient lighting that people dislike is not installed, and lighting that is not installed saves nothing. Human response to lighting — visual preference, color rendering, acceptability, comfort — is therefore a variable in a program whose object is to displace one technology with another, and the Department of Energy has supported research of that kind for many years, including at Pacific Northwest National Laboratory. The Foundation sees nothing improper in it. It observes only what the question is for. The Department of Energy asks how people respond to lighting because it needs people to accept the lighting. Section 360ii directs this Department to ask how people respond to radiation because people are exposed to it whether they

accept it or not. The inquiries overlap in their methods and diverge in their purpose, and only one of them is a duty.

c. Where that research is pointed

The divergence is visible in the paper itself. Having set out their findings, the authors identify what they take to be the next steps:

> As a society, it will be important to determine the extent of the physiological and psychological responses, to establish dose-response relationships, and then to make critical decisions about how energy should be used in buildings.

The Foundation draws attention to the destination of that sentence. The physiological finding is an input, and what it is an input to is a decision about energy. That is not a criticism of the investigators, who wrote accurately about the program that funded them. It is the frame their authorizing statute supplies, and it is the only frame available to them. Routed instead through § 360ii, the same measurements answer a different question: whether the radiation a product emits, or fails to emit, serves the person exposed to it. Part II.D.2. The data are identical. The statutory destination is not.

d. What the Foundation objects to, stated precisely

The Foundation does not object to the Department of Energy conducting research into the human effects of lighting. It welcomes that research and relies on it in Part V. The objection is to what happens at the other end of it, which is nothing. No federal body receives this work as electronic product radiation information. None evaluates it against the emissions of the products Americans are actually exposed to. None coordinates it with the research funded elsewhere, publishes a federal account of what it shows, carries it to a report to Congress, or considers whether it bears on the necessity for a performance standard. The research is produced and then it stops.

That is not a gap Congress overlooked. Congress wrote the machinery for exactly this, and wrote it twice.

e. The loop Congress built, and the step at which it is open

Taking the provisions in the order in which they would operate:

Receive. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests on present and future potential electronic product radiation. A department that funds research into the physiological effects of the spectral content of lighting has a related interest as a matter of demonstrated fact. The question does not require argument and is not open to characterization.

Coordinate and support. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate, and support research to minimize the emissions of and the exposure of people to unnecessary electronic product radiation. Research funded by another federal department on precisely that subject is what there is to coordinate. A coordination duty is not discharged by the absence of anything to coordinate; here there was something.

Invite. Section 360jj(b) provides that, in carrying out the studies the section directs, "the Secretary shall invite the participation of other Federal departments and agencies having related responsibilities and interests, State governments—particularly those of States which regulate radioactive materials under section 274 of the Atomic Energy Act of 1954, as amended, and interested professional, labor, and industrial organizations."

Organize. Section 360jj(c) provides that "the Secretary or his designee shall organize the studies and the participation of the invited participants as he deems best." The subsection adds that any dissent from the Secretary's findings and recommendations shall be included in the report if the dissenter so requests.

Study and evaluate. Paragraph 360ii(a)(4) directs the study and evaluation of emissions of, and conditions of exposure to, electronic product radiation. Part II.F.

Report. Section 360jj(a)(2) directs a study to determine the necessity for the development of standards for the use of nonmedical electronic products, and a report of the result to Congress. Part II.I.

Decide. Section 360kk(a)(1)(A) conditions a performance standard on the latest available scientific and medical data in the field. A Secretary who does not receive the data cannot satisfy the predicate of the Secretary's own standard-setting provision. Part II.C.1.

Publish. Section 360ii(b)(1)(A) authorizes the Secretary to collect and make available, through publications and other appropriate means, the results of, and other information concerning, research and studies relating to the nature and extent of the hazards and control of electronic product radiation. This is the step that closes the loop, and it is the step at which research funded by one department would become available to the public, to purchasers, and to the state and local entities described at Part VIII. Part II.B.

Two features of § 360jj(b) deserve particular notice, because they show what Congress pictured. The subsection goes on to provide that, on request from interested congressional committees, the Secretary shall keep those committees currently informed as to the progress of the studies and shall permit them "to send observers to meetings of the study groups." Congress contemplated study groups that hold meetings, running long enough and regularly enough that a committee might send someone to watch. And § 360jj(c) contemplates that participants will disagree with the Secretary and that their dissent will be recorded — which presupposes participants.

Every step in that sequence is a verb Congress wrote, and the sequence closes: information is received, coordinated, organized, evaluated, reported, and acted upon or not for stated reasons. The Foundation submits that the loop is open at the first step. The research exists. Nothing receives it. Everything downstream of receiving it is therefore empty, not because the Secretary considered the material and found it wanting, but because the material never arrived.

f. Three agencies, one duty

The position may be stated compactly. Three federal departments touch artificial light in the respects this comment concerns. The Department of Energy is under no duty to study its health effects and is studying them. The Environmental Protection Agency is under no duty to study them and is not, and has said so to the Foundation in writing, for the documented reason set out at Part II.H.3. The Secretary of Health and Human Services is under a duty to study them, in terms Congress made mandatory, and is not.

The Foundation's complaint is not that the Department of Energy overstepped, and it is not that the Environmental Protection Agency shirked. Neither is true, and the Foundation would not have this Department waste a paragraph of its response defending either of them. The complaint is that the research function and the regulatory function have come apart. The department that can fund the question cannot act on the answer; its only instrument, if its own researchers established a harm tomorrow, would be to relax or decline an efficiency standard, since nothing in the Energy Policy and Conservation Act authorizes it to prescribe what an electronic product may emit. The department that can act on the answer is not asking the question. Section 360ii is the provision that was supposed to hold those two things together, and the liaison it directs is the hinge.

13. Significance for the Department's duties under § 360ii

The Foundation states the significance of this subsection in one proposition. Another federal agency regulated a product class into the exposure environment of the entire country, while the agency holding the radiation control authority conducted no evaluation of what that class emits and appears nowhere in the record of the rulemakings that did it.

That is the circumstance the liaison duties were written to prevent. Part II.E and Part II.H set out those duties and the record of their performance, Part IV.G.6 establishes that the duty was triggered in this instance and not discharged, and Part II.M sets out what the Foundation says follows. The Foundation does not contend that the Department of Energy should have performed the evaluation; Part IV.G.4 establishes that its statutory measure does not reach the question. It contends that the evaluation was this Department's to perform and that nobody performed it.

H. The National Environmental Policy Act, and the Consequence of Absent Federal Evaluation

Part IV.G.7 set out the environmental determinations the Department of Energy made for the general service lamp rulemakings. This section states the general proposition those determinations illustrate. It concerns every federal agency that must assess the environmental effects of an action involving artificial light, and it concerns this Department because of what those agencies have to consult.

1. What NEPA requires, and what it does not

The National Environmental Policy Act, 42 U.S.C. § 4321 et seq., requires a detailed statement of environmental effects for major federal actions significantly affecting the quality of the human environment. It is a procedural statute. It requires an agency to consider and disclose effects before it acts. It does not dictate any outcome, and it does not direct anyone to generate knowledge that does not yet exist.

That distinction governs this entire section. Section 360ii is substantive in the relevant sense. It directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and the direction does not depend on anyone proposing a federal action. NEPA asks whether an agency said what it knew. Section 360ii directs the Secretary to find out.

2. The present state of NEPA, stated accurately

The Foundation sets out the current position rather than the position as it stood when the determinations at Part IV.G.7 were made, because the two differ and the difference bears against an argument the Foundation might otherwise be tempted to advance.

The Council on Environmental Quality rescinded its NEPA implementing regulations, formerly at 40 C.F.R. parts 1500 through 1508, by interim final rule published February 25, 2025 and effective April 11, 2025.

It did so following Marin Audubon Society v. Federal Aviation Administration, decided by the Court of Appeals for the District of Columbia Circuit in November 2024, which held that the Council lacks rulemaking authority under NEPA, and Iowa v. Council on Environmental Quality, decided February 3, 2025, which vacated the Council's 2024 rule.

Federal agencies now apply their own NEPA procedures. The Department of Energy's remain at 10 C.F.R. part 1021, and the categorical exclusions described at Part IV.G.7 are that Department's own.

The government-wide definition of effects, which encompassed ecological and aesthetic effects and was the route by which lighting impacts customarily entered environmental documents, is no longer a binding government-wide rule. The requirement to analyze cumulative effects derived from the same rescinded regulations.

In Seven County Infrastructure Coalition v. Eagle County, decided in 2025, the Supreme Court directed substantial deference to an agency's own judgments about the scope of its NEPA analysis.

The Foundation states all of this plainly because it would be convenient to argue that every federal analysis touching artificial lighting must address its effects, and that argument is weaker today than it was two years ago. The Foundation does not make it.

3. Why NEPA cannot answer the question this comment raises

Three reasons, each sufficient on its own.

Occasion. NEPA operates on proposed federal actions. The exposure described at Part VII arises from hundreds of millions of installations by private parties and by State and local governments, the overwhelming majority of which involve no federal action and trigger no environmental review at all.

Content. NEPA requires the disclosure of what is known. It does not require research. An agency that does not know the health effects of a change in the spectral composition of lighting complies with NEPA by saying that it does not know.

Deference. After Seven County, an agency's judgment about what lies within the scope of its analysis receives substantial deference from a reviewing court.

NEPA is therefore not an alternative route to the evaluation that paragraph 360ii(a)(4) directs. It is a disclosure obligation that operates downstream of knowledge, and the knowledge is the thing that is missing.

4. An environmental analysis is only as good as the authority it can cite

This is the operative point of the section, and the Foundation submits that it has not previously been put to this Department.

When a federal agency must assess the environmental effects of an action involving artificial light, it looks for federal authority to consult. For ambient air it has national ambient air quality standards. For water it has criteria documents. For ionizing radiation it has federal guidance. For optical radiation emitted by electronic products there is nothing. No federal characterization of what these products emit, no federal evaluation of the effects of that emission, and no federal criterion against which a change in it could be measured. Parts II.C.3, II.F.4 and V.J.

The determinations at Part IV.G.7 illustrate the consequence. The Foundation does not contend that the analysts at the Department of Energy were careless, and it withdraws nothing it has said about the reasoning in those determinations. It contends that the question was substantially unanswerable on the materials available to them. No federal body had characterized the emission of the technology the rules would select. None had evaluated its effects on people. None had published a criterion by which a change could have been assessed. An agency cannot disclose what no one has determined.

So the consequence of non-performance under § 360ii does not stop at the boundary of this Department. It propagates outward. Every other agency that must analyze a lighting action inherits the same absence, and will continue to inherit it until the evaluation is performed. That is a cost of non-performance that is borne entirely by other agencies and by the public, and it is invisible in this Department's own records.

5. The review function of the Environmental Protection Agency

One federal function survives the rescission untouched, because it is statutory rather than regulatory. Section 309 of the Clean Air Act, 42 U.S.C. § 7609, directs the Administrator of the Environmental Protection Agency to review and comment in writing on the environmental impact of federal actions, and to refer to the Council on Environmental Quality any matter the Administrator determines to be unsatisfactory from the standpoint of public health or welfare or environmental quality.

That review is conducted with whatever federal criteria exist. Part II.H.3 sets out what that agency holds on radiation and what it does not. On optical radiation emitted by electronic products it holds nothing, and so its review of a lighting action can say nothing authoritative about the emission. The Foundation identifies this not as a criticism of that agency but as a second instance of the same propagation: a statutory review duty is performed, and performed faithfully, against an empty shelf.

6. What the Foundation asks under this head, and what it does not

It does not ask this Department to participate in, review or comment upon any other agency's environmental review. That is not its function and the Foundation does not suggest otherwise.

It does not ask the Department to treat NEPA as a source of authority for anything. The authority is in § 360ii, and NEPA neither adds to it nor subtracts from it.

It asks the Department to recognize that the research, testing and evaluation directed by paragraphs 360ii(a)(2), (a)(4) and (a)(5) would, if performed, supply the thing every other agency's environmental analysis of a lighting action presently lacks, and that this is among the practical consequences of performing the duty. Part IX.C.

A federal criterion for exposure to optical radiation would be consulted by every agency that had to assess a lighting action, in the ordinary way that federal criteria are consulted. Its absence is felt in the same ordinary way, and has been felt as to this radiation since 1968.

7. A note on this Department's own obligations

For completeness, and so that the comment cannot be said to have overlooked it: if the Secretary were to prescribe a performance standard under § 360kk, that would itself be a federal action to which NEPA applies, and this Department maintains NEPA procedures of its own. The Foundation does not regard that as an obstacle to anything it asks. The requests at Part IX are in the first instance for research, evaluation, liaison and reporting, none of which presents any difficulty of this kind.

I. What the Record Establishes

This Part has set out the administrative, judicial and legislative record. What follows states what that record establishes. Each proposition is supported by material already given above and is cross-referenced to it, and the Foundation adds no characterization that the underlying documents do not carry on their face.

1. Actual notice to the Department and to the FDA

Four citizen petitions were docketed with the agency between June 2022 and September 2023 and were disposed of by a single response on May 24, 2024. A fifth, submitted December 30, 2025, remains pending. Parts IV.C.1 and IV.C.2.

More than six hundred LED Incident Reports and more than four thousand LED headlight reports were transmitted to the Center for Devices and Radiological Health at its own radiological health correspondence address, and receipt was acknowledged. Parts IV.B.2 and IV.B.3.

The comments and signature totals from the public petition were transmitted to the agency on more than one occasion. Part IV.B.5.

A Notice of Defective Technology was addressed to the Commissioner of Food and Drugs on December 1, 2025. Part II.J.1.c.

A Member of the House of Representatives wrote to the Commissioner on July 28, 2023, identifying 21 U.S.C. §§ 360ii(a) and 360kk(a) by section. A United States Senator inquired of the agency on February 16, 2023. Part IV.F.5.

Whatever else is in dispute, notice is not. The subject has been before the agency continuously since June 2022, through its own dockets, through its own correspondence address for radiological health, and through Members of Congress.

2. Requests directed to the correct agency under the correct statutory authority

The Foundation did not select this Department from among several candidates. It was directed here. The agencies listed at Part II.H each stated, in writing and in their own words, that the subject was not within their authority, and several identified this Department by name as the body to which the question belonged. One of them offered assistance if this Department were to request it. Part II.H.11.

The authorities invoked are those Congress enacted for this purpose: the research and coordination duties of § 360ii(a)(2), the study and evaluation duty of § 360ii(a)(4), the minimization duty of § 360ii(a)(5), the liaison and consultation duties of §§ 360ii(a)(3) and (a)(6), the reporting duty of § 360jj, the standard-setting authority of § 360kk, and the defect provisions of § 360ll.

No question therefore arises on this record of a petitioner having approached the wrong body, or the right body under the wrong authority, or of a subject that fell between agencies. It did not fall between them. It was assigned to one of them by statute and identified as that one by the others.

3. Congress has now spoken to the subject matter

July 28, 2023: a Member of the House wrote to the Commissioner asking that the agency give full and fair consideration to prescribing performance standards for automobile LED headlights. Part IV.F.5.a.

An enacted appropriations directive urges the Secretary of Transportation to report to Congress on gaps relating to the impact of the brightness of low beam headlamps. Part IV.F.1.

March 3, 2026: H.R. 7772, the LIGHT Safety Act, was introduced and referred. Part IV.F.4.

September 30, 2026: S. 1568 was reported favorably from the Senate Committee on Energy and Natural Resources. It would terminate the three rules described at Part IV.G.2.

The Foundation draws no conclusion from these items about what Congress intends. It states only that the emission of light by light-emitting diode products is a subject now before both chambers, in correspondence, in an enacted directive and in legislation, and that it is not a subject that has escaped congressional attention.

4. Federal policy drove the exposure; no federal agency evaluated the emissions of the selected technology

Between January 2017 and April 2024 the federal government conducted five rulemakings that determined which lighting technology could lawfully be sold for general illumination in the United States. The requirement they impose on a manufacturer consists of one parameter, lumens per watt. Federal law imposes no requirement as to the spectral content of the emission, the luminance of the emitting surface, the apparent size of that surface, or the temporal structure of the output. Parts IV.G.2 and IV.G.4.

The Foundation has identified, in the records of those five proceedings, no evaluation of the photobiological effect of the emission of the technology the standards selected, and no record that the liaison or consultation directed by §§ 360ii(a)(3) and (a)(6) occurred as to any of them. Parts IV.G.5 and IV.G.6.

The exposure described in Part VII is therefore not an accident of the market. It followed a federal determination, and the federal determination was made on a criterion that cannot register what this comment is about.

5. No performance standard, study, or surveillance system has resulted

No performance standard under 21 U.S.C. § 360kk governs the visible light emitted by LED products. Part 1040 of title 21, titled Performance Standards for Light-Emitting Products, contains four standards, and none of them is this one. Part II.C.3.

No study or evaluation of emissions of, or conditions of exposure to, this radiation has been identified under § 360ii(a)(4). Part II.F.4.

No channel exists by which a member of the public may report an adverse response to optical radiation from an LED product to this Department. Parts II.L and VII.J.

The Technical Electronic Product Radiation Safety Standards Committee, which the Secretary must consult before prescribing any standard, has not met since 2016. On the Department's own published roster twelve of its fifteen seats are vacant, the office of Chairperson is vacant, and no member at all is listed in the industry category, so the quorum its regulations require cannot be constituted. Parts II.K.4 and II.K.5.

The study and report to Congress directed by § 360jj(a)(2) has not been made as to these products. Part II.I.4.

Four years have passed since the first petition. The instruments of the electronic product radiation control program stand, as to this radiation, where they stood before it was filed.

6. The agency's own records on the subject remain unavailable to the public

A request under the Freedom of Information Act for the agency's records concerning these products was submitted on March 30, 2025. Nothing has been produced. The disclosure office of the Center for Devices and Radiological Health estimated completion on January 15, 2027. In the litigation described at Part IV.D.3, the United States has acknowledged that as of August 12, 2026 no determination had been made, no record had been produced, and no exemption had been asserted.

Separately, the literature search and systematic review on which the response of May 24, 2024 rested has not been published, and the organization that performed it has not been named. Parts I.C.6 and IX.H.2.

These six propositions are set beside one another because the Foundation believes the comparison is the most useful thing it can offer this Department, and because the comparison requires no adjective.

This request for information invites the public to supply evidence bearing on non-ionizing electromagnetic radiation and human health, and it closes on October 21, 2026. The Foundation has supplied what it holds. The Department's own component has stated that its records on the same subject are expected to become available on January 15, 2027.

The Foundation does not ask the Department to resolve the disclosure litigation and takes no position here on its merits. The observation is narrower, and it is the one with which this Part closes. The public is being asked to supply a record that the agency has not itself made available, on a schedule that closes before the agency expects to make it available.

V. SCIENTIFIC RESEARCH

A. Methods, Sources, and Standard of Evidence [RFI Q4, Q12]

Before stating its methods the Foundation sets out the shape of the subject, because a good deal turns on it.

The effects at issue in this Part are not one effect. They arise in five physiological domains, by distinct mechanisms, and the literature on each is largely separate from the literature on the others.

Photobiological. The direct action of optical radiation on ocular tissue, including photochemical injury to the retina, and the optical effects of high-luminance sources within the eye. Part V.C.

Neurological. Photosensitive responses including seizure, migraine and photophobia, and the trigeminal and melanopsin pathways that mediate light-induced discomfort. Part V.E.

Hormonal. The neuroendocrine response to light, including the suppression of nocturnal melatonin and the entrainment of circadian timing. Part V.F.

Psychological. Affective and behavioral responses, including those mediated by the circadian pathway and those arising from aversive sensory environments. Part V.G.

Mitochondrial and metabolic. The action of optical radiation on cellular respiration, by absorption in the mitochondrial respiratory chain, with consequences for adenosine triphosphate production and for the functions that depend on it. Part V.B.6.

The Foundation separates them because they are separately established, separately studied, and separately unresolved. A conclusion reached about one does not dispose of the others, and the mechanisms do not stand or fall together. An assessment that treats the adverse health effects of LED light as a single question will understate every one of them, because the evidence bearing on each is thin when considered alone and is not aggregated by a question posed in the singular.

The fifth domain requires a word of its own, because it does not fit the framework within which this subject is ordinarily discussed. The other four concern what light-emitting diode products emit. The fifth concerns, in part, what they do not emit. Sunlight and the incandescent lamp both extend well into the infrared; the light-emitting diode is engineered to the band in which the eye forms images and produces little above 700 nanometers. If long-wavelength radiation performs a physiological function, then a lighting transition that removed it is a subtraction as well as an addition, and no hazard framework built around limiting emission can detect a subtraction. Part V.B.6.

Underlying all four is a fact about the stimulus rather than about any one response. Light is not an incidental feature of the human environment. It is the signal by which the timing of human physiology is set, and the human visual and non-visual photoreceptive systems developed under a particular range of spectra, intensities, source geometries and daily patterns. Artificial sources are properly evaluated against that range, and Part V.B.5 describes it. The Foundation does not draw from this any conclusion that artificial light is harmful. It draws the narrower conclusion that a change in the spectral, spatial and temporal character of the light under which a population lives is a change worth measuring, and that no federal body has measured it.

A note on vocabulary belongs here, because it governs how every study in this Part should be read. The literature uses the terms light pollution, artificial light at night, and ALAN. Those are the field's words for its subject and this comment reproduces them when quoting. They describe the same physical quantity that 21 U.S.C. § 360hh(1)(A) calls electronic product radiation when it is emitted by an electronic product, and that § 360ii(a)(2) calls unnecessary when it serves no purpose for the person exposed to it. Part II.D.3 sets out that correspondence and the limits of it. A study is not outside the subject matter of this subchapter because of the words in its title.

1. Literature selection and search strategy

The Foundation maintains a standing bibliography on the effects of artificial light, published at softlights.org and organized in twelve subject categories: human health, eye hazards, neurology, ecology, the physics of light, flicker, crime and safety, flashing lights, vehicle lights, street lighting, electronic billboards, and other research. It also maintains a shared reference library of research

on artificial light at night. The collection has been assembled over several years and the entries range in date from the 1990s to the present.

The Foundation states at the outset what that collection is and what it is not, because the distinction bears on the weight this Department can give it.

It is a curated bibliography. The majority of its entries are articles in peer-reviewed journals, including journals of general scientific standing and specialist journals in ophthalmology, chronobiology and lighting research. A minority are standards documents, reports of governmental and intergovernmental bodies, and items of press reporting, and these are distinguishable on inspection but are not separately labeled on the page.

It is not a systematic review, and the Foundation does not offer it as one. There is no registered protocol, no pre-specified search string, no documented inclusion and exclusion criteria, no dual independent screening, and no formal assessment of risk of bias. A reader who approached it expecting those things would be entitled to say so.

The Foundation is explicit about this for a practical reason. The most likely way for a body of literature to be set aside is for the party submitting it to overstate what the submission is. The Foundation therefore identifies the limits of its own collection first, and asks the Department to weigh what remains on its merits rather than on the form in which it has been assembled.

The method used for this comment

For the purposes of this Part the Foundation has drawn on that collection subject to the following restrictions, which are stated so that any proposition in Parts V.B through V.K can be traced to a source of known type.

Propositions of fact about physiological or health effects are supported only by peer-reviewed primary research or by peer-reviewed review articles, and the citation identifies which.

Standards documents are cited as statements of what a standard requires or recommends, never as evidence of an effect.

Reports of governmental and intergovernmental bodies are cited as statements of the position of those bodies, with the authorship and sponsorship identified, as at Part V.C.2.f.

Press reporting is not cited in support of any scientific proposition.

Preprints are excluded. A manuscript posted to a preprint server has not been peer reviewed, and this Part relies on peer-reviewed research. Where a preprint has since been published, the published version is cited and the preprint is not counted separately.

Records are deduplicated. The same study may appear under more than one identifier — as a preprint and as a published article, or in a conference abstract and a full paper — and counting such records separately would overstate the weight of the evidence. One instance arose in assembling this appendix and is noted at Appendix C.8.

The first-hand reports described in Part VII are treated separately and are not offered as scientific evidence of causation. Subsection 2 states what they are offered for.

An illustration of the form

One entry is set out here in the form the appendix will use, both to show what the Foundation means by a summary and because the study is among the most directly relevant in the collection.

Citation. Barrett EM, Jeffery G. LED lighting (350–650 nm) undermines human visual performance unless supplemented by wider spectra (400–1500 nm+) like daylight. Scientific Reports 2026 Jan 23;16:3061. doi:10.1038/s41598-026-35389-6. PMID 41577976.

Design. Controlled before-and-after study with an independent control group. Twenty-two adults aged 23 to 65, eleven exposed and eleven control.

Intervention and endpoint. Ordinary LED lighting was supplemented with broad spectrum lighting for two weeks. Color contrast sensitivity was measured on the protan and tritan axes at baseline and at intervals afterward.

Finding, in the authors' words: "Here we supplement LED light with broad spectrum lighting (400–1500 nm+) for 2 weeks and test colour contrast sensitivity. We show significant improvement in this metric that last for 2 months after the supplemental lighting is removed."

Proposed mechanism, in the authors' words: "The 420–450 nm dominant in LEDs suppresses respiration while deep red/infrared (670–900 nm) increases respiration in aging and some diseases including in blood sugar regulation."

What it supports. That a measurable deficit in a visual function, attributable to the spectral composition of ambient lighting, is present in working adults and is reversible by changing the light.

What it does not support. It is a small study. The authors advance the systemic mechanism as a possibility and say so in terms: the effect "likely involves shifting patterns of serum cytokine expression, raising the possibility of wider negative impacts of LEDs on human health." The Foundation reproduces that hedge rather than removing it.

The Foundation offers that entry as an example of why the collection cannot responsibly be set aside as a body. The study was published in a peer-reviewed journal of general scientific standing in January 2026, after the determination of May 24, 2024. It sits within a mechanistic literature that the paper itself cites, on mitochondrial complex activity, adenosine triphosphate production, body weight, lifespan and glucose regulation in animal models, together with a human glucose tolerance result. It concerns a property of light-emitting diode emission that no part of the existing federal framework addresses and that the blue light hazard framework does not reach.

The asymmetry, and why it is part of the request

The Foundation has not conducted a systematic review because it cannot. It has no funding for one, no subscription access to the indexed databases a search would require, and no trained reviewers. It is a small nonprofit corporation.

The Department is differently situated. It engaged an organization to conduct a comprehensive literature search and systematic review of precisely this question, as its response of May 24, 2024 states. The Foundation does not complain of that. It is what a federal agency with the authority and the appropriation should do, and it is what paragraph 360ii(a)(2) contemplates when it directs the Secretary to plan, conduct, coordinate and support research. The Foundation's request is not that the Department should have refrained. It is that the product should be published. Part IX.H.2.

And the Department would not be starting from a scattered literature, because the index already exists and is free

The Foundation has just said that it cannot conduct a systematic review because it lacks the money, the subscription access and the reviewers. It should say in the same place that the first obstacle to such a review, which is finding the literature at all, has already been removed by somebody else.

A curated bibliographic database of research on artificial light at night, known as ALAN_DB, is maintained by DarkSky International together with the Loss of the Night Network and is published as a Zotero group library. Described at Appendix D.9. The organization states on its own website that the library is free for public use and that no login is required. It is the same database that the organization identifies as the main source of the briefing document at Appendix D.9, as the entry there records.

The scale, taken first from the maintainer and then from the library itself. The organization states that the briefing drew on nearly five thousand pieces of scientific literature listed in the database; that in recent years an average of about four hundred and thirty publications have been added each year; and that the contents have grown by roughly twenty-two percent a year on average. Its 2023 edition is described as surveying four hundred and fifty-seven papers published in the single year 2022, against the three hundred and twenty-one references in the 2022 edition that this comment uses. The Foundation then went and looked. On October 16, 2026 the library held 6,754 entries.

The Foundation does the arithmetic rather than leaving it, and marks it as its own. The maintainer's five thousand figure carries no date on the page that gives it, but it is attached to a briefing announced in July 2023. If it was current then, the library has added about seventeen hundred and fifty entries in the three and a quarter years since, which is about five hundred and forty a year. That is the same order as the four hundred and thirty a year the organization reports and somewhat above it. It is not the same order as twenty-two percent a year compounded, which from five thousand in mid-2023 would put the library well over nine thousand today, and the observed figure implies compound growth closer to ten percent. The Foundation therefore reports the twenty-two percent figure as the organization's statement and does not rely on it. Nothing in the argument below turns on the growth rate. It turns on the count, and the count is larger than the figure the organization published.

The Foundation draws one conclusion from those figures and declines to draw a second. The conclusion it draws is about availability. Whatever else may be said about the state of this literature, it is not obscure, not dispersed across inaccessible holdings, and not expensive to locate. A federal agency directed by paragraph 360ii(a)(4) to plan and conduct research into the effects of electronic product radiation, and directed by paragraph 360ii(a)(2) to coordinate and support it, can reach the whole of this field from a browser without paying anything. The conclusion the Foundation declines to draw is that volume equals maturity. A field growing at twenty-two percent a year may be growing because it is unsettled as easily as because it is productive, and the Foundation does not argue that five thousand entries settle anything. What the volume establishes is that the literature is large enough to require evaluation and accessible enough that evaluating it is a matter of deciding to.

The Foundation also states what that count does to its own submission, before anyone else does. Appendix C contains one hundred and fifty-three peer-reviewed articles. Against 6,754 entries that is about two and a quarter percent, or about one entry in forty-four. The Foundation does not claim to have read the field. It claims to have read what it cites, to have said in each entry what the study does and does not establish, and to have recorded the findings that run against its own position, of which Parts V.A.2, V.I and V.J.4 contain many. Those are different claims and the Foundation makes only the second. The right response to the first is not to take the Foundation's word for the field. It is to open the index.

So the request at Part IX.H.2 can be put more precisely than it has been. The Department engaged an organization to conduct a comprehensive literature search and systematic review of this question and has not published the result or named the organization. The Foundation asks that the product be published. It adds here that the Department need not treat the task as one that must be commissioned afresh behind a contract: the population from which any such review would draw is a public web page, and the Department can check the Foundation, check its contractor, and check itself against the same list.

2. Categories of evidence and how each is weighted

Evidence of different kinds supports conclusions of different kinds. The Foundation sets out the categories it relies on and what each can and cannot establish, so that no proposition in this Part is read as resting on more than it does.

Physical and radiometric characterization. Measurements of what a product emits — spectral power distribution, radiance, luminance, modulation. These establish the exposure and nothing about its effect. Part V.B.

Mechanistic and in vitro studies. These establish that a pathway exists and is biologically plausible. They do not establish that it operates at the exposures encountered in ordinary life.

Controlled human exposure studies. These establish effects at the exposures and durations actually administered, in the populations actually studied. They are the strongest evidence available for short-term and acute responses, and they are structurally incapable of addressing exposures measured in years.

Animal studies. These permit exposures, durations and endpoints that cannot be used in humans, including histological examination of the retina. They carry the indirectness that attaches to any inference from another species, and the Foundation states that indirectness wherever it relies on one.

That indirectness has specific grounds in this literature, and the Foundation sets them out here rather than leaving the word to do the work. Thirty-three entries in Appendix C rest wholly or partly on non-human subjects: C.9, whose animal arm accompanies a human analysis, and C.15, C.23, C.26, C.36, C.48, C.49, C.50, C.51, C.125, C.126, C.127, C.128, C.131, C.132, C.133, C.134, C.135, C.136, C.137, C.138, C.140, C.141, C.142, C.144, C.145, C.146, C.147, C.148, C.150, C.151, C.152 and C.153. Appendices C.139 and C.149 are deliberately not among them, neither having observed any organism: the first is a remote-sensing study and the second a radiometric characterization of street lights in which animal visual systems appear only as models. Eighteen animal taxa are represented — laboratory mice, rats, wild spiny mice, an endangered heteromyid kangaroo rat, cattle, a urodele amphibian, the fruit fly, the mosquito, nocturnal moths, dragonflies, the monarch butterfly, two species of intertidal littorinid snail, a coral reef anemonefish, domestic fowl kept as disease sentinels, a seabird, four species of resident and migratory songbirds together with the captive zebra finch, an assemblage of Mediterranean marine fishes and invertebrates, and a flying-insect assemblage identified to order and suborder — and the distance from a human is not the same in each. Appendix C.142 is the only entry that samples a larval stage; every other study of moths in this appendix sampled adults. Two of the thirty-three are not used for their findings at all: Appendix C.131 is not an organism-level study but a satellite observation of urban vegetation across four hundred and twenty-eight cities, and Appendix C.134 is an entry whose findings the Foundation declines and from which it takes only the authors' lighting recommendations and an error in their units. The grounds of indirectness set out below do not apply to either in the same way. Appendices C.136 and C.137 are also different in kind: what the first tests is not an organism but a luminaire, and what the second establishes is a mechanism of flight control rather than an effect on a population; and Appendix C.138 is relied on principally for the limitation in its own exposure variable, its finding being recorded as suggestive only. Appendix C.50 states the grounds in its own entry at length, because the subject there is an insect whose photoreceptive biology is not homologous with a mammal's, and the Foundation does not repeat that here; Appendices C.125, C.128, C.132 and C.135 do the same for the mosquito and for moths, and Appendices C.133, C.141 and C.149 are the three entries in which the investigators resolved the question by modeling a visual system rather than assuming it, the second doing so for three predators at once and for the appearance of the prey to each of them, and the third for five visual systems and four non-visual photoreceptors against nine measured street lights.

For the rodent work, which is most of it, three grounds of indirectness are specific enough to state. The Foundation takes them from a review by investigators who conduct rodent studies of this exposure themselves — Bedrosian and Nelson, in Translational Psychiatry in 2017 — because a limitation carries more weight when stated by those whose own models it qualifies. Randy Nelson is an author of the entries at Appendix C.25 and C.49, as those entries record.

Nocturnality inverts the phase of the exposure. In the authors' words: "Many rodent species are nocturnal, unlike humans, meaning that exposure to light at night occurs during their active and awake phase." Light at night is therefore not the same intervention in a mouse as in a person. In the person it falls in the rest phase and competes with sleep; in the

nocturnal animal it falls in the active phase and does not. Any inference that carries a rodent result across to a human carries that difference with it.

The same fact is also a methodological strength, and the Foundation states it because the point is symmetrical and the comment would be misleading if it gave only the unfavorable half. The standing alternative explanation for the human findings in this literature is that the effects are consequences of disturbed sleep rather than of light. Because a nocturnal animal is not attempting to sleep when the light is on, a result obtained in one cannot be attributed to sleep disruption. The authors put it so: "Indeed some effects of nighttime light are likely attributed to sleep disruption in humans, but studies using nocturnal species show that it is not the only cause." Nocturnal models are accordingly poor analogues of human exposure and good instruments for separating the light pathway from the sleep pathway. The Foundation relies on them for the second purpose and not the first.

Diurnal models exist and have been used to address the phase problem directly. The review records that "Studies in diurnal Nile grass rats have attempted to overcome this difference." When this Part was first drafted the Foundation recorded that no entry in Appendix C used a diurnal model, and that this was a gap in the collection rather than in the field. That gap is now closed, and closed in the strongest form the design admits. The study at Appendix C.126 exposed a diurnal mammal and its nocturnal congener to the same light, in the same enclosures, at the same time, and measured the same endpoints in both. Its principal finding is addressed to exactly the difficulty set out in the paragraph above: the effect tracked the animal's rest phase and not its temporal niche. The Foundation returns to this at Part V.I, and states there both what that does and does not license.

Melatonin is not reliably present in the standard laboratory mouse. The review states: "Although both nocturnal and diurnal species produce melatonin during the dark phase, certain inbred laboratory strains of mice have no detectable pineal melatonin rhythm at all." That bears on any entry whose mechanism is said to run through melatonin suppression, and it bears directly on the animal arm of Appendix C.9, in which melatonin was administered to mice and partially reversed the effect observed. A result in which melatonin matters, obtained in a strain that may have no melatonin rhythm of its own, requires the strain to be identified before the result can be weighed. The Foundation has not established the strain used in every rodent entry and says so.

The Foundation draws two consequences for how this Part should be read. The first is that no proposition in Part V rests on an animal result alone, and where an animal result is the only support for a proposition the entry says so. The second is that the function of the animal evidence in this comment is narrower than its volume suggests. It is relied on to show that a pathway exists, that it responds to the spectral and temporal variables the Foundation asks to have characterized, and that effects are obtainable at exposures that are not injurious. It is not relied on for the magnitude of any effect in a human being, and paragraph 360ii(a)(4) does not require that it be: the provision directs the Secretary to study and evaluate emissions and conditions of exposure, and a demonstration that a pathway responds to a variable is a reason to study it rather than a substitute for having done so.

Observational epidemiology. These establish associations in populations, subject to confounding. Studies of outdoor artificial light at night, in particular, face the difficulty that light exposure covaries with urbanization and with much else.

One limitation attaches to an identifiable subset of that evidence rather than to the whole of it, and the Foundation records it here so that no entry is read as resting on more than it does. Eleven of the fifty-two entries in Appendix C take radiance detected from orbit as their exposure variable, and two further entries are reviews of literatures composed substantially of such studies. The instrument from which that measure derives is sensitive only above approximately 500 nanometers, which is above the emission peak of the products this comment concerns. Part V.J.4 sets the matter out with citation, and the weight the Foundation accords those entries follows from it. They are evidence of an association between outdoor light at night and the stated

outcome. They are not evidence about the spectral content of that light, and the Foundation does not advance them as such. Appendices C.32 and C.38 are the two entries in which exposure was measured at the person rather than from orbit, and Part V.J.4 describes the one study that resolved wavelength.

Case reports and clinical observation. These establish that a presentation has occurred and has been recorded by a clinician. They do not establish frequency or causation.

Consensus standards and assessments by governmental and intergovernmental bodies. These establish what expert bodies have concluded and recommended. They are evidence of the state of expert opinion, not primary evidence of effect, and the Foundation cites them as such.

First-hand reports from members of the public. Part VII. These establish that people report a response, in numbers and with a consistency that can be described. They cannot establish causation, they have no denominator, and they are not offered for either purpose. What they are offered for is stated at Part VII.J.1: they are the only systematic collection of such reports in the United States, because no federal system exists to collect them.

Evidence that does not rest on light at night

One further observation belongs with these categories, because it answers an objection that could otherwise be made to much of this Part. A great deal of the human evidence described below concerns artificial light at night. It would be open to the Department to say that such evidence is about sleep and circadian timing rather than about what a product emits, and that the remedy for it lies in behavior rather than in a performance standard.

Not all of the evidence has that shape. Chang and others, publishing in Ecotoxicology and Environmental Safety in 2024, exposed mice to light-emitting diode light under a maintained twelve-hour light and dark cycle, without alteration of diet, and reported hepatic injury on histological examination — inflammation, hepatocellular ballooning and pyknosis — with the injury more severe in older animals. Appendix C.15.

The Foundation draws attention to the design rather than to the finding. The circadian cycle was not disrupted. The animals were not exposed at night, and they were not deprived of darkness. The variable was the light itself, delivered during the light phase of a normal cycle. Whatever weight the Department gives the result, and Appendix C.15 sets out several reasons for giving it a measured one, the study is not susceptible to the objection that it is really about sleep. It is an experiment in which the exposure was an emission and the outcome was an injury to an organ.

That matters to the statutory question in a way the epidemiology cannot match. Section 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. An experiment that varies the emission while holding the conditions of exposure constant is the form that duty contemplates. The Foundation does not suggest that one study in mice establishes anything about human liver health, and says so again at Appendix C.15. It suggests that the design is available, that it has been used, and that it has not been used by this Department.

On confounding by urbanization, and the study that addressed it directly

The second standing objection to this literature is confounding. Outdoor light at night is among the closest available proxies for urbanization, and urbanization brings with it air pollution, traffic, noise, population density, socioeconomic position and differences in access to medical care. An association between outdoor light and disease may be an association between city life and disease. The Foundation has stated that objection against its own entries at Appendices C.5 and C.16 and states it again here.

One study in this appendix addressed the principal component of that objection by measuring it. Wu and others, publishing in Stroke in March 2024, followed 28,302 participants in Ningbo,

China through 127,877 person-years, identifying 1,278 incident cases of cerebrovascular disease confirmed against medical records and death certificates. Outdoor light at night was estimated from satellite imagery, and fine and coarse particulate matter and nitrogen dioxide were estimated separately using land-use regression models. Both were then entered into the same proportional hazards models.

In single-exposure models, each interquartile-range increase carried a hazard ratio of 1.17 (95 percent confidence interval 1.06 to 1.29) for outdoor light at night, 1.25 (1.12 to 1.39) for particulate matter of aerodynamic diameter 2.5 micrometers or less, 1.14 (1.06 to 1.22) for particulate matter of 10 micrometers or less, and 1.21 (1.06 to 1.38) for nitrogen dioxide. In the multiple-exposure models the associations of light at night and of particulate matter with cerebrovascular disease persisted. No interaction between them was observed, and the authors conclude that the two effects may be mutually independent.

The Foundation states the qualifications immediately, and they are real. The association did not persist for ischemic stroke specifically in the multiple-exposure models, and no association with hemorrhagic stroke was observed at any stage. This is one cohort in one Chinese city, and the lighting stock of Ningbo is not that of the United States. Residual confounding by urban factors other than air pollution is not excluded. And the exposure is satellite radiance, so this study is subject to the same spectral blindness as the rest. Appendix C.17 sets all of this out.

What it does establish is narrower and still useful. The most frequently offered alternative explanation for the association between outdoor light at night and disease — that the light is standing in for air pollution — was tested in this cohort by measuring air pollution and adjusting for it, and the association survived. That does not make the finding causal. It removes one specific explanation in one specific population, which is how a confounding objection is properly answered: by measurement rather than by assertion on either side.

A comparison the Foundation offers with care

There is an observation in those figures that the Foundation puts forward cautiously, with its limits stated first. Hazard ratios expressed per interquartile-range increase are not strictly comparable across different exposures, because an interquartile range means a different thing for each; the comparison is within a single cohort in a single city; and the confidence intervals overlap substantially. Nothing in this comment depends on the comparison.

Subject to those limits: in this cohort the hazard ratio for outdoor light at night, 1.17, was of the same order as the hazard ratio for fine particulate matter, 1.25. Fine particulate matter is the subject of a National Ambient Air Quality Standard, a national monitoring network, state implementation plans and decades of federal research. Outdoor light at night is not measured by any federal program at all, as Part V.J establishes. The Foundation does not suggest that the two exposures are equivalent, or that light should be regulated as an air pollutant, which Part II.H.3 explains it cannot be. It observes that an exposure producing associations of a comparable order in a peer-reviewed cohort study has attracted no federal measurement whatever, and that § 360ii(a)(4) directs this Department to supply it.

On the finding that the quality of the evidence was low

The response of May 24, 2024 states that the review the agency commissioned "concluded that the overall quality of evidence in the literature for any health effects was low." The Foundation asks the Department to consider carefully what that sentence does and does not say, because the phrase is a term of art and the conclusion drawn from it in the same letter does not follow.

In the frameworks ordinarily used to rate bodies of evidence, the rating is a statement about confidence in an effect estimate, and it is driven substantially by study design. Randomized controlled trials begin at high confidence and observational studies begin at low, before any examination of the individual studies at all. Ratings are then adjusted for risk of bias, inconsistency, indirectness, imprecision and other factors.

Apply that to this exposure. No one can randomize human beings to decades of exposure to one lighting technology against another. The exposure is ambient, involuntary and lifelong, and the endpoints of interest develop over years. The available evidence will therefore consist of laboratory exposures of short duration, animal models, and observational epidemiology. Under a framework that starts observational evidence at low confidence, the rating of the body of evidence is substantially determined before the first study is read.

This is a recognized difficulty. It is why purpose-built frameworks exist for environmental and occupational health evidence, developed precisely because instruments designed to evaluate clinical interventions systematically understate evidence about ambient exposures. The Foundation does not know which framework the review applied, because the protocol has not been published and the organization has not been named.

Three consequences follow, and the Foundation puts them as propositions rather than as argument.

A finding that the quality of evidence is low is a finding about the state of the evidence. It is not a finding that the exposure is safe, and it is not a finding of no effect. Insufficient evidence of harm and evidence of no harm are different findings, and only the first was made.

A review framed around the question whether exposure has been shown to elicit adverse health effects can return the answer not shown for any exposure that has not been adequately studied. It cannot return the answer safe. The question posed determines the range of available answers.

A finding that the evidence on a question is of low quality is the classic occasion for research, not the classic occasion for closing a file. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, and paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions and conditions of exposure. A low-quality evidence base is the condition those paragraphs address.

The Foundation accordingly does not dispute the review's rating. It may well be right. The Foundation disputes the inference drawn from it in the same letter, which is that the products have a long history of safety and that performance standards have historically not been considered necessary. A body of low-quality evidence will not support a conclusion of safety in either direction. Part I.C.

A further feature of this literature, which goes not to the confidence of the evidence but to its form

The preceding passage concerns how a body of evidence is graded. This one concerns the shape of the experiments in it, and the Foundation puts it last among the observations in this subsection because it is the one that bears most directly on what the Department could lawfully prescribe.

In October 2023 the Royal Society published a theme issue on light pollution in complex ecological systems. Its guest editors introduced the collection with an assessment of the field they had just assembled, and the Foundation reproduces the substance of it because an assessment of that kind is more useful from the people who solicited the papers than from a commenter. Described at Appendix D.7.

Their observation is this. Light intensity is among the most important and most widely studied properties of artificial light at night. But the majority of studies of it, they write, rest on binary comparisons — the presence or absence of light — or include only a limited number of intensity levels, and they name only two exceptions in the literature they surveyed. They attribute this to the practical difficulty of running experiments at many levels, particularly at the level of a community, and they are careful to say that such studies have provided a solid foundation for recognizing that light pollution matters.

They then state the two consequences, and the Foundation adopts both. A study with too few levels risks misinterpreting the true impact of light, and it limits the ability to predict. Their own illustration makes the first concrete in a way worth setting out: an experiment comparing two conditions may find nothing where a real effect exists, if the two conditions happen to sit on a flat part of the curve; and an experiment comparing two conditions may miss that the relationship saturates, and so overstate what a further increase in light would do. Two papers in the same issue show the shapes at issue are real: one reports a nonlinear relationship between irradiance and the survival of barnacles, and another a saturating relationship in which more than half of the measured change in invertebrate movement had already occurred at illuminances below that of a full moon.

Why the Foundation puts this in a comment about a performance standard

Because a performance standard is a number. Section 360kk authorizes the Secretary to prescribe performance standards for an electronic product to control the emission of electronic product radiation, and such a standard prescribes a limit on a characteristic of the emission. A limit is a point chosen on a curve. To choose it, the Department needs the curve: the relationship between how much is emitted and what follows.

A comparison between light and no light does not produce a curve. It produces the proposition that something happens at some unstated level. That proposition is enough to justify research, and it is enough to defeat a claim that nothing happens. It is not enough to yield a number, and no quantity of such studies will become a number by accumulation.

The Foundation therefore asks the Department to recognize a distinction that the response of May 24, 2024 does not draw. The obstacle between this literature and a performance standard is not principally that effects are unproven. It is that the literature is the wrong shape to yield a limit, and the people who edit the field say so. That is a diagnosis with a remedy attached, and the remedy is the one paragraph 360ii(a)(2) and paragraph 360ii(a)(4) describe: research planned, conducted, coordinated and supported, and emissions and conditions of exposure studied and evaluated. What is needed is not another demonstration that light at night has effects. It is a characterization of the relationship between the quantity emitted and the effect produced, across a range of levels wide enough to show the shape. Part IX.C makes that request and this is its evidentiary basis.

One finding in the same issue bears on where that range must begin, and the Foundation flags it because the intuition it corrects is a natural one. More than half of the change those investigators measured occurred below the illuminance of a full moon. A dose-response study that begins at street lighting levels and works upward would therefore miss most of the relationship. If the Department commissions such work, the range must extend down to and below natural nocturnal light. Appendix C.128 measured the ambient night at its field sites at a median of 0.0168 lux, and Part V.I records why that figure is not the natural level but a measure of how far above it field work is conducted; a moonless natural sky is conventionally placed one to two orders of magnitude lower.

And one attempt has been made to assemble the thresholds, which the Foundation reports with its provenance stated first

Seymoure and seven colleagues have published what appears to be the only compilation of the illuminance levels at which effects have been reported, arranged across species. Described at Appendix C.147. The Foundation has read the 2019 preprint of that work under its earlier title and has not read the published article, which appeared in 2025 under a different title and which a National Park Service summary indicates contains at least two findings the preprint does not. Everything in this paragraph is therefore provisional and is offered to show that the exercise has been attempted, not to supply numbers the Department could rely on.

As the preprint has it, a systematic review found effects of light at night reported in 117 species from 23 orders across 8 classes, covering foraging, movement, activity patterns, vigilance, mating and reproduction, population and community measures, predation and mortality, physiology and development, and vocal behavior. Sorted by the illuminance at which the effect was reported: 77

species between one tenth of a lux and three lux; 25 species between one hundredth and one tenth of a lux; 18 species between one thousandth and one hundredth; and 28 species below one thousandth of a lux, a level below that of a moonless natural sky, with five of those being cases of elevated mortality in prey species.

Two things follow for this subsection and the Foundation keeps them apart from the numbers. The first is that the shape of the distribution is the opposite of what a reader would expect: the bin with the fewest species is not the dimmest one. Effects are reported across four orders of magnitude of illuminance, and the authors say the studies are not evenly distributed across light levels, which is a statement about where the research has been done and not about where the effects are. The second is that if any part of the lowest bin survives peer review, it describes effects occurring below the ambient level at which the field studies collected in this appendix set their dark controls, which is the gap Part V.I now identifies. The Foundation asks the Department to obtain the published article and its supplementary data, which is where the species-by-species thresholds are, and notes that this is the nearest thing in the record to the compilation paragraph 360ii(a)(4) would require.

There is in fact an earlier and better compilation, and it settles the question of where a natural night is

Gaston K.J., Bennie J., Davies T.W. and Hopkins J., The ecological impacts of nighttime light pollution: a mechanistic appraisal, Biological Reviews, volume 88 (2013), pages 912 to 927. Described at Appendix D.7. The Foundation states the authorship first: Gaston and Bennie are authors of Appendix C.94 and Appendix C.128 and of the satellite instrument paper relied on at Part V.J.4, Davies is an author of the marine review at Appendix D.7 and of Appendix C.141, and the fourth author was then at Natural England, a government body. This comment therefore leans on one research group in several places and says so wherever it does. The review is also thirteen years old and the Foundation uses it for two tables rather than for its account of the literature.

The first table, which discharges a question this comment had left open

Part V.I records that the Foundation had to withdraw a characterization of two field measurements as agreeing measurements of natural darkness. This review supplies a reference table of illuminance, compiled from the British Standards Institute, a standard reference work on ecological consequences of artificial light, and a third source. In lux:

> Full sunlight, 103,000. A partly sunny day, 50,000. A cloudy day, 1,000 to 10,000.
>
> An operating table, 18,000. A bright office, 400 to 600. Most homes, 100 to 300.
>
> Main road street lighting at average street level, 15. A lighted parking lot, 10. A residential side street, 5.
>
> A full moon under clear conditions, 0.1 to 0.3. A quarter moon, 0.01 to 0.03. A clear starry night, 0.001. An overcast night sky, 0.00003 to 0.0001.
>
> Urban skyglow, 0.15.

Three things follow and the Foundation separates them. First, the correction made at Part V.I is confirmed: a clear starry night is a thousandth of a lux, so the 0.0168 lux measured at the English field sites is roughly seventeen times a natural unlit sky and the 0.03 lux measured in the lagoon is the illuminance of a quarter moon. Neither is natural darkness and the comment no longer says they are. Second, the span this comment is concerned with covers about four orders of magnitude between an overcast natural night and a lit residential street, and about ten orders of magnitude from an overcast night to full sunlight, which is the range the authors give for the natural day and night cycle. A performance standard operates somewhere in that span and nothing in the American regulatory record identifies where.

Third, and this is the figure the Foundation asks the Department to hold in mind through the rest of this Part: urban skyglow is given as 0.15 lux, and a full moon under clear conditions as 0.1 to 0.3 lux. On these figures the diffuse background of a lit city is of the same order as moonlight, which is to say that in such a place the moon has in effect been switched on permanently. The Foundation offers

that as the scale of the alteration and not as a biological claim, and notes that the figure is a single representative value in a reference table rather than a measurement with a stated location, instrument or method, which is why the comment states it as the review gives it and relies on it for order of magnitude only.

The second table, which is the compilation itself

The review also tabulates, in its own words, examples of the levels at which nighttime lighting has been observed to have biological effects: a species, a setting, an effect, an illuminance and a source, ordered by increasing intensity. Twenty-odd rows spanning from millionths of a lux to a thousand lux. It is a better object than the compilation described above because every row names the study behind it. Selected rows, in ascending order of illuminance: prey detection in a common toad at 0.00028 lux; altered circadian rhythm in a Syrian hamster at 0.01 lux; shifted activity peaks in the fruit fly at 0.03 lux; increased rates of tumor growth and metabolism in the brown rat at 0.2 lux and increased rate of tumor growth in the brown rat at 0.21 lux; higher prey intake in five species of wader in a field experiment at 0.74 lux; earlier singing in the American robin at a mean of 1.26 lux in field observations, range 0.05 to 3.06; suppressed immune response in the Siberian hamster at 5 lux; altered timing of nocturnal migration in Atlantic salmon at 14 lux measured at the stream surface; reduced feeding and disturbed flight in pond bats below 30 lux; reduced activity and delayed onset of commuting in the lesser horseshoe bat at 51.67 lux; and disruption of circadian rhythm in a field mouse at 1,000 lux delivered as a fifteen-minute pulse.

And the footnote to that table, which the Foundation treats as the most important thing in the review

The authors append two cautions to their own table and the Foundation quotes both. “Note that: (i) in many cases these represent levels of experimental treatments, and precisely where thresholds might lie remains unknown; and (ii) although widely used, lux measurement places emphasis on brightness at wavelengths perceived by human vision.”

The first limb is the proposition this subsection has been arguing. A table of twenty effect levels is not a table of twenty thresholds; it is a table of the intensities investigators happened to use, and the authors say so. The lowest figure at which an effect has been observed is not the lowest figure at which an effect occurs, and no one has looked below most of these numbers. That is the gap paragraph 360ii(a)(4) directs the Secretary to fill, stated by the field about itself in 2013, and the abstract states it again among the review’s three principal conclusions: that major research gaps exist, particularly in “identification of intensity thresholds, and the spatial extent of impacts in the vicinity of artificial lights.”

The second limb belongs with the attestations collected at Part V.J.4 and is the earliest of them. In 2013, in a table caption in Biological Reviews, the investigators on whom several parts of this comment depend recorded that the unit in which the entire table is expressed is weighted to human vision. Thirteen years later the literature still reports in that unit, as the review at Part V.J.4 demonstrates by counting. The Foundation has not added this instance to the tally kept there, because the tally is of papers whose own exposure variable was affected and this is a review tabulating other people’s work; but the date is the point, and it is recorded here.

Two rows the Foundation flags and does not yet use

The two brown rat rows are increased tumor growth at 0.2 and 0.21 lux, cited to work of 1997 and 2006. Those figures sit within the full-moon range and above the urban skyglow figure in the same review’s other table. The Foundation does not advance that juxtaposition as an argument and sets out why. Both rows describe constant light rather than light at night, the table says so; both are laboratory rodent tumor models, whose relation to human carcinogenesis is the subject of Part V.F and is not assumed here; and the Foundation has read neither paper. They are recorded because if they hold they are the lowest illuminance in this comment at which a disease endpoint has been reported in a mammal, and because the Department should know that the figure exists in a review of this standing. Obtaining those two papers is an acquisition of the first rank.

And one experiment demonstrates the footnote's first limb better than any argument could, because it is the same investigators and the same species

The table above lists lesser horseshoe bats at 51.67 lux, for reduced activity and delayed commuting, citing work of 2009. The Foundation has obtained both that paper and the one that followed it, and they are very nearly a matched pair. Stone E.L., Jones G. and Harris S., Street lighting disturbs commuting bats, Current Biology, volume 19 (2009), pages 1123 to 1127, described at Appendix C.153; and Stone E.L., Jones G. and Harris S., Conserving energy at a cost to biodiversity? Impacts of LED lighting on bats, Global Change Biology, volume 18 (2012), pages 2458 to 2465, described at Appendix C.152. The same three authors, the same species, the same region of Britain, field seasons in consecutive summers, the same seven- and six-night regime of control nights, generator-noise nights and lit nights, luminaires from the same manufacturer obtained under guidance from the same professional body, and exposure measured in both with the same model of illuminance meter. Two things differ. The earlier study used high-pressure sodium and the later one used white diodes; and the earlier study illuminated at one level while the later one illuminated at three — a mean of 3.6 lux, a mean of 6.6 lux and a mean of 49.8 lux.

Activity of the lesser horseshoe bat and of Myotis species was significantly reduced at every intensity, including the lowest, and for Myotis the low and medium treatments did not differ from each other. The authors then state the consequence in terms this subsection has been arguing for:

> "reducing light intensity has often been advocated as a potential mitigation strategy for lighting schemes affecting bats; this assumes that there is a critical light threshold below which there are no negative effects on bat activity. However, for these species, we have shown that light levels would have to be lower than at least 3.6 lux before a potential threshold is found."

Now set that against the earlier study. The 2009 experiment illuminated hedgerows to a mean of 53.09 lux and compared lit nights with unlit nights. One level against darkness. It found a large effect, no habituation over four consecutive lit nights, and the onset of activity at the hedge delayed from a mean of 29.9 minutes after sunset to a mean of 78.6 minutes. What it could not do, and did not claim to do, is locate a threshold, because an experiment with one lit level cannot. It is a binary design of exactly the kind this subsection has been describing, and it is the source of the number in the table.

So the sequence is this. The same investigators studied the same animal twice. The first time they tested one intensity against darkness and found an effect at about 53 lux, and that figure entered a reference table as a level at which lighting has been observed to have biological effects. The second time they tested three intensities and found an effect at the lowest, 3.6 lux, about a fifteenth of the first figure, and reported that they had not reached a level at which the effect disappeared. The table entry was never a threshold. It was the one number the first experiment happened to use. That is what the review's own footnote says about every row in it, and this is the row where the Foundation can show it rather than assert it.

The Foundation states the limit of the comparison in the same breath. Two variables changed between the experiments, not one: the intensity and the lamp. A white diode and a high-pressure sodium lamp are not the same stimulus, and the Foundation does not claim that the 3.6 lux result is the 53 lux result with the dial turned down. What the comparison establishes is narrower and sufficient: that the figure tabulated for this species was a treatment level and not a floor, and that when the same group looked lower they found the effect still there. It is also worth recording that the authors of the later study, who had used both lamp types, considered them comparable in the one spectral respect they addressed, writing that although the diodes emit white light they are comparable with high-pressure sodium in spectral content because they emit very little ultraviolet. That statement is about the ultraviolet alone; the two sources differ most in the blue, and neither paper publishes a measured spectrum of either lamp. Part V.J.4 takes that up.

Three features of the design deserve notice because they are rare in this appendix. The lights were driven by a petrol generator, so the authors added a treatment in which the lamps were installed and the generator ran all night with the lamps switched off; control and noise nights did not differ, which separates the effect of the light from the effect of the apparatus. The three intensities were randomized in sequence across nights to control for order. And activity on the unlit side of the hedge did not change, which means the animals did not relocate to the dark side: the activity was lost rather than displaced. Observation confirmed the avoidance directly, with 44 percent of lesser horseshoe bats turning back or flying over the hedge rather than passing the lights.

One further comparison between the two studies is the best thing in either of them, and it belongs to the authors and not to the Foundation. In the 2009 experiment the unlit side of the hedge was not dark: the high-pressure sodium units spilled across it, and the authors measured a mean of 4.17 lux there on lit nights against a mean of 0.03 lux at the same places on unlit nights. Few bats used it. The authors offered an explanation in 2009 which they were in no position to test, writing that even these relatively low light levels may make established routes unsuitable for commuting. Three years later, having built an experiment that could test it, the same group reported a significant reduction in the activity of the same species at 3.6 lux. Their 2009 conjecture about a spillover of 4.17 lux was confirmed by their own 2012 experiment at a level below it. The Foundation asks the Department to notice what that sequence means for a standard: the light that mattered was not the light the experiment was about. It was the light that leaked off the far side of a hedge, at a level that would not register as lighting to anyone specifying the installation.

Two qualifications, one of which the Foundation volunteers against itself. The effect was confined to the slow-flying species: no effect was detected on three faster-flying taxa, and the comment does not say that all bats avoid light, because this study says they do not. And the authors themselves doubt that their own finding points to a workable remedy, writing that achieving light levels that low may not be practical because public perception of safety and the practicality of dimming often preclude it. The Foundation records that because it is the honest position: an experiment that fails to find a threshold above 3.6 lux does not thereby establish that 3.6 lux is achievable on a public road, and Part IX asks for a standard the Secretary can write rather than one nobody could meet.

The limits of what the Foundation takes from this

Three. The document is an editorial introduction and reports no data of its own; the Foundation uses it for the editors' assessment of their own field and not as evidence of anything. Their assessment concerns studies of light intensity, with community-level work identified as the most constrained; whether the human literature has the same shape is a separate question this comment has not answered, although the exposure characterizations audited at Part V.J.4 point the same way. And the Foundation has not audited its own Appendix C against the editors' claim. It notes that the designs described there are predominantly two-level, that Appendices C.128, C.132 and C.136 are among the exceptions, each using three or more levels, and that the audit is recorded as a task rather than asserted as a result.

3. What is established, what is emerging, and what is unresolved

The Foundation sorts the subject matter of this Part into three classes. The purpose of doing so is to make clear that it is not asking the Department to accept the whole of the literature, and to identify which propositions it does ask the Department to accept.

a. Established

The following are not in serious scientific dispute, and the Foundation relies on them as settled.

> Light is the principal stimulus that entrains the human circadian system, acting through a retinal pathway distinct from the one that mediates image formation. Part V.F.

Photochemical injury to the retina from short-wavelength optical radiation is a real mechanism, distinct from thermal injury. It is the basis of an international standard and of an exposure limit. Part V.C.2.

Discomfort glare is a real and common response to lighting, and is the most frequent immediate complaint about it. Part V.C.4.

Temporal light modulation produces visual artifacts and physiological effects, and is present in many LED products. Part V.D.

Light-emitting diodes differ from the thermal sources they replaced in spectral power distribution, in the luminance and apparent size of the emitting surface, and in temporal structure. Part V.B.

b. Emerging or contested

On the following the literature is active, the findings are mixed, and the Foundation does not ask the Department to resolve them in its favor. It asks only that they be recognized as open.

Whether exposure to light-emitting diode products at the levels encountered in ordinary life contributes to retinal injury in humans. The intergovernmental assessment described at Part V.C.2.f reports that independent groups have found retinal damage below the current exposure limit and that there is no consensus on revising it.

Whether long-term exposure is associated with age-related macular degeneration. The same assessment states that it is not yet possible to conclude anything on this question.

The magnitude of circadian effects at the exposure levels produced by domestic and roadway lighting, as distinct from the laboratory.

The proportion of the population that experiences severe effects from temporal light modulation.

c. Unresolved because unstudied

The third class is the one this comment is principally about. These are not questions on which the evidence conflicts. They are questions on which there is substantially no evidence, because the studies have not been done.

Cumulative exposure across years to the emission of these products, against an exposure limit constructed for episodes of under three hours. Part V.C.2.c.

Real-world exposure from many emitters at once, against a literature in which sources are characterized singly. Part V.J.3.

Radiometric characterization of the products actually in service in the United States, as opposed to products selected for study. Part V.J.1.

Effects on the populations identified at Part VII as disproportionately affected, including people with photosensitive conditions, migraine, and sensory processing differences.

Whether any of the mitigation techniques described at Part II.G.3 reduces human exposure, and by how much.

The Foundation asks the Department to note the character of the third list. Every item on it is a question that 21 U.S.C. § 360ii(a)(4) directs the Secretary to study and evaluate. The absence of evidence on these questions is not a reason to defer the inquiry. It is the subject of the statutory duty.

What the leading advocacy organization in this field concedes about the same evidence

The Foundation adds one source to this sorting and adds it for a reason that has nothing to do with its authority. In May 2022 the International Dark-Sky Association published a briefing titled Artificial Light at Night: State of the Science 2022, compiled from a curated database of the research literature and, the document states, externally reviewed by subject experts. It is described at Appendix D.9. It is an advocacy organization's publication. It carries no named authors, it reports no measurement of its own, and the Foundation does not offer it as evidence of anything. It is cited for a small number of sentences, each of which concedes a limitation that the organization publishing it had every incentive not to concede.

On the health literature, which is the concession that matters most and which runs against this comment

The document's summary of its own human health section reads:

> "These conclusions are largely drawn from controlled studies of exposures to indoor lighting, suggesting caution in interpreting the influence of outdoor lighting on health."

And in the text of that section:

> "It is not possible now to directly connect outdoor light at night exposure to the incidence of disease in individual people."
>
> "whether outdoor light pollution influences human health and wellbeing awaits further research."

The Foundation adopts all three without qualification and asks the Department to read them against the request this comment actually makes. This comment does not assert that outdoor light at night causes disease in any person, and Part V.A.2 and the entries at Appendices C.5 and C.7 are written to prevent that assertion being read into it. It asserts that the question is open, that resolving it is work paragraph 360ii(a)(2) and paragraph (a)(4) assign to the Secretary, and that the Department should not treat the absence of a demonstrated outdoor effect as a demonstration that there is none. The organization whose purpose is the reduction of outdoor lighting says the same thing about the same literature, in a document written to persuade.

On the exposure variable, from a fifth direction

The same document states the proposition of Part V.J.4 twice. On the instrument:

> "the best available satellite cameras are not sensitive to some colors of light. In particular, they do not see the blue light emitted by white LED lighting. This means that key light pollution indicators are probably underestimated."

And on the use made of that instrument in the health literature:

> "critics point out the reliance on the use of satellite data to predict disease-related ALAN exposure. This may make the results of some studies less reliable because satellite measurements are only crude estimates of the actual doses of ALAN from outdoor sources that most people receive."

The Foundation does not add this to the count of attestations kept at Part V.J.4. That count is of peer-reviewed papers in which investigators disclosed the limitation of an instrument they had themselves used, and this document is neither peer-reviewed nor a report of original work. It is recorded because of the company the statement now keeps. The same proposition has been stated by the authors of the instrument paper, by a continental mapping study, by the most comprehensive cancer meta-analysis in this field, by a review of marine ecology, by nine research groups about their own data, and now by the organization most committed to the subject — which adds one thing the others do not, in saying that the need for new dedicated orbital instruments to answer these questions is urgent, while existing Earth-observing missions are scheduled to end.

On lighting and safety, and on the absence of a dose-response relationship

Two further sentences are recorded here and taken up at Part V.M. The document's summary of its public safety section states that there are cases in which the careful application of outdoor lighting may improve nighttime safety "but there is no general benefit supported by scientific evidence." In the text it goes further, and in a direction that costs the organization something:

> "many of the claims about outdoor lighting and its impact on crime and traffic safety – for better or worse – may be fundamentally wrong."

And on the quantity:

> "There is no clear known 'dose-response' relationship that may predict appropriate lighting levels."

That last sentence is the proposition of Part V.A.2 in a line. The field cannot say how much light is required, which is why a literature composed of comparisons between lit and unlit conditions cannot yield a number, and why no quantity of such comparisons becomes a number by accumulation. The document adds that international lighting standards often do not establish benchmarks for the amount of light drivers and pedestrians need on the basis of scientific evidence, and that decision makers substitute their intuition when guidance is lacking.

What the Foundation does not take from this document, which is nearly all of it

Every affirmative factual claim in it. The document reports no measurement and its statements of fact are summaries of three hundred and twenty-one cited sources, written for a general audience. Where this comment needs such a fact it takes it from the source, and Appendix D.9 lists the sources in it worth obtaining for that purpose. The Foundation also records a relationship rather than leaving it to be found: two of the five authors of the mapping study at Appendix C.139 disclosed in that paper that they serve as uncompensated members of the board of directors of this organization. That disclosure was theirs and the Foundation repeats it here only so that the two citations are not read as independent of each other.

The principle on which this document is used is the ordinary one. A statement by a party against its own interest carries weight that the same statement from a neutral source would not, because the incentive runs the other way. The Foundation has applied that principle to itself throughout this Part, and it applies it here. Nothing in this subsection rests on the document agreeing with the Foundation. It rests on the document conceding, where it would have preferred not to, that the outdoor health question is unresolved and that the instrument used to study it cannot see the emission at issue.

B. Physical Characteristics of LED Emission, and Their Departure from the Sources Under Which Human Vision Developed

Three emission characteristics, and the form a standard would have to take

This Part is organized around three characteristics of what a light-emitting diode product emits, and the organization is not the Foundation's invention. It follows from the statute. Section 360kk(a)(1) authorizes the Secretary to prescribe performance standards for electronic products to control the emission of electronic product radiation, and a performance standard of that kind must specify an emission characteristic: it must say what a product may emit, in what quantity, measured how. A standard cannot be written about a technology in the abstract. So the question this comment puts to the Department – what limits should exist – resolves into three questions, one for each characteristic by which optical radiation can be described.

The three are the spatial distribution of the emission, its spectral distribution, and its temporal structure. Subsection 8 below treats the first, subsections 1 and 3 the second, and subsection 7 the third. For each the Foundation states what the evidence in Part V.C and Appendix C reports, and then what federal limit applies. The second answer is the same in all three cases.

Spatial distribution. A light-emitting diode delivers its output from a small, flat, high-radiance surface, so that for a given quantity of light the emitting area is smaller and its radiance higher than in any source that preceded it. Appendix C.64 records a documented macular injury to a thirteen-year-old from a marketed handheld light-emitting diode device. No federal instrument limits the radiance or the luminance of the emitting surface of any visible-light product.

Spectral distribution. Appendix C.70 reports that the biological response to two light-emitting diode lamps of the same manufacturer and part number, differing only in spectral distribution, differed at matched illuminance; and that two lamps of identical correlated color temperature, differing in the structure of their spectra, also differed. No federal instrument limits the spectral distribution of a visible-light product, and none requires that it be disclosed to a purchaser, to a procuring municipality or to this Department.

Temporal structure. The modulation produced by a switching driver is periodic, often approximates a square wave, and occurs at frequencies set by the convenience of the circuit. Subsection 7 below, Part V.D and Part V.J.3 treat it. No federal instrument limits modulation depth or modulation frequency for general illumination.

The three are independent of one another, and that independence is the reason they must be addressed separately. A product may be unobjectionable in its spectrum and present a hazard in its radiance, or be acceptable in both and modulate in a way that matters to a person with photosensitive epilepsy. A standard that addressed one and not the others would leave the others unregulated, and a finding of safety directed at one is not a finding about the others. The Foundation notes that this triad is a division of emission characteristics and should not be confused with the three axes of product classification discussed at Part V.C.2.k, which concern which products a regime reaches rather than what they may emit. The two work together: classification establishes the class, and an emission characteristic supplies the limit.

The division also has a basis in the photobiology and not only in the statute, which the Foundation notes because it answers the objection that the three characteristics are an administrative convenience. The review at Appendix C.72 sets out the three mechanisms by which optical radiation between 400 and 1,400 nanometers injures tissue. Photomechanical damage arises from very high irradiance over very short exposures and, in the review's words, is not determined by the wavelength of light. Photothermal damage is also governed by irradiance thresholds, over somewhat longer exposures. Photochemical damage is the wavelength-dependent mechanism, and it is the one the blue-light hazard framework addresses. So two of the three recognized injury mechanisms turn on how much radiant power is delivered to a point on the retina, which is governed by the spatial characteristic treated at subsection 8, and all three turn on duration. The emission characteristics are the terms in which the injury mechanisms are themselves described.

That division is not peculiar to the review cited. Appendix C.80 records an independent review of retinal light injury published in 2010 by the Department of Ophthalmology and Visual Sciences of the University of Wisconsin, in the journal of the Royal College of Ophthalmologists, which is organized on the same three mechanisms and gives photomechanical injury in substantially identical terms: irradiances of the order of megawatts to terawatts per square centimeter over nanoseconds to picoseconds, producing microcavitation bubbles lethal to the pigment epithelium. The Foundation relies on the American review for the framework in preference to the other, for the reason given in that entry.

The Foundation's request is the same for each of the three, and it is stated at Part I.C.7 and Part IX.B.4. It does not ask the Department to find that these products are unsafe. It asks the Department to read the literature collected in Appendix C and to determine, for each of the three characteristics, the level at which a limit should be set. That is a determination the statute commits to the Secretary, and in the sixty years since the Radiation Control for Health and Safety Act it has not been made for any of the three.

1. Spectral power distribution of phosphor-converted white LEDs and the short-wavelength peak

The characteristic treated in this subsection is the one the agency's own determination put in issue. A phosphor-converted white light-emitting diode does not generate white light. It generates blue light, at a narrow peak near 450 to 460 nanometers, and converts part of that emission to longer wavelengths by passing it through a phosphor. What leaves the lamp is the sum of two things: the unconverted blue peak and the broad phosphor emission. The spectral distribution of the product is therefore not a property of the light the device makes but of the ratio between what the phosphor converts and what it does not.

The consequence the Foundation asks the Department to consider first

That ratio is not fixed for the life of the product. Phosphors degrade. As they do, a smaller proportion of the blue emission is converted and a larger proportion leaves the lamp unconverted. The study at Appendix C.77, published in this Department's own journal, states the point directly, and cites a 2009 publication of the Department of Energy for the lumen maintenance figure:

> "Although it is robust in the beginning, a PC LED progressively releases more short-wavelengths (blue light) when LED lumen depreciation occurs because of phosphor degradation. The quality of the light deteriorates after the lights pass the 70% lumen maintenance level."

If that is correct, and the Foundation has found no contrary authority, then the emission characteristic this comment asks the Department to address drifts over the service life of the product, in the direction of more short-wavelength content. Three consequences follow and each is a consequence for a standard rather than for a person.

A measurement at manufacture does not describe the product in service. Part V.C.2.k sets out that the risk group classification is performed once, at a reference distance, on a sample. Nothing in the framework requires that it be repeated, and a classification assigned to a new lamp is not a statement about the same lamp after several thousand hours.

A performance standard under 21 U.S.C. § 360kk would have to specify the point in the product life at which the limit applies. For the four classes in 21 C.F.R. part 1040 the emission being limited does not drift in this way, so the question has not previously had to be answered. For this technology it does, and the Foundation does not know of an answer in any existing instrument.

The direction of the drift is adverse. A lamp that ages toward dimmer and warmer would present a diminishing question. A lamp that ages toward a larger proportion of unconverted blue presents an increasing one, and it does so invisibly, because the quantity that changes is the one no instrument available to a purchaser reports.

The Foundation states the limits of what it is asserting. It does not quantify the drift, and the sentence quoted above does not quantify it either; it gives a threshold in lumen maintenance rather than a change in spectral composition. Whether the shift in the blue fraction over a product life is large enough to matter for any of the effects in Part V.C is unknown to the Foundation, and it is a question that measurement would answer. It is precisely the kind of question 21 U.S.C. § 360ii(a)(4) directs the Secretary to study, and the Foundation asks for it at Part IX.C.

2. Point-source geometry, peak luminance, and non-uniform emission

The characteristic treated in this subsection is geometric rather than spectral, and the Foundation gives it a subsection of its own because it governs how every other quantity in this Part reaches the eye. A light-emitting diode delivers its output from a small, flat, high-radiance surface. The sources it replaced delivered comparable output from a larger and dimmer one. That difference is not a matter of degree in the way a difference in wattage is. It determines the quantity in which the

exposure must be expressed, and it defeats the most common intuition about how optical exposure varies with distance.

a. The quantity that determines exposure at the retina

Radiance is the optical power leaving a surface per unit area of that surface and per unit solid angle, in watts per square meter per steradian. It is the quantity in which the retinal hazards are expressed in the international guidance described at Part V.C.2, and the reason is the following relation. For a source of radiance L that the eye resolves, the irradiance delivered to the retinal image is

$$E(\text{retina}) = (\pi / 4) \times \tau \times L \times (d / f)^2$$

where L is the radiance of the source, d is the diameter of the pupil, f is the posterior focal length of the eye, and τ is the transmittance of the ocular media at the wavelength in question. Taking the conventional values used in the exposure guidance — a focal length of 17 millimeters and a transmittance of 0.9 in the visible band — the relation reduces to a single coefficient. A dark-adapted pupil of 7 millimeters gives an E(retina) of approximately 0.12 times the radiance of the source. A light-adapted pupil of 3 millimeters gives approximately 0.022 times. The ratio between the two is the square of the ratio of the pupil diameters, or a factor of 5.4.

That relation is not the Foundation's construction and it is worth saying whose it is, because the whole of this subsection proceeds from it. It is equation 2 of the governing exposure guidelines, which state that "Retinal irradiance E r (W m-2) is related to source radiance, L s (W m-2 sr-1), ("brightness"), the transmittance of the ocular media, τ (rel.), the pupil diameter, d p (mm), and inversely related to the effective focal length of the eye, according to the Gullstrand eye (Gullstrand 1909) f = 17 mm". The focal length of 17 millimeters used above is therefore the guidelines' own value, attributed by them to a schematic eye published in 1909, and the two pupil diameters used above are the two the guidelines assume. The guidelines attribute the relation itself to Sliney and Wolbarsht and to Henderson and Schulmeister.

The Foundation draws attention to what is absent from that relation. The distance to the source does not appear in it. That is not an omission, and the reason it is not is the refracting optics of the eye.

Two things happen as a source recedes, and they are equal and opposite. The optical power passing through the pupil falls as the inverse square of the distance, without exception: the pupil is an aperture of fixed area and it intercepts a diminishing fraction of what the source emits. At the same time the retinal image of the source grows smaller, also as the inverse square of the distance. The eye therefore delivers a diminishing power onto a diminishing area, and the quotient of the two — which is the irradiance at the retina — does not change. The cancellation in the relation above is not an algebraic coincidence. It is what a lens does.

The magnitude of the concentration is worth stating, because it is not a modest effect. The ratio of the area of the pupil to the area of the retinal image is the optical gain of the eye. For a source of diameter D at distance d, that gain is the transmittance multiplied by the square of the quantity (d multiplied by the pupil diameter, divided by D multiplied by the focal length). The Foundation sets out the result for the same apertures used in the table at paragraph c, at a dark-adapted pupil of 7 millimeters.

Source and viewing distance	Angular subtense	Optical gain of the eye
1 millimeter aperture at 0.67 meter	1.5 milliradians	approximately 67,800
25 millimeters at 5 meters	5.0 milliradians	approximately 6,100
25 millimeters at 16.7 meters	1.5 milliradians	approximately 67,800
150 millimeters at 10 meters	15.0 milliradians	approximately 680

150 millimeters at 50 meters	3.0 milliradians	approximately 17,000
150 millimeters at 100 meters	1.5 milliradians	approximately 67,800
300 millimeters at 100 meters	3.0 milliradians	approximately 17,000

That gain is not a constant of the eye. It rises as the square of the distance to the source, which is precisely the factor by which the collected power falls, and the two cancel exactly. It rises until the retinal image reaches the smallest size the eye can form, and then it can rise no further. At a dark-adapted pupil of 7 millimeters that ceiling is approximately 67,800; at a light-adapted pupil of 3 millimeters it is approximately 12,500. Those two pupil diameters are not the Foundation’s choice. They are the two the governing guidelines assume, which state that in deriving the retinal thermal limits “two different pupil diameters were assumed, 7 mm for the dark-adapted eye and approximately 3 mm for bright light conditions.”

The physical meaning of the minimum angular subtense discussed at paragraph c below is now apparent, and it is worth stating plainly because the quantity is otherwise opaque. It is the angle at which the eye exhausts its capacity to concentrate. Within it, gain rises with distance and offsets the inverse square exactly. Beyond it, gain is fixed while the power entering the eye continues to fall, and retinal irradiance falls with distance at last. The inverse square law does not fail and then resume. It governs the power entering the eye throughout. What changes at the minimum angular subtense is whether the eye is still able to compensate for it.

The same result can be stated formally, as the conservation of radiance along a ray bundle in a lossless medium. The Foundation gives the mechanical account first because the formal one, while correct and more general, explains nothing about why the result holds.

That formal statement can now be attributed rather than asserted, and with it two further relations this subsection and Part V.B.8 depend on. The conference paper described at Appendix D.6, by an officer of the two standards bodies whose instruments Part V.C.2 examines, sets out the same physics as settled radiometry. On why radiance is the governing quantity, that it is “a measure of the irradiance level in the image plane of a system that images the source (such as the human eye)”. On its photometric counterpart, that “In the field of lighting, radiance is referred to as brightness (more correctly, luminance) when it is weighted with the luminous efficiency function”. On the conservation itself, that the product of area and solid angle is constant in a lossless system and that “This quantity A × Ω is referred to as etendue or throughput.”

And on the result this subsection argues at length, the same author gives the mechanical account the Foundation gave above, with an illustration the Foundation did not have. The irradiance from the sun falls as the inverse square of the distance to it while the solid angle it subtends falls in exactly the same proportion, so that “the sun has the same brightness from all planets when one looks into the sun, but the size of the sun changes. However, the ‘lighting level’ (irradiance) of the surface of the planet changes with distance.” That is the distinction at paragraph b above between the quantity an illuminance meter reads and the quantity the eye poses, stated for two planets instead of two tissues. The same paper gives the retinal relation in the form this subsection uses, that retinal irradiance is the radiance multiplied by the solid angle subtended by the pupil and reduced by transmission losses; and it gives the Lambertian relation on which the arithmetic at Part V.B.8 rests, that the radiance of a Lambertian emitter is its exitance divided by pi steradians.

The arithmetic admits of a check against a familiar case, and the Foundation offers one so that the Department need not take the method on trust. The solar disc subtends approximately 9.3 milliradians. At a pupil constricted to 2 millimeters the gain is therefore approximately 144, and a solar irradiance at the cornea of the order of 1,000 watts per square meter delivers of the order of 100,000 watts per square meter to the retina. That is the order of magnitude the ophthalmic literature reports for solar retinal irradiance. The agreement is offered as verification of the method, not as a finding.

A note on terminology is required, because the comment uses the word lens elsewhere in a different sense. The refraction is performed principally by the cornea, which supplies roughly two-thirds of the refractive power of the eye, and secondarily by the crystalline lens. The Foundation accordingly refers to the refracting optics of the eye rather than to its lens, and does so deliberately. Part II.F.4 relies on the aphakic hazard weighting used by the scientists of the Center for Devices and Radiological Health in their 2010 characterization, and in that weighting the absence of the crystalline lens signifies the removal of a short-wavelength filter rather than the removal of focus. An eye without a crystalline lens still forms an image and still concentrates, and it concentrates a greater proportion of the short wavelengths with which this Part is concerned. An eye without a cornea would form no image at all. The two senses of the word must not be conflated.

b. The consequence, and the error it corrects

The consequence is that within the range described at paragraph c below, the irradiance delivered to the retinal image of a source does not diminish as the observer moves away from it. The source grows smaller without growing dimmer.

The clearest statement of that consequence is a comparison between two tissues of the same person, facing the same source, at the same moment.

Skin has no optical element in front of it. A patch of skin is a bare detector of fixed area. The irradiance upon it falls as the inverse square of the distance to the source, exactly as intuition holds and exactly as a meter reads.

The retina has the cornea and the crystalline lens in front of it, and is not a bare detector. It receives the same diminishing power through an aperture of fixed area, compressed onto an image that diminishes in step with it. The irradiance upon it does not fall.

Those two surfaces belong to one person and face one source at one distance, and they are subject to different physics, because one of them sits behind a refracting system and the other does not. It follows that any characterization of exposure resting on a quantity measured at the body surface, or by any flat detector, understates ocular exposure, and understates it by the gain set out at paragraph a, which across the ranges at issue is of the order of a thousand to fifty thousand.

The Foundation states this because the contrary proposition is asserted routinely, and because it is asserted in response to complaints about the products at issue. The assertion takes the form that the inverse square law governs, so that a person standing twice as far from a light receives a quarter of the exposure. The underlying physics is sound and the conclusion does not follow, because the two statements are about different quantities that share a name.

Irradiance at a flat surface held at the observer’s position does fall as the inverse square of the distance. This is the quantity an illuminance meter reads, and it is the quantity cited.

Irradiance at the retinal image of a resolved source does not. The total power entering the eye falls as the inverse square, exactly as the meter indicates, and the area of retina it is delivered to falls by the same factor.

Both quantities are irradiance and both are measured in watts per square meter. The meter reading is a correct answer to a question other than the one the eye poses. The everyday observation that establishes the point is that a painted wall does not darken as a person walks away from it, and a photograph of a lamp taken at ten meters and at one hundred meters records the same brightness over fewer pixels. A camera and an eye are the same kind of instrument in this respect.

What does fall with distance is the extent of retina exposed, not the intensity of the exposure upon it. For a photochemical mechanism of the kind described at Part V.C.1, which is driven by irradiance and duration rather than by total power delivered to the eye, that distinction is the

material one. Retreating from the source reduces the area at risk. It does not reduce the dose rate within that area.

c. Where the regime changes, in numbers

The relation above holds while the eye resolves the source. It ceases to hold when the source subtends so small an angle that its retinal image can shrink no further, because diffraction, aberration and eye movement set a floor on image size. Below that angle the image area is fixed while the power entering the eye continues to fall, and retinal irradiance does then fall as the inverse square of the distance. The exposure guidance encodes that floor as a minimum angular subtense, 1.5 milliradians for the retinal thermal hazard, and it encodes an upper bound of 100 milliradians beyond which radiance is averaged over a fixed field. For the retinal photochemical hazard it provides an alternative criterion expressed in irradiance for sources subtending less than approximately 11 milliradians.

The retinal image diameter corresponding to an angular subtense is that angle multiplied by the focal length of the eye. At 17 millimeters, 1.5 milliradians corresponds to an image approximately 25 micrometers across, 11 milliradians to approximately 187 micrometers, and 100 milliradians to approximately 1.7 millimeters.

The distance at which a source of a given physical size subtends a given angle is the size divided by the angle. The Foundation sets out the result for a range of emitting apertures, because the numbers are the substance of the point and because they are arithmetic that the Department can check.

Diameter of emitting aperture	100 milliradians at	11 milliradians at	1.5 milliradians at
1 millimeter (a bare high-brightness die)	0.01 meter	0.09 meter	0.67 meter
10 millimeters	0.1 meter	0.9 meter	6.7 meters
25 millimeters	0.25 meter	2.3 meters	16.7 meters
50 millimeters	0.5 meter	4.5 meters	33.3 meters
150 millimeters	1.5 meters	13.6 meters	100 meters
300 millimeters	3.0 meters	27.3 meters	200 meters

The Foundation asks the Department to read the final column. It is the distance beyond which the inverse square law begins to govern retinal exposure, and within which it does not.

For a single bare die of a millimeter across, that distance is approximately 0.67 meter, and at any ordinary viewing distance the inverse square law does govern. The Foundation states that because it is the case against its own general proposition and the proposition should not be stated more broadly than it holds.

For an emitting aperture of 25 millimeters, which is the order of magnitude of a single module in a vehicle warning lamp assembly, the resolved regime extends to approximately 16.7 meters, or 55 feet. For an aperture of 150 millimeters, the resolved regime extends to approximately 100 meters, or 328 feet. An observer at the far side of a parking lot and an observer at the near side receive, at the retinal image, the same irradiance from such a source. For a luminaire aperture of 300 millimeters the figure is approximately 200 meters.

Those distances exceed the distances at which members of the public encounter the product classes described at Part VI. The practical consequence is that for most of the products at issue, across most of the range at which people are exposed to them, distance is not a material variable in retinal exposure at all.

d. What follows, and what does not

The Foundation states the limits of the foregoing before stating its use, because the proposition is a statement about a quantity and not about a magnitude.

It does not establish that any product is hazardous. It establishes what must be measured in order to find out, and in what units. The magnitude question is addressed at Part V.J, where the Foundation states that the measurements have not been made.

It does not establish that all light-emitting diode products present comparable exposure. They do not, and the reason is the one this subsection identifies. Radiance for a fixed luminous output is inversely proportional to the area of the emitting aperture, so products differ in retinal exposure by orders of magnitude according to how widely they spread their emission. A high-output luminaire behind a large diffusing aperture and a bare-die module of the same luminous output are not comparable exposures. The difference between them is in radiance and in position within the visual field. It is not in distance.

It does not hold below the minimum angular subtense, where the inverse square law governs, nor in air carrying appreciable fog, rain, smoke or dust, where attenuation is not negligible. It assumes an eye focused at or near the plane of the source; an eye accommodated elsewhere spreads the image over a larger retinal area and the irradiance falls accordingly.

It concerns a source that the eye resolves, and it is not a statement about scattered light. Skyglow is radiation emitted upward, scattered by the atmosphere and returned to the ground as a diffuse luminance spread across the whole sky. The relation governing that field is the one described at Part V.J, in which brightness at a location falls with distance from the emitting city as a power of that distance. A resolved emitter within the field of view and a diffuse luminance distributed across the sky are different physical situations. The Foundation relies on the first here and on the second there, and there is no inconsistency between them.

It is one of three distinct mechanisms by which darkness aggravates a given emission, and the Foundation keeps them separate rather than running them together. The pupil term in the relation at paragraph a above is this one: a dark-adapted pupil raises retinal irradiance by a factor of approximately 5.4 over a light-adapted pupil, from the same source, at the same distance. The second is the background luminance term in the discomfort glare metric, treated at Part V.C.4. The third is circadian phase, treated at Part V.F. They are different mechanisms with different remedies and the comment does not merge them.

e. The regulatory consequence

Two consequences follow for the form of any standard, and the Foundation puts them as propositions.

First, a limit expressed in illuminance, in luminous intensity, or in a required separation distance does not constrain retinal exposure within the resolved regime. The photometric standards for warning lamps described at Part VI.D are expressed in candelas, which is luminous intensity. Lighting ordinances and siting conditions are commonly expressed as setbacks, mounting heights and illuminance at a property line. None of those quantities constrains radiance, and a product may satisfy every one of them while delivering an unchanged irradiance to the retinal image of anyone who looks at it. The Foundation does not contend that those conventions are without purpose. It contends that they do not address this hazard, and that an agency relying on them is not regulating the quantity that reaches the retina.

Second, the remedy is a radiance limit, and the means of complying with one are established. Because radiance is luminous output divided by the product of emitting area and solid angle, the radiance of a product can be reduced at unchanged luminous output by enlarging the aperture from which it emits — through a diffusing optic, a larger lens, or a greater number of emitters

operated at lower drive current. Doubling the linear dimension of the emitting aperture reduces radiance by a factor of four. Products embodying each of those techniques are in commerce today. Section 360kk(a)(2) directs that a performance standard be technically achievable and that it take into account the reasonableness and practicability of its application. A radiance limit satisfies that direction, because the engineering by which it would be met is neither novel nor costly, and because it is already practiced by some manufacturers in the same product classes.

The Foundation accordingly asks the Department to note that the quantity in which the hazard is expressed, the quantity in which the existing conventions are expressed, and the quantity in which a remedy would have to be expressed are three different quantities, and that only the first and third coincide.

A third consequence bears on the scope of this inquiry rather than on any product, and the Foundation states it here because this subsection is where the ground for it is laid. The Department's notice concerns electromagnetic radiation across the spectrum. For every band within it other than the optical, the human body presents no organ that concentrates the incident field. Radiofrequency, microwave and extremely low frequency radiation are absorbed by tissue in proportion to the field present at that tissue, and the dose quantities in which they are assessed are constructed accordingly. Optical radiation is the exception, and the exception is anatomical rather than physical. The human eye is a refracting instrument that concentrates incident optical radiation onto a layer of non-regenerating neural tissue by a factor that reaches approximately fifty thousand, and it is the only such instrument in the body.

That is why optical radiation cannot be assessed with the dose concepts or the instruments used for the remainder of the spectrum, and it is why the Foundation asks the Department to treat it as a distinct subject within this inquiry rather than as one band among several. It is also the answer to the objection that visible light is ubiquitous, ancient and self-evidently tolerated. What the eye evolved to tolerate is the radiance of the sources described at Part V.B.5, concentrated by the same factor. A source of far higher radiance presented to the same instrument is not a familiar exposure, whatever the illuminance in the room.

A fourth consequence: the quantity is specifiable, and in one industry it is specified

The consequences stated above identify a mismatch between the quantity in which retinal exposure arises and the quantities in which the governing conventions are written. An objection is available at this point and the Foundation meets it here, because the objection is practical rather than scientific. It is that a criterion expressed in source luminance would be difficult to specify, difficult to measure, and difficult to certify against. The answer is that it is none of the three, and the demonstration is an industry that already does it. The Foundation sets out what four product classes report.

Displays. Source luminance, in candelas per square meter, is the headline specification and the basis of certification. The Video Electronics Standards Association' display certification scheme states three separate luminance requirements for each performance tier, measured under three named test procedures: a ten percent center patch, a full-screen flash, and a full-screen long-duration test. A product certified at the 1,400 tier must reach 1,400 candelas per square meter on the center patch and 900 on sustained full-screen output. The quantity is specified, the test geometry and duration are specified, and products are certified against them.

General illumination. Luminous flux, in lumens, together with correlated color temperature. Flux is the total light emitted and is indifferent to the area it departs from. Two products of identical lumen rating may differ by orders of magnitude in source luminance, as Part V.B.8 shows from a manufacturer's own figures.

Roadway and area lighting. The luminance of the road surface, in candelas per square meter, and not the luminance of the luminaire. The distinction is not the Foundation's. A

manufacturer states it, in the document described at Appendix D.3 and Part V.C.4.f, as the complaint that the metrics in use "do not consider true luminaire luminance." What is regulated is the illuminated pavement. What enters the eye is the luminaire.

Warning lamps, including the beacons described at Part VI.C. Luminous intensity, in candelas. Intensity is flux per unit solid angle and is likewise indifferent to the area of the emitter. A reduction in emitting area at constant intensity raises source luminance without altering the reported figure or affecting compliance.

Three of the four report quantities from which source luminance cannot be recovered, and the three are the product classes a member of the public encounters without choosing to. The fourth reports source luminance directly, measures it under published test procedures that specify both the area of the measurement patch and its duration, and certifies products against the result. It is the one class whose purchasers acquire the product in order to look at it.

The Foundation is careful about what that comparison establishes and about what it does not. The display criteria are minimum levels for certification, not maximum permitted emission, and the scheme is a performance mark rather than a safety standard; the Foundation does not present it as one and does not suggest the Department adopt its numbers. The comparison goes to feasibility and to nothing else. Whatever reason there may be for the absence of any source-luminance criterion from the conventions governing the products at issue, it is not that the quantity cannot be specified, cannot be measured repeatably, or cannot be certified against. It is specified, measured to a published procedure, and certified against, in the one product class whose users look at it deliberately. The Foundation asks the Department to weigh that against the position recorded at Part V.C.4.f, where a manufacturer states that the metrics applied to its own outdoor products do not reach luminaire luminance at all.

3. Correlated color temperature and its limits as a descriptor

Correlated color temperature is the descriptor in which the spectral character of a lamp is almost always reported. It appears on the package, in the lighting standards, in the specifications by which municipalities procure street lighting, in the Foundation's own petition to the National Highway Traffic Safety Administration described at Part IV.C.5, and in the recommendation the International Commission on Non-Ionizing Radiation Protection offers for mitigating circadian disruption. It is therefore worth being exact about what the quantity is, because this comment relies on the proposition that it does not describe what a product emits.

a. What the quantity is, and the information it discards

Correlated color temperature is the temperature of the blackbody radiator whose perceived hue most nearly matches that of the source. It is arrived at by a chain of reductions. The spectral power distribution, which is a function of wavelength and carries the whole of the information about what the source emits, is integrated against three color-matching functions to give three numbers; those are reduced to a two-dimensional chromaticity coordinate; and that coordinate is reduced to the single temperature of the nearest point on the blackbody locus. Information is discarded at each step, and what survives is a statement about appearance to a standard observer.

The consequence is that correlated color temperature cannot distinguish sources that look alike and differ in composition. Two lamps of identical correlated color temperature may differ substantially in short-wavelength output, as Part I.G records and as the Foundation states at Part IV.C.5. A blackbody at 2,700 kelvin emits a continuous spectrum. A phosphor-converted white light-emitting diode reported at 2,700 kelvin does not: it emits a narrow peak in the blue and a broad phosphor emission, with the proportions chosen so that the mixture matches the blackbody in hue. The match is in appearance. It is not in spectral content, and nothing in the quantity requires it to be.

b. The published characterization, and where the descriptor fails worst

The Foundation does not rest that proposition on its own analysis. Galadí-Enríquez, of the Centro Astronómico Hispano-Alemán at the Calar Alto Observatory, published in the Journal of Quantitative Spectroscopy and Radiative Transfer in February 2018 a quantitative treatment of exactly this question. The paper opens:

> "Correlated color temperature (CCT) is a semi-quantitative system that roughly describes the spectra of lamps. This parameter gives the temperature (measured in kelvins) of the black body that would show the hue more similar to that of the light emitted by the lamp. Modern lamps for indoor and outdoor lighting display many spectral energy distributions, most of them extremely different to those of black bodies, what makes CCT to be far from a perfect descriptor from the physical point of view."

The paper then computes a spectral index for a set of lamps of many kinds and plots it against correlated color temperature. The author's statement of the result is the sentence this subsection exists to make, and the Foundation asks the Department to note the range it identifies:

> "CCT would be a bad descriptor for the evaluation of the content of blue light, specially in the interval of the most frequent CCTs, from 2000 to 4000 K. All lamps analyzed are redder than the black bodies with the same CCT."

Two thousand to four thousand kelvin is the interval in which domestic lamps, interior commercial lighting and modern roadway lighting are specified. The descriptor is reported as performing worst over precisely the range in which it is used. And the second sentence states a systematic bias rather than scatter: every lamp examined contained less short-wavelength energy than the blackbody of the same nominal temperature, so the descriptor does not merely fail to resolve blue content but misstates it in a consistent direction.

c. The guidance offers its remedy in this descriptor

That bears directly on the assessments treated at Part V.K. The 2020 statement of the International Commission on Non-Ionizing Radiation Protection addresses circadian disruption and offers a remedy expressed in correlated color temperature:

> "Traditional incandescent lamps have a CCT of approximately 2,700 K. There have been recommendations and efforts to lower the CCT of "white" LEDs to below 3,000 K. These efforts should serve to lessen concerns about circadian rhythm disruption from "white" LEDs."

The Foundation sets the two passages side by side and draws the consequence narrowly. A recommendation to reduce correlated color temperature below 3,000 kelvin is a recommendation expressed in a descriptor that the published characterization reports to be a bad predictor of blue content between 2,000 and 4,000 kelvin, which is the interval the recommendation operates in. Two lamps may both satisfy the recommendation and differ in the emission the recommendation is directed at reducing. The Foundation does not say the recommendation is wrong in its aim, which it is not. It says the recommendation is not capable of being verified in the quantity in which it is stated, and that this is a defect of the quantity rather than of the aim.

d. The quantities that do describe spectral content

Four quantities are available, and the Foundation sets them out together because they weight different things and the comment relies on keeping them distinct. Nothing below should be read as suggesting that one may be substituted for another.

- The spectral power distribution itself, measured by spectroradiometry. Part V.J.1. It carries all of the information and any weighted quantity can be computed from it afterwards. It is the only one of the four that presupposes no choice of biological endpoint.
- Melanopic equivalent daylight illuminance, standardized by the International Commission on Illumination as CIE S 026:2018 and described at Part V.F and Part V.J.4. Weighted by the melanopsin sensitivity function, which peaks near 490 nanometers. This is the quantity

apt to the circadian question, and it is the quantity the 2020 statement's recommendation is not expressed in.

Blue-light-hazard-weighted radiance, weighted by the function described at Part V.C.2.a, which peaks at 445 nanometers. This is the quantity apt to acute retinal photochemical injury and to nothing else. Part V.K.6 addresses the consequences of treating it as a general measure of hazard.

The spectral index system of the 2018 paper described above, of which the index relevant here is written $L_{500} - V$: the energy emitted below 500 nanometers compared with the photopically weighted output, expressed as 2.5 times the base-ten logarithm of the ratio. A larger value means less blue per lumen. The system is self-normalized and unit-independent, so no reference source is required.

The Foundation is careful about the last of those and states its limits before its uses. A step at 500 nanometers is not a biological weighting. It is neither the melanopsin function nor the blue-light hazard function, and it does not approximate either. The index was developed by an astronomer, for the characterization of lamp spectra in connection with artificial light at night, and the author describes it as a quantitative description of what a lamp emits rather than as a measure of effect. The Foundation offers it for what the author offers it for: as an objective, computable descriptor of blue content that correlated color temperature is not. The author's own summary of the comparison is that the system is "quantitative, providing the numerical and physical meaning that CCT lacks."

Nine street lights measured, five visual systems modeled, and the finding that the descriptor problem is worse than this subsection has said

Everything above concerns whether correlated color temperature describes what a lamp emits. One study goes further and asks whether the category of lamp does. Seymoure B.M., Linares C. and White J., Connecting spectral radiometry of anthropogenic light sources to the visual ecology of organisms, Journal of Zoology, 2019, doi 10.1111/jzo.12656. Described at Appendix C.149. Working with the municipal utility of Fort Collins, Colorado, the authors measured the radiance of nine street lights actually in service, at a distance of twenty-five meters, with a sensitive spectroradiometer, recording energy flux in watts per square meter per second per nanometer and converting to photon flux. The nine were five high-pressure sodium lamps at 70, 100, 150, 250 and 400 watts, two mercury vapor lamps at 175 and 250 watts, a 1,000-watt metal halide and a 73-watt light-emitting diode. They then computed, for five visual systems and for four non-visual photoreceptors, how many photons each photoreceptor would catch under each lamp, and whether the lamps would be told apart.

Two findings bear on this subsection and the Foundation takes the more important one first.

The first is that a human sees a different city at night from the one a bird or an insect sees, and that the difference is not of degree. In the authors' words: "humans see a much different nocturnal urban environment than other animals as humans see most lights as the same color, yet birds and insects are likely seeing a myriad of differently colored lights in their environment." The modeled chromatic contrasts were above the discrimination threshold for most lamp comparisons in the avian and insect visual systems and below it for many of the same comparisons in the two mammalian ones. The lamps that a human eye cannot tell apart are not the same lamps, and three of the five modeled receiver systems can tell them apart.

The second finding is narrower and, for a Department writing a performance standard, more awkward. Lamps of the same type at different powers do not have the same spectrum. The authors state that this corroborates an earlier measurement study and that it contradicts what they call current doctrine, that similar light sources have the same spectral composition regardless of power. They add that previous research in this field has assumed that light sources within a type are the same color, and they name three papers that did so, two of which this comment has recorded as acquisitions. If that holds, a standard written by lamp technology — sodium, halide, diode — does

not control the emission, because the same technology at a different wattage emits differently. A standard written on the spectrum does control it. That is the conclusion this subsection reached from the spectral-index literature and it is reached here from measurement of hardware in the street.

The Foundation records two things in the same study that do not run its way, because a subsection built on this paper cannot omit them. The diode measured here was not the most short-wavelength-rich of the nine; by the hue metric the authors use, the metal halide had the greatest short-wavelength composition and the diode and the sodium lamps the greatest long-wavelength composition. And only the 1,000-watt metal halide was significantly brighter than the others, the authors observing that subtle differences in brightness are probably irrelevant to an eye that adapts. What they say against the diode is different and more precise than the usual claim, and the Foundation adopts their formulation rather than the louder one: the diode was the least chromatic of the nine, which is to say the most broadband, and was therefore "most likely to stimulate photoreceptors regardless of visual system." A source that spreads its energy across the spectrum reaches every receptor, and that is a different objection from an excess of blue.

One limitation the authors state and the Foundation repeats: these were lamps in service, so fixture height, cleanliness and bulb age could introduce differences their method did not control. And no organism was observed in this work. Every statement about perception is the output of a model of a visual system, resting on published photoreceptor sensitivities and cone ratios and on three assumptions the authors list about how color discrimination works. Part V.A.3 records this as one of three entries in which a visual system was modeled rather than assumed, and the Foundation relies on it for what the lamps emit rather than for what any animal does.

And a field experiment that varied correlated color temperature under radiometric control, which is the test this subsection has been reasoning toward

The argument of this subsection is that correlated color temperature does not determine what a lamp emits. The question it does not answer is whether varying that number changes a biological outcome. One experiment put exactly that question and the Foundation sets out its design before its result, because the design is the reason the result is worth having. Pawson S.M. and Bader M.K.-F., LED lighting increases the ecological impact of light pollution irrespective of color temperature, Ecological Applications, volume 24, number 7 (2014), pages 1561 to 1568. Described at Appendix C.151.

Six white diodes of six different correlated color temperatures were operated in the field in New Zealand, in three blocks, with flying invertebrates collected in traps. The critical feature is how the lamps were equalized. Each diode's drive current was adjusted through a programmable driver until all six produced the same radiant power, 12 milliwatts plus or minus 1, measured by collimating the emission onto a thermopile sensor and averaging over ten-second intervals with a laboratory power meter. Emission spectra were measured for each. That is radiometric matching, and it is the opposite of the photometric matching at Appendix C.148, where two lamps were equalized at a stated illuminance in lux and the cooler lamp therefore delivered more energy by construction. Here the energy was held constant and only its distribution across wavelength was allowed to vary.

Twelve thousand eight hundred and sixty invertebrates were caught. The lamps attracted significantly more flying invertebrates than unlit control traps. And, in the authors' words, irrespective of taxon the color temperature had no significant effect on invertebrate attraction.

The Foundation states carefully what that does and does not show, and the limits are as important as the finding. It does not show that spectrum is irrelevant; it shows that this descriptor, varied across its commercial range at constant radiant power, did not move this endpoint. It does not show anything about human beings. And the endpoint is attraction measured in light traps, which is the quantity Appendix C.142 establishes is not a good proxy for ecological impact and which Appendix C.135 establishes captures only a fraction of the animals affected. A reader could fairly say that the study asked whether a poor descriptor moves a poor proxy.

What survives that is still the thing this subsection needs. If correlated color temperature described the biologically operative content of a lamp's emission, then six lamps differing in it at identical radiant power should have differed in their effect on organisms whose photoreceptors are known to be sensitive to the wavelengths in question. They did not. That is a result about the descriptor, obtained under the only matching condition that could isolate it, and it is the empirical counterpart of the spectral analysis set out above. Taken with the measured correlation of 0.62 between correlated color temperature and a composite wildlife index recorded earlier in this subsection, and with the field comparison of two lamps of identical rating that differed by a fifth in insect attraction, the Foundation submits that the descriptor has now failed three different tests put to it by three different groups.

Two further results in the same paper run in directions a reader should know about. The effect of the lamps was strongly taxon-dependent: marked in flies and in moths and butterflies, and absent in thrips, in bees, wasps and ants, and in beetles. And in a separate comparison at an industrial site, traps at a white diode luminaire caught 48 percent more flying invertebrates than traps at a high-pressure sodium luminaire. The Foundation does not use that second figure in support of anything, for a reason given at the appendix entry: those were two real installations rather than two matched sources, and the paper does not state that their outputs were equalized, so the comparison is between lighting installations and not between spectra at equal power.

Two lamps of the same correlated color temperature, tuned differently, tested in the field, and the author who reports it is the one who calls the descriptor a reasonable rule of thumb

The proposition at the head of this subsection is that correlated color temperature does not determine what a lamp emits. The Australian guidelines at Appendix D.1 demonstrate it with two spectra of identical rating and different blue content. One source reports the biological counterpart, and the Foundation sets out both what it says and what the same author says against this subsection in the same four pages. Longcore T., Hazard or Hope? LEDs and Wildlife, LED professional Review, issue 70, 2018. Described at Appendix D.1. It is a signed essay in a trade magazine of the lighting industry, addressed to lighting professionals, and it is not research.

The experiment it reports is not its own and is described at second hand. Spectral response curves for bees and moths were used to choose between configurations of two prototype tunable lamps rated at 2,700 kelvin and one at 3,000 kelvin, built from red, green and blue diodes, in a manner predicted to reduce insect attraction. Those custom configurations were then compared in a field study against an off-the-shelf lamp of 2,700 kelvin and a fluorescent lamp of the same rating. The result reported is that the tuned lamp attracted twenty to twenty-one percent fewer insects than a similar lamp not designed with that objective, the effect being large for moths.

Two lamps carrying the same number on the package differed by a fifth in a measured biological response. That is the proposition of this subsection established on an organism rather than on a spectrum, and the Foundation states its limits in the same breath: the figure is reported at second hand in a trade essay, the primary study has not been obtained, the subject is insect attraction and not any human endpoint, and a twenty percent reduction is a reduction and not a remedy. What it establishes is narrow and sufficient. A procurement specification, an ordinance or a performance standard written in correlated color temperature cannot distinguish the better of those two lamps from the worse, because it is the same number for both.

And what the same author says that tells against this subsection

The Foundation would not cite an essay for one proposition and suppress its contrary one. The same four pages state that correlated color temperature "is not a perfect predictor of effects on wildlife, but it is a reasonable rule of thumb that lower CCT will be less disruptive to wildlife," and, later, that "As a rule of thumb, CCT can be used as an indicator of wildlife effects, but this may not hold true across all applications." The essay reports modeled results in which lower correlated color temperatures had lower predicted effects on average and for every species group examined.

The Foundation accepts that and says what follows from it, which is less than it appears. A descriptor may correlate with an effect on average across a sample of lamps and still fail to distinguish two particular lamps, and the same essay demonstrates both facts about the same quantity. The comment has never asserted that correlated color temperature is unrelated to blue content; it asserts that it does not determine it, that two compliant lamps may differ in the emission a limit is meant to control, and that a performance standard must prescribe an emission characteristic rather than a rule of thumb. An author who recommends the quantity for rough guidance and in the same essay reports a field experiment distinguishing two lamps that share it has stated the Foundation's case and his own without contradiction, because they are answers to different questions.

Three further things in the essay the Foundation records rather than uses. Its concluding recommendation is a numerical one and it is lower than any American instrument this comment has found: that with amber and filtered products on the market, color temperatures of 2,200 kelvin and below are, in the essay's words, "feasible and desirable to minimize adverse impacts." Its examples of where a simple spectral rule fails are two, that migrating birds cannot orient under red light so solid red lamps are to be avoided on communication towers, and that green light has support for minimizing attraction of nocturnal migrant birds; which makes this the third source in the comment, with the Australian guidelines and the note at Appendix D.6, to say that one spectral rule will not serve every taxon. And its statement of what is missing is a statement of what paragraph 360ii(a)(5) directs: that the relationship between light intensity and spectral responses "is largely unknown and needs research across nearly all wildlife groups," and that "taxonomic-specific metrics of both radiance and irradiance are needed."

e. Numerical limits on lamp spectra already exist in law

The objection most readily made to Part IX.H is that no one knows how to write a spectral limit, and that the Foundation is asking for something that cannot be drafted. The 2018 paper answers it. Table 3 of that paper sets out existing regulations whose requirements the author expresses in this formalism, and they are in three jurisdictions on two continents:

Andalusia, Spain, by regulation of 2010, article 13.a. In general, L_{525} – bolometric greater than 0.753. In protected areas, L_{440} – bolometric greater than 2.060 for non-LED sources and L_{500} – bolometric greater than 2.060 for light-emitting diodes. The author translates the last of those into plain terms: it requires that the total emission below 500 nanometers be less than fifteen percent of the total. That instrument has since been replaced, and the regulation now in force is set out below; the Foundation reports the 2010 provision because it is what the paper analyzes, and does not rely on it as current law.

The Canary Islands, Spain, by the 2017 revision of the Instituto de Astrofísica de Canarias specifications, section G.8. An "amber LED" requires L_{500} – bolometric greater than 4.560; a "warm LED" requires L_{500} – V of at least 1.505; a "super-warm LED" at least 2.060.

Antofagasta, Atacama and Coquimbo, Chile, by decree of 2013, article 7, which imposes three conditions simultaneously, each expressible as a ratio between emission in a defined wavelength interval and emission in another.

The Foundation asks the Department to note the form of those provisions rather than their numbers. Each states a limit on the proportion of a source's emission falling in a defined band. Each is verifiable from a measurement laboratories already perform. None is expressed in correlated color temperature. Section 360kk requires that a performance standard prescribe an emission characteristic, and these are emission characteristics prescribed.

One calibration in the paper is worth stating because it bears on the comparison this Part makes throughout. For the three lamps the author uses as examples, the index L_{500} – V takes the values 4.491 for a phosphor-converted amber light-emitting diode, 1.522 for a classical incandescent bulb and 0.833 for a discharge metal halide lamp; the corresponding fractions of below-500-

nanometer energy relative to photopic output are 0.016, 0.246 and 0.464. The warm threshold of the Canary Islands specification is 1.505. The incandescent lamp, at 1.522, therefore just satisfies it. The author states the point and its qualification: “Not surprisingly, the PC amber LED overruns both criteria, but also the incandescent lamp would fit in the ‘warm’ box (although these IAC definitions are intended only for LEDs).” The Foundation does not represent the threshold as having been set by reference to the incandescent lamp. It notes that a threshold arrived at independently falls within two percent of the lamp that light-emitting diode products replaced, which is the comparison Part V.B.5 and Part V.B.6 draw on other grounds.

The Andalusian instrument as it now stands, verified against the regulation rather than the paper

The drafting of this comment required the three instruments above to be checked against their own texts and not against the paper’s summary of them, and to be checked for whether they remain in force. That check has been performed for the first of the three, and it changed the answer. The Andalusian regulation of 2010 has been superseded. The instrument in force is Decreto 37/2025, de 11 de febrero, por el que se aprueba el Reglamento de protección frente a la contaminación lumínica en Andalucía, published in the Boletín Oficial de la Junta de Andalucía, number 31 of 2025. It is binding regional law, not a technical annex and not a recommendation. Described at Appendix D.2.

The replacement is more useful to this comment than what it replaced, for three reasons.

First: the instrument regulates a named spectral index, and defines it

The decree does not express its spectral requirement in the paper’s notation. It adopts an index by name, the índice espectral G, defines it in article 3.c, and caps its value at 10.00 for all results above that figure. The definition published by the environmental authority of the autonomous community is this. G is minus two and one half times the base-ten logarithm of a ratio: in the numerator, the lamp’s emission summed without weighting from 380 to 500 nanometers; in the denominator, its emission from 380 to 780 nanometers weighted by the photopic luminous efficiency function. A larger value of G means less blue radiation per unit of visible light. The quantity is self-normalizing, so the absolute units of the measured spectrum are immaterial and no reference lamp is required. The authority gives its reasons for the two boundaries: 500 nanometers because it is the threshold commonly used in studies of the effects of light at night, and 380 nanometers because it is a practical lower limit of the spectrometers used by certification laboratories.

That is the same construction as the index described at paragraph d of this subsection, and the same caution applies to it. A step at 500 nanometers is not a biological weighting function. It is neither the melanopsin function nor the blue-light hazard function, and the Foundation does not present it as either. What it is, and all the Foundation offers it for, is a computable description of how much of a lamp’s output lies in the short-wavelength region, obtainable from a measurement that laboratories already make.

Second: the limits are stated as plain numbers, by zone

The environmental authority publishes the minimum value of G required according to the lighting zone in which an outdoor installation is located: not less than 2.00 in zones E1 and E2, and not less than 1.50 in zones E3 and E4. Article 4.1.m permits municipalities to establish exceptions to the annex value in E4 zones, which the Foundation records because a limit with a local exception is a weaker instrument than one without.

The authority also publishes computed values of G for particular products, and these are what make the limits legible. A high-pressure sodium lamp, whose correlated color temperature it gives as approximately 1,880 kelvin, computes to 2.342. A light-emitting diode product labeled 2,500 kelvin computes to 2.044. A light-emitting diode product labeled 3,500 kelvin computes to 1.109. The authority states expressly that correlated color temperature does not determine G, and that the figures given are the labels of those particular products rather than general values for a color temperature.

Three things follow from those three numbers, and the Foundation states them as statements about three specific products in one official document and not as general claims about lamp classes. The diode product labeled 3,500 kelvin satisfies neither limit; on this index it would not be permitted in any lighting zone in Andalusia. The diode product labeled 2,500 kelvin clears the strictest limit by 0.044. And the high-pressure sodium lamp, which is the lamp the conversions described at Part V.M and Part VI.D replaced, outperforms both diode products on the quantity the decree regulates.

The Foundation draws the narrow consequence and not a broad one. It does not submit that sodium lighting should be restored, which is not its position and does not follow. It submits that where a jurisdiction has put a number on short-wavelength content, the conversion of a public lighting estate turns out to be a question that can be asked and answered quantitatively, and that the answer is not supplied by the nominal color temperature printed on the product. That is the proposition this subsection exists to establish, and an instrument in force establishes it better than a paper does.

Third: the instrument distinguishes a warm lamp from a narrow-band lamp, by wavelength and bandwidth

For the protected surroundings of astronomical observatories the requirement is not a color temperature and not merely a higher index. The authority's technical description states that amber sources in those zones must have G not less than 3.5, an effective wavelength between 585 and 605 nanometers, and a spectral width not exceeding 25 nanometers.

The Foundation places that beside a distinction it drew at Part V.I and regards as important. A lamp of low correlated color temperature is not a narrow-band lamp. Warm white light is broad-spectrum light with a reduced blue fraction and it retains blue content. A narrow-band amber source is a different thing: its emission is confined to a stated interval of wavelengths with a stated maximum width. The distinction is not the Foundation's invention and it is not merely a scientific nicety. A regulator has written it as law, in nanometers, with a bandwidth limit, because the two kinds of lamp are not interchangeable for the purpose the rule serves.

What else the same instrument regulates, which bears on Part IX

The Foundation records the remainder of the decree because Part IX asks this Department to characterize four things — spectrum, quantity, direction and duration — and the objection it expects is that no instrument does all four. One does.

- Duration. Article 9.1.a defines the night period as the hours between eleven at night and six in the morning, which article 9.2 permits a municipality to extend or to begin up to one hour later with justification. Article 9.3.b requires installations to remain switched off during those hours except those necessary for an activity or for safety. Article 12.3 requires ornamental lighting to be off during the night period, article 12.4 permitting temporary exceptions until two in the morning.
- Quantity. Article 9.3.d requires installations of one hundred kilolumens or more that must remain lit during the night period to reduce their luminous flux by at least fifty percent.
- Direction. Article 12.2 refers the maximum installed upward hemispherical flux to the annex and provides that in no case may the values of the basic national rules be exceeded. Article 11.2 requires that sign and poster lighting be achieved with devices directing the flux downward. And the first transitional provision requires that existing luminaires inclined above the horizontal with any installed upward flux be reaimed within two years, where doing so does not require replacing components.
- Zoning. Article 17.2 provides that as a general rule no E3 or E4 zone may be established in the adjacent zones of influence of the reference points, which are the observatories.

The Foundation states the limits of this material plainly. Decreto 37/2025 is the law of an autonomous community of Spain. It binds no one in the United States, it was not adopted on a public health rationale that the Foundation has verified, and nothing in it is evidence of a health

effect. The Foundation does not ask the Department to adopt it, to follow it, or to treat it as persuasive authority. It is offered for one purpose, which is the purpose paragraph e of this subsection was written to serve: to answer the objection that a numerical limit on the emission characteristics of a lamp cannot be drafted, cannot be measured and cannot be enforced. It has been drafted, it is measured by a formula the authority publishes together with a calculation tool, and it is in force.

An independent proposal of the same kind, published seven years earlier

The objection answered in the preceding paragraphs is answered a second time, by a different research group, in a different journal, in a different formalism, seven years before the paper described above. The Foundation sets it out because two independent proposals are harder to dismiss as idiosyncratic than one, and because the form this one takes is already in use by this agency.

Falchi, Cinzano, Elvidge, Keith and Haim published in the Journal of Environmental Management in 2011 an analysis of outdoor lamp spectra assessed against three response functions: the photopic, the scotopic, and the band in which light suppresses melatonin. Appendix C.57. They proposed two numerical criteria, and the criteria are plain ratios rather than logarithmic indices.

A limit on the fraction of a lamp’s output falling in a protected band. The authors define the band as 440 to 540 nanometers and propose that a lamp not be installed outdoors if its emission in that band exceeds 15 percent of its photopic energy flux, measured in watts. They write the quantity as R subscript P and the limit as R subscript P less than 0.15.

A limit on the ratio of scotopic to photopic output, measured in lumens, which they write as R subscript sp and set at less than 0.66. The authors confine this second criterion to settings where accurate color perception is essential.

The values they compute for common sources place the technologies in an order that bears on this comment. On the scotopic-to-photopic ratio, low-pressure sodium stands at 0.20 and high-pressure sodium at 0.55, while a white light-emitting diode described as natural white stands at 3.5. On the protected-band fraction, low-pressure sodium stands at 0.0027 and the white diode at 0.87. The spread between the first and the last is three orders of magnitude on the second measure.

Why the form of that proposal matters to this Department

The Foundation asks the Department to notice what kind of requirement R subscript P is. It is a limit on the ratio of a source’s emission in one defined wavelength interval to its emission measured another way. It is not a limit on total output, not a limit on correlated color temperature, and not a limit expressed in any photometric unit alone.

That is the form of a requirement this agency has already prescribed. Part II.C records that 21 C.F.R. § 1040.20, the performance standard for sunlamp products, does not merely cap intensity: it limits the ratio of the irradiance a product produces in one ultraviolet wavelength interval to the irradiance it produces in another. A band-ratio limit on the spectral composition of a light-emitting product is therefore not a novel instrument that this Department would have to invent. It is an instrument this Department has used, in this part, for a light-emitting product, since 1985.

The Foundation draws the conclusion narrowly. It does not assert that the numerical values proposed in 2011 are the right values, and the passage immediately below records one proposal in that paper the Foundation does not adopt. What the paper establishes for present purposes is that the quantity is computable from measurements laboratories already make, that independent researchers have proposed specific numerical values for it, and that the formal structure of such a limit already exists in title 21. The objection that a spectral limit cannot be drafted is answered three times over: by two independent research proposals and by the agency’s own sunlamp standard.

A proposal in that paper the Foundation does not adopt

Candor requires the Foundation to report that the same authors proposed, as their primary rule, something considerably more restrictive than the band-ratio limit described above: a total ban on the outdoor emission of light at wavelengths shorter than 540 nanometers, benchmarked to the emission of high-pressure sodium in that range. A requirement in that form would effectively exclude white light from outdoor use.

The Foundation does not adopt that proposal and does not ask the Department to adopt it. It reports it for two reasons. The first is that a comment which cited the paper for its band-ratio criterion while omitting its principal recommendation would be presenting the source selectively. The second is that the distance between the two proposals is itself informative: researchers working on this question in 2011 regarded a measure of that severity as warranted, and the Foundation's own request – that the Department study and evaluate, and then prescribe a standard on the evidence – is a great deal more modest than what the published literature has proposed.

f. The instrument was proposed for labelling in 2018 and was not adopted

Part II.H.13 records that the label is the only disclosure of emission characteristics most purchasers ever see, and that the quantities it reports are the quantities this comment identifies as insufficient. In February 2018 the author of the paper described above submitted to a European consultation a proposal that an index measuring the weighted content of blue light be stated on lamp labels alongside the energy class, the wattage, the luminous output and the correlated color temperature. In the same month, a lighting academic writing in Nature recommended that light sources be defined by their spectral characteristics in nanometers rather than only by correlated color temperature in kelvin.

Neither recommendation was adopted in any labelling requirement applicable in the United States. Eight years later the quantities on the label are lumens, watts and correlated color temperature. The Foundation states that as a fact about the record and not as an allegation against anyone: a method of reporting blue content was published in a peer-reviewed journal, proposed for labelling, implemented in three jurisdictions abroad, and is absent from every federal requirement.

The author's own expectation, written in 2017, measures the outcome: the index "has some chances to become a kind of standard to classify lamps according to their amount of blue emission." It did not become one.

g. The Foundation's own petition, explained rather than defended

An inconsistency in the Foundation's record is apparent at this point and the Foundation identifies it before it is identified for it. On May 15, 2024 the Foundation petitioned the National Highway Traffic Safety Administration to limit the correlated color temperature of vehicle headlamps, as Part IV.C.5 records. This subsection argues that correlated color temperature does not describe what a source emits. The Foundation therefore petitioned for a limit in a quantity it says is inapt.

The explanation is not a defense of the petition's drafting. Correlated color temperature is the only descriptor of spectral character that appears in the federal motor vehicle safety standard, on the package, or in the procurement specifications of any purchaser the Foundation could address. A petitioner asking for a limit must ask in a quantity the agency recognizes, and there was no other. That is itself a consequence of the absence this comment describes, and the Foundation would rather state it than have it found. If the Department prescribes a limit on the spectral content of any product, the Foundation asks that it not be prescribed in correlated color temperature, and it does not ask that its own petition be treated as a model for the form of such a limit.

h. What follows for a performance standard

Section 360kk(a)(2) directs that a performance standard be technically achievable and that the Secretary take into account the reasonableness and practicability of its application. The 2018 paper addresses that directly, and the Foundation quotes it because the sentence is about implementation rather than about science:

> "The spectral index system is extremely easy to implement from the spectral data that are routinely measured at laboratories. Thus, including this kind of computations in the standard protocols for the certification of lamps will be really straightforward, and will enrich the technical description of lighting devices."

The measurement is already being performed. Spectral power distributions are measured as a matter of routine in the laboratories that certify lamps, because the photometric and colorimetric quantities reported on the package are themselves computed from them. What is absent is not the measurement and not the method of expressing it. What is absent is any requirement that the result be computed, reported or limited. Among the author's own statements of the system's purpose is that it is "potentially useful for industrial certification, legal regulation and biophysical studies."

A second demonstration that the computation is practicable, from a different direction, and a warning about which quantity it is written in

Everything above establishes that a spectral limit can be expressed and that three jurisdictions have expressed one. It does not establish which quantity predicts biological effect best, and that is a separate question which somebody has attempted to answer empirically. Longcore T., On the Use of Summary Metrics of Light Spectral Characteristics to Assess Effects of Artificial Light at Night on Wildlife, posted 13 May 2020 on FIRES, the forum of the Illuminating Engineering Society. Described at Appendix D.6. The Foundation states what the document is before what it says: a short signed note on a standards body's own forum, carrying the forum's printed disclaimer that views expressed there do not necessarily reflect those of the Society, not peer reviewed, and written by an investigator whose other work this comment relies on in several places.

What was done. The author took the database of lamp spectra built for his 2018 paper, twenty-five light sources, added some further sources, and tested four candidate summary descriptors against measured or modeled wildlife responses. The four were correlated color temperature; the melanopic response of the source relative to a standard daylight illuminant; the ratio of melanopic to photopic light; and the percentage of visible light emitted below 530 nanometers. The responses were a composite index and its four components, being insects, juvenile salmon, a seabird and an average of sea turtle responses. The ultraviolet range was considered only down to 350 nanometers.

The result bearing on this subsection is a number, and it is the only number the note states in its text. The correlation between correlated color temperature and the composite wildlife index is 0.62, which the author describes as "adequate but not outstanding." Everything else in this subsection establishes that correlated color temperature fails to describe spectral content as a matter of physics. This is the first quantification the Foundation has of how much it fails by when tested against biology, and the Foundation states its weight accurately: twenty-five sources, in a note that is not peer reviewed, with the remaining coefficients presented in a figure whose values do not appear in the text and which the Foundation therefore cannot report.

The second result is structural and matters more than the first. No single descriptor won. The melanopic response and the melanopic to photopic ratio predicted the composite best; correlated color temperature was better for insects; the melanopic to photopic ratio was better for the seabird. A descriptor that is best overall and worse than a descriptor it replaces for one of the four components is not a quantity on which a single national limit can be written for all of them. That tells in favor of the form the three foreign instruments use and that this subsection has preferred throughout — a stated limit on the proportion of emission falling in a defined wavelength band — and against a single biologically weighted scalar.

And the warning, which the Foundation states against its own convenience because a standard that can be evaded is worse than no standard

The note identifies a specific way in which a limit written in the wrong quantity could be satisfied while making matters worse. Of the two descriptors that performed best overall, the author writes: “Neither the M/P value nor the melanopic response can be used to evaluate effects on insects, however, because any light source that avoids the peak of the melanopic response by using shorter wavelengths (e.g., a violet LED pump) will be extremely attractive to insects.” The mechanism is given earlier in the same note: the insect action spectra indicate high response at short wavelengths, where the melanopic response is approaching zero.

The Foundation sets out why that is directed at its own request and not only at somebody else’s. Melanopic equivalent daylight illuminance is the quantity this comment identifies at paragraph d above as apt to the circadian question, it is standardized, and it is the obvious candidate for a limit addressed to the effect Part V.F describes. A performance standard expressed in that quantity alone could be met by a manufacturer moving the pump diode from blue into the violet, which would reduce the melanopic figure while increasing emission in the band to which the comment’s own spectral material says many organisms are most sensitive, and while increasing the ultraviolet content that paragraph d records the index system as reaching. The Foundation does not know whether such a product is commercially practical and does not assert that anyone would build one. It states the mechanism because section 360kk requires a standard to prescribe an emission characteristic, and the choice of which characteristic is the whole of the drafting problem.

The index this subsection prefers is not defeated by that move, and that is a reason for preferring it that the Foundation did not have before reading this note. An index expressed as the energy emitted below five hundred nanometers relative to the photopically weighted output rises when the pump is moved into the violet, because violet emission lies below five hundred nanometers. A melanopic weighting falls. The two quantities move in opposite directions under the same change to the product, and only one of them moves in the direction that describes what the lamp is actually emitting. The Foundation asks the Department to note that this is an argument for a band-ratio form and not an argument against limiting melanopic output, which may be the right limit for the circadian endpoint considered on its own; it is an argument against using one weighted scalar as the whole of a spectral standard.

On practicability the note adds a second item to the one quoted above. The author records that he and his colleagues published the code so that designers can supply their own spectral power distributions and obtain the assessment with a web browser and a server, and gives the public repository. Taken with the 2018 paper’s statement that the computation is straightforward from spectral data routinely measured in certifying laboratories, there are now two independent statements, by two authors in two disciplines, that the arithmetic of a spectral descriptor is not the obstacle.

Two statements in the note qualify the whole approach, and the Foundation adopts both rather than quoting around them. The first: “Adjusting spectrum is not a panacea,” followed by the other tools the author directs be considered, which are to light only when needed, only as brightly as needed, directed where needed, and reduced or switched off when possible. Those are the quantity, geometry and duration this comment asks to have characterized alongside spectrum, named by the investigator whose subject is spectrum. The second is the sentence the note opens with, that from the position of wildlife the best artificial light at night is no artificial light at night, which the author immediately qualifies by recognizing that this is not feasible while maintaining safety and achieving other goals. The Foundation asks for neither darkness nor the abolition of any product, and records the qualification because it is the same one this comment makes.

One thing the Foundation must say against the note, and it concerns the component that carries most of its weight. The insect responses in this database derive from modeling of insect flight to light, which is to say from attraction. The moth experiment described at Appendix C.128 and at Part V.I states, on its own evidence, that the attractiveness of a light is not a good proxy for its other

effects, and found that a composite source engineered to match a broad-spectrum source produced the largest suppression of activity of any treatment tested. That experiment is of 2026 and this note is of 2020, and it did not address the metric question this note asks. The Foundation does not treat the note as refuted on a point its author was not writing about. It declines to present the ranking of descriptors as settled, and relies on the note for the three things that do not depend on the ranking: the measured inadequacy of correlated color temperature, the evasion mechanism, and the practicability of the computation.

A biological demonstration of the same defect

Everything in this subsection to this point establishes by spectral analysis that correlated color temperature does not determine blue content. One study supplies the biological counterpart, and it is reported here for a proposition about spectra and not about product types. The Foundation records the funding before the findings because the funding bears on how much of the study can be used. The work was conducted at the Institute of Vision Research of Yonsei University College of Medicine and is recorded at Appendix C.70. It was supported in part by LG Display Co., Ltd., which manufactures organic light-emitting diode panels and supplied the organic panel used as a test article, and the authors conclude that a change from light-emitting diode to organic light-emitting diode lighting may be warranted. The Foundation does not adopt that conclusion, does not ask the Department to prefer any technology, and does not treat the study as a comparison of product types. What follows is the part of it that concerns spectra.

The design used three lamps. A white light-emitting diode at 5,700 kelvin; an organic light-emitting diode panel at 4,000 kelvin; and a third lamp, a warmer light-emitting diode at 4,000 kelvin, included for the express purpose of matching the correlated color temperature of the organic panel. Exposures were set by illuminance, not by irradiance or by blue content. The biological measures were reactive oxygen species production and interleukin-8 expression in four human ocular cell lines, and in albino mice the thickness of the photoreceptor layer and the electroretinogram.

Two comparisons are available in the data, and together they identify the variable. The first holds the technology constant. The white lamp and the warmer lamp were the same manufacturer’s same part number, differing in correlated color temperature. In conjunctival epithelial cells, reactive oxygen species rose to approximately eighteen times the unexposed level under the lamp at 5,700 kelvin and approximately eleven times under the lamp at 4,000 kelvin. One product line, one emitting technology, two spectral distributions, and a difference of roughly forty percent in the measured response.

The second holds the correlated color temperature constant. At 4,000 kelvin, the light-emitting diode lamp raised reactive oxygen species to approximately eleven times the unexposed level while the organic panel produced no statistically significant increase at all. The Foundation states the qualification: that separation appears on the oxidative stress marker and not on the inflammatory one, interleukin-8 having been significantly raised only by the lamp at 5,700 kelvin. The matched-descriptor comparison therefore rests on one of the two markers.

The authors explain the difference by reference to how each technology makes white light, and the explanation is checkable independently of their conclusion. A phosphor-converted light-emitting diode produces two peaks in its spectrum, one narrow peak in the blue and one broad phosphor emission in the yellow. The organic panel produces three, in the red, the green and the blue. A source that must reach a given correlated color temperature using two peaks requires proportionally more energy in the blue peak than a source that reaches the same correlated color temperature using three. The descriptor is satisfied either way. The short-wavelength content is not the same, and the biological response was not the same.

So the proposition stated at subsection a is not only true as a matter of spectral composition. It is true as a matter of measured biological response. Two sources that a purchaser would find described by the same number on the package, and that a procurement specification written in

that number could not distinguish, differed in the quantity that bears on the effects described at Part V.C. That is the defect this subsection identifies, demonstrated on a biological endpoint rather than inferred from a spectrum.

Read together the two comparisons establish the proposition this subsection needs, and it is narrower and more useful than a statement about either technology. The variable that moved the biological response was the spectral power distribution. It moved when the technology was held constant and the spectrum changed, and it moved when the correlated color temperature was held constant and the spectrum changed. Neither the name of the emitting technology nor the correlated color temperature predicted the response. The spectrum did.

That has a consequence for every descriptor presently in use, and the Foundation sets them out in order of how much they discard. Lumens integrate the spectrum against the photopic response and return one number, discarding the distribution entirely. Correlated color temperature reduces the distribution to the hue of a blackbody and discards the peak structure that produced it. The name of the emitting technology discards more still, because it identifies a method of manufacture rather than any emission characteristic: the two lamps in the first comparison above were both light-emitting diodes, from the same part number, and differed in the quantity that bears on the effects described at Part V.C. A purchaser, a procurement officer and a federal standard written in any of those three descriptors would be unable to distinguish sources that this study distinguishes.

One refinement follows, and it bears on the Foundation's own record. Within a single family of phosphor-converted lamps, correlated color temperature is produced by the ratio of the blue emission to the phosphor emission, so within such a family it does track blue content, and the first comparison above shows the response falling as the correlated color temperature falls. Across technologies that generate white by different means it does not track blue content, and the second comparison shows that. So the descriptor is a usable proxy within a technology and an unreliable one across technologies. Part IV.C.5 records the Foundation's petition to the National Highway Traffic Safety Administration to limit the correlated color temperature of vehicle headlamps, and this subsection records the Foundation's acknowledgment that the descriptor is defective. The two are reconciled on the distinction just drawn: headlamps are, at present, overwhelmingly one emitting technology, and within one technology the descriptor carries information. A general federal characterization of products in commerce cannot rely on it, because it must span technologies.

A second consequence bears on what this comment asks for, and the Foundation states it rather than leaving the agency to find it. Part V.C.2.k asks the Food and Drug Administration to establish product classes for light-emitting diode products, which is a classification on the emitting technology axis. If the biological variable is the spectral power distribution, a class defined by emitting technology does not by itself identify a hazard. The answer is that the two do different work, and the agency's own regulation already does both: a class establishes which products are subject to a regime, and an emission limit establishes what any product within it may emit. Part V.C.2.k sets out how 21 C.F.R. part 1040 classifies on four different bases within a single part, and Part V.B.3 above identifies the form such a limit would take, namely a constraint on the ratio of emission in a defined wavelength interval, which is the form 21 C.F.R. § 1040.20 has used for a light-emitting product since 1985. The Foundation asks for a class defined by technology and application and a limit expressed in spectral terms. Neither alone is sufficient.

A third consequence is the one that matters most in this forum, and the Foundation states it plainly. No federal instrument imposes any limit on the spectral distribution of a visible-light emitter, and none requires that the distribution be disclosed. The determination of May 24, 2024 nonetheless rests in part on a finding that light-emitting diode products have a long history of safety with respect to the visible wavelengths being emitted. The study described above reports that the biological response to two such products differed according to their spectral distribution, at matched illuminance and at matched correlated color temperature. The Foundation does not read that study as establishing harm in ordinary use and does not advance it for that purpose. It

advances it for this: a finding of safety framed in terms of emitted wavelengths was made with respect to a quantity for which the agency has set no limit, prescribed no measurement, and required no disclosure. Part I.C.7 sets out what follows, and Part IX.B.4 asks the Department to identify the level at which it regards such emissions as ceasing to be safe.

The Foundation states the limits of the demonstration. The animals were albino mice, which the authors themselves identify as more susceptible than pigmented animals; the illuminances were 1,000 and 2,000 lux delivered for twelve hours a day across eight weeks to caged animals that could not look away, and 10,000 lux to the cell preparations; and the clean matched-descriptor comparison was made on a cellular marker of oxidative stress rather than on vision. Appendix C.70 sets out those limits and one further problem with the animal data in full. None of them touches the point taken here, which is a point about the descriptor and not about the magnitude of any hazard.

A second demonstration, and the illuminances run the wrong way

The study just described compared two sources at matched illuminance. A second study, recorded at Appendix C.74, compared two sources at illuminances that were not matched, and the result is the stronger of the two because the mismatch runs against the finding. Investigators at Gifu Pharmaceutical University exposed pigmented mice to blue light-emitting diode illumination at 1,100 lux and, separately, to white fluorescent illumination at 12,000 lux, for comparable durations of one to three days. The blue diode exposure at 1,100 lux damaged the retinal pigment epithelium and the photoreceptors. The white fluorescent exposure at 12,000 lux did not produce severe retinal damage.

The same paper sets its result against three earlier studies of pigmented animals under fluorescent light, and the Foundation reproduces the comparison because the pattern is what matters rather than any single figure.

Source	Illuminance	Exposure and animal	Reported outcome
White fluorescent	1,200 to 1,600 lux	24 hours, pigmented mice	No retinal damage
White fluorescent	10,000 lux	6 consecutive days, 12 hours light and 12 dark, pigmented rats	No severe retinal damage
White fluorescent	12,000 lux	1 to 3 days, pigmented mice	No severe retinal damage
Blue light-emitting diode	1,100 lux	1 or 3 days, pigmented mice	Damage to the retinal pigment epithelium and photoreceptors; outer nuclear layer thinning; macrophage accumulation and pseudodrusen-like material

A source delivering roughly a tenth of the photometric quantity produced injury that sources delivering ten times as much did not. Illuminance is the quantity in which lighting is specified, procured, labeled and regulated where it is regulated at all, and in this comparison it does not merely fail to predict the outcome; it predicts the outcome backwards. The Foundation asks the Department to notice that the same authors had reported the same relationship the previous year in albino animals, finding that blue diode light of lower intensity than the fluorescent light induced retinal damage. The 2018 study was undertaken to establish whether the finding held in pigmented animals, and it did.

The limits of the comparison are stated at Appendix C.74 and the principal one belongs here as well. The peak wavelength of the diode source is not reported in the text available to the Foundation, so the blue content cannot be quantified and the two arms cannot be compared in

radiometric terms. What can be said is what the Foundation says: the two sources were measured in the same photometric unit, that unit was an order of magnitude higher for the source that did no severe damage, and the difference between them is a difference of spectral distribution. The exposures in both arms are far above ordinary domestic levels and no threshold is established by either.

A third demonstration, which runs the comparison both ways

The two studies just described each hold one quantity constant. A third, recorded at Appendix C.79, holds each of the two candidate quantities constant in turn, which settles the question between them. Investigators at Gifu Pharmaceutical University exposed cone photoreceptor-derived cells to blue, white and green light-emitting diode light in two separate sets of conditions: first at a single matched radiometric irradiance of 0.38 milliwatts per square centimeter, and then at a single matched illuminance of 2,500 lux. Their conclusion, in the abstract, is that the damage was wavelength-dependent and not energy-dependent.

The incidental arithmetic of their first condition is the clearest statement of this subsection's point that the Foundation has found. At one and the same radiometric irradiance of 0.38 milliwatts per square centimeter, the authors record the corresponding illuminances as 450 lux for the blue source at 464 nanometers, 1,600 lux for the white source, and 2,500 lux for the green source at 522 nanometers.

Three sources delivering identical radiant power to the same cells differed in measured illuminance by a factor of five and a half. The reason is the one given at Part V.J.1: illuminance is radiant power weighted by the photopic response, which is near its maximum at 522 nanometers and small at 464. Nothing is wrong with either quantity. They are measures of different things, and a specification written in one of them does not constrain the other. A procurement specification, an energy conservation standard, a lamp package and the reference conditions of the photobiological standard are written in photometric quantities. The damage in this experiment followed the wavelength.

The Foundation states the limitation, which is substantial. This is a monolayer of a transformed murine cell line in a plate, illuminated from below for twenty-four hours, and Appendix C.79 sets out why that is not a retina. The proposition the comment takes from it is not about any human and not about any dose. It is that at constant radiant power the biological effect varied with wavelength, and that the photometric quantity in which lighting is specified varied by five and a half times across sources of constant radiant power. The first is a finding about cells. The second is arithmetic, and it holds wherever the two units are used interchangeably.

The Foundation accordingly asks the Department, at Part IX.C, to include in the characterization it requests the spectral power distribution of representative products in commerce, and not the correlated color temperature alone. The distinction is not a refinement. A characterization expressed in correlated color temperature would reproduce the defect this subsection describes, and would not support any limit the Department might afterwards wish to prescribe.

f. Whether the discarded quantity matters, and an industry statement that nobody had asked

The subsections above establish that the descriptor in which these sources are reported discards the shape of the spectrum, and that two sources of identical descriptor may differ substantially in composition. A question follows which the comment has not yet put: does the discarded shape make a difference that a person can perceive? If it does not, the descriptor loses information of no consequence. If it does, the descriptor conceals something that matters, and the concealment has been in place across the whole of the transition described at Part IV.G.

The Foundation found the question asked, and answered with an absence, in a place it did not expect. In a paper delivered at a symposium of the National Academy of Engineering in 2009 and published in the proceedings volume the following year, an industry technologist in solid-state

lighting set out the spectral consequence of blue-pumped phosphor conversion: the emission is smooth and follows the blackbody curve closely, unlike the sharply peaked spectrum of the fluorescent lamp it replaced. He then wrote this.

> "One might assume that this provides a more natural appearing light, compared to the high-intensity peaks of the FL spectrum, but as of this writing the author is aware of no studies of the effects of smooth vs. spiked spectra on human perception."

The Foundation is careful about the document and about the claim. The document is described at Appendix D.6, and it is a symposium paper by one engineer published under the imprint of the National Academies Press; it is not a consensus report of the National Academies and the Foundation does not present it as one. The claim is a statement of what its author was aware of in 2009, not proof that no such study existed. What makes it worth having is who made it. A specialist developing the technology, writing for an audience of engineers, recorded that the perceptual consequence of the spectral change his industry was bringing about had not been studied. That is a statement against the interest of the party making it, since it is that party which would be asked to wait for an answer.

Seventeen years have passed. The Foundation states what it can and cannot say about the interval. It has not found, among the literature collected for this comment, any study comparing perceptual or visual-performance outcomes between a spectrally smooth source and a spectrally peaked one at matched chromaticity. That is a statement about this comment's own collection and not about the literature, the collection was not assembled to answer this question, and the Foundation does not assert that the gap persists. It asks instead that the question be put, because it is precisely the kind of question paragraph 360ii(a)(4) directs the Secretary to study: an identified absence, recorded by the industry itself, about the biological consequence of a characteristic of electronic product radiation that no federal requirement addresses and that the governing descriptor does not report.

The Foundation adds one observation about the shape of the interval, because it bears on the request rather than on the science. The same chapter carried a projection of what the technology would achieve by 2018, attributed to a report commissioned by the Department of Energy in 2009. The efficiency of these products was therefore the subject of federally commissioned forecasting in the same years in which, on this author's account, their perceptual consequences were unstudied. The Foundation does not offer that as criticism of the Department of Energy, whose remit is energy. It offers it as the answer to a question the Department may fairly ask of this comment, which is why a characteristic of a product in universal use should still be unexamined in 2026. It was not that the technology went unstudied. It was that what was studied was its efficiency.

4. Radiofrequency emissions from LED drivers and control circuits

A light-emitting diode is driven by a switching converter, and a switching converter produces electrical emissions as well as the temporal modulation Part V.D treats. Those emissions take two forms: energy conducted back onto the supply wiring, and energy radiated from the product and from the wiring attached to it. Part VI.L.4 sets out the product class and the regulatory position, and Part VII.B.7 sets out the accounts at Appendix A describing interference attributed to these products.

The Foundation includes the characteristic in this Part for one reason and confines itself to it. Both emissions are electronic product radiation within § 360hh(1)(A), as Part II.B.5 establishes, and both arise from the operation of an electronic circuit in the same product. The Foundation asserts no health effect of conducted or radiated electrical emissions, relies on no study about them, and does not ask the Department to find anything about them. What it records is that the statutory definition reaches both and that the program has addressed neither.

5. The sources under which human visual and circadian physiology developed

Human photoreception developed under a small number of sources. Daylight is the dominant one: a continuous spectrum, broadly blackbody in character, varying in intensity and in spectral balance through the day, and present for roughly half of each cycle. Moonlight is reflected daylight at very low intensity. Fire, available for a substantial part of the species' history, is a low color temperature blackbody source, dominated by long wavelengths, flickering irregularly and at low frequency.

Those sources share features that are easy to overlook because they were universal. All are continuous across the spectrum, without narrow peaks or gaps. All carry substantial long-wavelength and infrared content. None is a small, flat, high-radiance emitter: the sun subtends a fraction of a degree and the sky is diffuse. And none is modulated periodically at high frequency.

6. Long-wavelength and infrared content

Sunlight extends from the ultraviolet to beyond 2000 nanometers. The incandescent lamp, which illuminated American buildings for a century and which federal policy displaced, had a comparable reach: the spectrum of a 60-watt incandescent bulb runs past 1700 nanometers and continues beyond the range of ordinary instruments. The light-emitting diode does not. Its output is engineered to the band in which the human eye forms images, running from approximately 350 to 720 nanometers with a peak near 450 and negligible emission above 700.

That is a deliberate design choice and a sound one in its own terms. Radiation outside the visual band produces no illumination and consumes power, so a lamp optimized for lumens per watt will not emit it. Part IV.G.4.

The question this Part raises is therefore not only what light-emitting diode products add to the human environment. It is what they removed from it, and whether the removal matters. The Foundation asks the Department to attend to this question with particular care, because it is invisible to every existing regulatory instrument. A performance standard limits what a source emits. An exposure limit caps a dose. Neither can register an absence. If long-wavelength radiation performs a physiological function, no hazard framework in existence would detect its disappearance.

There is now direct human evidence that it does. Barrett and Jeffery, publishing in Scientific Reports in January 2026, studied twenty-two adults working in a London building lit entirely by ceiling-mounted LEDs delivering 1000 lux at the desk, in a space whose glazing carried an infrared-blocking film. Infrared photography of the interior returned black images. Eleven subjects had incandescent desk lamps added to their benches for two weeks; eleven comparable subjects in a similar LED-lit space did not.

Color contrast detection thresholds improved in every exposed subject on both the protan and tritan axes, at p less than 0.001. At the end of the two-week exposure the reduction was 28 percent on the protan axis and 24 percent on the tritan, in all eleven exposed subjects. The concurrent control group showed no significant change on either axis. The incandescent lamps were then removed and the subjects returned to LED lighting alone. At the second follow-up the reduction was 24 and 21 percent in ten subjects, and at the third it was 25 and 26 percent in six.

The Foundation asks the Department to note four features of that result, each of which bears on its weight.

The deficit was produced by ordinary ambient workplace lighting, not by an experimental exposure. The subjects had worked under that lighting for more than two years before the study began.

It was reversed by restoring a part of the spectrum that the lighting transition removed. The intervention added nothing novel; it added the lamp that preceded the LED.

The effect was present in every exposed subject and absent in the concurrent controls, and it was still present at the final follow-up. The Foundation states the qualification in the same breath as the finding, because the qualification is material: the final follow-up retained six of the eleven exposed subjects. Persistence is supported by the data, on a sample that had lost nearly half its members by the time it was measured, and the Foundation does not rest weight on it that it will not bear. Appendix C.1.

> The study ran from October to December in London, as daylight hours fell from approximately 10.4 to 7.5. Natural light exposure was decreasing across the study period while measured performance improved. That trend runs against the finding rather than producing it.

The authors attribute the effect to mitochondrial function, on the basis of a body of work they cite: short-wavelength light in the 420 to 450 nanometer range reduces mitochondrial complex activity and adenosine triphosphate production in animal models, while deep red and near-infrared light in the 670 to 900 nanometer range increases it. The Foundation does not ask the Department to accept that mechanism. It asks the Department to note that a measurable functional difference attributable to the spectral composition of ambient lighting has been demonstrated in working adults, and that no federal body has examined it. Appendix C.1 sets out the study in full, including its limitations.

One enzyme, two absorption bands, and the connection between the two halves of this Part

The mechanism referred to in the preceding paragraphs can now be stated with a molecule attached to it, and doing so connects this subsection to the blue-light material at Part V.C. The review at Appendix C.72 identifies the enzyme. Complex IV of the mitochondrial electron transport chain, also called cytochrome oxidase or cytochrome c oxidase, carries heme groups and has an absorption peak at approximately 420 nanometers in its oxidized form and approximately 440 nanometers in its reduced form.

That is the same enzyme, and the same absorption, that the near-infrared literature relies on. Cytochrome c oxidase is the accepted chromophore for the stimulatory effects of deep red and near-infrared light reported in the 670 to 900 nanometer range. So the two bodies of work this comment has treated separately – the blue-light hazard literature at Part V.C and the long-wavelength literature in this subsection – converge on one molecule with absorption in two spectral regions and effects in opposite directions. Light near 420 to 440 nanometers is reported to inhibit the enzyme; light near 670 to 900 nanometers is reported to stimulate it.

The Foundation states what that does and does not do for this comment. It does not establish either effect, and the Foundation continues not to ask the Department to accept the mechanism. What it does is remove the objection that the two claims are unrelated and must be assessed in isolation. A single enzyme with a blue absorption band and a red one supplies a coherent reason why the removal of long-wavelength content and the addition of short-wavelength content, which the transition to light-emitting diode illumination accomplished together, might act on the same target in the same direction. Three independent observations now bear on it: the review at Appendix C.72, which reports that at least two of the four respiratory complexes are implicated in blue-light injury and that blue light at 404 nanometers irreversibly inhibited the enzyme in the rat retina; the measurement at Appendix C.69, which found Complex II and succinate dehydrogenase activity reduced by 460 nanometer light in an intact animal; and the review at Appendix C.71, which gives direct action on ganglion cell mitochondria as the first of three injury routes.

One finding reported in that review bears directly on what a limit would have to measure, and the Foundation sets it out separately because it recurs throughout this comment. The review records that cytochrome oxidase activity was significantly altered across the layers of the rat retina over time while no visible morphological change was observed by ophthalmoscopy or by light microscopy. A measurable change in the activity of a respiratory enzyme, in the absence of any lesion an examiner could see, is precisely the kind of effect that an exposure limit calibrated to

threshold lesion formation is not constructed to detect. Part V.C.1.g develops that point and Part V.C.2.f gives the dose figures on which the limit rests.

Section 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. The Foundation submits that the spectral content of the light under which the American population now works and lives, including what that light no longer contains, falls within those words.

A second study bears on the same characteristic, and it bears on it experimentally. Roddick and others published in the Journal of Environmental Psychology in December 2024 a preregistered, double-blind, within-subjects experiment on the effects of near-infrared radiation in ambient lighting. One hundred fifty-one participants each spent about forty-five minutes under each of two lighting conditions in a single session. Both conditions were white light-emitting diode lighting at a nominal 3500 K and at matched illuminance, 741 and 748 lux. What differed between them lay entirely above 700 nm: irradiance in that band was 0.12 watts per square meter in one condition, which the authors describe as typical of modern office lighting, and 14.11 watts per square meter in the other.

The Foundation asks the Department to attend to what was held constant. Melanopic irradiance was 0.532 watts per square meter in the condition without near-infrared and 0.539 in the condition with it. The rhodopic and the three cone-opic irradiances differed by comparably small amounts. Every quantity by which American lighting is specified, purchased, regulated and studied was, for practical purposes, the same in the two conditions. A photometer could not have told them apart. Neither could a melanopic measurement, which is the most spectrally informed instrument in general use. The two conditions differed by a factor of more than one hundred in a band that no such instrument reports.

Under those conditions the authors observed differences. Resting high-frequency heart rate variability, a measure of parasympathetic cardiac activity, was higher under the lighting containing near-infrared, and remained so after adjustment for covariates. The cardiovascular response to cognitive demand was larger under that lighting for four of the five tasks administered. Ratings of pleasure differed between conditions in a manner that depended on the order of exposure. Appendix C.13 gives the estimates.

The Foundation states the rest of the result as the authors found it, because the comment is not advanced by selective reporting. Of five cognitive tasks, lighting condition predicted performance on one, visual search, and in the direction opposite to the authors' hypothesis: performance was worse under near-infrared. There was no effect on perception, short-term memory, working memory or executive function, and none on self-reported alertness. Asked which lighting they had preferred, a majority in both order groups chose the condition without near-infrared. The authors describe their findings as preliminary, and the Foundation adopts that word.

That mixed result is the point, and it is worth being plain about why. A finding that near-infrared is good for people would support a conclusion. A finding that it produces measurable physiological and affective effects, in directions that are not all the same, that depend on the order of exposure, and whose long-term consequences the investigators describe as unknown, supports something different and, for present purposes, more useful. It supports the proposition that there is a question here, that the question is answerable by experiment, and that it has not been answered. That is the condition to which § 360ii(a)(4) speaks. The Secretary is directed to study and evaluate emissions and the conditions of exposure; the Secretary is not directed to study only those emissions whose effects are already known.

The authors state the policy consequence themselves, and the Foundation quotes rather than characterizes it:

> "the move away from the natural balance of visible and near-infrared radiation found outdoors —the condition under which humans evolved—may not be optimal for well-being, even if it is better for delivering more light output for less energy."

Two further features of the study are relevant independently of what it found. The authors include researchers at the National Research Council of Canada and at Pacific Northwest National Laboratory. And the work was funded by the Department of Energy. Part IV.G.4 sets out why that matters.

A third study carries the same characteristic beyond the eye. Powner and Jeffery, publishing in the Journal of Biophotonics in 2024, randomized thirty healthy adults to a single fifteen-minute exposure of the upper back to 670-nanometer light, or to an identical sham in which the array was not switched on, and then administered a standard oral glucose tolerance test. Against the sham group, the exposed group showed a 7.3 percent reduction in total circulating glucose measured as area under the curve ($p = 0.0061$), a 27.7 percent reduction in the rise in glucose following the challenge ($p = 0.0002$), and a 12.1 percent reduction in peak glucose concentration, from 10.8 to 9.5 millimoles per liter ($p = 0.0102$). The sham group showed no change against its own baseline on any measure. Appendix C.19.

The Foundation states the inferential limit of that result before stating its use, because the limit is severe. This was a therapeutic exposure, not an ambient one: 40 milliwatts per square centimeter delivered to roughly four percent of the body surface, which is nothing like living under a lamp. The study does not show that lighting lacking long wavelengths impairs glucose regulation, and the Foundation does not advance that proposition. The subjects were healthy and not diabetic, and the authors state expressly that their results cast no light on diabetes.

What it establishes is a premise, and the premise is what Part V.B needs. Light in the long-wavelength band that light-emitting diode sources largely omit is biologically active in human beings at the systemic level, on a timescale of minutes, with effects measurable in blood chemistry rather than in reported experience. Taken with the contrast-sensitivity finding at Appendix C.1 and the cardiovascular and affective findings at Appendix C.13, the spectral content of ambient light is shown to be a physiologically consequential variable and not a matter of appearance or preference. Whether its absence from the built environment does harm is a different question, and an open one. It is open in the direction of requiring study.

The authors draw the connection to lighting themselves, in the discussion, and the Foundation quotes rather than characterizes it:

> LED lighting is fundamentally blue dominant — However, LEDs fundamentally lack longer wavelengths. They peak strongly around 450 nm, but have little content beyond 620 nm. Hence, lengthy exposure to them in the absence of sunlight may have significant long-term consequences for human health including dysregulation of blood sugars. This problem remains to be fully appreciated but is likely to be a potential public health issue.

The Foundation asks the Department to weigh that sentence as what it is. It is not a finding, and the Foundation does not present it as one. It is the judgment of investigators working in this field, published in a peer-reviewed journal, that the spectral composition of the lighting Americans now live under is likely to be a public health question that has not yet been appreciated. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from organizations on present and future potential electronic product radiation. The word potential is in the statute. A published judgment that a problem is likely and not yet appreciated is precisely information about potential electronic product radiation, and the statute directs that it be received.

A fourth study, by substantially the same investigators, addresses the step the third one left open. The Foundation sets it out because of what it measured, and then states plainly the inference it does not support.

Jeffery, Fosbury, Barrett, Hogg, Rodriguez Carmona and Powner published in Scientific Reports in July 2025 a study in two parts. Appendix C.60. The first part is a measurement: they placed a spectrometer behind the human thorax in direct midday sunlight and recorded what came through. The transmitted spectrum peaked at approximately 800 to 875 nanometers, with very little energy below 600 nanometers, and the average transmitted irradiance at 850 nanometers was approximately 5.6 microwatts per square centimeter. They also report that layered clothing attenuated but did not block the band, describing the garments as roughly a hundred times more transparent at 850 nanometers than in the visible.

That is a direct measurement of a quantity this comment has previously had to argue for. The human body is substantially transparent in the near infrared and substantially opaque in the visible, so sunlight deposits long-wavelength radiation inside the body and does not deposit short-wavelength radiation there. Part V.C.2.h argues that the photobiological safety framework is ocular while the evidence is not; this is the transmission spectrum that makes the extraocular route physically available, measured in people rather than inferred.

The second part is an exposure experiment. Subjects received fifteen minutes of 850 nanometer light to the bare upper back at approximately 9 milliwatts per square centimeter, in a dark room, and color contrast detection thresholds were measured twenty-four hours later. Thresholds fell – that is, performance improved – by approximately 9 percent on the protan axis and 16 percent on the tritan axis. In a separate group whose heads were wrapped in foil so that the eyes were shielded, the tritan improvement persisted at approximately 7 percent and reached significance, while the protan change did not.

The head-shielded result is the one the Foundation asks the Department to weigh. A measured improvement in a visual function, produced by light delivered to the back of a person whose eyes were covered, is direct human experimental evidence that optical radiation acts on the body by a route that does not pass through the eye. Appendix C.56 reports the same proposition from receptor work in mice. This reports it from a human psychophysical outcome.

Now the limit, which the Foundation states against its own interest because the paper does not state it in these terms and a reviewer would otherwise supply it.

The two parts of this study are not joined. The transmission measurement establishes that sunlight delivers approximately 5.6 microwatts per square centimeter at 850 nanometers through the thorax. The exposure experiment demonstrated an effect at approximately 9 milliwatts per square centimeter. Those differ by a factor of roughly 1,600. The study therefore shows that the band penetrates the body at ambient levels, and separately that the band produces a measurable effect at laboratory levels, and it does not show that the irradiance sunlight actually delivers through the body is sufficient to produce the effect. The Foundation does not assert that it is.

What the four studies establish together is accordingly narrower than any one of them read alone, and the Foundation states it in the form it is prepared to defend. Light in the long-wavelength band is biologically active in human beings; it acts at least partly by a route that does not require the eye; the band penetrates the body and is present within it under natural illumination; the measured performance deficit associated with lighting that omits the band is reversible by restoring it; and light-emitting diode sources omit it almost entirely. Whether the quantity of that radiation removed from the American indoor environment is enough to matter is precisely the question nobody has answered, and it is the question § 360ii(a)(4) assigns to the Secretary.

Daylight and incandescent sources carry substantial energy beyond 700 nanometers. Phosphor-converted white LEDs carry almost none. This is not incidental to their design: efficacy is measured in lumens per watt, and radiation outside the visual response contributes nothing to the numerator. The efficiency standards described at Part IV.G selected for sources that emit as little as possible outside the visible band.

7. Temporal characteristics

Daylight does not flicker. Fire flickers irregularly, at low frequency, and with a continuously varying waveform. The modulation produced by a switching LED driver is periodic, frequently approximates a square wave, and occurs at frequencies determined by the convenience of the circuit rather than by anything in the visual system. There is no natural antecedent for a light source that extinguishes and re-illuminates hundreds or thousands of times a second.

8. Spatial characteristics

An LED emits from a small flat surface at high radiance. For a given quantity of light delivered, the source is smaller and brighter than any artificial source that preceded it and than any natural source except the solar disc itself. The aversion responses that protect the eye from looking at the sun are not reliably triggered by a source of the same radiance and far smaller angular size, which is why a person will look directly at an oncoming headlamp.

The first of those propositions can now be supported from a manufacturer’s own published figures rather than asserted, and the Foundation does so because a claim of that kind is worth more when the party with the strongest interest in understating it supplies the numbers. Appendix D.3 describes a white paper published by a component maker in February 2023 on what it calls high-luminance directional lighting. In a worked comparison it states that a single emitter of 1.2 square millimeters produces a luminous flux of 500 lumens.

Those two figures fix the luminance of the emitting surface, and the Foundation sets out the arithmetic so that it can be checked. For a Lambertian emitter the luminance is the flux divided by the product of the emitting area and pi steradians. Five hundred lumens from 1.2 square millimeters is therefore of the order of 1.3 × 10 to the eighth candelas per square meter, about 133 million. That is a lower bound rather than an estimate, because the whole object of the document is to describe emitters that radiate into a narrower angle than a Lambertian source, and a narrower emission at the same flux and area implies a higher luminance.

The comparison that matters is with the sun. The luminance of the solar disc is of the order of 1.6 × 10 to the ninth candelas per square meter. A component on a shelf, 1.2 square millimeters in area, therefore emits at a luminance within about a factor of twelve of the brightest object in the sky, and does so at an angular size thousands of times smaller. The Foundation states the limits of that comparison at once. It is a comparison of source luminance and not of retinal dose, which depends on the angular subtense as Part V.B.2 sets out. And the figure is well below the luminance at which the photobiological framework places a source in its highest risk group, which Part V.C.2 records as approximately 4 × 10 to the ninth candelas per square meter at 6,000 kelvin. Nothing here suggests that this component would be classified as hazardous under the existing scheme. The point is the one this subsection is making: the emitting surface of a light-emitting diode is in a luminance regime that no previous artificial source occupied, and the regulatory framework contains no limit on that quantity at all.

The geometry that produces the pattern, derived

The two propositions with which this subsection opens are geometric, and the geometry has been derived in closed form. Khan, publishing in the IEEE Photonics Journal in 2019 and described at Appendix C.86, obtained an analytic solution for the near-field luminous intensity distribution of a finite flat light-emitting diode and showed that it reduces to the Lambertian form used in the arithmetic above. The paper is a derivation rather than a health study and the Foundation relies on it as such. Three results from it bear on this subsection.

The first concerns directivity, and it meets an objection the Foundation encounters. The objection is that a light-emitting diode is a lamp like any other and that its apparent intensity is an artifact of the optic fitted in front of it. The author addresses the point directly: “Fig. 17 also shows the directivity of the beam generated by a finite, flat LED and such a behavior is never observed from a point radiant source that generates intensity distribution omni-directionally over the full solid

angle range spanning from 0 to 4π steradians." The beam is therefore a consequence of the shape of the emitter, present before any lens or reflector is fitted, and absent from any source that approximates a point. The author reports further that the transverse confinement is circular where the emitting surface is square and elliptical where its two dimensions differ, which is the mechanism behind the difference between the square and the round emitter recorded at Appendix D.3.

The second concerns the peak, and it is the proposition this subsection exists to establish. In the author's derivation the peak of the surface distribution scales with the product of the emitting area, the number of radiative electron-hole pairs within that area, and the luminance each pair contributes. She states the consequence in her own word: "the peak of the parabola shown in Fig. 11 would become enormous when L avg for the LED is very high due to very high inherent quantum efficiency, high light extraction efficiency form the LED chip, and driven by a large current. The peak of the parabola would also become very large when the size of the LED chip is very large." The spelling form appears in the original. The Foundation asks the Department to read that expression for what it contains: the area of the emitting surface, the number of radiative pairs within it, the luminance each contributes, and the drive current. It asks the Department to note also that not one of those four quantities is reported on a component data sheet, required by any standard this comment examines, or recoverable from the lumen rating by which the product is sold. The quantity that governs the peak is unreported, and the quantity that is reported does not constrain it.

The third is a comparison with the source the newer product replaced, and it is the cleanest statement of this subsection's thesis the Foundation has found in the technical literature. The author photographed a G12 corn lamp carrying seventy surface-mount modules, operating at 10 watts and producing 1,080 lumens, and observed the characteristic pattern from each flat face. She then states: "such patterns are never observed for fluorescent G12 lamp counterparts because their emitting surfaces are not flat." A lamp of the same fitting and comparable output does not produce the pattern. The difference is attributed to a single property of the newer source, which is that the surface it emits from is flat. That is the whole of the distinction this subsection draws, stated in a photonics journal and tested against a measured lamp.

The Foundation states the limit of all three results. The paper verified the angular shape of the distribution against measured data. It did not verify the magnitudes, and the author says so expressly, recording that the measured magnitudes are not tied to the analytic solution and that the dependence of the peak on emitter size remains to be measured. Nothing above establishes the luminance of any product. What it establishes is why the luminance of this class of product is high, what it varies with, and that none of what it varies with is presently reported.

The reported number, and what it does not determine

The derivation above concerns a flat emitting surface. A manufacturer of these components has published an account of its own chip architectures that confirms the derivation for one of them, limits it for the other, and then states what the number on the data sheet is worth. The Foundation takes all three, including the limitation, because a limitation the Foundation states itself cannot later be put to it. The document is described at Appendix D.3.

The confirmation first. Of the two ways these chips are built, the surface emitter carries a reflector beneath the light-emitting layer, and the manufacturer describes the result in the terms of the derivation above: "The result is what is known as a surface emitter that emits light only in the front half-space of the LED with a lambertian emission curve. The maximum possible emission angle here is 90 degrees." The distribution Khan derives from the geometry of a flat emitter is therefore also the distribution this manufacturer designs for, and says it achieves.

The limitation next. The other architecture is the volume emitter, in which light leaves the chip in all directions and the phosphor must surround it rather than lie as a thin layer across its face. With chip heights of 100 to 150 micrometers, the manufacturer reports, "emission surfaces of 200

μm and more are easily generated, emitting white light over a wide range of angles," with the consequence of "significant intensity at angles greater than 90 degrees." That is not a flat emitting surface and it does not produce a Lambertian distribution. The Foundation therefore confines the derivation at Appendix C.86, and the propositions it supports in this subsection, to devices that emit from a flat surface, and records that a substantial part of this product class does not.

Then the reported number. The quantity a data sheet gives for the spatial distribution of emission is the half width, defined as the angle at which luminous intensity has fallen to half its maximum. The manufacturer states what that figure is and is not, and the Foundation quotes the sentence in full because it comes from the party that prints the figure: "This information is not sufficient, however, as the basis for selecting an LED because the half width specifies only a single point along the LED emission curve, and the luminous intensity distribution is not an accurate measure of the brightness of the LED in a luminaire."

The article then demonstrates it twice. Of two devices both specified at a half width of 120 degrees, one Lambertian and one not, "Both curves are almost identical at low angles but at more than 60° there are significant differences – despite the same value for the half width"; the non-Lambertian device emits about ten percent of its output beyond 90 degrees and delivers about ten percent less cumulative flux within a 60-degree cone. And of a named product in the manufacturer's own range, the Oslon Square: "the half width corresponds to that of many LEDs and is 120°. Within the half width the luminous intensity is greater than that of a lambertian emitter, and smaller outside the half width."

The Foundation asks the Department to read the second of those together with the first. Products sharing a reported half width differ in where their light goes. Where they differ, the device engineered to concentrate its output delivers more intensity on axis than the shared figure implies, and the manufacturer presents that as the product's advantage. So the single number that is reported does not determine the distribution, and for the devices designed for concentration it errs in the direction of understating what arrives on axis. That is the same failure as the one recorded at Part VI for two indicator components of identical size differing by about fifty times in the solid angle into which they emit, and it is the reporting counterpart of the quantity problem set out at Part V.B.2.

The same emission described from the application side, and where the point-source assumption fails

The propositions above are drawn from a derivation and from a component manufacturer. They are also stated, in nearly the same terms, by optical engineers designing luminaires for the roadway. Babadi and others, publishing in the IEEE Photonics Journal in 2017 and described at Appendix C.88, explain why a street lighting luminaire requires a lens or reflector at all: "In spite of the advantages of LEDs, it is impractical in many cases to use them in street light luminaires directly without a suitable secondary optic due to their lambertian radiation pattern. Normally, the LED produces high light intensity at the centre and low light intensity at the edge of its circular illumination footprint." The spelling is the authors'. The distribution is Lambertian and the intensity is concentrated at the center, which is what the derivation predicts and what the manufacturer says it designs for.

The same authors state where the approximation that underlies most optical design fails. Their method assumes a point source, and they record the condition on that assumption: "Using an extended light source reduces uniformity on the target plane. To keep uniformity the size of the light source and the optic have to be taken into account. An extended light source acts as an approximate point light source when the size of the optic is five times larger than the light source."

The Foundation now has three statements of that threshold from three sources, and sets them beside one another because the agreement is the point. The derivation at Appendix C.86 establishes that Lambert's law holds exactly only for an infinitesimal emitter and that a finite one must be treated as finite. The metrology reference work at Appendix D.5 gives a photometric

distance of five to fifteen times the extent of the source, below which a measurement does not record luminous intensity as defined. And these authors give five times the source size as the condition on the optic. The three are expressed in different terms, two about measurement distance and one about optic size, and the Foundation does not treat them as the same quantity. What they share is that each identifies a regime in which these emitters cannot be treated as points, and each places the products at issue inside it.

The authoritative treatment, which corrects the threshold above and supplies the mechanism

The three statements set out above are each from a source addressing something else. The question has a literature of its own, and the standard reference in it is described at Appendix C.89: Moreno and Sun, publishing in Optics Express in 2008 and cited several hundred times since. They open on the difficulty itself, writing that "LEDs are far more difficult to model than the conventional sources", which is worsened because "there is a wide variety of LED radiation patterns." Three things in that paper bear on this subsection and the first of them corrects it.

The correction concerns the threshold. The rule that a source may be treated as a point beyond about five times its largest dimension is a general rule of radiometry, and these authors state that it does not carry over to this technology: "this rule of thumb is not so easily applied to LEDs because of the radiance complexity and wave effects." A separate regime, which they call the mid field, had to be defined for these sources. And they give the measured consequence: "Using the radiometric definition, a high-power LED with a 1mm2 chip should have a 5-mm near field, but in practice up to 20-mm mid fields are found." Their own laboratory places the onset of the stable far-field pattern at about 20 millimeters from the tip for some power devices, and longer for multi-chip ones. So for this technology the distance within which the device cannot be treated as a point is up to four times what the general rule predicts. The factor of four is the Foundation's arithmetic on the authors' two figures.

The Foundation states what that does and does not do to the paragraph above. It does not make the three thresholds agree, and they remain three different quantities: the smallest retinal image the eye can form, the distance at which a measurement records intensity as defined, and the distance at which the normalized angular pattern stops changing. This is a fourth, and it is the last of those three. What it establishes is that the general rule from which two of the others are drawn was examined for this technology by the specialists in it and found to under-predict. Every threshold in this subsection should therefore be read as a lower bound.

The second matter is the mechanism, and it settles a question this subsection left open. The Lambertian form belongs to the emitting region and not to the product: "From the radiometric point of view, the emitting region is a Lambertian light source", and the pattern of each chip face will "generally be Lambertian" subject to microstructures and waveguide effects within the chip. The pattern of the finished device is then that pattern as modified by the reflecting cup and the encapsulating lens, and the authors give the direction of the modification: "In most cases, the lens angularly narrows the radiation pattern (due to the chip and the mirror), though sometimes it enlarges the pattern." That is the explanation the Foundation preferred, over coherence, for the measured departures recorded above, and it is now attributable rather than inferred. The literature calls a distribution of that kind an imperfect Lambertian.

The third matter is the one the Foundation asks the Department to weigh most heavily, because it is a recommendation rather than a finding and because of its date. Having set out that manufacturers characterize the angular distribution by the half angle, and having noted the one further published attribute, the authors write this.

> "However, additional parameters are needed to render the shape of the radiation pattern. Therefore, we propose that the manufacturer should include a simple formula (like those reported here) with its coefficients in their technical data sheets."

That is the request this comment makes at Part IX.F, published in a peer-reviewed optics journal in 2008 by the authors of the standard treatment of the subject, and addressed to the manufacturers directly. The Foundation does not assert that nothing has changed since. What it states now is narrower. The proposition that the published half angle is insufficient to describe what a light-emitting diode emits is not the Foundation's contention. It is the settled view of the specialist literature, it has been in print for eighteen years, it was accompanied by a concrete and simple remedy, and the data sheets of the products described at Part VI still report the half angle.

Three incidental findings in the same paper bear on how much weight any published distribution will carry, and the Foundation records them here because they qualify its own use of manufacturer data throughout this Part. Of the single device in their set best described as Lambertian, the authors report that a simple cosine fit carries a 5.1 percent root mean square error, which exceeds the five percent threshold they set themselves. Several manufacturers publish not a curve but an envelope, an upper and a lower bound, and the authors attribute the spread to "manufacturing errors related to the emission, reflection and transmission of the optical flux." And to fit one manufacturer's published data the authors had to rotate the whole distribution by 2.55 degrees, which they attribute to "a misalignment of the optical axis of the LEDs tested by the manufacturer." A published angular distribution is accordingly a nominal figure for a population of parts, not a property of the part in hand.

What the distribution is when it is measured, rather than derived or designed

The derivation at Appendix C.86 gives a Lambertian for a finite flat emitter. The manufacturer at Appendix D.3 states that its surface-emitting architecture is built to produce one and that its volume-emitting architecture does not. Neither is a measurement of a finished device, and the Foundation now sets out what two national metrology institutes found when they measured four of them.

The work is described at Appendix D.6. The Institute of Optics of the Spanish National Research Council built a goniophotometer for the purpose and measured four light-emitting diode transfer standards of 7 millimeter package diameter, one red, one green, one blue and one white, at the reference distance of the averaged-intensity geometry, with a stated relative uncertainty of 0.2 percent. The same four devices were measured at the Physikalisch-Technische Bundesanstalt, the German federal metrology institute, on a comparable instrument. Each measured distribution was then fitted to a cosine raised to a power, the exponent being unity for a true Lambertian emitter.

Not one of the four devices is Lambertian, and the two institutes agree closely about how far each departs.

LED transfer standard	g, CSIC	g, PTB	Anisotropy, CSIC	Anisotropy, PTB
F107, blue	3.64	3.54	0.052	0.047
F108, red	1.38	1.31	0.069	0.065
F126, green	1.86	1.76	0.016	0.015
F132, polar white	1.62	1.62	0.014	0.015
A Lambertian emitter	1	1	not applicable	not applicable

Two things follow and the Foundation separates them. The first is a qualification of its own argument. The Lambertian form is the correct description of a bare flat emitter, as the derivation shows and as a manufacturer confirms for one chip architecture, and it is the form in which a component manufacturer presented the figures from which this subsection computes a peak luminance. It is not the measured form of a packaged device with an integral lens, which is what reaches a product. The Foundation accordingly confines the Lambertian relation to the bare emitter and does not represent it as describing a finished lamp.

The second is the direction of the error, and it runs against the products rather than against this comment. An exponent above unity describes a narrower distribution than Lambertian, which is to say output concentrated more tightly about the axis. For a given total luminous flux the on-axis intensity of such a source exceeds that of a Lambertian source by a factor of one plus the exponent, divided by two: on the measured values that is 1.19 for the red device, 1.31 for the white, 1.43 for the green and 2.32 for the blue. The integration is the Foundation's and is not stated by the authors. Where this comment assumes a Lambertian distribution in order to compute a peak, as it does above, the assumption is therefore conservative, and for a device of this kind the true on-axis figure is higher than the figure stated.

The Foundation states what it does not take from this, because the available inference is tempting and the sample will not support it. Four devices from one supplier, chosen for metrological stability rather than for representativeness, do not establish that blue emitters are generally more concentrated than red ones. What they establish is narrower and sufficient: that the angular distribution of a real device is a measured property which varies from device to device, that it is not recoverable from the Lambertian assumption, and that two national metrology institutes had to build instruments and compare them against one another to determine it at all. The authors state the reason the work was necessary, and it is the proposition this Part advances: "New methods of measurement are required, because these sources have different emission characteristics than traditional lighting sources."

What the measurement community reports instead, and the reason it gave for reporting it

Everything above concerns what a light-emitting diode emits. The remaining question is what is reported about it, and for that the Foundation turns to the people whose profession is measurement. The document described at Appendix D.6 is a lecture given in April 2002 at the Institute for National Measurement Standards of the National Research Council of Canada, which is the national metrology institute of that country. The Foundation states its form plainly: it is teaching material from a measurement course, not a research paper, and it is relied on for what a metrologist told a room of practitioners about the limits of their instruments. Four things in it bear on this subsection, and the fourth is a concession the Foundation did not expect to find.

The first is the point of principle, and it is stated of this technology by name. Having introduced the point source as the diagram by which intensity is defined, the author writes that "point sources have several inherent implicit properties which can mislead us when we apply our ideas of intensity to other sources such as LEDs which do not possess these properties." The lecture then names the properties. The intensity of a point source is the same in all directions; it is the same at all distances; and, third, "it means that the intensity measurements we make do not depend on the particular size (or shape) of the input aperture of our detector." For a source that is not a point, each of the three fails, and the Foundation draws attention to the third because it is the one least often noticed. Where it fails, the reported figure is a property of the instrument as much as of the device.

The second is what the lecture says these devices actually look like, and it is more useful to this comment than the Lambertian description would have been. Of real parts the author writes that "the intensity is quite nonuniform in the angular variation, and is often not even symmetric with respect to any angle in this planar view." The cause is given as the package: "The problem can be worse for LEDs since the packaging introduces many components which act as reflectors and concentrators of the light which is emitted from the small source itself." That is the mechanism described at the preceding heading, stated at a national metrology institute six years before it was modeled. The Foundation also records what this lecture does not say, since the question is live in this subsection. The author introduces the Lambertian source as a second idealization alongside the point source, each with its own equation, and then applies neither of them to a light-emitting diode. A lecture devoted to measuring these devices declines to classify them as either.

The third is that the measurement is forced into the regime where the quantity is still changing. "The small size and low output of typical LEDs demands that we place our detectors at small distances from the LED. This will aggravate most of the problems indicated above." And the reason the proximity matters: "These considerations show that even at constant solid angle Ω the intensity output of extended sources will change with distance from the source." So the practitioner must measure close, and close is where the number depends on how close.

The fourth is the concession, and the Foundation quotes it in full because the whole of it matters.

> "If all these conditions can be specified exactly, it is possible to present an accurate representation of the intensity (distribution) of the LED. However, this is too demanding of experimental accuracy, and too much of a burden for efficient comparison of LEDs during the manufacturing process, or comparison of LEDs between manufacturers, or selection of LEDs for any specific purpose."

An accurate representation of the distribution was achievable. It was set aside as too demanding and too burdensome, and the lecture names the three purposes for which it was too burdensome: comparison during manufacture, comparison between manufacturers, and selection of a part for an application. The Foundation makes a narrow point about that list. Not one of the three is the protection of health, and there is no reason it should have been, because the people making the trade-off were designing a tool for industry and said so. The Foundation does not contend that the judgment was wrong for the purposes stated. It contends that a quantity selected for ease of commercial comparison, by a committee that was not asked about exposure, is the quantity on which the emission of these products is now reported, and that the Department should know on what basis it was chosen before relying on it.

What was adopted instead is named for what it is. Because an intensity measurement of such a source is, in the author's words, "an average which is dependant on the measurement configuration used", the quantity is called the Averaged LED Intensity, and the configuration is fixed by definition rather than derived. The reference point is the front tip of the device and the reference axis is its mechanical axis. The detector aperture is a circular area of 100 square millimeters. Condition A places that aperture 316 millimeters from the tip, giving a solid angle of 0.001 steradian; condition B places it at 100 millimeters, giving 0.01 steradian. Two conditions means that one device has two values of the quantity, each correct under its own condition, and the subscript carries which. The Foundation asks the Department to notice that the standard's own name for the figure concedes the point this subsection has been establishing: what is reported is an average over a stipulated geometry, not the intensity of the source.

One further fact about that quantity bears on how this comment is read. In April 2002 it did not yet exist as a standard. The lecture states that the Commission "is working on a standard which proposes (it is not yet accepted) two defined geometrical configurations for measuring the luminous intensity of LEDs", and the figure in which the two conditions appear is captioned as proposed. Three technical committees are named as then at work: one revising the governing report, one preparing a joint standard on intensity measurement, and one on the optical properties of clusters and arrays. What became of each is a question of fact the Foundation has not yet answered. The Foundation notes only that the measurement convention on which reported intensity now rests was, a quarter century ago, an acknowledged compromise still awaiting acceptance.

9. The progression of artificial sources, stated accurately

The Foundation does not contend that LEDs are the first artificial source to depart from natural spectra. Gas and incandescent lighting were blackbody sources, rich in long wavelengths and close in character to fire. Fluorescent lighting introduced a discontinuous line spectrum, very little infrared, and periodic modulation at twice the supply frequency. LED lighting carries each of those departures further: a narrower and more pronounced short-wavelength peak, still less long-

wavelength content, higher source radiance in a smaller emitter, and modulation that is periodic, square in waveform, and at frequencies with no precedent.

10. What follows from this, and what does not

The Foundation does not argue that a natural stimulus is for that reason safe or that an artificial one is for that reason harmful. The argument is narrower and is about knowledge rather than about virtue. The response characteristics of the visual, circadian and nervous systems were shaped by the stimuli under which those systems developed. Where a stimulus falls outside that range in spectrum, in geometry, and in temporal structure at once, evolutionary history supplies no basis for predicting the response, and the response must therefore be determined empirically.

It has not been. That is the gap this comment identifies, and it is the gap 21 U.S.C. § 360ii(a)(4) directs the Secretary to close by studying and evaluating emissions of, and conditions of exposure to, electronic product radiation.

C. Optical Radiation and the Human Eye

1. Retinal phototoxicity and photochemical injury

This subsection concerns acute photochemical injury to the retina: what it is, how it is recognized, and what is known to cause it. It is distinct from the chronic and cumulative questions at subsection 2, and the Foundation keeps them apart because conflating them is the fastest way to lose both.

a. The injury, and how it is recognized

Photochemical retinal injury is damage produced by the absorption of light rather than by heating. The energy is absorbed preferentially by the pigment of the retinal pigment epithelium, the damage extends to the outer segments of the photoreceptors, and the clinical signature is a disruption of the outer retinal layers visible on optical coherence tomography, accompanied by reduced visual acuity and by a scotoma at the point of fixation.

The classically recognized causes are three: staring at the sun, which produces solar maculopathy and is the reason eclipse viewing requires filters; viewing a welding arc without protection, which produces the same picture; and laser exposure. The Foundation sets those out because they are the comparison class, and because each of them is the subject of a regulatory instrument.

The injury described above is the gross end of a range. Below it sits a cell-biological literature which characterizes the pathways by which short-wavelength light damages photoreceptors, and the Foundation introduces it here because one feature of that literature bears on the question this comment puts, while its findings do not.

One such pathway is stress of the endoplasmic reticulum, the organelle in which proteins are folded. Blue light is reported to cause the aggregation of short-wavelength opsin, a photoreceptor protein; misfolded protein accumulates; the cell mounts the unfolded protein response; and if that response fails to restore function, it terminates in programmed cell death. Appendix C.65 sets out a study tracing that sequence in a photoreceptor cell line under blue light-emitting diode illumination at 470 nanometers.

The Foundation notes a convergence rather than a conclusion. Appendix C.61 reports blue light at 447 nanometers damaging proteins inside their own structure by an entirely different route, worked out by different methods in a different field. Two literatures that do not cite each other arrive at protein integrity as the thing short-wavelength light disturbs. The Foundation has no basis for saying the two mechanisms are related and does not say so.

The feature of this literature that bears on the statutory question is not any of its findings. It is the role blue light-emitting diode illumination plays within it. In this branch of research, blue diode light is the standard insult: it is the means by which photoreceptor damage is reliably produced in

order that candidate protective compounds can be tested against it. The study at Appendix C.65 is an instance. Its subject is a plant extract. The blue diode exposure is the assay.

The Foundation draws from that the narrowest inference it can. Among researchers who use it as a tool, the capacity of blue light-emitting diode illumination to damage photoreceptor cells at laboratory doses is not in dispute; it is relied upon. That is not evidence that the products described at Part VI damage anyone's retina, and this comment does not offer it as such: the laboratory doses are prolonged and continuous in a way no eye experiences, and a cell line in a dish lacks the pigment epithelium, the circulation and the repair machinery of a retina. It is evidence about what is taken as settled by the people who work on it, and about where the open question actually lies, which is not whether this radiation can damage retinal cells but at what exposure it begins to. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions and conditions of exposure, and that is the form the unanswered question takes.

b. A documented human injury from a consumer light-emitting diode device

In July 2023 ophthalmologists at the West China Hospital of Sichuan University published in Heliyon what they describe as the first case report of human retinal damage from a handheld light-emitting diode lighting device. Appendix C.64.

The patient was a thirteen-year-old girl. A classmate directed a handheld light-emitting diode light at her right eye several times, at very short distance, in flash mode. The device was bought online. It was a product for outdoor lighting, built from thirty chip-on-board emitters rated together at 5 watts and 100 lumens per watt at 500 milliamperes.

Three days after the exposure her best corrected visual acuity in the affected eye was 6/20. Optical coherence tomography showed a hyperreflective area in the external retinal layers corresponding to disruption of the ellipsoid zone and of the photoreceptor outer segments. She was treated at five days with a single retrobulbar injection of triamcinolone acetonide. Acuity recovered to 16/20 at nineteen days and to 20/20 at thirty-three days, and the restoration of the outer retinal layers was documented by imaging through three months.

c. What the Foundation does not draw from it, stated before what it does

The authors of that report make a statement that forecloses the broadest use of their own case, and the Foundation adopts it rather than working around it. They write that no evidence of direct adverse health effects from light-emitting diodes has been found in conditions of normal use, and that it is misuse which may cause damage to the eye, particularly in children.

The Foundation therefore does not offer this case as evidence that ordinary light-emitting diode illumination injures the retina. It does not, on this record. Nor is a single case report evidence of risk at the population level; Part V.A sets out how this comment weights evidence, and a case report sits at the bottom of that ordering. What a case report establishes is that a thing happened once, in a documented way, to an identified person.

d. What it does establish, which is a fact about the regulatory system

The authors observe that the imaging findings in their patient were particularly similar to those seen in solar maculopathy, in welding arc maculopathy, and in maculopathy following exposure to the plasma flash of a femtosecond laser, and they suggest that these may share the same phototoxic cause.

The Foundation asks the Department to set that observation beside the contents of its own regulations.

Laser products are the subject of a performance standard at 21 C.F.R. § 1040.10, with a classification scheme, accessible emission limits, labeling requirements and reporting obligations, and specific purpose laser products are further addressed at § 1040.11, which for some applications restricts which classes may lawfully be used at all. Part V.C.2.k.

Sunlamp products are the subject of a performance standard at § 1040.20, which limits irradiance, limits the ratio of irradiance between two ultraviolet bands, and prescribes labeling, timers and a recommended exposure schedule. Part II.C.2.

Exposure to welding arcs is addressed in the occupational setting through eye protection requirements administered by another department. Part II.H.10.

A handheld lighting device assembling thirty emitters at five watts, purchasable online by a schoolchild, is the subject of no performance standard within this Department's authority. It has no classification, no emission limit, no mandatory labeling as to optical hazard, and no reporting obligation. Part II.C.

The Foundation does not contend that a handheld lamp and a laser present hazards of the same magnitude, and it does not ask the Department to treat them alike. The contention is narrower and is about the structure rather than the severity. Where an injury of the same clinical description is produced by four different sources, the agency reaches three of them and not the fourth, and it does so not because it determined that the fourth is safe but because of where the definitional boundary described at Part II.C happens to fall. The Final Response of May 24, 2024 states that light-emitting diode products have a long history of safety with respect to the visible wavelengths being emitted. A documented macular injury in a child from a marketed diode product does not refute a history of safety, and the Foundation does not say it does. It does establish that the question of what such products may emit has an answer in at least one direction, and that no federal instrument asks it.

e. The aversion response, in the circumstances of an actual injury

One feature of the case bears directly on the assumption examined at Part V.C.2.k. The protective premise of the moderate risk group in the photobiological framework is that a person will look away from a bright source within a quarter of a second. In this case the light was directed at the patient's eye by another person, without warning, repeatedly, and in flash mode.

Those are precisely the conditions in which an aversion response cannot operate as the framework assumes. A person cannot avert from a source before it appears, and a source that re-presents returns to the retina each time the eye returns to it. The Foundation does not assert that this device would have fallen into any particular risk group, because no one classified it and the voluntary system described at Part V.C.2.k would not have required anyone to. The point is about the assumption rather than about this product.

f. The person injured was a child

The patient was thirteen years old and the device was bought online by another child. Part V.C.2.g sets out the measured age dependence of ocular transmission: the retina of a child under nine receives about 65 percent of incident light at 460 to 480 nanometers against about 40 percent in an adult aged 60 to 70. Part VI.E describes the settings in which children are exposed to lighting they did not choose, and Part IX.L asks that populations differently exposed to an identical emission be addressed expressly. The Foundation notes that the one documented human case it has located of retinal injury from a consumer diode product involved a child, and asks that the coincidence be treated as a reason for inquiry rather than as evidence of anything.

g. The endpoint is a lesion in one tissue, and the retina contains others

The structure the weighting function describes

The blue-light weighting function B(λ) discussed in Part V.C.2.a is an action spectrum. An action spectrum is not a general statement about what light does to an eye. It is a measured statement about the relative efficiency of each wavelength at producing one particular effect, in one particular tissue, assessed by one particular endpoint. The effect B(λ) describes is photochemical lesion formation in the outer retina – the retinal pigment epithelium and the photoreceptors – and the endpoint by which that lesion was recognized in the threshold experiments that generated

the function was a visible or histologically detectable lesion at or above threshold. Part V.C.2.f sets out the dose figures and the regulatory margin drawn from them.

Two consequences follow, and neither is controversial as a matter of photobiology. First, the function carries no information about wavelengths that do not produce that lesion; Part V.B.6 and Appendix C.63 address the red end on exactly that ground. Second, and the subject of this subsection, the function carries no information about other tissues, other molecular targets, or other endpoints – including other tissues inside the same retina.

A study of a different retinal tissue

Appendix C.66 records a 2023 study from Taipei Medical University that examined the retinal vascular endothelium rather than the photoreceptors or the pigment epithelium. The inner retina is supplied by capillary beds whose endothelial cells are sealed to one another by tight junctions, and that seal is the inner blood-retinal barrier. The barrier is what keeps fluid and solutes out of the retinal layers; its failure is the mechanism of macular edema and of the retinal leakage seen in diabetic eye disease.

The study reports that blue light exposure reduced claudin-5, the endothelial tight junction protein, to roughly half of control levels in a murine endothelial line and roughly two thirds in primary human retinal microvascular endothelial cells, after six hours; that electron microscopy showed the junctions replaced by a gap; that the loss was produced by activation of a metalloprotease, ADAM17, which cleaves the junction protein; that blocking that protease pharmacologically or genetically prevented the loss; that in the resting state the protease is held inactive by a retina-enriched inhibitory G protein, GNAZ, from which blue light releases it; and that removing that G protein reproduced the damage without any light at all. In mice, a regimen of six hours per day for three consecutive days produced angiographic leakage together with attenuation of the electroretinogram b-wave and of the oscillatory potentials – that is, a measured change in the electrical response of the inner retina, not only a change in a protein.

What the Foundation draws from it, and what it does not

The Foundation does not cite this study for any proposition about dose. That restraint is deliberate and the reason is recorded in full at Appendix C.66. The study reports its exposures in lux and does not report irradiance or the peak wavelength of the diodes it used. Lux is a photometrically weighted unit, weighted by a function that is small in the blue, so a stated illuminance of near-monochromatic blue light corresponds to a radiometric exposure one to two orders of magnitude greater than the same stated illuminance of white light. The study's own comparison of its chamber to a display screen at reading distance is therefore a comparison of illuminance and not of blue-light dose, and the comment does not repeat it. Nor does the comment adopt the study's opening assertion of a rising incidence of retinopathy from consumer devices.

What the Foundation draws from it is narrower and does not depend on the exposure level. Blue light acting on the retina has at least one route of action that runs through vascular endothelium, proteolytic cleavage of a junction protein, and the integrity of a barrier – a route whose target tissue, molecular mechanism, and functional endpoint are all different from those of the photochemical lesion that $B(\lambda)$ was measured to describe. The study also establishes that this route is wavelength-dependent and not merely energy-dependent: red light at the same facility left both the junction protein and the activation state of the protease unchanged. So there is an action spectrum for this effect. Nothing in the record establishes that it is the same action spectrum as $B(\lambda)$, and no one has measured it.

Why this matters to a limit

A numerical limit is only protective against the mechanism whose threshold it was derived from. A limit calibrated to outer-retinal photochemical lesion thresholds in primates is a statement about

outer-retinal photochemical lesions. It is not, and was never measured to be, a statement about the concentration of a tight junction protein in the inner retinal vasculature, about the activation state of a metalloprotease, or about the amplitude of the oscillatory potentials. Whether the lesion limit happens also to be protective against these other routes is an empirical question that has not been asked.

This is the same structural point the comment makes in Part V.C.2.h about effects outside the eye, applied one level in: the framework does not merely stop at the boundary of the eye, it stops at the boundary of one retinal tissue and one injury mode. The Foundation accordingly asks that any framework the Department or the Food and Drug Administration adopts state on its face which tissue, which endpoint, and which action spectrum its numerical limits rest on, and that a limit derived from outer-retinal photochemical lesion thresholds not be represented, in agency guidance or in reliance on a recognized consensus standard, as establishing that an exposure is without effect on the retina.

h. The most adverse review of the human evidence, and why the Foundation cites it

The Foundation states the following at the outset of this subsection, because a comment that conceals adverse authority forfeits the credibility of everything else in it. The most directly adverse peer-reviewed document in this comment's record is Appendix C.67, a 2023 review of the human clinical literature on blue light and the retina. Its concluding assessment is this:

> "We find it difficult to express with certainty that blue light exerts a harmful effect at the level of the human retina".

The Foundation does not dispute that assessment, does not characterize it as an outlier, and does not ask the Department to set it aside. It is the considered conclusion of three authors at a university department of physiology and ophthalmology, reached after a search of five databases restricted to human clinical studies and trials, and the Foundation treats it as the current state of the human clinical literature.

Why that conclusion does not answer this comment

The proposition the review declines to affirm is not the proposition on which this comment rests. This comment does not assert that light-emitting diode products in ordinary use have been demonstrated to injure the human retina. Part V.A.2 states the evidentiary standard the Foundation holds itself to, and Part V.C.2.e states what the Foundation asserts and what it does not. The assertion is that a class of electronic products emitting optical radiation is in universal use, that the Secretary's duties under 21 U.S.C. § 360ii apply to it, and that no performance standard, no exposure limit, and no systematic program of research or testing has been established for it. Whether harm has been demonstrated is a different question from whether the statutory duties have been discharged.

And the reasons the review gives for its uncertainty are, when read, a description of an inadequate research record rather than a description of an established absence of effect. The review states that many findings are "theoretical or based on observations in cell culture or animal experiments"; that the small number of participants makes generalization difficult; that few studies have adequate follow-up; and that research groups have defined the mesopic condition inconsistently, "ranging from 0.1 lx to 50 lx", with wavelength and stimulus duration likewise varying between studies. A literature that cannot answer a question because its exposures are not standardized, its samples are small, and its follow-up is short is a literature that has not been required to answer it.

The review does not stop at uncertainty. The same concluding passage states that as more groups study the subject with designs resembling contemporary conditions, results are beginning to converge, and that they "all point towards the possible noxious effect of long-term blue light exposure". The Foundation quotes both halves of that conclusion and relies on neither beyond its terms.

What the review supplies that the Foundation does rely on

Three things. First, the methodological findings just quoted, which are direct evidence on the research-needs question and are used at Part V.K and in the Foundation's response to that question: the absence of a standardized exposure specification is itself the reason the literature cannot be synthesized, and that is a condition a federal standard would remedy. Second, the review's own Future Directions section, which is a research agenda written by clinicians in the field and recommends objective electrophysiological and imaging endpoints in place of the questionnaires that dominate the existing studies.

Third, and most consequential, the review reports a human study the Foundation had not previously identified. It describes work by Gagné and colleagues as the first to show that short exposures to blue light can affect both cone and rod electroretinogram responses – in the review's characterization, even where the exposure fell within the standard safety range – with the b-wave reduction present under both scotopic and photopic conditions and still measurable an hour after the exposure ended, and with that study's authors treating the reduction as temporary and declining to draw a conclusion about hazard. If that report withstands direct examination, it is a measured change in human retinal electrophysiology at an exposure within the range the present framework treats as acceptable, and it bears directly on Part V.C.2.f. The Foundation states it here at second hand, attributed to the review, and draws no conclusion from it pending reading of the underlying paper.

2. Blue-light hazard assessment — IEC 62471 and ANSI/IES RP-27

The vocabulary in which optical radiation injury is assessed is the vocabulary of hazard, and it carries with it a quantitative structure that this comment relies on. The structure is worth setting out before the literature is reviewed, because it determines what the published compliance statements about LED products actually mean.

a. The recognized hazards, and the weighting function

IEC 62471, Photobiological safety of lamps and lamp systems, published jointly as CIE S 009, assesses a lamp against several distinct optical radiation hazards: the actinic ultraviolet hazard to skin and eye, the near-ultraviolet hazard to the eye, the blue light hazard to the retina, the retinal thermal hazard, the infrared hazard to the eye, and the thermal hazard to skin. The corresponding American document is the ANSI/IES RP-27 series. The ICNIRP guidelines on limits of exposure to incoherent visible and infrared radiation are the underlying source for the limit values.

The blue light hazard is the one principally at issue. It is a photochemical injury to the retina, distinct in mechanism from thermal injury, and it is assessed not on raw emitted power but on radiance weighted by a hazard function, written $B(\lambda)$, which expresses the relative effectiveness of each wavelength in producing the injury. The function peaks in the short-wavelength region of the visible band, at 445 nanometers on the guidelines of the International Commission on Non-Ionizing Radiation Protection of 2013, and falls away steeply to either side.

b. The exposure metric is a dose

This is the point the Foundation asks the Department to carry forward into the rest of this comment. The quantity the standard limits is not a radiance. It is a radiance accumulated over time. The blue light hazard dose is the weighted radiance multiplied by the duration of exposure, and it is expressed in joules per square meter per steradian. The limit is:

$$D = L \cdot t, \text{ not to exceed } 10^6 \text{ J/(m}^2\cdot\text{sr)}$$

where L is the blue light hazard weighted radiance in watts per square meter per steradian and t is the exposure time in seconds. Dose and duration are therefore not concepts imported into this subject from chemical toxicology. They are the native terms of the field, and they appear in the governing international standard in exactly that form.

The Foundation makes the point because the vocabulary has caused confusion. Optical radiation is not a chemical agent, and the vocabulary of chemical injury does not belong to it. But the two properties that make chemical exposure a regulated subject — that effect depends on how much is delivered, and that delivery accumulates with time — are both expressly built into the way optical radiation exposure is measured. Nothing about electromagnetic radiation places it outside a dose-and-duration framework. The framework is already there.

c. Where the framework stops: ten thousand seconds

The limit has a structure that is not always noticed, and the arithmetic of it is the most important technical fact in this subsection.

A source whose weighted radiance is 100 watts per square meter per steradian reaches the dose limit of 10^6 joules per square meter per steradian in exactly 10,000 seconds. Below that radiance a source cannot reach the dose limit within 10,000 seconds at all. Above 10,000 seconds the standard ceases to integrate, and the criterion becomes a limit on radiance itself rather than on accumulated dose.

Ten thousand seconds is two hours and forty-six minutes.

The exposure limit is accordingly constructed around a single viewing episode of at most that length. It is not a limit on what a person accumulates across an eight-hour shift beneath the luminaires described at Part VI.F; across a night spent in a bedroom reached by a roadway luminaire; across a career of driving at night facing oncoming headlamps; or across a lifetime. For exposures of that kind the standard supplies no accumulated quantity, because beyond its breakpoint it stops accumulating.

The Foundation is not criticizing the standard for failing to do what it never undertook to do. IEC 62471 is addressed to acute exposure and says so. The criticism is of the use that is made of it. A product described as compliant with IEC 62471, or classified in the Exempt Group or Risk Group 1, has been assessed against an acute limit evaluated over a single episode. That classification is frequently reported, and read, as though it answered the question whether long-term exposure to the product is safe. It does not answer that question. It does not address it.

The same limitation, stated in 2014 by the author of the 2024 review

The Foundation has set out that argument from the arithmetic of the standard. It is able to set it out a second way, which carries more weight, because the proposition is stated as a limitation of the framework by the author who later led the intergovernmental review described at subsection f.

Christophe Martinsons of the Centre Scientifique et Technique du Bâtiment published in 2015, in the Springer Handbook of Advanced Lighting Technology, a chapter titled Photobiological Safety. Appendix D.5. Its section 4.6 is headed Limitations of the CIE/IEC blue light hazard assessment and is divided into three subsections: Potential effects of low-level chronic exposures, Potential effects of long-term exposures, and Sensitive populations. Those are the three propositions this comment advances. They appear as section headings in a reference work written by a specialist in the field, eleven years before this comment and ten years before the Final Response of May 24, 2024.

On chronic exposure the chapter states:

> "The maximum exposure limits defined by the ICNIRP and used to define the risk groups in IEC 62471 are not appropriate for repeated exposures to blue light as they were calculated for a maximum exposure of one eight hour day."

That sentence supplies something the Foundation's own arithmetic did not. Above the ten-thousand-second breakpoint the criterion becomes a limit on radiance rather than on accumulated dose, and the Foundation has said that the standard then stops accumulating. The chapter says what the radiance limit was constructed for: a maximum exposure of one eight-hour

day. The two statements are consistent and together they are more precise than either alone. The framework integrates dose up to 10,000 seconds, and above that applies a radiance limit derived for a single working day. Neither reaches a year, and neither reaches a lifetime.

On what had already been measured by 2014, the same subsection states:

> "The first published results show that retinal damage induced by chronic exposure to white LEDs can be detected at much lower levels than the ICNIRP exposure limits."

The Foundation asks the Department to set that sentence beside the chronology at subsection f. The 2024 intergovernmental review reports that since 2012 several independent teams have found retinal damage well below the exposure limit. The chapter shows that its author was already reporting that as a published result in 2014. The finding on which the 2024 review rests was not new in 2024. It was a decade old, in print, in a reference work, from the same author.

The first published results, identified, and what the limits were constructed to detect

The Foundation can now identify the first published results to which that chapter refers, because its author is one of their nine authors. In July 2015 Jaadane, Boulenguez, Chahory, Carré, Savoldelli, Jonet, Behar-Cohen, Martinsons and Torriglia published in Free Radical Biology and Medicine a study of retinal damage from commercially available light-emitting diodes. Appendix C.78 records it. It is the earliest of the three studies by this group that this comment relies on, the others being at Appendix C.75 and Appendix C.63, and it is the one that states what the exposure limits were built to detect.

The passage is in the first paragraph of their results, and the Foundation quotes it in full because every element of it matters. The word used for injury is the authors' own.

> "Until today, regulations of light toxicity on the retina have established ELV (exposure limit values). These ELV are based on a study of fundus examination following a single exposure to light during 8 h. They establish that light is toxic to the eye when there is a bleaching of the retina."

Three elements of the limit are named in two sentences, and the Foundation asks the Department to notice each of them separately.

The endpoint is bleaching of the retina. Not loss of function, not loss of cells, not oxidative modification of proteins or nucleic acids. A visible whitening of the tissue.

The method is fundus examination. The injury must be of a kind, and of a magnitude, that an examiner looking into the eye can see.

The exposure is a single episode of eight hours. Subsection b and the arithmetic above establish that the limit integrates dose only to ten thousand seconds; this sentence states the experimental basis from which that construction came.

The same authors then applied that endpoint to their own animals. Dilated fundus examination was performed immediately after exposure by a veterinary ophthalmologist with two assistants. In rats exposed from twelve hours to three days, to commercially available white light-emitting diodes and to four blue sources at 507, 473, 467 and 449 nanometers, no bleaching of the retina was detected in any animal.

In the same animals the authors report interphotoreceptor edema; activation of microglia and infiltration of macrophages, indicating retinal inflammation; oxidation of DNA and RNA and of proteins, by two separate markers; loss of photoreceptors; and three modes of cell death, caspase-independent apoptosis, necroptosis and necrosis. The regulatory endpoint was negative. The injury was extensive.

That is the whole of the Foundation's argument in this subsection, and it is now stated from a primary source rather than inferred. A limit that defines injury as bleaching of the retina visible on

fundus examination cannot detect injury that does not bleach the retina. This is not a criticism of the limit's arithmetic, which is sound, nor of the investigators who established it, who were measuring what the instruments of their time could measure. It is a statement about what the limit was constructed to find. An exposure assessed as presenting no risk under a framework built on that endpoint has been assessed as unlikely to produce a visible lesion in a single day. It has not been assessed for anything else, and Part I.C.7 sets out why a determination of safety that rests on such an assessment is not a finding about the matters this comment raises.

One number from the same study belongs here with a warning attached. The authors state that the irradiance flux in their experiments was about one thousandth of that used in the earlier experimental work they cite, and give their own figure as a corneal irradiance dose of approximately 0.0026 joules per square centimeter, obtained from commercially available sources rather than from the laboratory devices used previously. The warning is that this is a corneal quantity and the 2.2 joules per square centimeter discussed at subsection f is a retinal quantity. The two differ by the optical gain of the eye and must not be compared. Appendix C.78 records both figures and states the distinction, and no arithmetic relating them appears anywhere in this comment.

On long-term exposure the chapter is equally direct:

> "The ICNIRP exposure limit values do not take into account the possibility of an exposure over an entire lifetime. Very little is known about the effects of life-long cumulated exposures to blue light emitted by LEDs."

And it characterizes the predecessor European Opinion described at Part V.K.9 in these terms: that IEC 62471 gives limits protective against acute effects, while long-term effects are only marginally considered and estimated to be of negligible or small risk.

On sensitive populations the chapter states that IEC 62471 does not take into account the sensitivity of certain specific population groups, and lists four:

- People with a pre-existing eye or skin condition that artificial lighting can trigger or aggravate.
- Aphakic and pseudophakic subjects, who cannot or can only insufficiently filter short wavelengths.
- Children, because their skin and visual system are not mature.
- Elderly people, because their skin and eyes, and particularly the retina, are more sensitive to optical radiation.

The chapter then makes a recommendation, and the Foundation quotes it because it is the recommendation this comment makes at Part IX.L, published in a reference work in 2015:

> "The photobiological standards relative to lighting systems should be extended to cover children – especially infants less than 2 year old – and aphakic or pseudophakic individuals, taking into account the corresponding phototoxicity curve A(λ) published by the ICNIRP in its guidelines."

One technical point in that recommendation deserves separate mention, because it concerns the structure of the limit rather than the policy. The guidelines define two action spectra for blue-light photoretinopathy: B(lambda) for the eye with a crystalline lens, and A(lambda) for the eye without one. The chapter records that the guidelines themselves recommend using the aphakic spectrum A(lambda) when assessing infants under the age of two, because of the greater transparency of the infant crystalline lens.

The Foundation draws the consequence that follows and no more. The hazard framework already contains a second, more protective weighting function, and the body that wrote the limits already recommends applying it to the youngest children. A product-compliance statement expressed as a risk group does not say which weighting was used. Part V.C.2.g sets out the measured

transmittance differences by age, and Part IX.F asks that emission characteristics be disclosed; a statement of which action spectrum a determination applied belongs in that disclosure.

d. Cumulative optical dose is an established framework for one waveband and absent for another

It is worth stating why this matters beyond the drafting of one standard. Cumulative dose is not a foreign idea in optical radiation photobiology. For ultraviolet radiation and the skin it is the accepted framework: cumulative lifetime ultraviolet dose is the organizing concept of photocarcinogenesis, and regulatory and clinical practice are built on it. The agency's own performance standard for sunlamp products, 21 C.F.R. § 1040.20, regulates a lamp in spectrally resolved radiometric terms precisely because of what accumulated ultraviolet exposure does. Part II.C.2.

So the field accepts that optical radiation delivers a dose, that the dose accumulates, and that accumulation across years is the relevant exposure for some injuries. What is absent for the visible band is not the concept. It is the evidence, and the research that would produce it.

An experiment published in 2023 illustrates what the absence of a long-term dose framework means in practice, and the Foundation sets out its exposure figures because they are the kind of figures a federal evaluation would have to produce. Hiramoto and others exposed hairless mice to light-emitting diode illumination for ten minutes a day, every day, for one year. Four spectral conditions were used. The blue condition ran from 380 to 500 nanometers with a peak at 479, the green from 500 to 560 with a peak at 538, and the red from 600 to 700 with a peak at 629; each of those three delivered 40 kilojoules per square meter per session. Skin cancer was induced in the blue group and in no other. Appendix C.26.

Converted to the units in which optical exposure is ordinarily expressed, 40 kilojoules per square meter is 4 joules per square centimeter per session, delivered over ten minutes, which is an irradiance of approximately 6.7 milliwatts per square centimeter. Over 365 daily sessions the cumulative delivered energy is approximately 1,460 joules per square centimeter. The Foundation states those figures because they can be stated: the study reports its exposure in radiometric units and the arithmetic follows.

Now set that against the framework described at subsections b and c. The blue-light hazard exposure limit is a dose, radiance-weighted and integrated over time, and it stops at ten thousand seconds — under three hours. This experiment delivered 3,650 minutes of exposure spread across a year and reported an outcome at the end of it. Whatever the merits of the study, and Appendix C.26 sets out several reasons for caution, no federal instrument describes the exposure it administered. The hazard framework cannot express a dose accumulated over a year because it was not built to; it addresses acute photochemical injury to the retina, and this concerned the skin over twelve months.

The Foundation draws the conclusion it has drawn throughout this Part. The missing quantity is not a concept. The concept is dose, and the Department has used it: § 1040.20 prescribes a recommended exposure schedule with duration and spacing for sunlamp products, which is a dose framework for a light-emitting product administered over repeated sessions across a lifetime. Part IX.J.5. What is missing is any determination of what cumulative optical dose, in what waveband, over what period, is acceptable for the products described in Part VI. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure to electronic product radiation. A cumulative dose over time is a condition of exposure, and for the visible spectrum the Foundation has found no federal statement of one.

e. What the Foundation asserts, and what it does not

The Foundation does not assert that a cumulative dose-response relationship has been established between long-term exposure to visible light from LED products and any particular injury. It has not been established, and Part V.A sets out how this comment weights evidence.

The Foundation asserts four things, each of which is either a matter of record or a matter of arithmetic.

Optical radiation exposure is measured as a dose, in the governing international standard, in units of joules per square meter per steradian.

The exposure limit in that standard is constructed for exposures not exceeding 10,000 seconds, and above that duration it ceases to accumulate.

The exposures that this comment is concerned with — occupational, residential, roadway and lifetime — are longer than that by orders of magnitude, and are therefore outside what the limit was constructed to assess.

Section 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. The gap between an acute limit and a chronic exposure is precisely the subject that direction describes.

The question is not whether the Department should assume an answer. It is that the question has not been asked, and the statute assigns the asking of it to the Secretary.

f. Whether the limit itself is settled

One further matter belongs in this subsection, because it bears on the weight the governing standard can carry. In October 2024 the International Energy Agency's 4E Solid State Lighting Annex published Solid State Lighting: Review of Health Effects, by Christophe Martinsons of the Centre Scientifique et Technique du Bâtiment, Jennifer A. Veitch and Ashley Nixon of the National Research Council of Canada, Sarah Loughran and Rohan Mate of the Australian Radiation Protection and Nuclear Safety Agency, and Rachael Harris and Linda Shen of Monash University.

The Foundation identifies the authorship because it bears on how the document should be read. It is an intergovernmental technical review rather than advocacy, and one of its authoring institutions is a national radiation protection authority — the body that performs in Australia a function this subchapter assigns to the Secretary. On the blue light hazard it reports the following, at page 31:

> "Since 2012, several independent teams have found retinal damage well below the ICNIRP exposure limit using more sensitive detection techniques and different animal models, including rats but also living macaques."

On the state of the question within the field, at the same page:

> "There is currently no consensus between the lighting community and many retinal experts about the need to revise the current ICNIRP exposure limit to the blue light hazard."

And at page 10, among its recommendations:

> "we recommend that photobiological safety committees engage in a systematic review and update of the blue light hazard exposure limits."

On the two questions this subsection has been concerned with — chronic exposure and the measurement of short-wavelength content — the report states at page 15 that "it is not possible yet to conclude anything about the effect of long-term chronic exposures to SSL products on the development of AMD," and at page 33 that "More measurement data are needed to know the risk levels of SSL technologies emitting below 430 nm".

The Foundation is careful about what it draws from this. It does not assert that the exposure limit is wrong, and it does not assert that retinal injury from general illumination has been established. The report says there is no consensus, and the Foundation adopts that characterization rather than a stronger one. Three propositions follow, each of which is a matter of record rather than of inference.

The exposure limit on which the Final Response of May 24, 2024 relied is the subject of an unresolved question among the bodies that set it, and the call for its systematic review is joined by a national radiation protection authority.

Section 360kk(a)(1)(A) directs the Secretary, in prescribing a standard, to consider the latest available scientific and medical data in the field. A report of this kind, published after the determination, is within that category.

The report addresses its recommendation to photobiological safety committees. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from professional organizations on present and future potential electronic product radiation. Part II.E.4.

The Foundation asks the Department to state whether it has considered this report, and if so what conclusion it drew from it. The question is not rhetorical. If the Department has reviewed it and is satisfied that the limit requires no revision, that is an answer the Foundation would accept as responsive, and it is an answer that would itself constitute the evaluation § 360ii(a)(4) directs.

The numbers behind that statement, and the regulatory chain they bear on

The 2024 review states that independent teams have found retinal damage well below the exposure limit. It does not say by how much. One of the studies in that literature does, and the Foundation sets out both the chain of derivation it challenges and the challenge, because the chain has not previously been stated in this comment.

The chain runs as follows, and it is short. Limit exposure values for domestic lighting rest on action spectrum curves. Those curves give a retinal threshold dose at 445 nanometers of 22 joules per square centimeter for primates and 11 for rodents. The primate value was used to establish the lighting regulations. The regulations weight polychromatic light by the blue light hazard function B(λ), which peaks at 445 nanometers, and a device is labeled as presenting no risk if after 10,000 seconds of exposure the weighted retinal dose is below 2.2 joules per square centimeter.

Two features of that chain deserve to be stated before it is challenged. The regulatory limit is one tenth of the measured primate damage threshold, which is the safety factor built into the standard. And the entire structure rests on animal threshold measurements, as Part V.K.3 records the 2018 Opinion acknowledging.

One of those teams, and the figure the 2024 review omitted

The Foundation can now identify one of the independent teams to which the 2024 review refers, and state the figure. In 2017 Jaadane, Behar-Cohen, Martinsons, Torriglia and colleagues published in the Journal of Cellular and Molecular Medicine a study of white light-emitting diode exposure on the retinal pigment epithelium of rats. Appendix C.75 records it. Two of its features matter here before any result is stated. The source was ten commercially available warm white lamps of a named retail model, which the authors describe as widely used in residential lighting, behind a diffuser fitted to suppress point-source effects. And the exposure was expressed not in lux or in watts per square meter but as a retinal radiant exposure dose in joules per square centimeter, computed by the same French building science laboratory that characterized the apparatus, which is the unit the exposure limit is expressed in. It is, so far as the Foundation has found, the only study in Appendix C whose exposure is reported in the units of the limit it is to be compared with.

The authors state their design in terms: the doses used were intentionally fixed below the damage threshold from which the exposure limit values were calculated. Rats received constant white light-emitting diode exposure for 4.75, 6, 12, 18 and 24 hours, corresponding to computed retinal doses of 4.14, 5.23, 10.5, 15.7 and 20.9 joules per square centimeter. Four animals per condition. At the lowest of those doses the actin cytoskeleton of the pigment epithelium was disorganized and a protein kinase marker of oxidative stress had translocated to the plasma membrane. At 5.23

joules per square centimeter the tight junctions were disrupted. Serum albumin leaked into the interphotoreceptor space, increasing with exposure, which is the direct demonstration that the outer blood-retinal barrier had failed. Cell death was by necrosis, apoptosis having been excluded by negative staining.

The figure the Foundation draws attention to is in the discussion. Taking the lowest dose at which damage was observed, 4.14 joules per square centimeter in total, the authors report that the blue part of the spectrum accounts for 14 percent of it, which is 0.58 joules per square centimeter. The basic restriction from which the blue light hazard exposure limit is derived is 2.2 joules per square centimeter. The damage was therefore observed at a blue-light retinal dose of roughly one quarter of the limit, and the authors say so: far below the figure presumed to be completely safe.

That is a strong claim and the Foundation states the three qualifications that bear on it, because a claim of this importance should be presented with its weaknesses rather than without them.

The 0.58 figure is a band fraction and not a weighted quantity. The limit is expressed as a dose weighted by the blue light hazard function described at subsection a, which rises to a peak at 445 nanometers and falls away on either side. Fourteen percent of the total spectral energy is not the same arithmetic. The two quantities are of the same order and the comparison is informative, but it is an approximation and the direction of its error is not stated in the paper.

The computed retinal dose depends on an assumed pupil diameter, and the assumption is generous. The authors took 5 millimeters, noting that they did not dilate the animals' pupils and reasoning that the irises of albino rats absorb little light. Their own cited sources give other values: one source between 0.4 and 1.2 millimeters, another 0.5 millimeters. Retinal dose scales with pupil area, so across that range the computed dose could overstate the delivered dose by a factor between about seventeen and about one hundred. The error runs in the direction that favors the Foundation's reading, since a dose smaller than stated would place the observed damage further below the limit rather than above it. But it means the absolute figures carry an uncertainty of as much as two orders of magnitude, and the Foundation does not treat 0.58 joules per square centimeter as a measured quantity.

The dose was delivered over far longer than the limit contemplates. The shortest exposure, 4.75 hours, is 17,100 seconds, and the longest is 86,400. The limit is constructed for exposures of no more than 10,000 seconds, as subsection c sets out. The authors raise this themselves. It cuts both ways: a dose spread over a longer period is less injurious per unit time, which is an argument for the limit; and the framework does not address exposures beyond its ceiling at all, which is the argument of subsection c and the reason this comparison is being made outside the domain the limit was written for.

With those qualifications the finding stands as this. A commercially available residential lamp, operated so as to deliver a retinal dose the investigators deliberately kept below the threshold on which the exposure limit is based, produced disorganization of the pigment epithelial cytoskeleton, disruption of tight junctions, failure of the outer blood-retinal barrier and necrotic cell death in a rat. And the detection required immunohistochemistry, electron microscopy and protein analysis: the authors note that the earlier work in this line found damage without any visible alteration at fundus examination, which is the examination the threshold was originally defined by. Subsection c explains why a limit calibrated to a visible lesion does not detect what these methods detect.

The Foundation sets this beside the 2024 study described in the following paragraphs, which shares three authors with it. The 2017 study reports damage below the threshold the limit was derived from. The 2024 study re-measures the threshold itself and reports it overestimated. The two are the same argument approached from opposite ends by overlapping investigators across

seven years, and Part V.A.1 records what that overlap means for the weight the two can bear together.

In February 2024 Françon, Behar-Cohen and Torriglia published in Environment International an in vivo study of that threshold in rats, funded by the French agency for food, environmental and occupational health safety. Appendix C.63. The second author was an external expert of the 2012 predecessor Opinion described at Part V.K.9. Their findings bear on the chain at three separate points.

On the threshold. They report that the phototoxicity threshold currently accepted for rats is overestimated by a factor of 50 for blue light and by a factor of 550 for white light. A tenfold safety factor does not survive an overestimate of either size.

On the weighting function, first ground. They report that green light drives the phototoxicity of white light by promoting an inflammatory response, and that the green content of white light produced eight times more macrophage invasion of the retina than the blue content. The hazard function weights 507 nanometers at a small fraction of its value at 445. A weighting function that discounts the wavelength doing the damage is not measuring the hazard.

On the weighting function, second ground. They report that red light mitigates damage, inhibiting the nuclear translocation of an enzyme involved in cell death and reducing the number of cells showing a marker of that death by 33 percent, and that the weighting does not evaluate the red content of white light at all. The function therefore omits a protective component as well as discounting a damaging one.

The Foundation asks the Department to notice that the second and third of those findings converge, from a different laboratory and a different mechanism, with the long-wavelength argument at Part V.B.6. That argument rests on work from a London group on mitochondrial function and visual performance. This is a Paris group working on retinal cell death. Neither cites the other's endpoint, and both conclude that the long-wavelength content which light-emitting diode sources omit is doing something the short-wavelength content is not.

The authors state the consequence for human limits themselves:

> "As current human phototoxicity thresholds were estimated with the same methods used for rats, our results suggest that they might need to be reconsidered."

And they state the consequence for products, which is the sentence this comment asks the Department to weigh most carefully:

> "the commercial LED that are currently classified as safe for the retina could actually induce retinal damage if used daily at high luminance."

The Foundation does not adopt that sentence as a finding about any product in American commerce, and Appendix C.63 sets out at length why it cannot: the work is in young albino rats, at acute doses, in a single laboratory, and the factor of 50 and the factor of 550 are overestimates of a rodent threshold rather than of the human limit. What the Foundation asks the Department to weigh is narrower and does not depend on accepting the finding. A peer-reviewed study, funded by a national health agency, co-authored by a member of the European scientific committee whose Opinion the determination of May 24, 2024 relies upon, published three months before that determination, concludes that the method by which the governing limit was derived requires re-assessment and that products classified as safe may not be. Section 360kk(a)(1)(A) directs the Secretary, in prescribing a standard, to consider the latest available scientific and medical data in the field. The Foundation asks whether this paper was among the data considered.

The authors also record a second and independent line to the same effect, which the Foundation notes without having read it: that Hunter and others, in work of 2012 and 2018, identified a potential overestimation by a factor of 20 in the current human safety standards.

g. Age-dependent ocular transmission, and who actually receives the dose

Subsection b describes the blue-light hazard exposure metric as a dose delivered to the retina. A dose at the retina is not the same quantity as a dose at the cornea, and what separates them is the eye through which the light passes. That eye is not the same at every age.

The crystalline lens absorbs short-wavelength light, and it absorbs progressively more of it over a lifetime as it yellows. The consequence is that the same source, viewed at the same distance for the same time, delivers a larger short-wavelength retinal dose to a child than to an adult, and a larger dose to an adult than to an elderly person.

The magnitude is available from an institutional source rather than from the Foundation. The Scientific Committee on Emerging and Newly Identified Health Risks, the predecessor of the committee whose 2018 Opinion is described at Part V.K, stated the following in its Opinion on the health effects of artificial light adopted on March 19, 2012. Appendix D.1.

Age	Reaching the retina at 400 nm	Reaching the retina at 460 to 480 nm
Children under 9 years	around 15 percent	about 65 percent
At 10 years	not stated	about 60 percent
Adults 60 to 70 years	about 1 percent	about 40 percent

The Committee adds a further observation about the youngest group which the Foundation reports because it concerns a waveband the eye is ordinarily assumed to exclude altogether. In children at or just below about nine years of age, the Committee states that a window exists allowing transmission of about 2 to 5 percent of ultraviolet radiation at 320 nanometers to the retina.

Two things follow from the table. The first is arithmetic: at 460 to 480 nanometers the retina of a child under nine receives roughly 1.6 times the proportion that the retina of a person aged 60 to 70 receives, and at 400 nanometers roughly 15 times. The second is that the variation is not a refinement at the margin. A limit written for one eye is a different limit, in its practical effect, for the other.

The Foundation notes that the narrative review at Appendix C.18 reports the 65 percent figure for children under nine, and that the figure is traceable to this Committee Opinion of 2012. Where this comment relies on it, the Opinion is cited rather than the review.

The regulatory consequence does not depend on the precise number. An exposure limit expressed at the cornea, and a hazard assessment performed against a standard observer, describe the dose received by the eye assumed in the standard. Where the population actually exposed includes eyes that transmit more short-wavelength light than that assumption, the limit understates the retinal dose for those people by a margin the standard does not state. The Foundation does not assert that any existing limit is thereby exceeded in ordinary use, and Part V.C.2.e states what the Foundation does and does not assert about these limits. It asserts something narrower: that the quantity the standard governs and the quantity deposited on a child's retina are related by a factor that varies with age, and that the variation is in the direction of greater exposure for the younger eye.

That bears on two things in this comment. It bears on Part VI, which describes the exposure conditions produced by classroom, street and vehicle lighting, because the populations under that lighting include children in the settings where they spend the most time. And it bears on the request at Part IX.L that sensitive populations be addressed expressly, because age-dependent ocular transmission is a mechanism by which a population is differently exposed to an identical

emission — which is the sort of fact § 360ii(a)(4) directs the Secretary to study and evaluate when it directs attention to conditions of exposure as well as to emissions.

h. The framework is ocular. The evidence is not.

Everything in this subsection so far concerns the eye. The photobiological safety framework assesses hazards to the retina, the lens and the cornea; the blue-light hazard weighting function is a retinal weighting; the exposure limit is expressed as a retinal dose; and subsection g concerns what the ocular media transmit. That is what the framework was built to do, and within its own terms it does it.

The Foundation asks the Department to notice that two of the studies in Appendix C report effects of light that did not enter the eye at all.

At Appendix C.19, a randomized sham-controlled trial delivered 670-nanometer light to an 800 square centimeter area of the upper back of healthy adults for fifteen minutes, and measured the result in capillary blood glucose. The irradiated tissue was skin and underlying musculature. The measured tissue was blood. At Appendix C.15, mice were exposed whole-body to light-emitting diode illumination and the outcome was examined by histology of the liver. In neither case is the eye the route, and in the first the authors chose a body site specifically to avoid it.

The consequence for this comment is structural rather than quantitative, and it is the same consequence Part V.B.6 draws about the absence of a wavelength band. A framework answers the question it was built to ask. A photobiological safety assessment performed against retinal exposure limits will return a result about retinal exposure. If light acts on a person through the skin as well as through the eye, that assessment is not wrong about the retina; it is silent about everything else. A product may conform to every applicable optical radiation safety standard, and that conformity will say nothing whatever about a pathway the standards do not assess.

Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. The conditions of exposure to a lamp include what reaches the skin of the person under it, and not only what reaches the retina. The Foundation is aware of no federal evaluation of the first. Part II.F.

The Foundation states the limit of what it claims. It does not assert that non-ocular exposure to light from any product in commerce injures anyone, and neither of the two studies cited supports that. The proposition is narrower: that a route of exposure exists, that effects through it have been measured in humans and in animals, and that no instrument in the federal or consensus framework describes it.

The mechanism is identified, and the Foundation now states it. Light is detected in the human body by proteins other than the visual pigments of the rods and cones. Karthikeyan, Davies and Gunhaga, reviewing the field in 2023, describe three non-visual opsins — OPN3, also called encephalopsin or panopsin; OPN4, melanopsin; and OPN5, neuropsin — and set out where they are expressed and what they do. Appendix C.28.

Two features of that account bear directly on this comment.

The first is where these receptors are. The review tabulates expression of OPN3 in human and animal tissue including blood vessels, many regions of the brain, the gastrointestinal tract, the liver and pancreas, immune cells including B-cells and T-cells, adipocytes, heart, kidney, lung, smooth and skeletal muscle, and skin -- fibroblasts, hair follicles, keratinocytes and melanocytes. OPN4 and OPN5 are likewise reported in skin, among other tissues. The review further records that specific wavelengths have been shown to penetrate skin, the skull and other bones, skeletal muscle and soft tissue, and through abdominal structures to reach the developing fetus, with longer wavelengths penetrating further but biologically relevant shorter wavelengths also passing into deeper tissues.

The second is what wavelengths they respond to. The peak absorbances reported are approximately 463 nanometers for OPN3, 480 for OPN4, and 380 for OPN5. The review notes that 480-nanometer light activates OPN3 to 90 percent and OPN4 to 100 percent of maximum, and that light at 400 nanometers activates all three. Part V.B.1 describes the short-wavelength emission peak of phosphor-converted white light-emitting diodes. These receptors are tuned to the region of the spectrum in which those products emit most strongly.

The functional consequences the review describes are not confined to the eye, and several of them correspond to findings already in this appendix:

Metabolism. OPN3 is expressed in adipocytes. The review reports that blue light applied to wildtype adipose cells produced enhanced mitochondrial activity and elevated glucose uptake, with no significant change in OPN3-knockout cells, and that animals lacking OPN3 showed reduced insulin sensitivity and diet-induced obesity. Compare Appendix C.19.

Blood vessels. Blue light between 400 and 460 nanometers is reported to relax the aorta and pulmonary arteries, an effect absent in OPN4-knockout animals and absent in darkness, and in vivo 455-nanometer light increased blood flow where red and green light did not.

Skin. The review reports that skin tissue from wildtype mice, but not from animals with OPN5 ablated, photoentrained in response to 415-nanometer light, and concludes that multiple local circadian clocks exist in mammals. On that account skin is not merely a surface that light falls on; it contains a clock that light sets.

Smooth muscle, immune cells and pigmentation are each described as under opsin-mediated photic control, and OPN3 variants are reported to be associated with asthma risk in one population. Compare Appendix C.20.

The Foundation is careful about one thing, because it would be easy to merge two different mechanisms and wrong to do so. The 670-nanometer effects at Appendix C.19 are attributed by their authors to cytochrome c oxidase in the mitochondrial electron transport chain, not to an opsin. Opsins and cytochrome c oxidase are distinct photoacceptors with distinct spectral sensitivities. What they have in common, and all that the Foundation asserts from both, is that the human body detects and responds to light through routes that do not pass through the retina.

The regulatory conclusion is the one stated above and is now supported rather than merely asserted. A photobiological safety assessment conducted against retinal exposure limits does not evaluate the pathways described in this subsection. It does not measure what reaches the skin, it applies no weighting function corresponding to any of these receptors, and it returns no quantity by which such an exposure could be compared against another. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure to electronic product radiation. The Foundation submits that the conditions of exposure to a lamp include the light that falls on the person beneath it, and that no federal evaluation of that exposure exists for any product emitting visible light.

One further line of work belongs here, and the Foundation introduces it with its limitation rather than with its finding. In December 2024 a group at the Ulsan National Institute of Science and Technology published in Nature Communications a study of how proteins are damaged by light. Appendix C.61. Working on single protein molecules held in magnetic tweezers, they found that blue light at a peak wavelength of 447 nanometers drives a reaction in which oxygen trapped inside the protein is converted by tryptophan residues into reactive oxygen species, which then damage the protein from the inside. The same decay did not occur in the dark, and did not occur under infrared light at 860 nanometers even at higher power.

The limitation is severe and the Foundation states it before the use. This was purified protein in a buffer and then cells in a dish. It is not a tissue, not an organism and not a health outcome, and the paper reports no irradiance for its blue light at all, so there is no way to relate the exposure to

anything a person encounters. The Foundation does not offer it as evidence that light-emitting diode products damage proteins in people.

It is offered for a narrower proposition that bears directly on this subsection. The target of that mechanism is not a photoreceptor, not a pigment and not a specialized light-sensing molecule. It is the interior of ordinary proteins, and the authors report that roughly nine in ten human proteins contain cavities and roughly a third contain large cavities holding tryptophan. The authors name the tissues they regard as relevant, and they are the tissues exposed to visible light: the skin and the eye.

That is the proposition this subsection has been advancing. A framework addressed to the retina is addressed to an organ. A mechanism that operates on a structural feature common to most proteins is not confined to an organ, and the quantity it would be assessed against is not one the photobiological safety standard measures. The Foundation does not say the mechanism is established in people. It says that the question whether it operates in people at the irradiances they actually receive has not been asked by anyone with the authority to answer it, and that § 360ii(a)(4) assigns the asking.

One convergence is worth recording because it is now the fourth instance, and the fourth is the most striking because it returns to the first molecule in a different role. Appendix C.54 reports riboflavin acting as a photosensitizer near 450 nanometers, producing free radicals and singlet oxygen in milk. The mitochondrial account at Part V.B.6 turns on porphyrin absorbing between 420 and 450 nanometers and producing singlet oxygen. Appendix C.61 adds tryptophan, generating singlet oxygen and hydroxyl radical at 447 nanometers. Appendix C.69 now reports blue light at a peak of 460 nanometers inhibiting succinate dehydrogenase, the enzyme of mitochondrial Complex II, in an intact animal, and proposes as the mechanism the degradation of that enzyme's flavin adenine dinucleotide cofactor – which is derived from riboflavin, and which those authors state is maximally activated at 450 nanometers.

So the same molecule appears twice: as a photosensitizer destroying nutrients in a retail refrigerator case, and as the cofactor of a respiratory enzyme in a living organism. Four instances, in four unrelated systems – food chemistry, mitochondrial respiration, protein folding and the retina – turning on absorption in the same narrow band, which is the band in which the dominant artificial light source of the present era has its peak. The Foundation draws no conclusion from the convergence beyond the obvious one: it is a reason to look. It notes only that a chromophore shared between a food-quality problem the dairy industry already measures and a respiratory enzyme in an animal is not a speculative target.

One qualification corrects the framing of the preceding paragraphs, and it makes the point more authoritative while making it less novel. The Foundation presented the convergence as a pattern it had noticed across unrelated literatures. It is not a discovery. A 2010 review of retinal light injury from the Department of Ophthalmology and Visual Sciences of the University of Wisconsin, recorded at Appendix C.80, gives the chromophores of the retina and the pigment epithelium as including the photoreceptors, flavoproteins, heme proteins, melanosomes and lipofuscin. Flavoproteins are the class to which riboflavin belongs as a cofactor; heme proteins are the class that includes cytochrome c oxidase; and lipofuscin is the pigment whose fluorophore is discussed above. Three of the four instances the Foundation assembled are therefore items on the standard list of retinal chromophores in an American ophthalmology review published before any of the four studies. The Foundation withdraws the suggestion that the convergence is a reason to look and replaces it with something stronger: that the molecules which absorb short-wavelength light in the retina have been identified in the clinical literature for at least fifteen years, and that the question is not what absorbs the light but at what level the absorption matters.

i. A distinction within the eye: hazard and non-image-forming response are different questions

Subsection h concerns routes of exposure that bypass the eye. This subsection concerns a distinction inside it, and the Foundation puts it after h because it is narrower rather than because it is less important. It may be the most consequential sentence in Part V.

Campbell, Sharifpour and Vandewalle, reviewing the non-image-forming effects of light on brain function in 2023, describe the relationship between the hazard framework and the pathway that governs those effects. Appendix C.30. Writing of the blue light hazard, they state:

> "The potential damage from the BLH region is particularly prominent for prolonged and/or intense exposure to wavelengths < ~440 nm, especially when arising from relatively focal light sources. The B[L]H region is therefore distinct from the NIF impacts of diffused light, which have a peak around 460–480 nm wavelength."

The Foundation asks the Department to read that against subsections a through f. The blue light hazard framework is an assessment of photochemical injury to retinal tissue. It is weighted toward wavelengths below about 440 nanometers, and it is most apt to focal sources. The non-image-forming pathway — the one that mediates melatonin suppression, circadian entrainment, alertness, and the effects on cognition and mood described in Part V.G — is driven by melanopsin, whose peak sensitivity these authors place at about 480 nanometers, and it responds to diffuse light filling the field of view rather than to a point source.

Two systems, two wavebands, two source geometries, two biological endpoints. They are not the same question, and conformity with the first is not evidence about the second.

That has a direct consequence for the determination of May 24, 2024 and for every assurance built on photobiological safety conformity. A manufacturer may demonstrate that a luminaire falls within the exempt group of IEC 62471. That demonstration concerns retinal photochemical injury from a focal source, below roughly 440 nanometers. It is silent about what the same luminaire does to the non-image-forming system of the person sitting under it for four hours in the evening, because that is a different waveband, a different geometry and a different pathway, and no standard the Department administers measures it. The Foundation is not asserting that the second effect is harmful. It is asserting that the first assessment does not address it, and that the record contains no federal assessment that does.

The Foundation notes that the two peaks are close enough to be confused and far enough apart to matter. A weighting function emphasizing wavelengths below 440 nanometers and a response peaking near 480 will return different answers about the same product, and a phosphor-converted white light-emitting diode emits across both. Part V.B.1.

j. Where a weighting function comes from, and why it matters that most do not exist

Subsection i describes two weighting functions that return different answers about the same product. The Foundation adds a word about where functions of that kind come from, because it answers a question the Department may fairly put to this comment: what, concretely, would the research it asks for consist of?

A weighting function is an action spectrum. It is a curve giving the relative effectiveness of each wavelength in producing one particular biological response. It is built by exposing subjects to one wavelength at a time, at controlled irradiance, and measuring the response at each. That is how the photopic luminous efficiency function V(λ) was constructed, how the blue-light hazard function was constructed, and how the melanopic sensitivity function was constructed.

Monochromatic exposure of that kind is not a model of how anyone lives. No person is ever exposed to a single wavelength, and a study that administers one is describing an artificial condition. The Foundation states that plainly and then states why it does not matter. The artificiality is not a defect of the method; it is the method. A function describing the separate

contribution of each wavelength cannot be derived from exposures in which the wavelengths are mixed, any more than the weight of each ingredient can be recovered from the weight of the cake.

The consequence is direct and the Foundation puts it as the answer to the question above. Part IX.C.4 asks the Department to adopt the weighting functions appropriate to each response studied. For the photopic response and for retinal photochemical injury, such functions exist and are in use. For the melanopic response one exists and is standardized but is not applied at population scale, as Part V.J.4 sets out. For the remaining responses described in this Part — metabolic, cardiovascular, affective, immune, and the non-ocular pathways at subsection h — no such function exists. The work that would produce them is at the stage of pilot studies with participants in single figures. Appendix C.34 is one such, and the Foundation offers it to show the state of that work rather than for its findings, which rest on seven people.

Until those functions exist, no standard can specify what a product may emit at each wavelength, because there is no agreed basis for saying which wavelengths matter for which endpoint and by how much. That is the gap between the present literature and a prescribable standard, described at Part V.J.4, stated in its most concrete form. It is also the clearest available answer to what the research directed by § 360ii(a)(2) and (a)(4) would consist of. It is not a vague call for more study. It is a specific, bounded, well-established experimental program — derive the action spectra — whose output is exactly the input a performance standard requires.

The Foundation observes finally that this is the precise respect in which the federal efficacy standard described at Part IV.G is inadequate as a lighting policy. A requirement expressed in lumens per watt is a single number relating luminous flux to power. It constrains neither the distribution of wavelengths that produces the flux nor the weighting of those wavelengths against any biological response. Two lamps of identical efficacy may differ entirely in spectrum. A standard that regulates the ratio and ignores the distribution is not a weak spectral standard. It is not a spectral standard at all.

k. How this emitting technology came to be assessed as a lamp, and what that assessment requires in the United States

The framework set out in the preceding subsections is the lamp framework. It has not always been the framework that applied to these devices, and the change is worth setting out, because it explains two features of the present arrangement: which document governs, and how little that document requires in this country.

The classification history

When light-emitting diodes first entered commerce in quantity they were not assessed as lamps. They were assessed under the laser safety standard. IEC 60825-1 brought them within its scope in its first edition of 1993, and that edition was followed by two amendments.

In March 2007 the standard was revised to Edition 2.0, a technical revision replacing the first edition and both amendments. Its foreword states the change in a single sentence:

> “Light emitting diodes (LEDs) have been removed from the scope of this part of IEC 60825”

The standard gives its own reason. The scope records that light-emitting diodes had previously been within scope, and states that lamp safety standards can more appropriately address the optical radiation safety of these devices. The revision does not preclude other standards from including light-emitting diodes wherever those standards refer to lasers, and the standard notes that CIE S 009 may be applied to determine the risk group class of a light-emitting diode or of a product incorporating one or more of them.

Two details of that pointer matter. The standard names CIE S 009 rather than IEC 62471, although IEC 62471 had been published in July 2006; the explanation is that IEC 62471 was created by adopting the text of CIE S 009, and the two are now published as a single dual-logo

document. And the removal is understood not to have been complete: light-emitting diodes used in optical fibre communication applications remained within the laser framework, addressed in IEC 60825-2.

The Foundation states the reason the standard states, and no other. It does not assert a motive for the revision, and it takes no position on who proposed it or why. The chronology and the standard's own explanation are the record. Anything beyond them would be inference, and this comment does not rest on inference where a document speaks for itself.

What followed in Europe is documented. By September 2011, on the account of Underwriters Laboratories, IEC 60825 was no longer usable for evaluating the optical radiation of a light-emitting diode under the European Low Voltage Directive, and conformity with the lamp framework had become mandatory there.

One further document completes the structure. IEC/TR 62778, first published in 2012 and reissued as Edition 2.0 in June 2014, is titled Application of IEC 62471 for the assessment of blue light hazard to light sources and luminaires. By its own account, product safety standards for high-intensity discharge and light-emitting diode products make reference to it. It is the bridge between the measurement standard and actual lighting products. It is also a Technical Report, which the Commission publishes when a committee has collected data of a different kind from what is normally published as an International Standard, and it is therefore not itself a normative requirement on any product.

The four risk groups, and the behavior they assume

The classification scheme assigns a source to one of four groups. For the blue light hazard the governing quantity is the weighted radiance described at subsection a, and the group boundaries can be stated either as radiances or as the maximum exposure duration each radiance implies. The values below are taken from a manufacturer application note and are subject to the verification recorded at the end of this subsection.

Group	Blue light hazard weighted radiance	Maximum exposure duration implied
Exempt Group, also Risk Group 0	up to 100 $W/(m^2 \cdot sr)$	more than 10,000 s
Risk Group 1, low risk	up to 10,000 $W/(m^2 \cdot sr)$	more than 100 s
Risk Group 2, moderate risk	up to 4×10^6 $W/(m^2 \cdot sr)$	more than 0.25 s
Risk Group 3, high risk	above 4×10^6 $W/(m^2 \cdot sr)$	0.25 s or less

The arithmetic of that table is the dose limit of subsection b. A weighted radiance of 100 $W/(m^2 \cdot sr)$ sustained for 10,000 seconds delivers 10^6 joules per square meter per steradian, which is the limit. The group boundaries are not four separate criteria. They are one criterion read at four durations.

The names of the groups describe risk. What the groups actually encode is how long a person may look. That distinction is the one the Foundation asks the Department to hold onto, and Risk Group 2 is where it bites. The ground on which a moderate-risk source is treated as presenting no hazard in ordinary use is not that its radiance is low. It is that a person will look away within a quarter of a second. Manufacturer guidance states this directly: an application note of a major emitter manufacturer describes even Risk Group 2 devices as presenting no risk under normal accidental glances, because the natural aversion reflex usually acts.

That is a behavioral premise, not a radiometric one, and it is load-bearing. Part V.K.1 sets out the Foundation's objection to the aversion response as a protective mechanism, and Part V.E.4

describes the pathway by which short-wavelength light produces discomfort and avoidance. Appendix C.51 reports an animal experiment in which blue light produced strong aversive behavior at an irradiance far below any injury threshold, while yellow light at the same irradiance did not. The Foundation draws the narrow conclusion that follows: aversion is a response to the light. A framework that counts it as a safeguard has taken a symptom and entered it on the other side of the ledger.

Where the measurement is made

The geometry of the assessment is specified, and it is not the geometry in which the products described at Part VI are encountered.

IEC/TR 62778, summarizing clause 6 of IEC 62471, states the condition. General lighting service lamps are assessed at the distance that produces 500 lux, but not closer than 200 millimeters. All other light sources, including pulsed sources, are assessed at 200 millimeters.

Two hundred millimeters is just under eight inches. A manufacturer application note describes it as a worst-case assumption, and for a component inspected at arm's length that is a fair description. For a roadway luminaire, a vehicle lamp or a video display it is not the encounter distance at all.

The assessment route also depends on the geometry. A source subtending less than 11 milliradians is assessed on blue light hazard irradiance; a source subtending more is assessed on radiance. At the 200 millimeter reference distance, 11 milliradians corresponds to a source diameter of 2.2 millimeters, and single-chip emitters up to about 2 square millimeters of active area fall below it. Part V.B.2 derives the angular relations and gives the distances at which apertures from 1 millimeter to 300 millimeters cross the same boundary.

The Foundation is careful about what it draws from this, because the obvious objection is not available to it. It does not argue that a risk group determined at 200 millimeters understates the radiance encountered at thirty meters. It does not. Radiance is conserved along the ray bundle, the retinal irradiance set by a resolved source does not fall with distance, and Part V.B.2 establishes that at length. The scientific committee of the European Commission says the same thing in terms, recording that because its assessment was carried out in terms of source radiance, the conclusion was independent of viewing distance. Part V.K.

The objection is narrower and it survives. What changes with distance is the angular subtense, and the angular subtense determines two things: which assessment route applies, and what the eye is actually imaging. A multi-emitter array assessed at 200 millimeters presents one extended source, and the radiance attributed to it is averaged across the aperture, including the dark area between the emitters. At the distance at which a person meets that luminaire on a street, the eye may resolve a single emitter, whose radiance is higher than the aperture average by the ratio of the aperture area to the emitting area. Part V.B.2 gives the transition distances.

So what a low risk group establishes is this: the hazard of an aperture-averaged radiance, measured at a reference distance, assessed against a limit constructed for a single episode of no more than 10,000 seconds, on the assumption that the viewer looks away. Not one of those four conditions describes the exposures set out at Part VI.

The effect of the reference distance has been measured

The preceding paragraphs state what the reference conditions are. The Foundation is now able to state what one of them is worth, because a national market surveillance authority has measured it on products in commerce.

Between 2021 and 2023 the French consumer protection and market surveillance authority anonymously purchased fifty toys containing one hundred and three light-emitting diodes and had them tested by accredited laboratories against the European standard for the safety of electric

toys, IEC 62115. The results were published in July 2026 by investigators at the French agency for food, environmental and occupational health safety, the national metrology laboratory, the Cochin Hospital ophthalmology research center and the national building science center. Appendix C.59.

Fifteen of the fifty toys, thirty percent, contained at least one light-emitting diode that failed the eye safety limits. Of the one hundred and three diodes tested, fifteen failed. Blue diodes failed at the highest rate, eleven of thirty-four, or thirty-two percent. Approximately eighty-seven percent of the failures were failures of the blue light hazard limit rather than of the thermal limit.

That is the first finding, and the Foundation returns to it below. The second finding is the one that belongs in this subsection.

The investigators tested against two editions of the same standard, the 2003 edition and the 2017 edition, which differ in the distance at which the measurement is made. The 2003 method measures at distances from 14 to 100 millimeters. The 2017 method measures at 200 millimeters. The results were these:

Across the full sample, the 2003 method found fourteen of sixty diodes non-compliant, twenty-three percent. The 2017 method found two of fifty-four, four percent.

In a paired subsample of ten toys and nineteen diodes, tested both ways, eight diodes failed under the 2003 method and one failed under the 2017 method.

The authors attribute the difference principally to the longer assessment distance. The Foundation asks the Department to hold that result still for a moment and consider what it is.

The products did not change. The diodes did not change. What changed was the distance at which the standard directs the instrument to be placed, and measured non-compliance fell by roughly seven-eighths. A compliance rate is not a property of a product alone. It is a property of a product and a measurement convention together, and in this instance the convention did most of the work.

Two further observations follow, and the Foundation separates them because the first is about this product class and the second is general.

As to toys, the direction of the change is the opposite of what the use condition would suggest. A toy is held by a child. Two hundred millimeters is just under eight inches, and the distance at which a small child holds an illuminated toy is not reliably greater than that; the earlier method’s range of 14 to 100 millimeters is closer to how such an object is actually handled. The revision moved the assessment distance away from the condition of use, and non-compliance collapsed. The Foundation does not assert that this was the purpose of the revision, and it has no evidence as to purpose. It states the measured consequence.

As to the general point, this is the clearest demonstration available to the Foundation of the proposition it has been advancing in this subsection on reasoning alone. A risk group, or a statement of compliance, is a statement about a product assessed under a stated set of conditions. Change the conditions and the statement changes, with no change in what the product emits. That is why the Foundation asks at subsection 5 below that a federal performance standard specify reference conditions matched to the geometry in which each product class is actually encountered, rather than adopt a horizontal convention written for a different purpose. Part IX.

One point of caution the Foundation states itself. These results are from the French market, tested against a European toy standard that has no application in the United States, and the sample was assembled by inspectors during store visits rather than by a statistical design, which the authors say in terms makes it unrepresentative. Nothing in it establishes a non-compliance rate for the American market, and the Foundation does not assert one. What it establishes is the sensitivity of a compliance determination to the measurement convention, which is a property of the method and not of the jurisdiction.

The agency that commissioned that campaign reached a further conclusion, about the limits themselves

The campaign described above was not freestanding, and the comment is able to identify the proceeding it belonged to because the two documents carry the same reference. The funding number recorded in the study, 2022-SA-0193, is also the number of a formal request put to the French agency for food, environmental and occupational health safety by two directorates of the French government, the health directorate and the enterprise directorate, on October 25, 2022. The question referred was whether the 2020 revision of the toy standard met an earlier recommendation of the same agency, and whether it adequately accounted for the greater transmission of the young lens. The agency answered on July 8, 2024. Appendix D.1.18.

The answer was not that compliance was uneven. It was that the limits are wrong, and the agency said where they came from. It traced the eye safety limits of the 2020 standard to a single journal article published in 2012, and identified three errors in that article which the standard inherited.

The first concerns which exposure scenario the limits were built on. The 2012 authors compared a normal-use scenario, at 200 millimeters for 10,000 seconds, with a foreseeable-misuse scenario at 100 millimeters for 100 seconds, and concluded that the misuse scenario was the less exposing of the two and could be set aside. The reviewing agency calculates that the misuse scenario is the more exposing, by a factor of about four, and that retaining it would have produced limits about four times lower than those adopted.

The second concerns the conversion of a luminance threshold into a limit on luminous intensity. The threshold taken was 10,000 candelas per square meter. The reviewing agency states that the conversion was performed using the area of the beam at the eye rather than the apparent area of the source, and that for a diode of about 2 millimeters the resulting limit on luminous intensity is too high by a factor of the order of one thousand.

The third is a unit conversion error which the reviewing agency states inflated the limits on radiant intensity, expressed in watts per steradian, by a factor of about ten.

The consequence stated is that the standard as written permits diodes in toys to emit at luminances of the order of 10 to the seventh candelas per square meter. Part V.C.2.i gives the method by which a luminance of that order should be compared with the luminance of the solar disc and states the limits of the comparison, and the Foundation does not repeat the comparison here or draw anything further from it.

What the agency then recommended is the part of the opinion that is unusual enough to state in its own words. It recommended suspending the application of the current version of the standard, using the 2005 version provisionally to assess whether toys meet the essential safety requirements, and beginning the revision of the ocular safety sections without delay. As to toys that pass the 2020 version but fail the 2005 version, it stated that ocular safety is not demonstrated, and that there is a strong presumption of non-conformity with the requirements of the governing European directive.

The Foundation sets out what it takes from this and, as elsewhere in this subsection, what it does not. It does not assert that the three errors are correctly identified. It has not performed the arithmetic, it is not in a position to perform it, and the authors of the 2012 article are recorded by the reviewing agency as having declined to discuss the matter, which means the comment has heard one side. What the Foundation reports is the fact of the finding: that a national health agency, asked by its own government whether a standard was adequate, answered that the standard rests on an arithmetical error and asked for its suspension.

That fact is what belongs in this subsection, and it belongs here for a reason distinct from the one the market surveillance results were offered for. Those results showed that the measured compliance of a product depends on the distance at which the standard directs the instrument to be placed. This shows something one step further back: that the limit against which the instrument reads was itself derived, by a calculation, from an exposure scenario and a geometric assumption that a reviewing

body says were chosen wrongly. A compliance statement is a statement about a product, a measurement convention, and the derivation of the limit. The Foundation asks at Part IX.C that a federal standard specify the first two. It adds here that the third has to be documented and capable of being checked, because in this instance it was checked and it did not hold.

What the assessment yields on actual components, measured

The Foundation is able to give measured figures rather than boundary values, from the same reference chapter, which reproduces assessments carried out by the French agency for food, environmental and occupational health safety on single-chip high-brightness white light-emitting diodes. Appendix D.5.

Source	Luminous flux	Luminance	Maximum permissible exposure and risk group
Cold white	100 lm	1.6×10^7 cd/m^2	Exposure limit never exceeded. Exempt Group.
Cold white	200 lm	3.2×10^7 cd/m^2	50 to 100 s, according to correlated color temperature. Risk Group 2.
Neutral white	100 lm	1.6×10^7 cd/m^2	Exposure limit never exceeded. Exempt Group.
Neutral white	200 lm	3.2×10^7 cd/m^2	100 to 10,000 s, according to correlated color temperature. Risk Group 1.
Warm white	100 lm	1.1×10^7 cd/m^2	Exposure limit never exceeded. Exempt Group.
Warm white	200 lm	2.2×10^7 cd/m^2	Not stated in the source consulted.

Three things in that table are worth stating plainly, and the Foundation states them in ascending order of importance.

First, the luminances. A single-chip white emitter of 200 lumens presents a luminance of approximately 3.2×10^7 candelas per square meter. Part V.B.2 establishes that luminance, and the source radiance it corresponds to, is the quantity that governs retinal irradiance. For comparison, an incandescent filament is of the order of 10^7 candelas per square meter and a sunlit white wall is of the order of 10^4. The emitter is at the filament's order of magnitude or above it, in a package a few square millimeters in area.

Second, the doubling. Between 100 and 200 lumens, with luminance doubling, the cold white emitter moves from the Exempt Group, where the limit is never exceeded at any duration, to Risk Group 2, where it is exceeded in 50 to 100 seconds. The classification is not a gentle gradient. A factor of two in output moved this component across two group boundaries. And the warm white emitter at the same flux presents a lower luminance than the cold white one, which is the spectral point this comment makes throughout: the color of the light and the hazard classification move together.

Third, and the Foundation gives this its own treatment below, the chapter reports that these determinations were made at 200 millimeters, and that the picture changes substantially at a greater distance.

A correction the Foundation makes to its own argument

The chapter states the following, and the Foundation reproduces it because it is adverse and because a comment that omitted it would be unreliable:

> "However, when the viewing distance is increased to one meter, the maximum permissible exposure duration rapidly increases to a few thousands of seconds, up to a few tens of thousands of seconds. These very long exposure durations provide a reasonable safety margin to assert that there is virtually no possible blue light retinal damage from LEDs at longer

viewing distances" – a statement the author confines to the state of the art at the time of writing.

That appears to contradict Part V.B.2, which establishes at length that the retinal irradiance produced by a source the eye resolves does not fall with distance. It does not contradict it. The two statements concern different quantities, and the Foundation sets out the reconciliation because the distinction is the most technically important one in this subsection and because getting it wrong in either direction would be a serious error.

The quantity Part V.B.2 treats is the irradiance delivered to the retinal image of the source. That is set by the source radiance, and it is distance-independent for as long as the eye resolves the source. Nothing in the chapter disturbs it.

The quantity the standard assesses is different. It is the blue light weighted radiance averaged over a field of view that depends on the exposure duration being assessed. The governing guidelines specify that field in three parts. For exposures of 100 seconds or less it is fixed at 11 milliradians. Between 100 and 10,000 seconds it is 0.0011 multiplied by the square root of the exposure time in seconds. At 10,000 seconds, which is the longest duration the blue light hazard framework contemplates, it reaches 110 milliradians. The guidelines give the corresponding retinal image sizes as 190 micrometers and 1.9 millimeters.

The consequence is arithmetic. When a source subtends less than the averaging field, the averaged radiance is the source radiance reduced by the ratio of the source solid angle to the solid angle of the averaging field. The source solid angle falls as the inverse square of the distance. So the assessed quantity falls with distance, by the inverse square, once the source is smaller than the averaging field, while the irradiance delivered to the image of the source does not. Both are correct. They are not the same measurement.

The averaging is not an artifact and the Foundation does not present it as one. It has a stated physiological basis: over a long exposure the eye moves, the retinal image wanders across the retina, and the dose is spread over a larger area than the image itself. Averaging the radiance over the area the image traverses is a reasonable model of that. The 2018 Opinion describes the same mechanism, and Part V.K.8 quotes it.

That analysis is corroborated from inside the committee that wrote the standard, and the Foundation records it because the proposition is unintuitive and its own statement of it rests on arithmetic. The conference paper described at Appendix D.6, by an officer of both the laser and the lamp standards bodies, states the deliberateness of the averaging in the same terms the Foundation has used: "In some cases, this is intended, such as when the field of view represents the angular extent of eye movements for the photochemical retinal limit." And it states the consequence for a small source without qualification: "For the case that the source is smaller than the averaging field of view, the measured radiance is correspondingly smaller than the actual radiance of the source, and the analysis is less restrictive." The Foundation had reached that from the geometry. It is stated as a known property of the method by a person who helps draft the method.

What follows is therefore not that the standard is wrong, but that its protective margin at distance rests on an assumption about how eyes behave, and that the assumption has conditions. Three of them bear on the products at Part VI.

The averaging grows with duration, so the dilution credited to a distant source is largest for the longest exposures. But it never falls to nothing, and the Foundation corrects an earlier version of this passage which said that at short durations there is almost no averaging. The floor is 11 milliradians, not the minimum angular subtense, and a source at the minimum subtense is therefore diluted by the square of the ratio between them even at the shortest duration assessed: about fifty-four fold. The guidelines state the basis for that floor, and it is not the wandering eye but its opposite: 11 milliradians "represents minimal eye movements that can be associated with

staring (fixating) a certain point." A framework that assesses a source at long duration credits it with a spreading of dose that has not occurred at the moment of first exposure, and even at the moment of first exposure it credits the source with the spreading produced by the tremor of a fixating eye.

The model assumes the eye wanders. A person looking fixedly at a source, or a person for whom the source is the brightest thing in a dark field, is not well described by it. Part V.C.3 treats fixation and glare.

A source that re-presents in the same position defeats the spreading rather than benefiting from it. A strobe operating at a fixed point in the visual field returns the image to the same retinal location each time the eye returns to it, which is the opposite of the condition the averaging models. The Foundation has no measurement for this and asserts none; it identifies it as a question for § 360ii(a)(4).

And the chapter supplies the author's own criticism of the reference distance, which the Foundation had reached independently from the geometry. It states that the choice of viewing distance in IEC 62471 is sometimes ambiguous and not realistic in the context of real usage conditions, and gives as examples stage lighting workers in theatres and concert halls, who are exposed at illuminances above 500 lux, and participants in stadia lit for television, who are exposed to levels much greater than 500 lux for extended periods.

The Foundation accordingly narrows what it asserts about distance, and states the narrowed version as the one it asks the Department to consider. It does not assert that a compliance determination made at 200 millimeters understates the hazard at thirty meters. For general illumination at ordinary viewing distances the chapter's conclusion is probably right and the Foundation does not dispute it. What it asserts is that the margin depends on the source being small compared with the averaging field and on the eye behaving as the model assumes, and that neither condition has been evaluated for a high-luminance source presented repeatedly at a fixed position in the visual field, which is what the products at Part VI.C and Part VI.I are. That is a narrower claim than the Foundation might have made and it is the one the record supports.

One further figure from the chapter bears on a question raised earlier in this comment. The chapter states that Risk Group 3 is highly unlikely to be reached for the blue light hazard by any artificial white light source, that it would require a blue light level approximately 400 times the lower boundary of Risk Group 2, and that at a correlated color temperature of 6,000 K it is reached only above a luminance of approximately 4×10^9 candelas per square meter – which is above the luminance of the solar disc. The Foundation records that because it forecloses an assertion it might otherwise have been tempted to make: the products described at Part VI.I are not Risk Group 3 sources, and the Foundation does not suggest they are. The question those products raise is the one at the end of this subsection, which is that no risk group has been determined for them at all.

What the framework requires in the United States

The answer is nothing, and the Foundation states the basis for that answer in the order of its authority.

The primary basis is the regulation itself. Part II.C sets out the contents of 21 C.F.R. part 1040 and establishes that no performance standard prescribed under it reaches a light-emitting diode product. Part II.E.4 establishes that the agency's recognition of IEC 62471, which is complete and rests on the standard's scientific and technical merit, is keyed to thirteen classes of medical device and reaches no other product.

Secondary corroboration is available from industry. Underwriters Laboratories, in a white paper on assessing the photobiological safety of light-emitting diodes published in 2012, stated the position in one sentence:

> "Compliance with photobiological safety requirements in the U.S. and throughout the rest of the world is still voluntary."

The paper identifies mandatory conformity only in the European Union, under the Low Voltage Directive. It makes no mention of this agency, and none of the Consumer Product Safety Commission.

Three further statements in that paper bear on what a conformity determination establishes, and each is adverse to the weight such determinations are commonly given.

On which products are assessed at all: single indicator light-emitting diodes are, in the paper's words, typically not evaluated under the current standards.

On what the limits mean: "Exposure limits are not intended to strictly separate safe from unsafe levels. They may not accurately reflect risk for people more susceptible to optical radiation, such as those with increased photosensitivity or lens transplants." The two populations named are precisely those this comment treats at Part V.C.2.g, on the eye that has lost its crystalline lens, and at Part V.E, on photosensitivity.

On the character of the standard: IEC 62471 "is a horizontal standard. It does not directly address end-product manufacturing, labeling, or user safety requirements."

That last statement is the structural point of this subsection, and it is the manufacturer's own characterization rather than the Foundation's. A horizontal standard supplies a method of measurement and a scheme of classification. It does not say what a product may emit, how it must be labeled, or what a purchaser must be told. Those are the provisions a performance standard contains, and for this emitting technology no federal performance standard contains them.

Three axes of classification, and the confusion between them

There is a category error at the base of the present arrangement, and naming it explains why the three mismatches set out below are not failures of execution. They follow from the structure.

A product that emits optical radiation can be classified on any of three independent axes.

By coherence. Coherent or incoherent. This is a physical property of the emission, and it is the axis on which IEC 60825 and IEC 62471 divide.

That first axis requires a qualification, and the Foundation supplies it because the qualification is the strongest thing it has to say about the present arrangement. Coherence is not a property a source either has or lacks. It is a continuous quantity, measured as a coherence length, and every real source lies somewhere on it. The division the two standards draw is a dichotomy imposed on a continuum.

The optics literature has measured where light-emitting diodes lie. Reported spatial coherence lengths for diode sources run from a few to several tens of micrometers at the emitting plane, the value being set by the material of the chip and the geometry of the emitting structure. A recent study measured 41 micrometers at 0.1 meter for a commercial 525-nanometer device, rising to 77 micrometers at 0.7 meter and 110 micrometers at 1.7 meters; earlier work on a 623-nanometer chip with a 3-millimeter emitting square gives about 0.7 millimeter at 5 meters. Miao Z, Zhang P, Lu F, Han X, Li Q, "Light field analysis for modeling and transmission characteristics of partially coherent light-emitting diodes," Frontiers in Physics 2023;11:1181343, doi:10.3389/fphy.2023.1181343, open access.

The Foundation states at once what does not follow. These are small quantities, and nothing in this literature suggests that a light-emitting diode approaches the coherence of a laser or should be regulated as one. The comment's position at Part II.C.3 is unchanged: diodes and lasers differ in coherence and in collimation and the difference is real. What the measurements establish is narrower, and it goes to classification rather than to hazard. The difference is one of degree along an axis, not a difference in kind between two boxes.

The two kinds of coherence, and the one that can be computed from a data sheet

A distinction has been implicit in the foregoing and the Foundation now makes it explicit, because the word on which the scope of the receiving standard turns covers two different quantities. Spatial coherence concerns the correlation of phase between points across the emitting surface, and it is the quantity the measurements described above report. Temporal coherence concerns the correlation of phase at a single point over time, and it is fixed by the width of the emission spectrum. A source may be appreciably coherent in one of those senses and negligibly so in the other. The word incoherent, standing alone, does not say which is meant.

The second quantity has been carried through a rigorous calculation for a diode device, in the paper described at Appendix D.6. The Foundation states its limits before its findings, because they are real: it is a model and not a measurement, its configuration is deliberately two-dimensional, the devices are organic rather than the inorganic diodes principally at issue here, and the authors expressly set spatial coherence aside for organic devices on the authority of a measurement of them. What the paper supplies is the role the temporal quantity plays, and a relation by which its value can be obtained.

On the principle, the authors state the matter in terms the Foundation adopts, citing the standard treatment of coherence and radiometry:

> "As temporal or spatial coherence decrease this phase difference is no longer consistent in time or space, thus averaging on a large ensemble of sources diminishes these effects dramatically."

A quantity that decreases, with consequences that diminish as it does, is not a category. And the authors do not treat these devices as sitting at the end of that scale: they state that coherence effects must be considered when analyzing such a device, and then specify which coherence they will consider, setting spatial aside and retaining temporal. That sentence is the one the Foundation asks the Department to notice, not for its conclusion but for its form. A working physicist analyzing one of these devices has to say which coherence he means. The scope sentence of the standard does not.

The finding is that the emitted pattern is governed by the ratio of the device thickness to the coherence length. Where the thickness is much smaller than the coherence length, interference effects are noticeable; where it is much larger, the authors report a quasi-Lambertian pattern. They then identify what each regime reflects, and the Foundation quotes it because it bears on Part V.B.8: "the two extremes correspond to radiation patterns which reflect either the device properties, i.e., thickness dependent interference, or the source characteristics, leading to spectral broadening dominated pattern." The Lambertian form, in other words, is what a source produces in the incoherent limit. A source that is not in that limit emits a pattern determined by its own internal structure.

The Foundation declines the inference that lies closest to hand, and says so because it would be convenient. Part V.B.8 records that four packaged inorganic devices measured at two national metrology institutes were none of them Lambertian. Those devices carry integral lenses, a lens is the obvious explanation, and nothing here attributes those measured departures to coherence. What this paper establishes is that coherence is one route by which a source departs from the Lambertian form, not that it was the route in any measurement this comment reports.

The relation that makes the quantity useful is the definition the authors employ: the temporal coherence length is the square of the wavelength divided by the spectral width. Spectral width at half maximum is a published specification for components of this class. The Foundation accordingly sets out what that relation yields for representative emitters, and states that the arithmetic is its own and the widths representative rather than taken from any particular data sheet. For a blue emitter at 450 nanometers with a width of 25 nanometers, about 8 micrometers. For a red emitter at 630 nanometers with a width of 20 nanometers, about 20 micrometers. For a phosphor-converted white source, whose spectrum spans hundreds of nanometers, of the order of

1 to 3 micrometers. The simulations in the paper span 5 to 150 micrometers, so the narrow-band emitters fall inside the range in which that paper finds coherence to govern the pattern.

What follows is narrow and the Foundation states it narrowly. Not that these sources are coherent, which they are not, and not that they should be regulated as lasers, which the comment has never asked. What follows is that the word incoherent names a limit rather than a class; that there are two coherence quantities and the word distinguishes neither; that for the temporal quantity the value follows by arithmetic from the spectral width every manufacturer publishes, and comes out in micrometers rather than at zero; and that an instrument which assigns an entire emitting technology to one side of that boundary by naming it has not measured the thing the word refers to. The Foundation asks for the measurement, not for the reclassification.

One contrary statement is recorded here rather than left to be found. The paper described at Appendix C.86, published in the same literature and relied on at Part V.B.8 for the geometry of diode emission, states the opposite proposition in terms: “LEDs in general have random polarization and they are incoherent light sources because of the spontaneous emission process.” The Foundation does not treat the two as reconcilable by paraphrase, and sets out the difference as it understands it. The measurements described above concern transverse spatial coherence at the emitting plane. The statement just quoted concerns the averaging of phase and polarization in the detected intensity, and its author advances it to explain why the measured angular distribution is Lambertian irrespective of phase. The two are different quantities and neither author addresses the other. The Foundation accordingly relies on the measured coherence lengths for the proposition in this subsection, relies on the other paper for geometry alone, and asks the Department to resolve the question on the primary literature rather than accept either statement on the Foundation’s characterization of it.

The consequence for this subsection is this. The scope of the receiving standard, in the words of the agency’s own recognition record quoted at Part II.E.4, reaches “all electrically powered incoherent broadband sources of optical radiation, including LEDs but excluding lasers.” That sentence does not report a measurement. It assigns a technology to one side of a boundary by naming it. The physics says the technology sits at a measurable, nonzero distance from that side of the boundary, and the standard’s own distinction between the thermal sources it was written around and the semiconductor sources it has absorbed is precisely the distinction the measurement finds. An incandescent filament is a thermal emitter and is close to incoherent in fact. A diode is not a thermal emitter, and its coherence follows from the structure of its chip.

There is a practical consequence as well, and the Foundation records it because it bears on measurement rather than on category. The same study reports that modeling a narrow-beam diode as fully incoherent misstates what arrives at a distant observer, and misstates it in the permissive direction: at two kilometers in vacuum the computed beam radius was 7.89 meters for the measured coherence length and 123.61 meters for the same source treated as fully incoherent, a factor of about 15.7 in radius and, by the Foundation’s arithmetic on those two figures, about 245 in area. The incoherent assumption predicts the light is more spread out, and so weaker at the eye, than it is. That result is confined to sources with a half-power angle of 10 degrees or less and to propagation in vacuum, and the Foundation does not extend it beyond those conditions.

Whether any product described at Part VI falls within those conditions, the Foundation cannot say, and the reason it cannot say is itself the subject of this comment. The half-power angle of a light-emitting diode is a published specification at the component level and is not disclosed at the product level. Part VI.G sets out what that means for one ordinary household article, and Part IX.F asks that the characteristic be disclosed.

By application. A lamp for general illumination, a display, a signal or warning device, a projector, a therapeutic instrument, an indicator.

By emitting technology. A laser, a light-emitting diode, an incandescent filament, a discharge arc, a fluorescent tube.

The three axes are independent of one another, and that independence is the whole of the difficulty. A light-emitting diode may be a general service lamp, a pixel in a video display, a vehicle warning lamp, an indicator on a household appliance, or the emitter in an optical fibre transmitter. Knowing the emitting technology does not tell you the application. Knowing the application does not tell you the technology either: a roadway luminaire may be a discharge lamp or a diode array, and the same street may carry both.

What the revision of 2007 did was move an entire emitting technology from a standard organized on the first axis to a standard organized, in its title, on the second. IEC 60825-1 is a laser safety standard, which is to say a standard about coherence. IEC 62471 is titled Photobiological safety of lamps and lamp systems, which is to say a standard about an application.

The receiving standard straddles the two axes, and the Foundation asks the Department to look closely at how. Its scope is written on the coherence axis and is correspondingly broad: all electrically powered incoherent broadband sources of optical radiation, in the words of the agency's own recognition record quoted at Part II.E.4. Its title and its reference measurement conditions are written on the application axis. The result is a document whose scope admits every incoherent source in existence and whose measurement conditions recognize two applications: general lighting service, and everything else.

Two categories of application, for the entire universe of non-laser optical sources. That is the origin of each of the three mismatches described next, and it is why they cannot be cured by measuring more carefully.

The Foundation says plainly what it does not say. It does not say the standard is defective, or that the committee which wrote it erred. A horizontal standard is meant to be general; generality is its function, and its own publishers state in terms that it does not address end-product manufacturing, labeling or user safety requirements. The error is not in the standard. It lies in treating a horizontal standard as though it discharged the office of a product standard, which the people who publish it say it does not.

Nor is the error the Commission's to correct. Supplying product classes and the conditions that attach to them is the step the international framework leaves to national authorities, and it is the step this subsection asks this Department to take.

How the boundary between the two standards is drawn, and what one of its draftsmen says it is not

The preceding paragraphs describe a division between two instruments and decline to call it an error. The Foundation now sets out how the boundary between them is drawn in practice, because an account of it has been published by a person who holds office in both bodies. The document is described at Appendix D.6. It is a conference paper and not peer-reviewed research, and the Foundation relies on it for what it is: the account of a draftsman. Its author's own biography identifies him as secretary of the working group responsible for IEC 60825-1 and as associated division director of the Commission division responsible for CIE S009 and IEC 62471, as well as a member of the non-ionizing radiation commission whose exposure limits both standards rest on.

The occasion for his paper was an amendment permitting light produced by a laser striking a phosphor to be assessed under the lamp standard rather than the laser standard, provided its radiance stays below one megawatt per square meter per steradian divided by the angular subtense in radians. He identifies the emission mechanism as the one at issue here, calling it "the same principle used to produce white LEDs based on blue LED chip." So the provision concerns a source that produces white light in the manner of the products at Part VI, and routes it between the same two standards this subsection is about.

The author then measures that threshold against the exposure limit. For a source of 5 milliradians the threshold permits 200 megawatts per square meter per steradian. The broadband retinal thermal exposure limit for the same source size at a quarter-second exposure is 5.7 in those units.

The ratio is 35, and because both quantities vary as the inverse of the angular subtense the ratio holds at every source size. His conclusion is the sentence the Foundation asks the Department to read twice: “This clearly shows that the value given in IEC 60825-1 of (1 MW m-2 sr-1)/α … is not a safety limit; thus the products that approach that value will be RG3 under the current as well as under the upcoming edition of IEC 62471.” On what that means for an eye, he writes that at a 2 millimeter pupil the risk stays negligible, but that at a 5 millimeter pupil and a factor of 35 above a limit built on a 7 millimeter pupil, “the injury threshold for retinal injury might be exceeded also for the human case.”

The Foundation states carefully what it takes from this and what it does not. It does not assert that any light-emitting diode product sits near that threshold, and this paper gives no measurement of any product in commerce. The proposition is about the architecture rather than about any device: the criterion that decides which of two safety standards governs a product is, on the account of one of the people who drafts them, not itself a safety criterion. A product may be routed out of the laser standard into the lamp standard and arrive there in the most hazardous group the lamp standard defines. That is consistent with what Part II.E.4 records of the scope sentence of the receiving standard, which assigns by naming the emitting technology rather than by measuring what it emits.

The same paper supplies a calibration for the exposure limits themselves, and the Foundation presents it in both directions because it runs both ways. The author computes the effective radiance of the sun at 7.2 megawatts per square meter per steradian and states that “The sun exceeds the exposure limit for 0.25 s exposure duration by a factor of 2.5,” noting that the older guidelines and the American threshold limit values are exceeded as well. Read one way that tells against the Foundation: a limit that a natural source everyone has looked at exceeds by two and a half times cannot be read as a boundary of injury, and exceeding it does not establish harm. The Foundation accepts that and says so. Read the other way it tells against the condition on which the safety conclusions at Part V.K rest, because the author explains the result by an assumption rather than by a measurement: the limit is built on a 7 millimeter pupil, and “When a pupil diameter of 4.5 mm is assumed for the determination of the effective ocular exposure, the exposure limit is not exceeded.” Whether a source exceeds the limit therefore turns on which pupil the assessor assumes. That is the proposition Part V.K.3 advances about conditional conclusions, stated here by a member of the commission that sets the limits.

Three products, and what the framework says about each

The Foundation takes three examples from Part VI, chosen because in each the reference conditions of the framework fail to correspond to the conditions of use, and because the three fail in different ways.

An indicator lamp on a household appliance. On the account quoted above, a single indicator emitter is typically not evaluated at all. Whatever the merits of that practice for a dim indicator, the category is defined by the component rather than by its output, and it is the category into which a bright short-wavelength indicator falls. Part VI.G sets out two ordinary components of the same physical size whose published specifications differ by a factor of about fifty in solid angle and by more than two hundred in luminous intensity, and which are indistinguishable to a purchaser of the appliance. The category reaches both and distinguishes neither.

A large video display. Part VI.J. The reference condition is 200 millimeters, or for a general lighting service lamp the distance producing 500 lux. A display some nine meters across is encountered at distances from tens to hundreds of meters, and Part VI.J gives the distances at which its angular subtense crosses the framework’s own boundaries. A self-luminous surface of that size at those distances is not the object the reference condition was written for.

A pulsed vehicle warning lamp or deterrent strobe. Here there are two mismatches rather than one. The reference distance for a pulsed source is 200 millimeters. And the protective

premise of Risk Group 2 is that the viewer looks away within a quarter of a second, which a strobing source defeats by construction: it re-presents, repeatedly, for as long as it operates, and a deterrent strobe is designed to be aversive. The safeguard the classification relies upon is the effect the product is built to produce.

The Foundation is explicit about what it does not assert. It does not assign a risk group to any of these products, and it cannot. No determination has been made and published for any of them in the United States, and the system under which such a determination would be made is voluntary here. The Foundation notes only that high-power blue and green emitters in the 450 to 510 nanometer range are described by a manufacturer as capable of reaching Risk Group 2, and it draws no conclusion from that about any particular product in American commerce.

The risk group of a blue light-emitting diode deterrent strobe in use on American streets is unknown. That is not a rhetorical observation. It is the finding, and it is a finding about the regulatory system rather than about the product: a classification scheme exists, the agency has recognized the standard that contains it on the ground of its scientific and technical merit, and no one is required to apply it to this product or to tell anyone the answer.

What the Foundation asks

The request follows from the agency's own practice and from its own stated preference, and the Foundation frames it that way deliberately.

Part II.E.4 records two things the agency has said and done. It has recognized IEC 62471 as a complete standard, on the ground that it has scientific and technical merit, with a stated scope covering light-emitting diodes and with the electronic product radiation control subchapter cited in the same record. And it has said, of international standards in the adjacent field, that it acknowledges the advantages of one set of criteria and requirements worldwide.

On that footing the Foundation asks the Department to prescribe a performance standard for light-emitting diode products under 21 U.S.C. § 360kk, taking the measurands, the weighting function and the classification scheme of IEC 62471 – the quantities the agency has already assessed and recognized – and supplying what a horizontal standard by its own terms does not: product classes; reference conditions matched to the geometry in which each class is actually encountered; a treatment of repeated and pulsed presentation; a duration basis not confined to a single episode of under three hours; and labeling and reporting sufficient to let a purchaser and a public entity know what they are installing. Part IX.

That is what the agency did for laser products. Section 1040.10 does not restate IEC 60825-1. It prescribes classification, reference conditions, labeling and reporting for the American market, and the agency has since recognized the international standard alongside it and accepted conformity with the international standard as an enforcement alternative. The two instruments are complementary, and the agency built both. For light-emitting diode products it holds the international instrument and has never written the domestic one.

The model already exists in part 1040, and it is built on two axes

The objection that this would be complicated is a fair one, and the Foundation answers it with the agency's own regulation rather than with reassurance. Part 1040 is already organized on more than one axis, and the arrangement works.

Part 1040 contains four sections. Set beside each is the basis on which it defines the class of product it governs.

Section	Heading	Basis on which the product class is defined
1040.10	Laser products	Emission. The section sorts products into classes by accessible emission limits, which is a property of what the product emits rather than of what it is

		for.
1040.11	Specific purpose laser products	Application, layered on top of § 1040.10. Its subsections address medical laser products; surveying, leveling and alignment laser products; and demonstration laser products.
1040.20	Sunlamp products and ultraviolet lamps intended for use in sunlamp products	Application, together with waveband.
1040.30	High-intensity mercury vapor discharge lamps	Emitting technology.

So within a single part the agency classifies by emission, by application, by application nested inside an emission class, and by emitting technology. The complication is not hypothetical and it has already been managed once, in the part that would receive the standard this comment asks for.

The mechanism of § 1040.11 is the one the Foundation particularly asks the Department to notice, because it is the answer to the problem described at subsection k above. A medical laser product must comply with all of the applicable requirements of § 1040.10 for laser products of its class, and, in the regulation's words, in addition the manufacturer shall do a series of further specified things. The emission classification stays generic. The application-specific requirements layer on top of it. One set of measurands serves every product; the obligations differ by use.

Paragraph (b) of that section goes further, in a way that bears directly on Part VI. A surveying, leveling or alignment laser product must comply with the requirements for a Class I, IIa, II or IIIa product. The application therefore caps the permissible class. The regulation does not merely require that a higher-class product be labeled; for that use it forbids the higher classes outright.

That is the instrument the Foundation asks for, and the analogy is close. A surveying laser is an intense source directed into public space by an operator for a purpose unrelated to the people who encounter it. So is a blue light-emitting diode deterrent strobe. The agency's response in the first case was to decide which classes may be used for that application. The Foundation asks for the same kind of determination in the second.

The product classes, and the federal definitions that already exist

The Foundation identifies five classes, and for each one says whether a federal definition is already available. This matters because it bears on how much work the Department would actually have to do.

- Light-emitting diode general service lamps. The class already exists in federal law. Title 10 C.F.R. § 430.2 defines general service lamp at length, expressly including general service light-emitting diode lamps and general service organic light-emitting diode lamps, and expressly excluding appliance lamps, colored lamps, bug lamps, infrared lamps, marine signal service lamps and a long list besides. The Department of Energy has conducted five rulemakings on that definition. Part IV.G. This Department would not need to define the class. It would need to prescribe an emission standard for a class that is already defined.
- Light-emitting diode vehicle lamps, including flashing warning lamps. The class exists in federal law. FMVSS No. 108 regulates vehicle lamps photometrically, Part II.H.5, and SAE J595 addresses the intensity of flashing warning lamps, Part II.E.4. What is absent is any photobiological criterion attaching to either.
- Light-emitting diode roadway and area lighting. Part VI.B. The Foundation has located no federal product definition. The Illuminating Engineering Society publishes recommended practice, which is voluntary and non-federal.

Light-emitting diode displays and dynamic message signage. Part VI.J. The Foundation has located no federal product definition. The Manual on Uniform Traffic Control Devices addresses changeable message signs as traffic control devices rather than as emitting products.

Light-emitting diode indicator lamps on consumer products. Subsection k above records that these are, on the account of a testing laboratory, typically not evaluated at all under the present standards.

The Foundation does not ask the Department to invent these classes from nothing. Two of the five are already defined in federal law and administered by other agencies, and paragraph 360ii(a)(3) directs the Secretary to maintain liaison with other federal departments and agencies. Part II.E. The definitions can be borrowed. The emission criteria cannot be borrowed from anyone, because no other agency holds the authority that § 360kk confers, and each of the agencies the Foundation asked has said so. Part II.H.

How this request relates to the one at Part IX.G

The Foundation sets the two requests side by side so that they are read together rather than as alternatives, because each is incomplete without the other.

Part IX.G asks the Department to develop a classification system organized by the spatial, spectral and temporal characteristics of the emission, rather than by luminous output alone. That request concerns what is measured. This subsection asks for the complementary thing: product classes that fix the conditions under which those characteristics are measured, and that determine what is permissible for a given use.

The emission characteristics are the measurands. The product class determines where the instrument is placed, over what duration the measurement is integrated, and which classes may lawfully be used for that application. Sections 1040.10 and 1040.11 are precisely those two things, and the agency wrote both. Neither alone would have been sufficient for laser products, and neither alone will be sufficient here.

The Foundation adds one point in anticipation, because the objection is foreseeable. A domestic performance standard of this kind would not divide the United States from the international framework. Adopting the international measurands is alignment, and it is the alignment the agency says it prefers. Supplying product classes and reference conditions is not divergence from the horizontal standard, because the horizontal standard expressly does not address end-product requirements and leaves them to be supplied elsewhere. The European Union supplied them through the Low Voltage Directive and the product standards that reference IEC/TR 62778. The question for this Department is not whether to depart from the international framework. It is whether to complete it domestically, as it has already done once, for the other half of the same subchapter.

3. Disability glare, veiling luminance, and intraocular straylight

Part V.C.1 sets out a framework that asks whether an exposure produces a lesion. This subsection concerns an effect of light that produces no lesion at all and that is, for one large class of the products at Part VI, the effect that matters most. The proposition is not the Foundation's. It is stated in the ophthalmic literature in the following form: because the remote risk of retinal injury from distant illumination is considered generally low, "glare-induced visual impairment has to be regarded the main hazard for mobility-related tasks i.e., road and air traffic." Appendix C.85.

If that is right, then for every product a driver or a pedestrian encounters in the public way, the framework Part V.C.1 examines is addressed to the wrong endpoint. A source may be incapable of injuring the retina and still be capable of preventing a person from seeing what is beside it. No federal instrument addresses the second possibility, and the Foundation is not aware that any federal body has considered it.

The definition, and the two divisions that follow from it

The International Commission on Illumination defines glare as a condition of vision in which there is discomfort, or a reduction in the ability to see details or objects, or both, caused by an unsuitable distribution of luminance or an unsuitable range of luminance values. Two kinds follow from that definition and the comment keeps them apart. Discomfort glare is a psychophysical sensation producing annoyance and avoidance, and is treated at Part V.C.4. Disability glare is a physiological interaction that impairs vision, in the words of the literature, up to the extent of visual incapacitation. This subsection is about the second.

Within disability glare there is a further division, and the Foundation adopts it because it determines what a standard would have to limit. Appendix C.85 states it as follows. Veiling glare is the generalized effect of forward scatter within the eye: light from the source is scattered by the cornea, lens and other media, floods the inner eye, and lays a veil of luminance across the whole retinal image, so that the contrast of every target is reduced. Scotomatic glare is spatially specific: the loss is tied to the retinal location that corresponds to the external source, and appears as a region of reduced or absent sensitivity around it. The first is a property of the observer's optics as much as of the source. The second follows the source.

That distinction matters for the statutory question in a way the Foundation asks the Department to notice. A hazard that arises from scatter within the eye can be mitigated at the eye, and much of the literature on straylight is addressed to exactly that: filters, coatings, surgical correction of ocular opacities, lens implants. A hazard that follows the source cannot be. It is a property of the emission, and the only place to limit it is at the emission. Part II.G.3 describes the mitigations that exist; none of them is a limit on what the product emits.

What has been measured in people, and what it showed

The Foundation has found one study that measures this effect functionally, in human subjects, with both a dose axis and a wavelength axis. It is set out at Appendix C.85 and the Foundation states its limits before its findings: thirty-one healthy volunteers, monochromatic sources, a clinical perimeter rather than a roadway, and a research framing addressed to deliberate dazzling rather than to illumination.

Subject to those limits, the findings are these. A source placed off the visual axis, 15 degrees below and 10 degrees to the left of center and deliberately kept off the fovea, produced measurable loss of sensitivity across the central visual field. The loss rose with intensity at every wavelength tested. It was distributed across all quadrants out to the 30-degree limit of measurement, with absolute scotomas appearing at that limit, and with the deepest loss near the retinal location corresponding to the source. In the quadrant most affected the number of absolute scotomas was comparable with the number found in the physiological blind spot. And the authors characterize the exposures that did this as subthreshold.

Three consequences follow for this Part. The first is that the observer does not have to be looking at the source. The impairment was produced by a source the subject was not fixating and which was kept away from the center of vision by design. The second is that the impairment is not confined to the direction of the source: it was scattered across the entire field measured. The third is that it occurred below the threshold at which the frameworks at Part V.C.2 operate. Taken together these describe an exposure that every instrument discussed in this comment would record as safe and that measurably degraded what the subjects could see.

The result that bears on units, and on Part V.J

One feature of that study is of more use to this Department than its findings about glare, and the Foundation sets it out separately because it is the clearest instance in the record of a proposition argued at Part V.J.1 from first principles.

The three sources were characterized in both systems of units, radiometric and photometric, and the measured values are reproduced at Appendix C.85. The impairment they produced was ordered 530, then 470, then 625 nanometers, at every intensity. The irradiance of those sources was ordered with 625 highest at every intensity. The illuminance was ordered 530, then 625, then 470 at every intensity. The impairment ordering matches neither.

The red source delivered about one and a half times the irradiance of the blue and nearly eight times its illuminance, and impaired vision least. The green source delivered slightly less irradiance than the blue and about thirteen times its illuminance, and impaired vision most. The authors describe the result as unexpected and resolve it by the state of adaptation: the background was mesopic, at 0.255 candelas per square meter, and the spectral luminous efficiency of the eye under those conditions is shifted toward the short wavelengths relative to the photopic function by which photometric units are defined.

The Foundation draws the conclusion, and states that the arithmetic comparing the three orderings is its own rather than a finding put in that form by the authors. Photometric reporting failed to predict the effect because it weights the emission by an observer who was not present. Radiometric reporting failed on its own because an unweighted total discards the distribution. What predicted the response was the spectral composition of the source read against the adaptation state of the eye. That is why the request at Part IX.C.1 is for spectral power distribution with photometric quantities supplied in addition rather than instead, and it is why Part V.B treats the spectral characteristic as independent and not as something a single brightness figure can stand in for. The conditions under which this matters most are the mesopic ones, which are the conditions of the roadway at night. Part I.G.

What a limit on this effect looks like, in the one field that has built one

The preceding paragraphs describe an effect for which the Foundation has located no limit of any kind. Before turning to that absence, the Foundation sets out what the corresponding limit looks like in the adjacent field, because it answers in advance the objection that an effect of this kind is too subjective, too variable between observers, or too dependent on circumstance to be the subject of a quantitative standard. It is none of those things. It has been quantified, from human subject experiments, and the result was proposed for incorporation into international safety standards.

Williamson and McLin, publishing in the Journal of Laser Applications in 2018 and described at Appendix C.87, derived exposure limits for visual impairment caused by visible laser light. The first author is at the United Kingdom's Defence Science and Technology Laboratory. The second is at the Optical Radiation Bioeffects Branch of the 711th Human Performance Wing of the United States Air Force. They define the limit as the irradiance at the eye above which a defined object can no longer be detected, name it the Maximum Dazzle Exposure, and state its relation to the limit the existing standards already contain: it "is analogous to the established concept of Maximum Permissible Exposure (MPE) which sets the laser irradiance limit above which there is a risk of permanent eye damage."

The reason they built it is the reason this subsection exists, and the Foundation quotes it because the parallel is exact except for the emitting technology. "Cases of permanent eye damage caused by lasers are still relatively rare, with the risks of eye damage from laser systems being well understood and comprehensively documented in international laser safety standards. However, despite the significantly greater frequency of laser eye dazzle events, there is an absence of equivalent guidance for laser eye dazzle effects in these standards." Substitute the emitting technology at issue in this comment for the word lasers and the sentence states the Foundation's position.

The limits are resolved by three variables, and the Foundation draws attention to them because each is a variable this Part has argued must enter any adequate specification. The extent of the impairment, as a defined obscured field running from 2 degrees to 40 degrees. The state of adaptation, as three ambient luminances approximating night, dusk or dawn, and day. And

wavelength, by a weighting applied to every value. The resulting limits, which the authors propose for adoption into standards, are these, in microwatts per square centimeter at the eye.

Acceptable dazzle level	Night (0.1 cd/m²)	Dusk or dawn (10 cd/m²)	Day (1,000 cd/m²)
Very low – 2° obscured	0.001	0.6	40
Low – 10° obscured	0.04	30	2,000
Medium – 20° obscured	0.16	120	8,000
High – 40° obscured	0.6	450	30,000

Two features of that table bear on this comment and the Foundation states that the arithmetic in both is its own rather than a finding the authors put in that form. The first is the dependence on adaptation. Holding the severity of impairment constant, the irradiance required in daylight exceeds that required at night by a factor of 40,000 at the mildest level and 50,000 at each of the other three. This subsection and Part V.B.2 both argue that darkness aggravates a given emission. Here is that proposition quantified, by a defence research establishment, at four severities.

The second is the relation between the two limits, and it is the more important. The same paper states that the injury limit for a ten-second visible exposure is 1,000 microwatts per square centimeter. At night, the irradiance that obscures 40 degrees of the visual field is 0.6 of those units, about one thousand seven hundred times below the injury limit. The mildest recognized impairment arrives about one millionth of the way to it. In daylight the relation inverts, and there the authors state it themselves: beyond the mildest level, “greater levels of dazzle require irradiances that exceed the visible wavelength MPE–i.e., the observer would be at risk of eye damage if exposed to these levels of dazzle.”

The Foundation asks the Department to take from that what it takes itself, which is a proposition about limits rather than about any product. A limit addressed to injury is not a conservative proxy for a limit addressed to impairment. Whether it constrains impairment at all depends on the ambient condition, and in darkness it does not constrain it within three orders of magnitude. Part V.K.3 records that the safety conclusion of the 2018 Opinion is conditioned on exposure below limits constructed from observed injury, and that the same Opinion states that reversible effects including dazzle and glare may nonetheless occur. The table above indicates how much room there is between those two statements.

The Foundation states the limit of the comparison before it is put to it. These are laser values and they do not transfer. They are derived for a monochromatic collimated beam, and the position at Part II.C.3, that diodes and lasers differ in coherence and in collimation and that the difference is real, is unchanged. The Foundation does not ask the Department to apply any number above to any product within 21 U.S.C. § 360kk. What transfers is the method and the demonstration that the method works: define the impairment, quantify its extent, resolve it by the state of adaptation, weight it for wavelength, and derive a limit in the units the existing instruments already use. That is a template, and it exists because one research community decided that an absence of guidance on impairment was a defect in its safety standards rather than a reason to confine those standards to injury.

What is limited, and what is not

What the governing guidelines say they do not address

Before stating the absence of any limit, the Foundation sets out a passage from the instrument that supplies the limits. The guidelines on limits of exposure to incoherent visible and infrared radiation are the document on which the photobiological safety standard rests and on which the safety conclusion examined at Part V.K is expressly conditioned. They address the effect this subsection concerns in one sentence, and the sentence is a disclaimer.

> "Just as optical radiation protection levels do not protect against visual disturbances from glare, these guidelines do not preclude potential light-induced modulation of physiological rhythms since the effects are not necessarily adverse responses."

The Foundation asks the Department to read the two halves of that sentence separately, because each disposes of a different question. The first half states that protection levels of this kind do not protect against glare. It is stated not as a limitation to be remedied but as a known property of the instrument, by way of analogy to the second half. So the effect described in this subsection is outside the exposure limits by the design of the exposure limits, and the absence of any federal limit on it recorded below is not an oversight in the translation of the international framework into American law. It is a faithful translation of a framework that does not reach the effect. The second half states that the guidelines do not preclude light-induced modulation of physiological rhythms, which is the subject of Part V.F.

The preceding paragraphs of the same discussion are worth having as well, because they show that the exclusion is not for want of awareness. The guidelines record that "Environmental illumination influences human health and well being by altering circadian, neuroendocrine, neurobehavioral and melatonin responses", that an action spectrum for some of those responses has been described, and that among the reported side effects of therapeutic levels of illumination are "photophobia, ocular discomfort, headache, and enhanced glare sensitivity." Four of the responses this comment is about are named in the document that sets the limits, in the passage in which it explains that they are not what the limits are for.

What follows is the proposition on which this subsection and Part V.K.3 converge, and the Foundation puts it without embellishment. A safety conclusion conditioned on compliance with these exposure limits is a conclusion about the injuries the limits were constructed to prevent. It is not a conclusion about glare, and the authors of the limits say so. The Department is accordingly asked to note that the three expert assessments examined at Part V.K, each of which conditions its safety finding on these limits, cannot by that route have addressed the effect this subsection describes, whatever else they addressed.

The Foundation has not identified any federal limit bearing on disability glare from any product within 21 U.S.C. § 360kk. There is no federal limit on the luminance of an emitting surface, which Part V.C.4 identifies as the quantity that drives glare and which the light-emitting diode has raised beyond any earlier source. There is no federal limit expressed as a permissible veiling luminance, and no federal measurement convention for straylight. Federal Motor Vehicle Safety Standard No. 108 limits luminous intensity at certain angles above the horizontal, which operates indirectly on glare, but it limits intensity rather than luminance and was not derived from any criterion about vision. Part II.E.5 and Part VI.B.

The Foundation accordingly asks for two things in this subsection, and both are at Part IX. The first is that the study required by paragraph (a)(4) include functional endpoints and not only injury endpoints, since an instrument that records only lesions will record nothing here. The second is that any measurement protocol adopted under paragraph (a)(2) characterize the emission spectrally and characterize the adaptation state of the observer it is meant to protect, because the evidence above shows that an exposure summarized in a single number, in either system of units, did not predict what it did to vision.

4. Discomfort glare and its measurement

The report described at Part V.C.2.f treats discomfort glare, and two of its statements belong here. On prevalence, at page 11: "It is the most common cause of immediate complaints about lighting." On the adequacy of the means of predicting it, at the same page:

> "Future lighting standards should include more accurate ways to predict discomfort glare by considering both the non-uniformity of SSL light source and the spectral distribution of light."

That recommendation names the two emission characteristics identified at Parts V.B.1 and V.B.2 — the non-uniformity of the emitting surface and the spectral distribution — and states that present standards do not adequately account for either. The Foundation relies on it for that proposition and for no more. Parts IX.H.6 and IX.H.7.

a. The quantity, and why it differs from the quantity used elsewhere in this Part

Discomfort glare is driven by luminance. Luminance is luminous intensity per unit of apparent emitting area, expressed in candelas per square meter, and it is a photometric quantity: it is weighted by the photopic luminous efficiency function described at Part I.G. The Foundation draws attention to that because it is a departure from the rest of this Part. The argument at subsections d and h above, and at Part IV.C, is that photometric units are the wrong units for the non-visual responses and that receptor-weighted quantities are required instead. Discomfort glare is the exception. It is a response of the visual system, and luminance is the appropriate quantity for it. The Foundation states this rather than allowing the two arguments to merge, because a comment asserting that photometric units are simply wrong would be overstating its case and would be corrected. Two distinct complaints are at issue in this Part: a non-visual aversion response, for which Appendix C.51 identifies a melanopsin-mediated pathway and for which melanopic quantities are required; and discomfort glare, which is visual and for which luminance is required. They call for different measurements and the Department should be asked for both.

A second feature of luminance bears on every product class at Part VI. Because luminance is intensity divided by apparent area, a source delivering the same luminous flux from a smaller emitting surface has a higher luminance. The light-emitting diode is the smallest and brightest emitting surface ever deployed at scale in general illumination, as Part V.B records. The quantity that governs discomfort is therefore the quantity on which this technology departs most sharply from everything that preceded it, and it is a quantity that no specification required of any product within this Department's authority reports.

There is a further point about luminance which the Foundation puts here because it bears on every product class at Part VI, and which it takes from the industry rather than asserting against it. Appendix D.3 describes a component maker's white paper of February 2023 addressed to what it calls high-luminance directional lighting. The document sets out five attributes it identifies as critical, and the first and third are a small light emitting surface and a small emitting angle. It states the design principle in terms: "What matters is not only flux, but flux per emitting area, called lumen density."

Flux per emitting area is luminance. The quantity the preceding paragraphs identify as the one that drives glare, and which no federal instrument limits, is the quantity the industry identifies as the thing to maximize. The Foundation does not suggest there is anything improper in that. A spotlight that is not concentrated is a failed spotlight, and the engineering is addressed to the purpose the product is sold for. What the Foundation asks the Department to notice is the direction of travel. There is a commercial and technical gradient pushing this quantity upward, it is explicit in the trade literature, and there is nothing on the other side of it.

The same document illustrates what that produces. In a comparison of two emitters of 1.2 square millimeters behind the same dome lens, each supplied with 500 lumens, it reports an on-axis intensity of 84,153 candelas for a square emitting surface and 112,940 candelas for a round one, with beam angles at half maximum of 3.13 and 2.77 degrees and beam distances to one lux of 290 and 336 meters. The change from a square emitting surface to a round one, with no change in the power supplied, raises the on-axis intensity by about 34 percent. The Foundation records those figures because they are among the few published values in this comment for what a contemporary directional product actually emits, and because the beam angles place these devices within the regime discussed at Part V.C.2.k.

b. The Unified Glare Rating, and the term that answers the question people actually ask

The established means of predicting discomfort glare from an interior lighting installation is the Unified Glare Rating of the International Commission on Illumination. It is a logarithmic function of a summation over the glare sources in the field of view, of the form:

$$UGR = 8 \log_{10} \left[(0.25 / L^{b}) \times \Sigma \left(L^{s2} \, \omega / p^{2} \right) \right]$$

Four quantities appear in it, and each corresponds to something a person experiences:

L^{s}, the luminance of the glare source, in candelas per square meter.

ω, the solid angle the source subtends at the eye, in steradians, which is a function of its apparent size and its distance.

p, the Guth position index, which weights the source according to its angular displacement from the line of sight; a source directly ahead contributes more than the same source in the periphery.

L^{b}, the background luminance against which the source is seen.

The Foundation asks the Department to attend to the last of these, because it is the term that answers the most common account given in the reports collected at Part VII. Background luminance sits in the denominator. The rating therefore rises as the surround darkens: the same source, unchanged in every respect, produces a higher predicted discomfort in a dark environment than in a lit one. A person who reports that a particular light is intolerable at night and unremarkable by day is not describing an idiosyncrasy, and is not describing a change in the product. That person is describing the behavior of the term the governing metric places in its denominator. The experience is not outside the standards. It is what the equation in the standards predicts.

Two consequences follow at once. The first is that an indicator lamp on a domestic appliance, a charging light, a display in standby, or a street luminaire seen from a darkened bedroom are the worst case the metric can describe, because each combines a high source luminance with a near-zero background. The second is that this is a computable and foreseeable condition rather than an unforeseeable one. Nothing about it requires new science.

c. The validity domain, which is where the metric fails for this technology

The Unified Glare Rating was developed and validated for the sources in general use when it was developed: comparatively large luminaires of moderate luminance, in interiors, viewed at the distances and angles of an office or a similar room. Two limits follow, and the Foundation states them as limits of the metric rather than as criticisms of it.

The first is geometric. The source term enters as luminance squared multiplied by solid angle. For a fixed luminous flux, reducing the emitting area raises luminance and lowers solid angle together, and the metric was neither derived nor validated across the range of source sizes that light-emitting diode products now span. The Commission places stated bounds on the solid angle over which the rating is applicable. A small, intensely bright emitter viewed at close range falls at or beyond the edge of that range, and an unshielded diode die is the clearest instance of such a source. The metric does not say that such a source is acceptable. It does not apply to it.

The second is that the Unified Glare Rating is a metric for interiors. It is not the metric used for roadway or exterior installations, which are assessed by different quantities again, and vehicle lamps are governed by neither: Federal Motor Vehicle Safety Standard No. 108 specifies luminous intensity in candela at defined angular test points, as Part II.G.3 records, and contains no luminance requirement, no background-luminance term and no glare rating of any kind. The exposures that generate the largest number of reports at Part VII are therefore distributed across three different measurement regimes, one of which does not address the phenomenon at all.

The position index, measured for this technology in 2024

One term of the rating has since been measured for light-emitting diode sources, and the Foundation sets out what was found because part of it supports the argument above and part of it does not.

The position index entered the literature in 1949, in work by Luckiesh and Guth. In April 2024 Abboushi, Miller, Rodriguez-Feo Bermudez, Irvin and Royer, of Pacific Northwest National Laboratory, published in LEUKOS, the journal of the Illuminating Engineering Society, a human-subjects study measuring the position index for overhead light-emitting diode sources. Appendix C.62. They state that the applicability of the index to modern diode sources had not previously been evaluated.

Three of their findings support the argument of this subsection.

The first is their statement of the gap itself. A term that has been in use in glare prediction since 1949 had not been evaluated for the source type that now dominates general illumination, and a national laboratory said so in 2024.

The second concerns source size, which is the characteristic Part V.B.2 identifies as the one on which this technology departs most sharply from its predecessors. The authors used a source of approximately 0.0004 steradian, about a third of the solid angle used in the 1949 work, and they attribute part of the difference in their results to that. They state that the present practice of applying the same position index irrespective of source size warrants further study, and that the interaction between source size and the index remains untested.

The third concerns luminance. The authors observe that the 1949 values may have been influenced by the use of a single anchor and a limited luminance range, and that this bears on their applicability to current light-emitting diode sources with potentially higher luminance. Their own test sources reached luminances of the order of a million candelas per square meter.

What the same study tells against

Two of its findings are adverse to positions this comment might otherwise take, and the Foundation states them here rather than in a footnote.

The first is the direction of the discrepancy. Measured against an on-axis reference, the geometric mean position index for a source 60 degrees above the line of sight was 53 in the 2024 study, against 16.9 in the 1949 work, and the gap widened with increasing vertical angle. The position index enters the rating in the denominator and squared. A value three times larger therefore reduces that source’s contribution to the summation by approximately a factor of ten, which on the logarithmic scale of the rating is a difference of about eight units. The consequence is that a rating computed with the 1949 values predicts substantially more discomfort from a high, off-axis source than the 2024 measurements support, not less. As to that term and that geometry the established metric is conservative, and the Foundation does not suggest otherwise.

The second is spectral. The authors compared a cool source of approximately 4,550 K with a warm source of approximately 2,500 K and found no statistically significant difference in the position index or in the luminance at the borderline between comfort and discomfort, at either background level, with the direction of the small differences inconsistent across positions. They state that their study calls into question the effect of spectral power distribution on discomfort glare.

That is directly contrary to the recommendation quoted at the opening of this subsection, that future standards predict discomfort glare by considering the spectral distribution of light, and it bears on the Foundation’s own petition to limit the correlated color temperature of vehicle headlamps, described at Part IV.C.5. The Foundation reports it for that reason. Three qualifications belong with it and none of them is offered as a rescue. The authors themselves hypothesize that the adaptation periods of two to five minutes between spectral conditions may have weakened any spectral effect. The comparison was between two correlated color temperatures of broadly similar sources rather than across the range of spectra at issue. And

discomfort glare is one response among several; a null result for it says nothing about disability glare at subsection 3, about the melanopsin-mediated aversion at Appendix C.51, or about the retinal hazard, each of which is spectrally weighted by a different function.

The Foundation accordingly does not claim that warmer light is less discomfort-glaring, and any passage elsewhere in this comment that implies it should be corrected. What it claims is narrower and survives: that the metric's terms were derived for sources unlike the present ones, that their dependence on source size is untested by the field's own account, and that no federal instrument requires any of it to be computed for any product.

Where the research capacity sits

One institutional observation follows and the Foundation makes it once. This study was performed at a national laboratory of the Department of Energy. So was part of the work on near-infrared content described at Part V.B.6, and researchers of the same laboratory are among the authors of the intergovernmental review at Part V.C.2.f. The federal capacity to conduct human-subjects research on the visual effects of light-emitting diode products exists, is in use, and sits in the department whose statutory concern is the efficiency of the product rather than its effect on the person. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with other Federal departments and agencies with related interests, and paragraph (a)(6) directs consultation. Part II.H.4 and Part IV.G.

d. What is and is not a property of the product, and which provision reaches each

The Foundation puts the following to the Department because it bears on the choice of instrument rather than on the existence of a problem, and because it concedes something.

Contrast is not a property of a product. It is a relationship between a source and its surround, and the surround is a function of where the product is installed, when it is operated and what else is lit. No emission limit on a lamp can control the background luminance against which the lamp will be seen, because the lamp does not know what room it is in. A performance standard prescribed under 21 U.S.C. § 360kk cannot, by itself, address the condition described at subsection b.

The two terms of the problem divide cleanly, however, and each falls to a different provision of the statute.

Source luminance is a product property. It is fixed by the emitting area and the drive current at the point of manufacture. A manufacturer can reduce it without reducing luminous flux, by distributing the same output over a larger emitting surface or by diffusing it, which is the elementary technique recorded at Part II.G.3 for indicator lamps. A limit expressed in candelas per square meter is a limit on a product characteristic, and that term is within the reach of § 360kk.

Background luminance, and therefore contrast, is a function of installation, timing and use. It is reached not by a performance standard but by the procedures and techniques for minimizing exposure that § 360ii(a)(5) directs the Secretary to develop, test and evaluate — shielding, aiming, dimming, adaptive control, curfews, and the defeat of standby illumination in sleeping areas — and by recommendations under § 360ii(b)(1)(B). Part II.G.3 sets out that these techniques already exist for every product class at Part VI, and that what is absent is the federal evaluation of them.

That division is the Foundation's answer to a question the Department may fairly ask of this whole Part: granted a problem, which of your provisions do you say reaches it? For discomfort glare the answer is both, in different parts, and the Foundation does not ask for a performance standard to do work that a performance standard cannot do.

e. The status of the metric

The Unified Glare Rating is a recommended practice. It is published by a standards body, used by lighting designers in the design of installations, and incorporated by reference into national lighting standards in some jurisdictions. It is not an emission limit on any product, it is computed for an installation rather than for a lamp, and no federal rule within this Department's authority requires its use or sets a value for it. The position is therefore the same as that recorded for temporal light modulation at Part V.D.3 and for the seven circadian lighting documents at Appendix C.42: a quantitative metric exists, the field uses it, and nothing binds anyone. The single metric that does describe the most common complaint about lighting is a voluntary design recommendation, computed for installations rather than for products, and not valid for the source geometry that provokes the complaint most often.

f. The metrics used outdoors, and a manufacturer's account of why each of them fails

Subsection c records that the Unified Glare Rating is a metric for interiors, that roadway and exterior installations are assessed by different quantities, and that vehicle lamps are governed by neither. This subsection identifies those different quantities and sets out what is said about them, and the Foundation takes the account from a manufacturer of the equipment rather than from a critic of it. Appendix D.3 describes a white paper published by Cree Lighting on March 3, 2022, under the title Is Street Lighting Damaging Our Health?

The document identifies five instruments in current use. Three are the methods within the European roadway standard EN 13201: the Threshold Increment, the G-star luminous intensity classes, and the D-star disability glare index. To these it adds the Glare Rating index of CIE 112, adopted for other outdoor purposes, and the G rating of the Illuminating Engineering Society technical memorandum, which the document describes as one of the most commonly used methods for outdoor lighting and which is the American instrument in the list. Its general statement is that each was derived from research conducted before light-emitting diodes existed as a light source, and that most lighting standards do not specify design targets for discomfort glare at all, while those that do are not used universally and rest on subjective ratings that favor older technologies.

Its criticism of each is specific, and the Foundation reproduces the substance because the specificity is what makes the document useful:

Of the Threshold Increment: the calculation averages the luminance of the luminaire rather than taking the highest value, it assumes point source optics, and it does not represent user experience for high luminance, non-uniform and multi-point luminaires.

Of the G-star classes: the calculation rests on maximum luminous intensity at angles above 70, 80 and 90 degrees, while the vision cone of the human eye above the horizon is limited to 50 degrees, so that the luminance delivered at the reference angles affects the human visual field only partially and only at distance. The document's conclusion is that this "renders the metric ineffectual."

Of the D-star index: it is based on luminance at 65 degrees only, dividing maximum luminous intensity by the flashed area of the luminaire, where the maximum intensity is not necessarily at 65 degrees and the flashed area is simplified to the optical surface, so that the non-uniformity and intensity of diode sources "make this metric ineffective."

Of the CIE 112 Glare Rating: it evaluates the average luminance over the luminaire aperture, which the document calls "a highly inaccurate assumption now that we have luminaires with visible arrays of LEDs," and which "misstates the area and the luminance."

Of the Illuminating Engineering Society G rating: it rests on zonal lumens, is therefore based only on luminous flux, "does not consider true luminaire luminance," and does not consider luminaire uniformity or the size of the luminance opening.

One further figure in that document is worth stating on its own because it is a numerical mismatch rather than a general criticism. The document states, twice, that the eye begins to see direct light at 65 degrees from the nadir of a streetlight while the luminaire visual comfort level is evaluated at 70 degrees, which it says is normally where most of the roadway optic's peak intensity lies. If that is right, the assessment angle and the angle at which a person first sees the source directly are not the same angle, and the difference falls in the direction that omits the peak.

The Foundation asks the Department to weigh the source of these criticisms rather than to take them on trust. They are made by a manufacturer of the luminaires being criticized, in a document addressed to specifiers and public authorities, and they are made against the instruments by which that manufacturer's own products are shown to comply. A party has little commercial incentive to publish that the measurements its products pass are inadequate to the hazard. Where such a party does so, the statement is worth more than the same statement from a critic, and the Foundation relies on it accordingly. It does not rely on it as a scientific finding: the document is not peer reviewed, it cites few sources, and it argues for a change in standards from which its author would benefit.

The consequence for this comment is the one stated throughout Part V.C. Every metric named above is voluntary in the United States. None is an emission limit on a product. The Threshold Increment, the G-star and D-star classes and the CIE Glare Rating are European or international instruments with no force here, and the Illuminating Engineering Society memorandum is a technical memorandum of a professional society. A person standing under an American streetlight is protected by none of them, and the manufacturer's position is that even where they are applied they do not describe what that person experiences.

5. Age, astigmatism, cataract, and intraocular lenses as modifiers

This subsection concerns the people for whom the quantities in this Part do not describe the exposure. The optics of the eye are not uniform across a population, and three of the departures are common, well characterized and relevant to every product in Part VI. The Foundation sets out what it can support and marks what it cannot, because this is a subsection where the temptation to argue beyond the evidence is strong.

The optical mechanisms, which are established

Astigmatism, uncorrected or incompletely corrected, spreads the image of a point source into a line or a flare rather than a point. The relevant consequence for this comment is not blurred vision but the distribution of light within the retinal image: the same flux from the same source is spread over a different area and in a different shape. Part V.B.8 establishes that these sources present small emitting areas at very high luminance, which is the condition under which the difference between a well-formed and a poorly formed retinal image is largest.

Age changes the crystalline lens. It becomes less transparent and acquires a yellow tint, which reduces the short-wavelength light reaching the retina, and it scatters more, which raises the veiling luminance across the retinal image. Those two changes work in opposite directions for blue-light exposure and in the same direction for glare. Part V.C.3 sets out the scattering mechanism and Part V.F the spectral one.

Cataract extraction and replacement with an intraocular lens removes the yellowed crystalline lens and substitutes an implant. Where the implant does not filter short wavelengths, the retina of a person in the eighth decade receives short-wavelength light at levels characteristic of a much younger eye, while the retina itself retains the cumulative exposure history and the age-related vulnerability of its own decade. This is the one instance in the whole of Part V where a medical intervention alters a person's optical exposure to a regulated class of emission, and the Foundation draws it to the Department's attention for that reason.

What the Foundation can presently support by measurement, and what it cannot

The mechanisms above are optics and are not in dispute. What the Foundation has been able to find far less of is measurement of the consequence in people exposed to these products. One study bears on it directly and the Foundation gives it with its weight stated.

A survey of 206 attendees at Portuguese summer festivals, described at Appendix C.95, asked about sensitivity to lighting and recorded refractive condition. Sensitivity differed significantly by refractive condition ($p = 0.0375$), with astigmatism at 3.51, hyperopia at 3.62 and presbyopia at 3.88 on a five-point scale, against emmetropes at 2.75 and myopes at 3.08. The authors report that 33.1 percent of festivalgoers with refractive errors experienced heightened sensitivity to artificial and stage lighting. The same survey found sensitivity to stage lighting varying significantly with age ($p = 0.0472$), highest in the 66 to 75 group.

The Foundation states the limits of that evidence in the same breath, and they are considerable. It is self-report, not measurement. It is cross-sectional, and the authors say expressly that the design limits any inference of causation. The sample of 206 carries a margin of error the authors give as 6.8 percent, and they state that they are identifying trends rather than drawing generalized conclusions. Nothing about the light at any festival was measured. And the scale anchors are not stated in the published paper as the Foundation read it, so the means above are comparisons between groups rather than values on a known scale.

What the study therefore supports is narrow and the Foundation claims no more than it: in one surveyed population, people with astigmatism, hyperopia or presbyopia reported greater sensitivity to artificial and stage lighting than people with no refractive error, and the difference reached conventional significance. That is consistent with the optics and it is not a demonstration of it.

What the people who administer the exposure limits say about this population

The subsection so far has argued from optics and from one survey. There is a third source, and it is better than either, because it is a statement about the limits themselves by a body that tests products against them.

A white paper of Underwriters Laboratories, described at Appendix D.3 and relied on at Part V.C.2 for the history of the standards, states that the photobiological exposure limits are not intended to strictly separate safe from unsafe levels, and that they may not accurately reflect risk for more susceptible people, including those with increased photosensitivity or lens transplants.

The Foundation asks the Department to weigh the source as well as the statement. Underwriters Laboratories sells photobiological testing against these limits. The statement is against its commercial interest, it is published in its own name, and it names the two populations this subsection and Part V.C.3 are about.

What follows is a sharper proposition than the optics alone support, and the Foundation states it in its final form. The argument of this subsection is not merely that certain eyes receive a different exposure from the average eye. It is that the numerical limits by which optical radiation is assessed are not represented by the body administering them as protective of the people whose eyes differ in exactly these ways, and that the person with a replaced lens is therefore outside the protection of a framework that was voluntary to begin with. A performance standard prescribed under 21 U.S.C. § 360kk would have to decide what it does about that population. The present arrangement has not decided; it has disclaimed.

Why this belongs in a comment to this Department

Because a performance standard prescribed under 21 U.S.C. § 360kk is written for a population and not for an average eye, and because the populations described here are large. Presbyopia is universal after middle age. Astigmatism is among the commonest refractive conditions. Cataract surgery is among the commonest surgical procedures performed in this country. A standard whose protective premise is the optical performance of a young emmetropic eye does not protect

any of them, and the Foundation asks the Department to make the population assumption explicit in whatever it prescribes rather than leaving it implicit as the present voluntary framework does.

D. Temporal Light Modulation (Flicker)

1. Pulse-width modulation, modulation depth, and frequency

This subsection states what temporal light modulation is, where it comes from in these products, how it is measured, what limits exist, and what the people who write the governing documents say is not yet known. It is built principally on a 2024 review in IEEE Transactions on Industry Applications, described at Appendix C.91, and the Foundation begins with who wrote that review because the authorship determines the weight of everything taken from it.

The source, and why its authorship matters

The review has six authors. One is of a French public research institute and one of a French university laboratory. The other four are of the lighting industry: the standards and regulations function of Signify, the director of engineering services of Cree Lighting, a lead scientist of Lutron Electronics, and a consultant who also holds a university appointment. The paper states its own standing: a joint working group of the IEEE Industrial Applications Society and the Illuminating Engineering Society was formed to review the knowledge on this subject, its survey was incorporated into the IEEE 3001.9 and IES RP-48-2023 Recommended Practice of May 2023, and "This paper is authored by members of the joint IES / IEEE working group." What follows is accordingly not the Foundation's characterization of the state of knowledge. It is the characterization given by the authors of the American recommended practice, four of them employed by manufacturers, published in a peer-reviewed journal of the institute that issued it.

Where the modulation comes from

The review identifies five origins, and the Foundation sets them out because the third is the one at issue throughout this Part. Modulation at twice the mains frequency, so 100 or 120 hertz, in sources run from an alternating-current converter, its depth depending on the electrical design of the driver. Modulation at the 20 to 100 kilohertz switching frequency of high-frequency drivers, often superimposed on a residual 100 or 120 hertz component. Pulse-width modulation, which the review describes as "a square wave modulation profile with constant frequency, usually of a few hundred Hz, and 100% modulation depth", with the duty cycle varied to set the average light level, and which "is used in many dimmable LED lighting systems." Low-frequency broadband modulation introduced by phase-cut dimmers. And transient modulation from disturbances on the supply, for which the review lists causes including sudden load changes, powerline communications, lightning and wind, and distributed generation from wind and solar.

The Foundation draws attention to one feature of that list. The dimming method in general use operates at full modulation depth by construction. The depth is not a defect of a particular driver that better engineering would remove; it is how the method works, and the only variables are the frequency and the duty cycle. Part V.D.2 sets out what is known about the visibility of exactly that waveform.

Modulation depth, and the objection that fluorescent lighting flickered too

That objection is the commonest and the most reasonable one this Part attracts, and the Foundation answers it here rather than waiting to be put to it. The objection is that modulation is not new, that fluorescent and even incandescent lighting modulated at mains-related frequencies for a century, that people lived under it, and that a comment complaining of modulation in the newer technology is complaining of a characteristic of electric light itself.

What the sources permit the Foundation to say about depth, and what they do not

The Foundation begins by stating what it does not have, because the temptation here is to compare two numbers that are not comparable. It has no measured peak-to-peak modulation depth for any fluorescent lamp or for any light-emitting diode product. It has three statements of different kinds from three sources, and it also notes that the sources use two different quantities: the flicker percent, which is the modulation depth and which Part V.D.1 defines above as the magnitude of the variation relative to the average, and the flicker index, which is the ratio of the area under the curve to that over it and which, in the instrument maker's words, "specifies the duty cycle of the signal". The two are not interchangeable and a figure given in one must not be reported as the other.

Arranged by technology, and with the quantity named in each case, the record is as follows.

- Incandescent lamps modulate at the supply frequency, and the ecological study at Appendix C.94 describes the "intensity of flicker" as low, giving the quantity as a low flicker index. The reason is the thermal inertia of the filament, which continues to radiate between current peaks.
- Fluorescent lamps on magnetic ballasts modulate at twice the supply frequency, and their depth is not fixed. The authors of IEEE Std 1789-2015 state that "The peak-trough modulation depth of the 100-120Hz flicker from older fluorescent lamps with magnetic ballasts varies with the component phosphors, some of which exhibit persistence, varying the chromaticity of the light through its cycle". The persistence of the phosphor is what prevents the lamp from extinguishing fully between half-cycles, and it is therefore a physical limit on how deep the modulation of such a lamp can be.
- Light-emitting diodes driven at twice the supply frequency are compared with fluorescent lamps by the same authors, and the Foundation quotes the comparison rather than quantifying it: such devices "may have a depth of modulation greater than that from most fluorescent lamps. The effects of the flicker are therefore likely to be more pronounced in these cases". The reason is the converse of the fluorescent case. The emitter has no thermal inertia and, in the ordinary case, no persistent phosphor intermediary of the kind that limits a fluorescent lamp, so its output follows its current.
- Light-emitting diodes dimmed by pulse-width modulation are the case in which a figure is available, and it is definitional rather than measured. The review at Appendix C.91 defines the method as "a square wave modulation profile with constant frequency, usually of a few hundred Hz, and 100% modulation depth", the duty cycle being varied to set the average output. Full depth is not an observed value of a particular product; it is what the method is.
- Light-emitting diodes dimmed by amplitude control are the case in which there is no modulation to measure, and the Foundation records it here because it is the answer rather than the problem. The authors of the standard describe a method "in which the current through the LED is continuous and not pulsing" and state that it "does not use flicker to adjust brightness and therefore, should not induce flicker related health risks".

What the figure of 35 percent is, and what it is not

The Foundation is precise about this because the figure is the most useful number in Part V.D and because it is easy to misuse. The authors of the standard state that "The peak-trough modulation depth known to induce headaches from fluorescent lighting at 100Hz is about 35%", citing the double-masked study described at Part V.D.3. That figure is the modulation depth of the lighting used in the experiment that doubled the incidence of headaches among office workers. It is therefore a dose shown sufficient to produce an effect. It is not the characteristic modulation depth of fluorescent lighting, it is not a maximum, and above all it is not a threshold below which nothing happens, because no lower depth was tested. The Foundation does not assert and does not imply that 35 percent is a safe boundary.

The three answers to the objection

The first answer uses the figure correctly. A modulation depth of about 35 percent at 100 hertz was shown, under masked conditions, to double the incidence of headaches in office workers. The dimming method in general use in the newer technology operates at full depth by construction, at frequencies of the same order. Whatever else is unknown, a method that operates at full depth operates above a depth that has already been shown sufficient to produce the effect in question. The comment does not need to know the depth of any particular fluorescent lamp to make that point, and it does not make the comparison numerically.

The second answer concerns where the depth comes from. In the fluorescent case the depth is a consequence of the physics and is bounded by it: the phosphor persists, and the lamp cannot modulate fully. In the pulse-width case the depth is the design. It is not a defect that better engineering would remove, because full extinction between pulses is how the method sets the average level. So the two technologies are not two instances of one phenomenon differing by degree of imperfection. One is limited by its physics and the other is maximized by its control method, and the comparison the objection invites therefore runs the wrong way.

The third answer is the one the Foundation asks the Department to weigh longest, because it accepts the objection entirely and is unaffected by it. The double-masked study that found a doubling of headaches was a study of fluorescent lighting. The reduced speed of visual search in two masked studies was under fluorescent lighting. The enlarged saccades over text, the increased heart rate in agoraphobic individuals, the phase-locked thalamic firing in the cat: all fluorescent. The evidence that modulated light affects people is, almost in its entirety, evidence gathered under the previous technology. The objection that fluorescent lighting flickered too is therefore not an argument that modulation is harmless. It is the observation that the predecessor technology modulated, that the studies run on it found effects, and that nothing was required of it either. A regulator told that a hazard is not new is being told that it has been present and unaddressed for longer than supposed.

What the Foundation does not claim

Four things, stated so that the passage is not read for more than it says. It does not claim that fluorescent lighting was safe; the one masked study run on it found an effect. It does not claim that every light-emitting diode product modulates deeply; a device on a well-filtered constant-current driver may modulate very little, and a device dimmed by amplitude control essentially not at all, which is why Part IX asks for a performance standard rather than for a prohibition. It does not claim that 35 percent and 100 percent are measurements of two comparable things. And it does not claim that depth alone determines effect: the sources are unanimous that frequency, depth, duty cycle, luminance, field of view and visual task all bear on it, and the authors of the standard say so in terms.

What is measured, and over what range

The quantities are the modulation frequency, the modulation depth and the flicker index, and the review records that these three were found insufficient because they were “loosely correlated to the temporal light artifacts perceived by human vision”, which is why the standards bodies formed joint groups to develop perceptual measures. The laboratory method for capturing the waveform is the joint American national standard ANSI and IES LM-90-20 of 2020, which the review describes as “covering modulation frequencies 1 Hz and 3 kHz”.

Two consequences follow and the Foundation separates them. The first is the Foundation’s own arithmetic and is attributed as such: the same review states that the phantom array effect occurs from about 100 hertz to about 10 kilohertz, so the American laboratory measurement standard covers less than a third of the frequency range in which these authors say one of the three effects occurs. The second is the review’s own statement, and it concerns verification rather than range: “Portable instruments are now available to perform on site TLM waveform measurements and return TLM and TLA metrics. However, there is no standard covering the field measurement of

these parameters.” There is, that is, no standardized way to measure what a product is doing where it is installed.

The conditions the review specifies for a valid measurement are worth stating for the same reason. Modulation “should be measured without daylight, without any unwanted light from another lighting/display installation nearby and without any moving objects or people in the field of view of the measurement device.” A quantity defined under those conditions is not a description of what a person is exposed to in a street or a store.

The Foundation records the statement in the review that runs against its position, and does so here rather than later. “The temporal light modulation in a real-world application, consisting of multiple light sources is generally lower than the TLM performance of a single light source due to the averaging out of the light modulation from the different light sources.” In a room lit by many luminaires the modulation seen is therefore expected to be less than any one product’s rating, and a comment that ignored this would overstate the interior case. The limit of the proposition is that the averaging requires several independent sources in the field of view. It does not reach a single dominant source seen against a dark field, which is the headlamp, the warning beacon, the message sign and the lone luminaire overhead at night, and those are the products at Part VI. The review adds that combination of waveforms “could, in principle, lead to beat frequencies if the frequencies slightly differ between luminaires”.

What limits exist, and the three tiers of coverage

The review’s survey of standards resolves into a gradient, and the Foundation sets it out in a table because the shape of the gradient is the point. For flicker there is a measure and a limit accepted worldwide. For the stroboscopic effect there is a measure but no agreed limit, and the American figure is four times the European one. For the phantom array effect, for the stroboscopic effect on machinery, and for eyestrain, migraine and headache, the review records the measurement method as nonexistent.

Effect	Measure	Measurement method	Limit value
Flicker	PstLM	CIE TN 012:2021; IEC TR 61547-1	PstLM = 1 (most standards and regulations worldwide)
Stroboscopic effect, hand and body motion	SVM	CIE TN 012:2021; IEC TR 63158	EU Ecodesign 2019/2020: 0.4. NEMA: 1.6
Stroboscopic effect, machines and tools	None stated	Nonexistent	None stated
Phantom array effect	None stated	Nonexistent	None stated
Eyestrain, migraine, headache, other neurophysiological effects	Normalized modulation	Nonexistent	IEEE Std 1789

The table reproduces the substance of the review’s own summary of standards and guidelines for the rows that bear on this comment. The word nonexistent is the review’s.

Three things in it require comment. First, the one firm limit is not firm in its domain. The response function behind it “was originally derived using a small size luminous stimulus with sharp edges, seen in central vision in well-lit conditions. However, PstLM can be assessed, and is now used, outside its original range of lighting conditions, included in dim environments (mesopic conditions).” Second, the stroboscopic measure is expressly confined: its “upper frequency limit is 2000 Hz”, it requires illuminance above 100 lux, and “It is not applicable in dark environments, nor with outdoor lighting.” The measure for the one artifact with an agreed measurement method does not reach outdoor lighting at night. Third, the divergence on the limit for that measure is large and is stated by these authors in these words: “Unlike the flicker metric

PstLM, there is currently no consensus on an acceptable upper limit for SVM. The European eco-design regulation EU 2019/2020 defined the limit at 0.4, following an interim two-year period during which the accepted limit had first been set at 0.9. The NEMA specifies a maximum SVM of 1.6, which is considerably higher than the EU limit." The European figure is binding and the American figure is a recommendation of a trade association, and the recommendation is four times the binding limit.

For displays the review states that neither perceptual measure applies, because they were built to predict human perception and not artifacts created by image sensors, and that "There is currently no standard metric associated with TLAs observed on electronic devices." That belongs with the asymmetry recorded at Part V.B.2, where the display industry was found to specify the one emission quantity the lighting industry does not.

What the authors of the recommended practice say is not known

The review treats the health effects as established. "The known health effects of TLM are eyestrain (asthenopia), headaches, migraine, and photosensitive epilepsy", and in the conclusions, "Headaches, migraines, and eyestrain have been commonly reported, studied, and confirmed in the scientific literature." It explains why such effects are hard to attribute to a cause, which is a point the Foundation makes at Part VIII in support of adverse event reporting: "Eyestrain, headaches, and migraine happen during, or after, prolonged exposures to TLM, typically of one or several hours. The delay in the onset of these effects makes it difficult to identify TLM as a critical factor of lighting systems."

It also states that the conditions of exposure have changed since the American standard was written: "the ubiquity of solid-state lighting and solid-state display technologies profoundly changed the characteristics of human exposure to TLM. Longer exposures to an increasing number of modulated light sources are becoming the norm. The human response to these repeated stimuli is still unclear but some recently published results are now available."

And then the passage for which the Foundation principally cites this review. On who is affected: "The case of sensitive people is worth considering because a significant fraction of the general population is known to suffer from symptoms associated with the exposure to TLM." On what is known about them.

> "An unknown fraction of the general population is particularly sensitive to temporal light modulation. This population is not well understood but includes migraineurs and people suffering from headaches induced by flickering lights, those suffering from pre-existing conditions such as photosensitive epilepsy, and some people who have suffered head injuries such as traumatic brain injuries."

And on whether they are protected.

> "Safe TLM levels were defined for photosensitive epilepsy, but there is insufficient data to define safe levels for other categories of sensitive people."

The conclusions put the same point as a recommendation rather than a finding. The symptoms "seem to occur more frequently and more intensely for a fraction of the general population which is yet to be rigorously identified. For these well-known effects, more research should be done to provide dose-response relationships to be able to improve health and safety requirements for sensitive people." And of one group specifically: "Other conditions, such as traumatic brain injuries, require specific protective measures against exposure to modulated light sources."

The Foundation asks the Department to take four things from that and states them in the order of their certainty. That the health effects of this characteristic are confirmed in the literature, on the authority of the authors of the governing recommended practice. That a significant fraction of the population suffers symptoms from it, while the size of the particularly sensitive fraction remains unknown and the people in it remain unidentified. That safe levels exist for one condition only,

photosensitive epilepsy, and that for every other category of sensitive person the data to set a safe level are insufficient. And that the improvement called for is not of research alone but of "health and safety requirements for sensitive people."

The Foundation adds the observation that the review's own account of the present position concedes, in the three qualifiers of a single sentence, what is missing: "International standards and regional regulations now include requirements providing a certain degree of protection against undesired visual effects of temporal light modulation that may occur at high levels." A certain degree of protection, against visual effects, at high levels. The paper nowhere states that existing requirements are sufficient, and where it addresses health effects and sensitive people it states the contrary. The Foundation does not suggest that these authors call for regulation of their employers' products. They call for research, for better design, and for improved requirements. The Foundation asks only that the Department notice who is saying that requirements need improving.

What the instruments can measure, and the condition they require

The subsection above establishes that the American laboratory standard covers 1 hertz to 3 kilohertz while the authors of the recommended practice place one of the three artifacts between 100 hertz and 10 kilohertz. The remaining question is what the instruments do, and for that the Foundation turns to a manufacturer of them. The knowledge-base article described at Appendix D.3 is product literature of a German instrument maker, written to tell purchasers what its flicker meters will and will not do. The Foundation relies on it for that and not for its account of the science.

The ceiling is stated plainly: "The meters are designed for the detection of flicker frequencies up to 5 kHz". The tables show that ceiling falling as the operator lengthens the measurement time to gain frequency resolution, to 2.5 kilohertz, then 1.2, then 0.6, and at the longest settings to 75 and 33 hertz; and that the full speed is available only in part of the amplifier range, the page noting "3dB Range 0 to 5 = 10 kHz, Range 6 to 8 = 200Hz".

The Foundation now sets the three figures beside one another, and the arithmetic is its own. The effect is placed by the authors of the recommended practice at up to 10 kilohertz, and a peer-reviewed experiment found it statistically visible to 7 kilohertz. The American laboratory method is written to 3 kilohertz. A current commercial field instrument is designed to 5 kilohertz. Neither the standard nor the instrument covers the range in which the people who write the standards say the effect occurs. The Foundation does not suggest that this is anyone's fault, and the tables show the engineering reason, which is that frequency ceiling and frequency resolution trade against each other in a sampled measurement. It states the consequence only: a product could modulate at a frequency at which this artifact is reported to be visible and no routine measurement would record it.

The illuminance floor, which matters most for the products at Part VI

The second limit is not about frequency at all, and the Foundation regards it as the more consequential of the two. A flicker measurement requires enough light to measure.

> "Basically, the signal to be measured should be strong enough (e.g. at least 100lx are recommended). Only then is it possible to guarantee a good signal to noise ratio for the flicker measurement".

Below that, the manufacturer states, the error in both the frequency and the flicker parameters "increases greatly", and "small flicker signals can be below the noise level and are thereby cannot be detectable". The worked illustration on the page is a reading at 78 lux, already described as a bad signal-to-noise ratio.

One hundred lux is an interior light level. The Foundation asks the Department to consider what follows for the products described at Part VI, which operate outdoors at night. Vertical

illuminance at a pedestrian's eye from roadway lighting is of the order of a few lux, and the ambient against which a vehicle lamp or a beacon is seen is lower still. At those levels this class of instrument is below the illuminance at which its maker says the measurement can be guaranteed, and small modulations fall under the noise floor altogether. The Foundation states the limit of the inference: the manufacturer is describing a general-purpose field meter measuring ambient illuminance with a cosine diffuser, and a measurement aimed directly at a bright source at close range is a different case which the page does not address. What the page establishes is narrower and sufficient, which is that the ordinary field instrument for this purpose is specified for interior light levels.

Read with the preceding subsection, three statements about the nighttime outdoor case now come from three independent sources and all point the same way. The authors of the recommended practice state that the stroboscopic measure "is not applicable in dark environments, nor with outdoor lighting", and that there is "no standard covering the field measurement of these parameters". The instrument maker states that the measurement needs about 100 lux. And the experiment at Appendix C.90 confines its one frequency recommendation to interiors, expressly excluding areas with "darker finishes or very low ambient light conditions". At night, outdoors, there is no applicable metric, no field measurement standard, and an instrument specified for an illuminance two orders of magnitude above the condition.

One further source bears on the nighttime case, and it is of a different kind from the three above. Those are statements by the authors of standards and by the makers of instruments about what can be measured. This one is a measurement of people. A cohort study of 400,343 attendees at stroboscopically lit events, described at Appendix C.99 and treated at Part VI.K, divided them by whether the event took place in darkness or in daylight and found an incidence density ratio for epileptic seizures of 3.5, with a 95 percent confidence interval of 1.7 to 7.8.

The Foundation offers that for one purpose and states the purpose narrowly. The state of adaptation of the viewer is treated in the measurement literature as a condition under which instruments work less well. In the clinical literature it is a variable capable of moving an incidence rate by a factor of three and a half. The products described in Part VI operate in the second condition and are assessed, when they are assessed at all, by instruments specified for the first.

Two refinements to the account above

The first concerns the domains of the metrics, which the instrument maker states more explicitly than the review did. The flicker severity metric is "proposed in CIE TN006 for the assessment of perceived light flicker for frequencies up to 80 Hz"; the Assist perception metric "mainly deals with signals below 80Hz"; and the stroboscopic measure addresses modulation "typically up to 2 kHz" and is appropriate only "when the average light level is > 100 lx". The table above should therefore be read with the frequency domain in mind as well as the limit value: the one metric with a worldwide limit is a metric for frequencies below about 80 hertz.

The second is a qualifier on the European requirement, and the Foundation flags it rather than resolving it. The same page describes the requirement as applying to "non-dimmed LEDs and OLEDs", with the stroboscopic limit of 0.9 in force from September 2021 and the tightening to 0.4 expected in 2024. The phrase will bear two readings, that the limits reach only products which cannot be dimmed, or that they apply to any product measured at full output. The Foundation has not read the regulation and takes neither reading. It records why the question matters: Appendix C.92 reports a lamp whose measured flicker rose from 63.9 to 80.1 percent when it was dimmed, with its duty cycle falling to one part in eight. If the only binding numerical limit on temporal modulation anywhere is tested at full output, it is silent about the state in which modulation is worst.

What determines whether modulation is seen at all, which is not frequency alone

Every criterion described in this subsection is expressed in two variables, frequency and modulation depth. A neurophysiological review of the processing of flickering light, described at Appendix C.96, states the determinants of whether modulation is distinguished from steady light, and the list is longer:

> "Distinguishing between flickering and steady light is dependent on the factors mentioned in the review article by Mankowska et al.: (1) the frequency of modulation, (2) the amplitude of modulation, (3) the average illumination intensity, (4) the position on the retina at which the stimulus occurs, (5) the wavelength or colour of the light-emitting diode, (6) the intensity of ambient light, or (7) the viewing distance and (8) size of the stimulus."

Two of those eight are what the measurement standards and the recommended practice address. The Foundation asks the Department to notice the other six, and to notice that the fifth names the light-emitting diode expressly. Average illumination intensity, ambient light intensity, viewing distance and the size of the stimulus are all properties of the exposure situation rather than of the lamp, and all four differ between an office ceiling and a roadway at night in the direction that makes the modulation more apparent, not less. The position on the retina is the variable that distinguishes the phantom array from flicker, treated at the following subsection. The wavelength is addressed by no instrument the Foundation has found, and Part VI.I describes a product in service whose emission is more than eighty percent blue.

This is the evidentiary basis for a proposition the comment advances throughout Part V and states here in its general form. The criteria in existence for temporal modulation are not wrong. They are partial. They constrain two of at least eight variables known to govern whether the modulation is resolved, they were developed for interior general lighting and for broadcast content, and nothing has been assembled that could be applied to a lamp aimed at a person outdoors at night.

The same review records an effect at the frequency band this subsection is principally about. It states that "light from lamps flickering at a high frequency, i.e., 100–120 Hz, can induce headaches or migraines". That is the band produced by rectification at twice the supply frequency, which the review at Appendix C.90 gives as the first of the five origins of modulation, and it is the band in which the one product this comment has measured was found to operate: Part VI.I reports a measured 100.1 hertz at 63.9 percent modulation in a lamp in service on American streets. The Foundation records the qualifier the review uses, which is "Occasionally", and does not enlarge it.

2. Stroboscopic effect and phantom-array effect

This subsection concerns two effects that are often named together and are not the same thing. The Foundation separates them before describing either, because the evidence it has bears on one of them and not on the other.

The stroboscopic effect is the apparent alteration of the motion of a moving object viewed under a modulating source. The observer is still and the object moves. It is the effect that makes a rotating tool appear stationary, and its hazard case is industrial.

The phantom array effect, also called the ghosting effect, is the appearance of a row of repeated images when the eye moves rapidly across a small bright modulating source. The source is still and the observer's eye moves. Its hazard case is anybody who looks from one thing to another in a space containing such a source, which is to say everybody.

The Foundation addresses the phantom array effect in this subsection and states plainly that it does not yet address the stroboscopic effect, which requires the literature on the stroboscopic visibility measure that the Foundation has not assembled. The heading is retained because the subsection will be completed.

The study the Foundation relies on, and who paid for it

The principal evidence is a 2024 experiment published in Lighting Research and Technology and described at Appendix C.90. The Foundation puts the funding first. The work was performed at Pacific Northwest National Laboratory and supported by the Lighting Research and Development Program of the Building Technologies Office within the Office of Energy Efficiency and Renewable Energy of the United States Department of Energy, and the authors declared no conflicts of interest. The Department is therefore not being asked to weigh the submission of an affected party. It is being asked to weigh federally funded research produced inside the government's own laboratory system by a sister agency with a statutory interest in promoting these products rather than in restricting them.

Fifty-five people, 25 with a history of migraine and 30 without, spanning ages 22 to 81, judged 85 modulation waveforms produced by a single small light-emitting diode against a black background while moving their eyes between two targets 45 degrees apart at a pace set by a metronome. The waveforms included sinusoids from 120 to 10,000 hertz at modulation depths from 100 percent down to 5 percent, rectangular waveforms across the same range at two depths and two duty cycles, six waveforms measured from commercial lighting products, and a non-modulating control against which every judgment was tested.

What the experiment found about frequency

Modulation remained visible far above the frequencies at which it is commonly assumed to stop mattering. Sensitivity peaked between 400 and 800 hertz. Stimuli up to 7,000 hertz were statistically more visible than the non-modulating control across all participants, and sinusoids at full modulation were still more visible than the control at 7,000 hertz. At 10,000 hertz the effect was not distinguishable from the control on sample averages, and the Foundation accepts that result as a genuine null because the authors report the false-positive rate alongside it: detection of the pulse-width-modulation waveform fell from 73 percent of all observers at 4,800 hertz to 16 percent at 10,000 hertz against a 15 percent rate of observers reporting the non-modulating control as visible. Five of the most reliable participants nonetheless reported seeing it at 10,000 hertz.

Two propositions follow for this Department, and the Foundation separates them because only the first is established by this study alone. The first is that the frequency range within which modulation is perceptible, by this mechanism, extends into the thousands of hertz and not merely to the hundreds. The second is that the frequencies at issue are exactly those produced by the drive electronics of these products, since pulse-width modulation at full depth was the most visible and the most annoying waveform class tested. Of the pulse-width waveforms below 1,200 hertz the authors report that they were visible to every participant capable of reliably detecting the effect at all, with mean annoyance above 4 on a scale whose upper anchor at 8 reads "extremely annoying, I need to leave the room".

What it found about who sees it

The authors state that the question had not previously been studied: "no research has investigated if or how PAE sensitivity varies between people with and without migraine. Likewise, there has been no research on physiological symptoms following exposure to the PAE – for either migraine or non-migraine groups." They found that it does vary. In the model of visibility, a history of migraine carried an odds ratio of 3.31, with a confidence interval of 1.22 to 8.94, and the interaction of migraine with frequency was significant, the migraine group being relatively more sensitive at the higher frequencies. Younger participants saw more stimuli, though the Foundation notes that while the direction of the age effect is firmly established its magnitude is not, the linear fit between age and the number of stimuli seen having an R-squared of 0.08.

The reported consequences outside the laboratory were larger than the differences in what was seen inside it. Of the migraine group, 72 percent reported being bothered by the effect more than rarely against 40 percent of the others; 84 percent reported physical symptoms they attributed to it against 47 percent; 64 percent reported headache against 10 percent; and 60 percent reported

having changed a behavior, such as leaving a restaurant, against 17 percent. In the four hours after the session, 64 percent of the migraine group reported discomfort or an adverse reaction against 19 percent, and 41 percent a headache against 8 percent.

The Foundation states the limit of those figures in the authors' own terms rather than in its own, and does so here rather than in a footnote, because the figures are striking and a reader is entitled to the qualification at the same time. The task was visually demanding, requiring an hour or more of repeated eye movements, and the authors write that accordingly "the negative outcomes (for the migraine group in particular) cannot be explicitly linked to the TLM itself." They further record that all participants were warned at recruitment that symptoms were possible and that the migraine group answered an additional symptom questionnaire, so that "It is possible the migraine group inferred a higher likelihood of headaches afterward, which could have increased the number of post-experiment headaches reported." The Foundation does not assert that this effect causes headache. It asserts that a federally funded experiment found a large difference in reported symptoms between two groups and could not exclude expectation as a contributor, and that the right response to such a finding is the further study the authors call for.

The range of individual sensitivity, which is the finding this comment has been unable to obtain elsewhere

Six participants saw fewer than one stimulus in ten above threshold, three of them saw none, and two never perceived the effect at all. Seven saw at least three quarters of the 85 stimuli. Some observers detected it at a modulation depth of 5 percent. Of the predictive measure the authors write that "it cannot predict any individual's ability to see the phantom array, as there is extreme variation in sensitivity to the PAE." The Foundation asks the Department to hold that sentence against the structure of every instrument described in this Part. Each of them sets a single threshold derived from a population average. The specialists who built the measure for this effect say that such a threshold cannot speak to an individual, and the spread in their own sample runs from people who cannot see the effect at all to people who see it at a twentieth of full modulation.

What it found about the governing document, stated in both directions

The international document for temporal light modulation is CIE 249. Its function for this effect was provisional, and the authors report that it was developed on data extending only to 1,200 hertz while the competing measure rests on data to 2,000 hertz, both well short of the range at which the effect was found here to be visible. Measured against it: "CIE 249 suggests threshold visibility at 76% modulation for 2400 Hz sine waves, but threshold visibility was 49% in this experiment." The authors' conclusion is unqualified: "This experiment does not support the use of the PAE threshold modulation function published in CIE 249."

The Foundation states the qualification that runs against its own position, because the paper states it and a comment that omitted it would be misrepresenting the source. The failure of that function is a failure about how sensitivity falls with frequency, not a uniform permissiveness. The authors write that "Aside from relative differences, both the CIE 249 function and PAVM function predict lower absolute threshold modulation", meaning that in absolute terms both predict visibility at lower modulation than this experiment measured. They add that absolute thresholds depend on background and contrast, ambient illumination, stimulus size and shape, the scanning angle, saccade speed and personal sensitivity. So the proposition the Foundation advances is the narrow one: the international function understates sensitivity at the frequencies lying beyond the data from which it was built, and those are the frequencies at which these products operate.

The frequency the authors propose, and why its conditions matter more than the number

The authors offer a figure, and they attach conditions to it in the same sentence. At 10,000 hertz the pulse-width waveform "was not statistically more visible or more annoying than DC, making this a reasonable target minimum frequency if PWM is utilized in lighted environments similar to

those in the experiment space (i.e. not areas with larger eye movements, darker finishes or very low ambient light conditions)."

The Foundation asks the Department to read the parenthesis. The three excluded conditions are larger eye movements, darker surroundings and very low ambient light. Those are the conditions of the nighttime street, which is where the products described at Part VI operate: roadway luminaires, vehicle headlamps and warning beacons, and dynamic message signs, all of them viewed against a dark field by an observer whose eyes are moving across a wide visual scene. The authors say what is known about that case: "Others have examined higher frequencies using luminous targets in very dark surrounds, in which case some observers can reliably see the PAE above 10 000 Hz." The one frequency figure in this literature that an engineer might take as a design target is therefore expressly limited to interior conditions, and above it, outdoors at night, the effect is reported to remain reliably visible.

What the authors asked for

The Foundation ends this subsection with the authors' own statements, because they are the statements of federal grantees at a national laboratory and not of this commenter. On the weight of what they found: "this is strong evidence that TLM is a major problem in lighting and should be remedied, even if it requires trade-offs with other performance attributes." On what any threshold depends upon, which is the proposition this comment makes throughout Part VII: "if a general population is used to model threshold visibility, and individuals with migraine and other sensitive individuals were excluded as subjects, then the average values may not be protective for some at the more sensitive end of the normal distribution. In that case, more strict performance criteria can be set to account for more sensitive observers." And on what should now happen: "We advocate for rapid uptake of metrics and specifications to mitigate the PAE – and other responses to TLM – such as those proposed in IES TM-39."

The Foundation adopts that call and states the one thing it adds. The measures the authors point to are a recommended practice of a professional society, which binds no manufacturer and reaches no product. The authors advocate rapid uptake because uptake is voluntary and has not occurred. Nothing in Title 21 prevents the Secretary from setting a performance standard for this characteristic under 21 U.S.C. § 360kk, and the quantity to be limited, the method of measuring it and the performance levels have all been worked out and published by the Department of Energy's own grantees and the society that received their work.

Corroboration from the authors of the recommended practice, and the fact that the international model was never validated

The preceding account rests on a single experiment, and the Foundation said so. Two of its propositions are independently confirmed by the review described at Appendix C.91, which matters because that review is written by members of the joint working group that produced the American recommended practice and four of its six authors are employed by lighting manufacturers.

On the frequency range, the review states in its conclusions that the phantom array effect may appear "from about 100 Hz to about 10 kHz" with maximum visibility at 600 hertz, and its summary table of effects against frequency runs to 10 kilohertz and marks the upper extent of both the neurophysiological and the health effects as an "Unknown boundary." The proposition that this effect reaches into the kilohertz range is therefore not the Foundation's inference from one experiment. It is the stated position of the people who write the recommended practice, and they draw from it a conclusion about design: "The electrical design of power supplies, drivers and dimmers should minimize the occurrence of undesired effects of temporal light modulation in this wide frequency range."

On the international document the review supplies something the experiment could not. The experiment tested the threshold function of CIE 249:2022 against measurement and found it

unsupported. The review states why that result was available to be found: the report "contains a tentative visibility model which has not been experimentally validated yet." And of the field as a whole, as of the review's writing, "There is currently no metric to quantify the visibility threshold or the sensitivity function to the phantom array effect." The Foundation notes that these two papers appeared in the same year and that the measure the experiment endorses was published in a recommended practice of 2024. What is not in doubt is that the only model in an international document had not been validated against experiment, and that when it was tested it failed.

The review also reports thresholds from experimental work the Foundation has not obtained, and they are far below anything in the American framework. At 600 hertz the threshold modulation depth for a sine wave was "7% for a white-light stimulus observed in dark conditions" and "about 3%" for a red-light stimulus in dark conditions. The effect was significant down to 80 hertz, where the threshold was 10 percent for red light against 35 percent for white. The Foundation does not rely on these figures.

Finally, the review names where the effect is met, and the Foundation quotes it because the naming is done by the industry rather than by this commenter: "In real-life application, the phantom array is best seen in indoor and outdoor luminaires (and displays) using PWM dimming at low illuminance levels. It is also noticeable in automotive headlights and rear lights." Outdoor luminaires at low illuminance, displays, automotive headlights and rear lights. Those are the products at Part VI.D, Part VI.E and Part VI.F. On waveform it corroborates the experiment: "The effect is more visible under rectangular versus sinusoidal TLM and when duty cycles are low (typically 10% or 30%, versus 50%)".

Whose response a limit should be built on, and what the same author says should be done in the meantime

The first author of that experiment published a letter in the same journal in the same year, described at Appendix D.7. The Foundation states its character before using it: it is correspondence, not research, its substance is reports made to the author by members of the public, and nothing in it is cited here as evidence that modulation causes any symptom. It is cited for two statements the author makes in her own voice.

The first concerns the structure of every instrument described in this Part. Having reported the finding that sensitivity differs with history of migraine, she writes this.

> "The significance of this is perhaps average response of a population is an inadequate target for establishing a flicker metric. Perhaps we should address the 15% of the population that gets migraines instead. Or, should we focus on the very sensitive few that are almost completely debilitated by this issue?"

That is the question this comment puts at Part VII, asked by the author of the measure the recommended practice adopted. The Foundation notes that the prevalence figure is given without a citation in the letter and is therefore presented here as the author's, and that the three candidate targets she names are a question and not a recommendation. What the passage establishes is narrower than an answer and sufficient for this comment: the choice of the population whose response fixes a threshold is a choice, it has not been made deliberately, and the specialist best placed to make it says the conventional choice may be inadequate.

The second statement concerns what should be done before the research is complete. The Foundation quotes the passage whole, including the half that tells against regulation, because an agency reading a selective quotation would be right to discount everything around it.

> "We need to know what populations experience these discomforting or disabling responses, how many people this represents, what characteristics of the TLM waveform are responsible for the problematic symptoms, and the mechanism by which the eye/brain system is affected. We need it soon if we are to avoid imposing limits on the manufacturing of products which are

> cost-effective, efficient, useful, fun and even inspiring. In the meantime, the responsible action is to reduce TLM in electric light sources to ensure fewer people are affected by them."

The Foundation reads that passage as it is written. The author hopes that research will make limits on manufacturing unnecessary, and she says so. She nevertheless states that the responsible action in the meantime is to reduce modulation. The Foundation asks the Department to weigh the second sentence at its full value and not to discount it on account of the first: a researcher who would prefer that her field avoid regulation, and who says so in print, has no interest in overstating the case for acting before the mechanism is known. That she states the interim duty anyway is the reason the Foundation quotes her.

Two further reports from the neurophysiological literature, both given with their weight

The review at Appendix C.96 reports two findings that bear on this subsection, and the Foundation gives them with the limits their own authors place on them, because neither is strong and the comment does not need them to be.

The first concerns the upper bound. Having given the ordinary critical fusion threshold as 50 to 90 hertz, and having noted a report of discrimination at 500 hertz which its authors explain by saccadic eye movement, the review states that "there have been reports that a stroboscopic effect can occur even with the light flickering at more than 1000 Hz if objects in the rest of the visual field are moving". The condition in that sentence is the whole of its interest. The effect is reported not for a stationary observer viewing a stationary scene, which is the condition under which flicker is assessed, but for a visual field containing movement, which is the condition of every road, workplace and public space in Part VI.

The second concerns whether modulation that is not seen is therefore without effect, which is the proposition on which a perception-based criterion depends. The review states:

> "There is limited evidence that the visual cortex responds to a flickering stimulus, not only when the flickering is perceivable, but also when the stimulus seem to be steady."

The Foundation reproduces the hedge as well as the claim. The review calls the evidence limited, says of the functional imaging study it rests on that few healthy subjects participated, and the Foundation has not read that study. What the sentence establishes is not that unperceived modulation has effects. It is that the question has been asked in the neurophysiological literature, that the answer presently available points toward a cortical response to modulation perceived as steady, and that the evidence is thin. That is a reason for the research directed by paragraph 360ii(a)(2), and the Foundation advances it as nothing more.

One caution from the same review belongs here rather than being left for a reader to supply. Its authors report a conclusion that critical flicker fusion "has limited value as a clinical measurement", because the threshold depends on both the gain of the visual system and its processing speed and does not separate them. Wherever this comment uses a fusion frequency, including in the ecological collation at Part V.I, that limit applies.

The upper bound, from the clinical review

The Epilepsy Foundation review described at Appendix C.98 states the upper frequency bound for this phenomenon in a single sentence, in the section it devotes to light-emitting diodes:

> "Frequencies up to 11 kHz generate a visible pattern on the retina when a saccade is made across a flickering LED, and this pattern is more visible to individuals who complain of eye strain."

Two features of that sentence bear on this subsection and on Part V.D.1. The figure is eleven kilohertz, against a measurement standard whose stated range reaches three kilohertz and commercially available instruments specified to five. A modulation that produces a visible retinal

pattern at eleven kilohertz is a modulation that no instrument in ordinary use can detect and no standard in existence addresses. And the association is with eye strain: the pattern is more visible to the people who report the symptom, which is the population Part V.D.5 and Part VII concern.

The Foundation records what the sentence is and is not. It is a statement in a review, carrying one citation, and the Foundation has not read the underlying study. It is nonetheless the highest frequency at which any document before the Foundation reports a visible effect of modulation, and it comes from the body whose criteria this comment otherwise applies.

One further matter belongs here and is developed at Part V.E.7. The phenomena described in this subsection are all effects occurring while the modulation is present. There is evidence, in an animal model and with the underlying cortical response reported in humans, that a flash produces cortical activity persisting for seconds after it has ended. If that is so for the products in Part VI, a lamp flashing more than twice a second is delivering each flash into the response evoked by the one before it. The Foundation does not assert a consequence. It observes that the measurement standards described in this Part characterize a waveform and that no criterion anywhere in them contemplates a response that outlasts the stimulus producing it.

3. IEEE 1789-2015 recommended practices and their status

Appendix D.2 sets out IEEE Std 1789-2015 in full. This subsection states what it recommends, what it excludes, what has become of it, and what follows for this Department. The Foundation treats it at length for a reason it states plainly: it is the only document in existence that attaches a number to the temporal characteristic of a light-emitting diode product, and the comment's argument at Part V.B is that each of the three emission characteristics needs one.

The present status of the document, which changed while this comment was being prepared

Two things about what this document is, and one about what has become of it.

It is a recommended practice and not a standard, and its title says so: IEEE Recommended Practices for Modulating Current in High-Brightness LEDs for Mitigating Health Risks to Viewers, published June 5, 2015. Nothing in it binds anybody and the Foundation has never suggested otherwise. Recommended Practice 3 is drafted as an obligation within the document, which is a different thing from being an obligation at law.

And the publishing body has stopped maintaining it. Its record for this document gives the status as inactive-reserved, with an inactivation date of March 26, 2026. The Foundation states what that does and does not mean so far as it has established it. An inactive designation does not withdraw a document or declare it wrong. It means the body is no longer maintaining it. The recommendations are unchanged, the reasoning is unchanged, and the research the drafters relied on is unchanged. What has lapsed is the maintenance.

The Foundation does not conceal that this cuts against it in one respect, and states the objection in its strongest form before answering it. This comment relies on this document in forty-two of its paragraphs, more than on any other single instrument, and an opponent is entitled to say that a document whose own body has ceased to maintain it is a thin foundation on which to ask for a federal standard. The Foundation agrees that it is a thin foundation. That is the point of this comment.

Because of what this document was carrying. As the opening of this subsection records, it is the only document in existence that attaches a number to the temporal characteristic of a light-emitting diode product, and Part V.B establishes that each of the three emission characteristics needs one while the other two have none. So the position as of March 2026 is this. The single numerical limit anywhere, addressed on health grounds to the temporal modulation of these products, is a voluntary recommendation which the body that wrote it has ceased to maintain, and the Foundation has identified no successor.

The Foundation asks the Department to read that as the answer to the objection this comment meets most often, which is that the voluntary consensus system is the proper place for these questions and that federal action is premature. Part I.C and Part II.E treat that objection generally. Here is the particular. The voluntary system's one numerical health limit for this characteristic lapsed into inactive status in March 2026, seven months before this comment was filed, with nothing in its place. A system which produced one such limit in its history and has stopped maintaining that one is not a system to which a health agency can defer. Part IX.I asks for a standard under § 360kk. This is why the asking cannot wait on the consensus bodies.

It is also an instance of the duty at paragraph 360ii(a)(3), which directs the Secretary to maintain liaison with and receive information from other agencies, professional organizations and standards bodies, and which Part II.E develops. The inactivation of the only health-based numerical limit on any emission characteristic of these products is precisely the kind of information that paragraph contemplates being received. The Foundation has identified no record that this Department is aware of it.

What it recommends

The regulated quantity is modulation, defined as 100 times the difference between maximum and minimum luminance divided by their sum. A source that goes fully dark between pulses has a modulation of 100 percent whatever its peak luminance. Three practices are given, in ascending stringency, and the third is different in kind from the other two.

Recommended Practice 1, for limited biological effects: below 90 Hz, modulation less than 0.025 times the frequency.

Recommended Practice 2, the no-observable-effect level: below 90 Hz, modulation less than 0.01 times the frequency.

Recommended Practice 3, seizure prevention: "For any lighting source, under all operating scenarios, flicker Modulation (%) shall satisfy the following goal: Below 90 Hz, Modulation (%) is less than 5%."

The first two begin with the words "If it is desired." The third does not, and the document explains why: it "is a strict rule for seizure prevention and should be adhered to at all times for all operating conditions." Its terms are any lighting source, all operating scenarios, and shall. Within a body of recommendations it is the one provision drafted as an obligation.

What it excludes, and why that matters here

The document is confined to the temporal characteristic and says so. Clause 7 provides that "Other possible negative lighting features, including those associated with wavelength (e.g., blue light hazard, ultraviolet), glare, and periodic arrays or patterns of lights are not considered."

The Foundation asks the Department to read that against the three emission characteristics identified at the opening of Part V.B. The spatial characteristic has no federal limit and is excluded here. The spectral characteristic has no federal limit and is excluded here. The temporal characteristic has no federal limit either, and the one document that quantifies it is a voluntary recommended practice of a professional institution which disclaims the other two. That is not a criticism of the institution, which confined itself to its subject. It is a description of the regulatory position: there is no instrument before this Department, binding or voluntary, that addresses all three, and the only one that addresses any of them quantitatively binds no one.

Three further features of its construction bear on the rest of this Part. The recommendations are independent of luminance, of spectral content and of exposure duration, the document reasoning that exposure duration is rarely controlled in practice and should in general be regarded as prolonged; so a brief exposure is not exempt under this framework. They apply to the entire light source and not to the modulation of a single emitter within it, which is the question Part V.J.3 raises about composite waveforms and which Part V.D.4 applies. And they are deliberately not

application-specific, because the drafters assumed that the flicker characteristics of future products would be uncontrolled and that nearly the whole United States population would be exposed to a potentially hazardous condition at least once in a year.

The sentence the Department should notice

The purpose clause of the document opens as follows: “Presently, there are no standards on safe modulating frequencies for high-brightness LEDs.” That was published on 26 March 2015. A working group of the IEEE Power Electronics Society, convened in December 2008 and reporting seven years later, recorded that no standard existed, assembled a formal risk assessment on the model used by government product-safety bodies, and published the numbers a standard would need. Eleven years after that, the sentence is still true, and the numbers are still voluntary. Part IX.B asks the Department to say at what modulation depth and frequency a light-emitting diode product ceases to be safe. One answer has been on the public record since 2015 and has never been adopted by anyone with the authority to make it binding.

What the drafters said they were concerned about, five years before the standard issued

The working group that produced this standard published an account of its own concerns in 2010, described at Appendix D.6. Its authors were Arnold Wilkins of the University of Essex, Jennifer Veitch of the National Research Council of Canada and Brad Lehman of Northeastern University, and it states that it summarizes a public report of the PAR1789 group and represents that group’s ongoing work. The Foundation sets out what it says because a standard is better understood against the account its drafters gave of the problem, and because this one is now old enough to be read against what the same people published fourteen years later.

The Foundation states the authors’ disclaimers first, because they are emphatic and because the rest is worth nothing if they are concealed. “This report does not attempt to make recommendations on safe flicker frequencies or modulation depths for LED lighting”. “This report endorses no technology for driving LED lamps”. And in its conclusions: “This paper assigns no health risk to the biological effects of flicker in the various LED lamps. The hope is that by discussing the issue of flicker within the power electronic community, it will be possible to decide as a community whether or not standards or recommended practices are necessary. We do not attempt to do so here”. In 2010 the drafters of this instrument were expressly not recommending that anything be required of anyone.

The distinction on which the standard rests

The document defines visible flicker as that “consciously perceivable by a human viewer” and invisible flicker as that which is not, and divides the health account accordingly: effects that are “the immediate result of a few seconds’ exposure, such as epileptic seizures”, associated with visible flicker at about 3 to about 70 hertz, and effects that are “the less obvious result of long-term exposure, such as malaise, headaches and impaired visual performance”, associated with modulation above the frequency at which flicker can be seen. The second of the four contributions the paper claims for itself is “Human biological effects due to invisible flicker at frequencies below ~165Hz”.

That proposition is the one this comment has most needed a source for, and the Foundation now states it in the drafters’ own words rather than its own. On the retina: “Measurements of the electroretinogram have indicated that modulation of light in the frequency range 100-160Hz and even up to 200 Hz is resolved by the human retina although the flicker is too rapid to be seen”. On the brain, in an animal model: modulation at 100 and 120 hertz was shown “to cause the phase-locked firing of cells in the lateral geniculate nucleus of the thalamus, part of the brain with short neural chains to the superior colliculus, a body that controls eye movements”. And in healthy people, two minutes of exposure to flicker about 20 percent above an observer’s fusion frequency produced a measurable loss of sensitivity to visible flicker afterward.

The Foundation is careful about the verb. The retina resolving a modulation is an electrophysiological measurement, not an injury, and the drafters do not say otherwise. What the sequence establishes is that light modulated too fast to be seen is nevertheless registered by the retina, reaches the thalamus in an animal model at the frequencies at which mains-driven lamps modulate, and changes visual sensitivity in healthy observers after two minutes. Whether the endpoint is adverse is the next question, and the drafters answer it with one study.

The one human health result, with its dose and its caveat

> “Under double-masked conditions the 100Hz modulation of light from fluorescent lamps has been shown to double the average incidence of headaches in office workers, although this effect is attributable to a minority that is particularly affected”.

And the dose: “The peak-trough modulation depth known to induce headaches from fluorescent lighting at 100Hz is about 35%”. So the drafters of this standard had, in 2010, a masked study reporting a doubling of headache incidence at a stated frequency and a stated modulation depth, and they recorded that the effect was carried by a minority. The Foundation asks the Department to hold the second clause beside the passage at Appendix D.7, in which the author of the 2024 measure asks whether the average response of a population is an adequate target at all. The observation is the same observation, fourteen years apart.

What the drafters said about this technology specifically

Their health account is largely of fluorescent lighting and displays, because that is where the literature stood in 2010, and the Foundation says so rather than implying a body of light-emitting diode research that did not exist. On this technology the drafters made one comparison and it is the one that matters: “LEDs driven so that they flicker at a frequency twice that of the AC supply may have a depth of modulation greater than that from most fluorescent lamps. The effects of the flicker are therefore likely to be more pronounced in these cases”. That is not a claim that the technology introduced a new hazard. It is a claim about degree at the same frequency, made by the authors of the standard, and it is the form of argument the Foundation adopts at Part V.B.9.

They also set out how a lamp that modulates invisibly comes to modulate in the seizure range, which is a failure analysis rather than a health claim and which the Foundation regards as the most actionable material in the document. Of the two common drive topologies, each modulating at twice line frequency when working, they write that “there is risk of failure that can cause LED current modulation at AC line frequency, thereby entering the range of frequencies that may induce photosensitive epilepsy”. A single open-circuit failure in one leg of a rectifier bridge does it. So does an open circuit in one of two anti-parallel strings. So, partially, does uneven aging: a 50 percent rise in one string’s resistance gives a 60 hertz component amounting to “over 33% of the DC component”. And they report a measurement: a commercial lamp of 64 red, green and blue emitters, connected to an ordinary residential dimmer, flickering at an average of 3.153 hertz, which “is in the range that has been shown to be a risk for causing photosensitive epileptic seizures”.

That the remedies were available in 2010 and were described as easy

The drafters identified two, and the Foundation quotes them because Part IX turns on whether a remedy is technically available. On dimming: there are “alternative approaches to dimming, such as amplitude dimming, in which the current through the LED is continuous and not pulsing”, and that approach “does not use flicker to adjust brightness and therefore, should not induce flicker related health risks”. On failure: “it is not difficult to create shut-down or other safety prevention circuits that prevent flickering in the 3Hz-70Hz range when the lamp is in failure mode”.

The Foundation draws no conclusion about any manufacturer from those two sentences and asks the Department to draw one about the regulatory position. In 2010 the people writing the American recommended practice stated that a dimming method without flicker exists, and that a circuit preventing failure-mode flicker in the seizure band is not difficult to build. Sixteen years

later the instrument they produced binds no one, pulse-width modulation remains the dimming method in general use as Part V.D.1 establishes, and no performance standard under 21 U.S.C. § 360kk addresses any of it.

Two things in the document that run against this comment

The Foundation records both. The first concerns geometry: "Point sources of light are less likely to induce seizures and headaches than a diffuse source of light that covers most of a person's field of vision", from which the drafters conclude that general lighting is more likely to be hazardous in this respect than an instrument panel. That is not a contradiction of Part V.B.8, where the concern is retinal irradiance from a small bright source rather than the cortical representation of a stimulated area, but the two must not be conflated and the comment does not argue that a small source is worse for every purpose. The second concerns natural light: the first row of the drafters' own table attributes seizures, on clinical histories, to "Sunlight through roadside trees or reflected from waves". Flicker capable of provoking a seizure is not peculiar to artificial sources, and the Foundation has never contended otherwise.

4. Flicker in vehicle lamps, warning beacons, and displays

The three preceding subsections concern modulation that nobody wants. Flicker from a switching driver is an artifact of the electronics, and the engineering question is how to suppress it. This subsection concerns the products in which modulation is the purpose. A warning beacon is built to flash, and the flashing is not a defect to be minimized but the function the purchaser is paying for. The Foundation sets this class apart because the regulatory consequence is different: where modulation is intended, no one has an incentive to reduce it, and the only thing that would limit it is a limit.

What the federal position is

For lamps on motor vehicles, Federal Motor Vehicle Safety Standard No. 108 specifies luminous intensity in candela at defined angular test points. Part II.E.5 and Part VI.B set out what it does and does not contain. It carries no limit on the luminance of the emitting surface, no spectral requirement, and no limit on temporal modulation. The Foundation notes that this is the only federal standard setting numerical limits on the output of any product this comment concerns, and that the quantity it limits is not one of the three identified at Part V.B as bearing on the biological response.

For warning beacons in the public way, the governing instrument is not a federal standard at all. It is the Manual on Uniform Traffic Control Devices, which States adopt or amend, and which is addressed to the uniformity of traffic control rather than to the exposure of persons. Part II.E.6 describes the agency that publishes it and the answer that agency gave when asked about health effects.

What the instrument prescribes, counted

The Foundation takes the rectangular rapid-flashing beacon as its worked example, because its operating pattern is prescribed element by element and can therefore be examined without measurement. Chapter 4L of the California Manual on Uniform Traffic Control Devices, Section 4L.03, provides at Standard 07 that within each 800-millisecond flashing sequence the left indication is illuminated for approximately 50 milliseconds; both indications are dark for approximately 50; the right is illuminated for 50; both dark for 50; the left illuminated for 50; both dark for 50; the right illuminated for 50; both dark for 50; both illuminated for 50; both dark for 50; both illuminated for 50; and both dark for approximately 250 milliseconds. Standard 06 provides that the device shall provide 75 flashing sequences per minute. Standard 08 provides that the flash rate "shall not be more than 5 flashes per second, to avoid frequencies that might cause seizures."

Counting the illuminations that sequence prescribes:

The left indication is illuminated four times per sequence, at elements A, E, I and K. Four illuminations in 800 milliseconds is exactly 5.0 per second.

The right indication is illuminated four times per sequence, at elements C, G, I and K. Again exactly 5.0 per second.

Across the assembly there are six illumination events per sequence, at elements A, C, E, G, I and K, which is 7.5 per second.

Two observations follow, and the Foundation states them separately because they are of different kinds. The first requires no assumption: the pattern the standard prescribes delivers, per indication, exactly the maximum the standard permits. There is no margin at all between the normal operating pattern of the device and the ceiling the standard sets for the stated purpose of avoiding frequencies that might cause seizures. The second requires a convention: whether the governing rate is the 5.0 per second of each indication or the 7.5 per second of the assembly depends on whether the pair is treated as one source or two, and the Manual does not say.

The convention the technical literature supplies, and the quantity the Manual omits

On the first question IEEE Std 1789-2015 is explicit. Clause 8.1.1.3 provides that its recommended practices "describe the boundary functions of operation for the entire LED light source and not for the individual modulation of a single LED within the light source." On that convention the assembly is the unit and the rate is 7.5 per second, above the ceiling the Manual sets. Part V.J.3 raises the same question in its general form for arrays of independently driven emitters.

The second point is larger and the Foundation asks the Department to weigh it beyond this one device. The Manual limits flash rate. It states no limit on modulation depth. IEEE Std 1789 limits modulation depth as a function of frequency and states no limit on rate as such. Modulation is defined in that document as 100 times the difference between maximum and minimum luminance divided by their sum, so a source that extinguishes completely between pulses has a modulation of 100 percent whatever its peak luminance. The prescribed sequence above extinguishes completely, for intervals of 50 and 250 milliseconds.

The consequence is a proposition about regulatory design rather than about this product. A device may satisfy a frequency ceiling exactly while operating at the maximum possible value of the quantity the frequency ceiling was adopted to control. Limiting one parameter of a modulated emission, while leaving the parameter that determines its magnitude unconstrained, does not constrain the exposure. That is the same structure the Foundation identifies at Part V.B.1 for photometric limits that leave radiance free, and at Part V.C.4 for intensity limits that leave luminance free. It recurs because the instruments were each written to control one variable for a purpose that was not photobiological.

The comparison the Foundation draws, and the limit of it

Recommended Practice 3 of IEEE Std 1789-2015 provides: "For any lighting source, under all operating scenarios, flicker Modulation (%) shall satisfy the following goal: Below 90 Hz, Modulation (%) is less than 5%." Appendix D.2 sets out why that provision is differently drafted from the rest of the document and is described by its authors as a strict rule for seizure prevention to be adhered to at all times for all operating conditions.

Read according to its terms, and taking the prescribed pattern above, the device operates below 90 Hz at a modulation of 100 percent, which is twenty times that figure. Against Recommended Practice 1 the ratio is of the order of eight hundred, and against the no-observable-effect level of Recommended Practice 2 of the order of two thousand. The Foundation sets out the arithmetic so that it can be checked rather than taken on trust.

The Foundation states the objection to that comparison itself, because it is a real one and the comment is worth less if the Department has to find it. The stated scope of IEEE Std 1789 is LED lighting and dimming applications. It addresses flicker as an artifact of driving electronics in

illumination products, and the Foundation does not assert that its drafters had signaling devices in view; nothing in the document suggests they did. Recommended Practice 3 is nonetheless drafted in terms of any lighting source and all operating scenarios, and the document's own explanation of why it declined to write application-specific practices was that the flicker characteristics of products then unbuilt could not be anticipated.

The Foundation therefore does not assert that these devices contravene IEEE Std 1789, which binds no one and which may never have been meant to reach them. It asserts something narrower and, it submits, more useful to this Department. The only document in the United States that attaches a number to modulation depth for seizure prevention sets that number at five percent below 90 Hz. Devices are installed in the public way, by public agencies, which operate at one hundred percent below 90 Hz. Whether the first figure ought to govern the second is a question of scope that no federal body has considered, because no federal body has taken responsibility for the question. Part II.E.6 records the answer the agency that approves these devices gave when it was asked. Part IX.B asks this Department to supply the figure that is missing.

Displays

The third class named in this subsection is treated elsewhere and is identified here so that the heading is not misleading. Dynamic message signs and billboards are at Part VI.J. Displays inside vehicles are the one class of modulated emitter in the transportation environment that is subject to a quantified federal attention protocol, which is described at Part V.E.1 together with the asymmetry it creates.

A report concerning these lamps, and the frequencies measured in them

The Foundation records one further item under this heading and states its status first. The document at Appendix D.7 is a letter to a journal, not research, and the accounts in it are reports made to its author by members of the public. It is recorded here for two things: an account that concerns the lamps this subsection addresses, and a measurement the author reports making herself.

The account is of a person who reported difficulty crossing streets safely at night, attributed to automotive tail lights, daytime running lights and marker lights which he described as switching fully on and off two hundred times a second and producing "a repeating retinal pattern that produces a deceptive impression of where the vehicle is and what direction it is moving." The author adds that it makes him disoriented and that he fears for his safety. The Foundation does not advance that account as evidence of anything and the frequency in it is the correspondent's estimate, not a measurement. It is recorded because of what it alleges, which is not discomfort but misperception of the position and heading of a vehicle by a pedestrian at night. If modulation of a vehicle lamp can do that, the consequence is a collision rather than a headache, and the agency with jurisdiction over the lamp is the one this comment addresses at Part I.

The measurement is the author's own and concerns a different correspondent, who reported seizures and named bus tail lights, aircraft cabin lighting, and dashboard and instrument lighting. Of those products the author writes: "Having measured them, I know the frequency can range from 120 Hz up to over 840 Hz, and they use pulse-width modulation (PWM) to control LED output. Seizures are not supposed to happen from those high frequencies. I used to discount these incidents. I do not anymore, although I still think they are rare."

Two things follow and the Foundation separates them by how much they rest on. The first is a measured fact about products in service: lamps of these classes are driven by pulse-width modulation at frequencies from 120 hertz to above 840 hertz. That is squarely within the range in which Part V.D.2 establishes the phantom array effect to be visible, and above the range the standard laboratory method was written to cover for other purposes. The second rests only on the author's own account of her reasoning: a specialist who holds that seizures are not expected at those frequencies, and who measured the products, nevertheless stopped discounting the reports.

The Foundation does not convert that into a claim that these lamps provoke seizures, and the letter does not either.

5. Interference with clinical measurement

The subsections above concern what modulated light does to a person who sees it. This one concerns something different in kind, and the Foundation gives it a heading of its own for that reason. Modulated light from one regulated product can corrupt the reading of another regulated product, and where that second product is a clinical instrument the harm reaches the patient through the treatment decision rather than through the eye. The Foundation raises it in this comment because both products are within the authority the Department exercises: the instrument as a medical device, and the lamp as an electronic product that emits optical radiation.

The event

The peer-reviewed report described at Appendix C.92 arose from an event in a neonatal intensive care unit. An infant, intubated and with ventilation well established, would not according to the monitor reach a saturation above 90 percent, and the fraction of inspired oxygen was being increased by a closed-loop controller in response. The authors report what happened next.

> "Surprisingly, an abrupt increase in the recorded saturation occurred when the examination LED (light-emitting diode) lamp … was switched off. Within seconds, the monitor indicated 100% saturation, and the FiO_2 was reduced to ambient air. Each time the lamp illuminated the infant, a similar drop in oxygen saturation (SpO_2) could be observed."

The sensor was never in the lamp's central beam and was lit only by scattered light. The effect was reproduced by putting another person's instrumented finger in that stray light, and it stopped when the sensor was covered. The authors draw the conclusion that matters for the scope of this comment: "The effect disappeared when an opaque shield was placed over the sensor. This indicated that the interference was caused by light and not electromagnetic interference."

The Foundation asks the Department to notice what was then done and what came of it. "For clarification, the occurrence was brought to the attention of all manufacturers involved. Neither the manufacturers, nor a review of scientific literature could provide an explanation for this phenomenon." The manufacturers of the monitor, the oximetry module, the oxygen controller and the lamp were told, and none could say why it happened.

What was measured, and what was modeled

The lamp was measured. It operates by pulse-width modulation at 207 hertz, with a compact flicker degree of 63.9 percent undimmed and 80.1 percent fully dimmed, emitting light for only 37 percent of the time undimmed and 13 percent fully dimmed. The Foundation records the direction of that result because it is counter-intuitive and bears on Part V.D.1: dimming the lamp made its flicker worse and cut its duty cycle to about one part in eight.

The mechanism was modeled rather than measured, and the Foundation keeps the distinction. A pulse oximeter alternates red and infrared emission with a dark measurement between each, and subtracts the dark measurement to cancel ambient light. That works on an assumption the authors state plainly: "Assuming the ambient light to be constant at least during the measurement cycle, this will eliminate the disturbance of the ambient light in the measurements of the red (infrared) signal. Ambient LED light, on the other hand, is not constant and therefore will not be eliminated by subtraction of the dark measurements, and can subsequently induce a stroboscopic effect." The instrument's cycle repeats 311.25 times a second, which the authors note is almost exactly one and a half times the lamp's modulation frequency.

In the model, a distortion of one tenth of the constant component of the signal produced a reported saturation of 85 percent, which then stopped falling however much the interference increased, and a reported pulse of 108 beats per minute against a true rate of 140. The error

depends on the frequency relationship and not on the light alone: at a sampling rate of 300 hertz the same distortion gave 96 percent instead of 85.

Why the false reading is dangerous, which is not because it is large

A saturation of 85 percent and a pulse of 108 are both unremarkable values in a newborn. That is the point. Of the erroneous pulse rate the authors write that it "corresponds to a plausible heart rate for neonatal patients. This pulse curve can be interpreted by the pulse oximeter as a valid measurement, particularly when the interference already existed at the beginning of each measurement. The incorrect pulse frequency therefore does not represent a warning signal for an incorrect measurement." The instrument does not know it is wrong, the number it reports is clinically ordinary, and nothing on the monitor indicates an artifact.

In the event that prompted the study, the value was not merely being read. It was being acted on by a closed-loop controller raising the oxygen automatically. The consequence the authors identify follows from that: "Erroneously low saturation levels can lead to unnecessary increases in oxygen administration, which increases the risk of retinopathy in preterm infants", and in the abstract, that the effect "can lead to the risk of blindness in premature infants due to excessive oxygenation." The Foundation states what this is and is not. No infant is reported to have been harmed, and the Foundation asserts no injury. What is reported is a mechanism by which a modulated lamp can cause an automated system to administer more oxygen to a premature infant than the infant needs, and the harm at the end of that pathway is a recognized one.

What the Foundation does not take from this paper

The authors do not claim the interference is peculiar to this technology, and the Foundation will not claim it either. "It can therefore be assumed that such phantom signals can be caused by any flickering light source. Both incandescent bulbs and fluorescent tubes flicker during standard operation with alternating current. Consequently, these light sources can also cause the interference signal we have shown." The proposition the Foundation advances is the narrow one the paper supports: the lamp that produced this event is a light-emitting diode lamp driven by pulse-width modulation at 207 hertz and emitting for 37 percent of the time, and the authors attribute the interference to that modulation. Part V.D.1 sets out why full-depth modulation is a property of the dimming method in general use rather than a defect of a particular driver.

Nor does the paper establish how often this happens. It reports one event, one informal reproduction, one lamp and one instrument, and its mechanism is a model with limitations the authors state. The Foundation relies on it for the existence of the pathway and not for its frequency.

The exclusion, and the question it puts to this Department

The last finding is the one the Foundation asks the Department to weigh longest, because it is about regulatory design rather than about physics.

> "There are EU regulations in place for the use of indoor lighting, which prohibit strong flickering light at the frequency of the lamps we tested. However, medical lamps, with their specific requirements such as spot brightness and color fidelity as essential diagnostic features, are excluded from these regulations. This should be fundamentally questioned, as the technical effort to produce flicker-free LED lamps seems manageable."

The instrument referred to is Commission Regulation (EU) 2019/2020, which Part V.D.1 identifies as the source of the only binding numerical limit on temporal light modulation that this comment has found anywhere. A lamp flickering as this one does would not be permitted in a European office. It is permitted over a neonatal incubator, because medical lamps are carved out of the regulation on the ground that brightness and color fidelity are essential to their diagnostic function. The specialists who found the problem say that exclusion should be fundamentally questioned, and they say the remedy is not technically difficult.

The Foundation makes two observations and asks one question. The first observation is that the European exclusion was presumably drafted on the assumption that the only thing flicker does is annoy people who see it, so that a lamp used for a few minutes by a clinician was not worth constraining. This paper identifies a consequence the exclusion cannot have contemplated, because the people who built the instrument it interferes with could not explain the interference when it was reported to them. The second is that the United States has no corresponding limit at all, so it has no exclusion either, and the absence of a requirement is not an improvement on an imperfect one.

The question is one of jurisdiction, and the Foundation puts it plainly because the answer is within this Department. A pulse oximeter is a medical device, cleared by the Food and Drug Administration, and its performance is the subject of that agency's attention. An examination lamp is an electronic product that emits optical radiation, and 21 U.S.C. § 360ii directs the Secretary to establish and carry out an electronic product radiation control program, while 21 U.S.C. § 360kk provides the authority to prescribe performance standards for such products. Both products are therefore within one Department. No requirement known to the Foundation connects them. No performance standard limits the modulation of the lamp, and the Foundation has not established whether any standard requires the instrument to be immune to modulated light. The Department is better placed than this commenter to answer the second half of that, and the Foundation asks it to do so.

E. Neurological and Photosensitive Responses

This subsection concerns responses mediated by the nervous system rather than by photochemical or thermal injury to tissue. The distinction matters because the exposure limits described at Part V.C.2 are constructed for injury, and none of the responses described here is an injury in that sense. They are responses of an intact nervous system to a stimulus it processes as noxious.

The Foundation separates three classes of response, and states the separation before describing any of them, because they are not the same phenomenon and the comment does not treat them as one.

Photosensitive epilepsy, at paragraph 1 below. A seizure is a discrete pathological event, it occurs in a small and identifiable fraction of the population, and the flash rates and spatial conditions that provoke it have been characterized and are the subject of published guidance.

Light-induced pain and photophobia, at paragraphs 2 and 4 below. This is a nociceptive response conveyed by the trigeminal system. It is not a seizure, it does not become one, and the population in which it occurs is different in kind and far larger.

Sensory processing differences, at paragraph 3 below. These concern how a stimulus is integrated rather than whether it provokes pain or a seizure.

The Foundation does not contend that these are one phenomenon, does not contend that a product capable of provoking one is for that reason capable of provoking another, and does not use evidence drawn from one to support a proposition about another. Where this Part relies on a study, it states which of the three the study addressed. The Foundation asks the Department to hold it to that.

What the three have in common is narrower, and it is the only thing the comment draws from the grouping. None of them is a photochemical injury. None of them is reached by any exposure limit in the international guidance described at Part V.C.2, which is constructed to prevent retinal injury and makes no provision for pain, discomfort or seizure at exposures below the injury threshold. And none of them is addressed by any federal performance standard for any light-emitting product, as Part II establishes. A limit set to prevent injury does not become a limit against pain merely because pain occurs at lower exposures than injury does.

1. Photosensitive epilepsy and flash-rate thresholds

This subsection concerns the one effect of artificial light on the nervous system that is not in dispute. That flashing light can precipitate a seizure in a susceptible person is established, is quantified, and is already the subject of numerical limits in five sets of guidelines and in at least one federal regulation of the United States. The Foundation therefore does not argue in this subsection that a hazard exists. It argues about where the limits apply and where they do not.

The condition, and the population that has not been counted

The analysis at Appendix C.81, funded by two components of this Department and published in 2024, supplies the figures the Foundation relies on. Photosensitive epilepsy is estimated at one person in four thousand. The proportion of the general population who might exhibit a photoparoxysmal response on testing is estimated more widely, at between 0.3 and 8 percent, though not all of those people have the condition. Photosensitivity is one and a half to two times more common in females than in males. It is most common between the ages of eight and twenty-five, with a mean age of onset of fourteen and declining incidence after twenty. Most people do not outgrow it: one study found 70 percent still photosensitive at long-term follow-up.

One further statement in that analysis bears on the argument the Foundation makes elsewhere in this comment about the absence of reporting. Its authors observe that it is uncommon to screen for photosensitivity, and that there is therefore an unknown population of people at risk who have not yet had a seizure or received a diagnosis. They call it the latent population. That is the same structure as the objection at Part I.C.7: a harm is not counted where no mechanism exists to identify the people subject to it, and the absence of counted harm is then read as evidence of safety.

The mechanism, as that analysis describes it, engages two of the three emission characteristics set out at the opening of Part V.B simultaneously. To precipitate a seizure a critical population of neurons in the visual cortex must be stimulated, and the area of brain involved corresponds to the area of the visual field stimulated, so that a larger illuminated area recruits a larger area of cortex. That is the spatial characteristic. And the activity of those neurons must be sufficiently rhythmic and synchronized, which is set up by regular flashing, flicker, oscillation or phase reversal. That is the temporal characteristic. Neither alone is sufficient.

The thresholds, which exist and are numerical

Five sets of guidelines limit flashing content, developed since the mid-1990s: the United Kingdom guidance, the Japanese broadcasters' joint guidance, ISO 9241-391, the International Telecommunication Union guidance, and the World Wide Web Consortium's Web Content Accessibility Guidelines. Appendix D.2 catalogues them. The thresholds they apply are close to one another and, for standard dynamic range content, substantially the same.

A general flash, in which the two states differ by more than 20 candelas per square meter, is treated as potentially hazardous if the darker state is below 160 candelas per square meter.

The more conservative of the two Web Content Accessibility Guidelines criteria prohibits any flashing more than three times per second, without reference to luminance or area.

Of people who would respond to maximal black-to-white flashing, an estimated 7 percent may still be at risk at a luminance change of 20 candelas per square meter, which is why that figure rather than a larger one was chosen.

The Foundation draws attention to the form of those limits rather than to their values. A limit on the magnitude of a luminance change, a limit on the rate at which that change may repeat, and a limit on the proportion of the field of view it may occupy are precisely the three quantities a performance standard for a flashing light source would have to specify. They have been specified. The question Part IX.B.4 puts to the Department is not whether such limits can be written.

Where those limits apply, and where they do not

Every one of the five is a guideline for content presented on a display. The Foundation states that plainly because the distinction is the whole of the point and because nothing in this subsection should be read as evidence about light sources. The United Kingdom guidance arose from a television advertisement in 1993 that caused seizures in at least three people. The Japanese guidance arose from a cartoon broadcast in 1997 in which flashing sequences sent 685 children to hospital. ISO 9241-391 governs image content on display screens. The Web Content Accessibility Guidelines govern web content. They are addressed to broadcasters, advertisers, content creators, game developers and web authors.

And one of them has been made binding in the United States. The analysis at Appendix C.81 records that the Web Content Accessibility Guidelines, including the photosensitive epilepsy success criteria, have been applied through Section 508 of the Rehabilitation Act to non-web digital documents and software that are purchased, procured or created by government, and in the European Union through EN 301 549. The underlying guidelines were also adopted as ISO/IEC 40500:2012.

The Foundation asks the Department to hold those two facts together, because stated together they describe the gap this comment exists to identify.

A federal agency procuring a training video, a software application or an electronic document must ensure that it does not flash more than three times per second. That obligation arises under Section 508 of the Rehabilitation Act and is enforceable.

A manufacturer selling a rectangular rapid-flashing beacon, an emergency vehicle light bar, a flashing deterrent light or any other physical light source is subject to no federal limit on flash rate, on luminance change, or on the proportion of the field of view the flashing source occupies. Part VI.C and Part VI.I describe those products. Part II.E.4 establishes that no performance standard under 21 U.S.C. § 360kk applies to them.

The condition is the same. The susceptible population is the same. The triggering mechanism, as described above, is the same: a sufficiently large area of the visual field changing luminance at a sufficiently regular rate. What differs is only whether the flashing reaches the eye from a screen or from a lamp. A person with photosensitive epilepsy is protected by federal regulation from a flashing sequence in a government training video and is not protected by any federal regulation from a flashing beacon at a crosswalk, which they cannot close, cannot look away from while crossing, and did not choose to encounter.

The Foundation does not suggest that the authors of Section 508 or of the content guidelines were in error, or that their scope should have been wider. Each instrument addressed the technology domain its drafters were responsible for. The point is the one Part V.C.2.k makes about the classification of optical radiation products generally: when the instruments are organized by domain rather than by emission characteristic, a hazard that crosses domains is addressed in one and not the other, and nothing in the structure causes anyone to notice. Part V.B.3 makes the same observation about 21 C.F.R. § 1040.20, which has limited a spectral ratio for one light-emitting product since 1985 while no comparable limit exists for any other. Here the instrument is not merely available by analogy. It is in force, in the United States, for this condition, expressed in the units required, and it does not reach the products this comment is concerned with.

2. Migraine and photophobia

Photophobia is the clinical term for an abnormal, light-induced aversive or painful response. It is a recognized diagnostic feature of migraine and is reported in tension-type headache, in headache following traumatic brain injury, in cluster headache and the other trigeminal autonomic cephalalgias, and in a range of ophthalmological conditions. Where the response includes pain referred to the eye itself it carries its own name, photo-oculodynia.

The Foundation relies principally on one review and on two of the primary studies it synthesizes. The review is Noseda, Copenhagen and Burstein, Current understanding of photophobia, visual networks and headaches, published in Cephalalgia on June 25, 2018 and appearing at volume 39, issue 13, pages 1623 to 1634. Two of the three authors are at the Department of Anesthesia, Critical Care and Pain Medicine at Beth Israel Deaconess Medical Center and Harvard Medical School; the third is at the Department of Ophthalmology at the University of California, San Francisco School of Medicine. The work was supported by three grants of the National Institute of Neurological Disorders and Stroke: R21-NS090254, R01-NS104296 and R37-NS079678. The authors declared no conflicts of interest. Part II.E.6 addresses the significance of the funding source and the Foundation does not repeat it here.

a. The response is not a visual preference, and a natural experiment establishes it

The objection most readily made to the reports described at Part VII is that an aversive response to light is a matter of taste, comfort or habituation rather than of physiology. The Foundation addresses that objection here rather than in Part VII, because the answer is a question of mechanism and the mechanism has been identified in human beings.

Noseda, Kainz, Jakubowski and others, publishing in Nature Neuroscience in 2010, studied migraine patients who were blind. The review describes the result:

> "Accordingly, intensification of headache was perceived only by blind migraineurs with an intact optic nerve who were able to partially perceive ambient illumination but unable to form images due to degeneration of rod and cone photoreceptors (i.e. patients diagnosed with retinitis pigmentosa, retinal prematurity or cone/rod dystrophy). Conversely, totally blind migraineurs lacking any type of visual perception due to damage of the optic nerve (i.e. those with optic neuropathy, retinal cancer or enucleation), which translates to complete absence of photic information reaching their brain, testified that light does not hurt them during migraine."

The Foundation asks the Department to consider what that comparison excludes. The first group could not see images. They had no visual experience of the light, no aesthetic response to it and no opinion of its appearance, and light intensified their pain. The second group retained no photic input to the brain at all, and light did not. The variable that distinguished them was neither preference nor expectation nor the appearance of the source. It was whether photoreception reached the brain.

The Foundation accordingly does not advance light-induced pain as a matter of comfort, and asks that the reports at Part VII not be read as reports of discomfort. A response that occurs in people who cannot see the stimulus is not a preference about how the stimulus looks.

b. Wavelength governs the response at identical intensity

Noseda, Bernstein, Nir and others, publishing in Brain in 2016, tested the effect of the spectral composition of light on headache in migraineurs with normal eyesight. The design is the material feature and the review states it:

> "White, blue (447 ± 10 nm), green (530 ± 10 nm), amber (590 ± 10 nm) and red (627 ± 10 nm) lights were applied using a full-field Ganzfeld stimulator calibrated to deliver narrow bands of visible light at equal intensity to the human eye for 3 minutes."

> "Surprisingly, green light significantly attenuated the headache intensity, as opposed to the exacerbating effect of white, blue, amber and red lights."

Intensity was held equal and wavelength was varied. The direction of the effect reversed. One narrow band reduced the pain and four increased it. The authors obtained mechanistic corroboration from color-selective electroretinography and visual evoked potentials in the same patients and from recordings of dura-sensitive thalamic neurons in the rat, reporting that green

evoked the smallest electroretinographic a-wave and the smallest cortical P2 amplitude of the five conditions.

That result bears on this comment in two ways, and the Foundation separates them.

It is the human clinical instance of the proposition advanced throughout Part V.J.4: that a quantity of light is not a description of its biological effect. Two exposures identical in intensity produced opposite changes in a clinical endpoint. A standard expressed in illuminance, in luminous intensity or in any other photometric unit cannot distinguish between them, because the quantity in which it is expressed was equal in both.

The exacerbating blue band in that experiment was centered at 447 nanometers. Part V.J.4 records that the emission peak of a phosphor-converted white light-emitting diode lies between approximately 450 and 470 nanometers. The Foundation states as its own observation, and not as a finding of the authors, that the band found to exacerbate headache in that experiment is the band in which white light-emitting diode products emit their primary radiation. The authors studied migraine. They did not study any product, and the Foundation does not represent that they did.

c. The comfort of a healthy observer is not a criterion for this population

Part V.C.2 describes the international guidance on which the Department is asked to rely, and records the position taken in the 2020 statement of the International Commission on Non-Ionizing Radiation Protection that where a source is comfortable to view its levels should not be considered harmful. The Foundation offers two sentences from the headache literature against that criterion, and offers them because they are not its own.

> "The common notion is that exposure to light that is otherwise comfortable to healthy people exacerbates the intensity of the headache."

And on the question whether a level exists below which the response does not occur, the review states the position of the ophthalmological literature it cites, Katz and Digre in Survey of Ophthalmology in 2016:

> "For migraineurs with normal eyesight, virtually all luminous intensities can trigger uncomfortable features of photophobia"

The Foundation does not read the second sentence as establishing that no threshold exists, and does not advance it for that. It reads it as the state of the published description, which is that no threshold has been identified. The consequence for the guidance is the same either way. A criterion that takes the comfort of an unaffected observer as the test of safety excludes from consideration the population in which the response occurs, and does so by construction rather than by oversight.

The review also identifies a setting in which this bears on a product class already before the Department. Having described hypersensitivity across photopic, scotopic and mesopic conditions, the authors note the last of these arises "when driving at night using both photoreceptors (mesopic vision)", "which is a serious challenge for photophobic migraineurs." Part VI.B and the citizen petitions described at Part IV concern vehicle headlamps. The Foundation notes the convergence and draws no further inference from it here.

d. What this does not establish

Four limitations, and the Foundation states them at the length they deserve because the third is a result that runs against a mitigation the Foundation has elsewhere described.

None of this work concerns light-emitting diode products. No study described in this paragraph exposed a subject to a named product, measured what any product emits, or

reported a spectral power distribution of a lamp in commerce. The experimental sources were laboratory stimulators delivering calibrated narrow bands.

Migraine is a disease and migraineurs are a patient population. Nothing in this paragraph establishes that light-emitting diode products produce pain in people who do not have a photophobic condition, and the Foundation does not contend that they do. The proposition is the affected-population one: there exists a population, of substantial size, in which ordinary ambient light produces pain through a characterized non-visual mechanism, and no federal standard for any light-emitting product takes account of it.

The evidence that filtering the implicated wavelengths helps is weaker than it appears, and the Foundation reports the complication rather than omitting it. A proof-of-concept study of notch-filter spectacle coatings designed to block 480 nanometers in chronic migraineurs reported benefit on the headache impact test and on a photophobia questionnaire — but, in the review's words, "not only blue but also sham lenses filtering red light (620 nm) were beneficial for the headache and photophobia." The explanation offered for the sham result was the bistability of melanopsin, and the review records that direct recordings of the relevant retinal cells under red light failed to show a response, "thus opposing the bistability hypothesis." A trial in which the sham arm performs as well as the active arm does not establish that the active mechanism operates. The Foundation accordingly does not offer spectral filtering as a demonstrated remedy, and Part II.G.3 should be read with this paragraph: the techniques listed there are available and untested, which is the Foundation's point about them, and this is an instance of a technique that was tested and did not separate from its control.

The review is a review. For each of the two load-bearing findings the Foundation cites the primary study, and it relies on the review for the synthesis, for the state of the field and for the research-gap statement at paragraph e.

e. The field's own account of what has not been done

The Foundation has stated throughout this comment that the research bearing on these questions has not been performed. On this question the authors say it themselves, in the second sentence of their background:

> "Over the years, multiple mechanisms have been proposed to explain its causes; however, scarce research and lack of systematic assessment of photophobia in patients has made the search for answers quite challenging."

Two features of that sentence bear on the requests at Part IX. The first is scarce research, which is a statement about volume. The second is the lack of systematic assessment of photophobia in patients, which is a statement about surveillance, and it is the same absence the Foundation describes at Part V.J in respect of exposure and at Part IX.D in respect of adverse event reporting. Investigators funded by the National Institute of Neurological Disorders and Stroke report that the symptom is not systematically assessed in the patients who have it. The Foundation asks the Department to read that alongside the reliance placed on an absence of reported harm, which Part I.C.7 addresses.

3. Autism and sensory processing differences

This subsection concerns a population for which the question this comment asks is both more acute and less answerable than for any other it treats. The Foundation sets out what the literature contains, and then states plainly that it does not contain what would be needed, because the gap is the finding.

Why the question arises, and the form the Foundation gives it

Atypical reactivity to sensory input is not an incidental feature of autism. It is part of the diagnostic construct itself: the criteria include hyper-reactivity or hypo-reactivity to sensory input,

or unusual interest in sensory aspects of the environment, and the visual examples given in the criteria concern lights and movement. The Foundation states the criterion in that two-sided form because that is how it is written, and because a comment that converted it into a general proposition that autistic people are sensitive to light would be asserting something narrower than the criterion says and broader than the evidence shows.

What follows from the criterion is not a conclusion about harm. It is that a recognized population, identified in part by its reactivity to sensory input, is exposed to the emissions described throughout Part V, and that the Department has never asked what those emissions do to that population. The request at Part IX.C.6 follows from that and from nothing stronger.

The two studies, and what each of them lacks

The Foundation examined the two most directly relevant studies it could identify. They are set out at Appendix C.82 and Appendix C.83. Taken separately each is of modest value. Taken together they describe the condition of the field precisely, because their weaknesses are exact complements.

Appendix C.82 measures. It records the pupillary light reflex objectively, by eye tracker, and reports that in adults a higher score on the restricted and repetitive behavior subscale was associated with smaller relative pupil constriction and longer constriction latency, both surviving correction for multiple comparisons. It has no autistic participants. Its samples were non-autistic, and autistic traits were measured dimensionally by questionnaire.

Appendix C.83 has the population. Eighty-seven autistic children aged six to sixteen, clinically diagnosed. It measures nothing. Its instrument is a forty-question survey of the children and their parents, scored on a suitability ranking, and it reports no physiological or behavioral observation of any kind.

And neither characterizes the light. In Appendix C.82 the stimulus is described as a white flash of 120 milliseconds, with no wavelength, no luminance and no statement of the background adaptation level. In Appendix C.83 the position is more complete than that: the Foundation searched the full text of that paper for every photometric and radiometric term it could think of, and for the common lamp technologies, and found none of them. The result is recorded in the entry. A paper on the effect of light on behavior states no illuminance, no luminance, no correlated color temperature, no wavelength, no spectral power distribution, and does not identify what kind of lamp was in the rooms it concerns.

What that pattern is, and what it is not

At Part V.E.2 the Foundation drew a distinction, taken from the words of investigators in that field, between scarce research, which is a statement about volume, and the absence of systematic assessment, which is a statement about surveillance. The position on this question requires a third category, and the Foundation states it as the finding of this subsection.

The difficulty here is not only that there are few studies. It is that the studies which exist are not of a design that could answer the question, and they fail in a consistent way. The study with the right population does not measure. The study with the measurement does not have the population. Neither describes the exposure. A third study of either kind would not remedy that, because the deficiency is in the design rather than in the count. What is required is a single study holding three things at once: a diagnosed population, a physiological or behavioral measurement, and an exposure characterized in the units Part V.J.1 sets out. The Foundation is not aware of one.

The Foundation accordingly asserts no dose-response relation for this population and asks the Department to notice that it cannot. It does not claim that autistic people are injured by light-emitting diode products at any stated level, because no study in the record before it would support that claim, and a comment that made it on the strength of the two studies described above would deserve to be discounted. What it asks is set out at Part IX.C.6: that the study be performed.

The condition neither study reaches

One further gap is worth identifying with precision, because it is the condition most often described by the people who report difficulty and it is addressed by neither study. Appendix C.83 concerns static interior lighting. Appendix C.82 used a single brief flash, with intervals of ten to fifteen seconds between trials included deliberately to prevent retinal saturation, and it did not measure redilation at all. The design therefore excluded repeated exposure by construction.

Repeated and flashing sources, encountered in darkness, engage a different mechanism from the one either study examined. Constriction amplitude describes the response to an increase in light. Recovery between successive flashes is a function of redilation kinetics and of light and dark adaptation, and neither is measured in either paper. Part V.D concerns the temporal characteristic generally, Part V.E.1 concerns the one neurological response to flashing light for which numerical thresholds exist, and Part VI.C concerns the products that produce the condition. The Foundation records here that the intersection of those three with this population is, so far as it can establish, entirely unstudied.

4. Trigeminal and melanopsin-mediated pathways

This paragraph states the anatomical route by which the responses described at paragraph 2 are understood to arise. The Foundation sets it out because the route explains three features of those responses that would otherwise appear anomalous, and because it is the point at which the human and animal evidence in this comment meet.

The convergence is in the thalamus. The review describes the finding:

> "Experiments using in vivo electrophysiological recordings of dura-sensitive (trigeminovascular) neurons in the thalamus showed that shining light into the contralateral eye induces robust and sustained increase in their activity."
>
> "These light/dura-sensitive neurons, which are located in the lateral posterior (LP) and posterior (Po) nuclei, receive input from ipRGCs."

The abbreviation is for intrinsically photosensitive retinal ganglion cells, the melanopsin-expressing cells described at Part V.F as the conduit for circadian entrainment. The same cells supply the thalamic neurons that carry pain signals from the dura. Light and cranial pain therefore converge on single neurons, and a photic signal arriving at such a neuron adds to a nociceptive one.

Three features of the clinical picture follow from that arrangement, and the Foundation identifies them because each corresponds to something stated elsewhere in this Part.

The response does not require image formation, because the input is from a non-image-forming photoreceptor. That is the mechanism behind the blind-migraineur comparison at paragraph 2.a. The review notes that the melanopsin system is driven optimally by photons of approximately 480 nanometers, and records the finding of Zaidi and others in Current Biology in 2007 that subjects lacking an outer retina, nominally unaware of light perception, could nonetheless identify a 481-nanometer test light and failed to detect it at other wavelengths.

The response is to light as a quantity reaching a receptor rather than to a scene, which is why it is not governed by the appearance of the source and why Part V.B.2 is relevant to it. What determines the signal is the irradiance delivered to the retina, and Part V.B.2 sets out why that quantity does not fall with distance from a source the eye resolves.

The autonomic and affective accompaniments of the response are not incidental to it. The review describes photic signals transferred to brain regions involved in sensory, autonomic and emotional regulation, and reports the finding of Noseda and others in the Proceedings of the National Academy of Sciences in 2017 on hypothalamic-mediated autonomic

responses to light during migraine. Part V.E.5 addresses that literature. The Foundation notes here only that nausea, lacrimation and the affective quality of the experience are features of the pathway rather than reactions to the pain.

The animal evidence in Appendix C.51 corroborates the receptor identity by a different method, and the Foundation sets the two side by side because neither alone would be sufficient. In that study a melanopsin antagonist reduced blue-light aversion while a blocker of the visual photoreceptors did not, and the investigators recorded trigeminal activation markers together with corneal inflammation that persisted for three days after a three-hour exposure. The human comparison at paragraph 2.a establishes that the pathway operates in people and does not require image formation. The animal study identifies the receptor pharmacologically and shows that the response outlasts the stimulus. Neither establishes the other and the Foundation does not present either as doing so.

One historical point belongs here because it bears on the glare analysis at Part V.C. The review summarizes the earlier literature as proposing that migraine involves "a subcortical inability to suppress glare and light-induced pain, and that trigeminal-autonomic reflexes further contribute to pain by promoting vasodilatation in pain-sensitized extra/intracranial vessels." Part V.C.3 and Part V.C.4 treat disability and discomfort glare as visual and photometric phenomena, which is what they are. This sentence identifies a population for whom glare is additionally a nociceptive one. The Foundation does not merge the two accounts and asks that they be read as describing different things that the same installation can produce.

The Foundation closes this paragraph with the authors' own statement of what remains to be done, because it is a research agenda addressed to precisely the subject paragraph 360ii(a)(4) directs the Secretary to study:

> "Due to the many anatomical structures and medical conditions that are associated with photophobia, efforts to identify the underlying neurobiological mechanisms behind its different forms must continue to focus on the relationship between visual networks, trigeminal pain pathways and autonomic regulation at multiple levels, from the eye to the cerebral cortex, in a pathology-specific manner."

And the conclusion with which they qualify the whole of it, which the Foundation reproduces because it is a caution against the overreading this paragraph could otherwise invite: "Photophobia phenotype is diverse, and the relative contribution of visual, trigeminal and autonomic systems may depend on the disease it emerges from."

5. Autonomic and acute stress responses

This subsection concerns reported responses that are neither seizure nor pain: the acute autonomic and stress responses that Part VII.B.4 records in the incident material, including the panic reactions, nausea, lacrimation and the affective quality of the experience described there.

The Foundation states the condition of the evidence before anything else, because the honest answer is that it has not assembled it. Two leads have been identified and neither has been obtained and read. One is work on cardiac autonomic function under colored light-emitting diode illumination, identified through a reference list rather than read in the original. The other is work on hypothalamic-mediated autonomic responses to light during migraine, which Part V.E.2 notes in passing for the proposition that nausea and lacrimation accompany the migraine response. The Foundation does not rely on either and does not state their findings. Part V.A.2 sets out the standard of evidence this Part applies, and material identified but not read does not meet it.

What the Foundation does say is confined to the structure of the question. An autonomic response is a measurable physiological event rather than a report of discomfort, which places it among the effects a study under paragraph 360ii(a)(4) could measure directly. Part V.G.7 sets out where the Foundation places material that rests on report alone, and this subsection belongs there until the literature is obtained.

6. Deliberate induction of altered perception, and the frequencies at which it is done

This subsection concerns a fourth thing, distinct from the three the opening of this Part separates. It is not a seizure, it is not pain, and it is not a difference in sensory integration. It is the deliberate use of flashing light, in laboratories and in recreational settings, to alter visual perception in people who are not unusual in any respect. The Foundation raises it for two reasons, and neither is the one a reader might expect.

What this does not say, stated first

The study described at Appendix C.93 used flicker at 3 and 10 hertz. The modulation of light-emitting diode products treated at Part V.D lies between about 100 hertz and 10 kilohertz. These are different phenomena at different frequencies, and the Foundation does not contend that the modulation of a lamp or a display induces an altered state of consciousness. Nor are the exposures comparable: the participants sat at about half a meter from a purpose-built stroboscope, in a dark room, wearing earplugs, with their eyes closed, for twenty minutes. Nothing in this subsection is offered as evidence about ordinary lighting.

The first reason: the frequencies are those of devices in the public way

Part V.D.4 establishes by counting the pattern the governing manual prescribes that a rectangular rapid-flashing beacon delivers exactly 5.0 illuminations per second at each indication and 7.5 per second across the assembly. Those rates fall between the two frequencies this study used. They are not near them or comparable to them; they lie inside the interval.

The band is wider than the two frequencies tested. The discussion in the same paper collects the literature. One study reported "most radial illusory percepts at ~10 Hz and spiral percepts to be most pronounced at the slightly higher frequency of ~15Hz". Another found the phenomena "most strongly pronounced between 10–25 Hz". Two more place "the strongest illusory percepts in the range of 15 to 30 Hz". So the band within which flashing light is established to alter visual perception runs from about 3 to about 30 hertz, and the devices described at Part VI, including pedestrian beacons, emergency vehicle lamps and the flashing elements of dynamic signs, operate inside it. The Foundation states the limit of the point: identity of frequency is not identity of effect, and the exposures differ in eyelid, duration, distance and ambient light. What the identity of frequency establishes is that these devices are not operating in a band about which nothing is known. They are operating in the band that researchers select when they wish to alter perception.

The second reason, which the Foundation regards as the stronger: what was required before anyone was exposed

To expose twenty-four healthy adult volunteers to twenty minutes of flashing light at 3 and 10 hertz, a European university required all of the following. A semi-structured interview with a psychologist, conducted before the experiment, "to ensure that they were not affected by an acute mental or neurological disorder, were not currently or regularly taking any psychotropic medication or drugs and were not pregnant". An instrumented screen for susceptibility, namely "a screening for indications of photosensitive epilepsy based on electroencephalography (EEG)", which itself comprised four-second flicker episodes at 1, 3, 10, 20, 30 and 40 hertz, each presented twice, together with a resting record and a period of hyperventilation, the whole reviewed by a trained expert. Approval by a hospital ethics committee. Written consent after being informed of the risks. And a familiarization session under constant light before any flicker was applied.

Even with all of that, one participant withdrew: "One participant dropped out of the study due to self-reported migraine symptoms after the first experimental session with FLS of 10 Hz". A person who had been interviewed by a psychologist, screened by electroencephalography, and found suitable, was made unwell by a single session.

Now set that beside the position of a person crossing a street. A beacon operating at 5.0 flashes per second at each indication is installed in the public way. No one is interviewed. No one is

screened by electroencephalography or by any other means. Pregnancy is not asked about and does not matter. Psychotropic medication is not asked about and does not matter. No ethics committee has considered the exposure, because it is not research. No consent is sought, informed or otherwise, and none could meaningfully be given, because the only way to decline is not to use the street. There is no familiarization session. And there is no mechanism by which a person made unwell can withdraw, be replaced, or be counted.

The Foundation does not argue that a pedestrian beacon is a research instrument or that installing one requires ethical review. The argument is narrower and is about knowledge rather than about procedure. The safeguards that a research institution imposes are a statement of what that institution believes flashing light in this band can do to a person. They are the considered judgment of the people who study the stimulus, expressed in the one form that costs them something, which is the form of a protocol they must follow. A regulator deciding what is known about flashing light may read that protocol as evidence of the state of knowledge, and what it says is that exposure in this band is understood to warrant screening for epilepsy, exclusion of pregnancy, exclusion of psychotropic medication, and the opportunity to decline.

None of those four protections attaches to any device described at Part VI. That is the proposition this subsection establishes, and the Foundation asks the Department to notice that it does not depend on any finding about altered states being alarming, or on the frequencies of lighting-product modulation, or on anything contested. It depends only on what the researchers did before they turned the lamp on.

7. Effects that outlast the exposure

Every mechanism treated in this Part so far operates while the person is exposed. The seizure occurs during the flash, the migraine is triggered by it, the autonomic response accompanies it. This subsection concerns a different question, which the Foundation has found addressed in one place only: whether a flash leaves anything behind.

The study is described at Appendix C.100 and the Foundation states at the outset what it is. It is an experiment in mice, conducted under craniotomy with intracellular recording and two-photon imaging, and its purpose was methodological: its authors set out to develop flashing light as a tool for inducing plasticity in the adult brain. It is not a study of exposure to any product and the Foundation does not present it as one.

What it establishes about the response itself

A brief flash does not produce a brief cortical response. It produces a fast transient response followed by a long-delayed response that persists for seconds after the flash has ended. The authors state in their significance statement that this delayed response occurs in mice, rats and humans, citing their own earlier work for the human case. The flash used was modest: a hundred milliseconds of white screen at 240 candelas per square meter against a background of 60, which is about 65 lux at the eye.

The Foundation draws the Department's attention to that single fact before going further, because it bears on every criterion discussed in this Part and in Part V.D. Those criteria are expressed in the properties of the stimulus while it is present. If the cortical response to a flash outlasts the flash by seconds, then a device flashing more than twice a second, which is what Part VI.I reports measuring, is delivering its next flash into the response evoked by the last one. Whether that matters is not known. That it has not been asked is the point.

What the experiment did beyond that, and the protocol that limits it

The authors paired the flash with a visual feature. A grating drifting in one particular direction was presented four hundred milliseconds after each flash, at the onset of the delayed response, and the pairing was repeated thirty to fifty times. The consequence was a suppression of the cortical response to gratings drifting in that direction, and a measurable fall in the animals' ability

to detect motion in that direction. Both the neuronal and the behavioral change persisted for at least several hours, and both were abolished when an N-methyl-D-aspartate receptor antagonist was applied to the visual cortex, which identifies a mechanism rather than merely an association.

The Foundation now states the limitation, and states it in the authors' own words rather than its own, because it is decisive for how far this can be taken:

> "Although the intensity of the flashing stimulus employed here (Δluminance = ~60 lx) is comparable to that experienced in our daily lives, such as that of a camera strobe, we rarely encounter such repeated, specific exposures to visual stimuli."

Two things follow and the Foundation separates them. The intensity was ordinary. It was not the intensity of anything described in Part VI, and the authors compare it to a camera strobe. And the exposure pattern was a conditioning protocol: a flash, a fixed interval, one specific stimulus, repeated dozens of times, with the resulting deficit confined to that one stimulus. A person driving past a warning lamp is not in that protocol, and the Foundation does not suggest that the deficit demonstrated here occurs on a roadway.

What the Foundation asks the Department to take from it

Three things and no more. That a brief flash produces cortical activity outlasting it, in humans as well as in rodents. That in an animal model, repeated flashing coupled with a visual feature degrades the perception of that feature for hours afterward, through an identified receptor mechanism. And that whether environmental flashing light, at the intensities and repetition rates actually deployed in the products described in Part VI, engages that mechanism in people has not been studied by anyone.

The authors say that we rarely encounter repeated, specific exposures to visual stimuli. The Foundation records, without asserting that the two are equivalent, that the deterrent lamp measured at Part VI.I presents a five-pulse burst repeating more than twice a second, continuously, for as long as the unit is switched on, directed at a public sidewalk. Whether a repeated environmental exposure of that kind has any relationship to the repeated laboratory exposure these authors used is precisely the sort of question paragraph 360ii(a)(2) directs the Secretary to have answered, and it is open.

F. Circadian Disruption and Melatonin Suppression

The circadian pathway is the one effect family in this Part on which large-scale human outcome data now exist, and the most substantial study appeared in September 2026.

Dai, Dai, Heianza and Qi, publishing in the European Heart Journal, examined light exposure and cardiac outcomes in the UK Biobank cohort. Light exposure was measured rather than reported: each participant wore a wrist accelerometer with an integrated light sensor for seven days, and nighttime exposure above 3 lux was derived from calibrated measurements aligned to each individual's own circadian phase. Eleven thousand and seventy-one participants underwent cardiac magnetic resonance imaging about three years later. Between 71,077 and 73,286 were followed for incident disease over eight to ten years.

On imaging, high versus no nighttime light exposure was associated with left ventricular concentric hypertrophy and subclinical functional decline: 2.4 percent greater left ventricular mass indexed to height (95% CI 1.6, 3.1), 1.5 percent greater mean wall thickness (1.0, 2.0), and 1.9 percent lower myocardial contraction fraction (1.1, 2.7). Myocardial deformation was impaired in all three directions. Adverse associations were also seen in the right ventricle and the left atrium.

The incident disease findings are the ones the Foundation asks the Department to read directly. Over eight to ten years of follow-up, participants with high versus no nighttime light exposure had:

a 29 percent higher risk of heart failure (95% CI 12, 49);

a 33 percent higher risk of stroke (11, 59);

a 24 percent higher risk of myocardial infarction (7, 44);

a 15 percent higher risk of atrial fibrillation (4, 27); and

a 26 percent higher risk of cardiovascular mortality (5, 52).

All associations showed linear dose-response relationships, and 24 to 49 percent of each was mediated by shorter sleep duration on formal causal mediation analysis. The models adjusted for age, sex, ethnicity, deprivation, education, employment, urbanicity, physical activity, diet, smoking, alcohol, body mass index, hypertension, dyslipidemia, diabetes, kidney disease, vitamin D, air pollution, photoperiod, season and sleep duration — that is, including the confounders ordinarily raised against studies of artificial light at night. The authors conclude that the findings "highlight dark nights and adequate sleep for cardiovascular health."

Two features deserve emphasis. The first is the threshold. Three lux is not bright. It is the order of light that enters a bedroom from a street lamp through a curtain, and the study found a linear dose-response relationship above it. The second is that the exposure was measured by instrument at the wrist, which removes the recall bias that weakens much of the literature on artificial light at night.

The Foundation states the limit of this study as plainly as its findings. It is observational and establishes association, not causation, and the authors describe it in those terms. More important for this comment, it measured ambient light at night from whatever source produced it. It did not isolate light-emitting diode products, did not characterize the spectral content of the light, and makes no claim about lighting technology. It cannot be cited for the proposition that LED products cause cardiovascular disease, and the Foundation does not cite it for that.

What it supports is narrower and sufficient. Exposure to light at night at low levels is associated with serious cardiovascular outcomes in a large cohort with measured exposure. Light-emitting diode sources are now the predominant contributors to that exposure in the United States, for the reasons given at Part IV.G.3. And no federal body measures what any American actually receives at night, from any source. Appendix C.2 sets out the study in full.

A larger analysis of the same question, confined to clinical events, had been published a year earlier. Windred and others, in JAMA Network Open in October 2025, examined 88,905 UK Biobank participants over 9.5 years, deriving exposure from approximately 13 million hours of wrist-worn light sensor data and taking outcomes from National Health Service records. Comparing those with the brightest nights, the 91st to 100th percentile, against those with dark nights, the 0 to 50th:

coronary artery disease, adjusted hazard ratio 1.32 (95% CI 1.18 to 1.46);

myocardial infarction, 1.47 (1.26 to 1.71);

heart failure, 1.56 (1.34 to 1.81);

atrial fibrillation, 1.32 (1.18 to 1.46);

stroke, 1.28 (1.06 to 1.55).

The associations survived adjustment for physical activity, smoking, alcohol, diet, sleep duration, socioeconomic status and polygenic risk. That last adjustment is unusual and worth noting: the analysis controlled for genetic susceptibility directly rather than assuming it away. Associations were larger in women for heart failure and coronary artery disease, and larger in younger participants for heart failure and atrial fibrillation. The authors conclude that avoiding light at night may be a useful strategy for reducing cardiovascular risk.

A caution about reading these two studies together

The Foundation draws attention to the relationship between that study and the cardiac imaging study described above, because the two must not be read as independent confirmations of one another and a reader who assumed they were would be misled.

Both analyze the UK Biobank. Both derive exposure from the same wrist-worn light sensors. The participants substantially overlap. Two analyses of one cohort using one instrument are not two studies in the sense that matters for replication, and the Foundation does not present them as such. What they jointly establish about generalizability is limited to that population.

What they do establish within it is of a different kind, and the Foundation submits that it is more interesting than replication would have been. The imaging analysis found structural and functional change in the heart: concentric hypertrophy, greater wall thickness, reduced myocardial contraction fraction, impaired deformation in all three directions. The incidence analysis found the clinical events that such changes characteristically precede: coronary disease, infarction, heart failure, atrial fibrillation, stroke. The subclinical finding and the clinical finding are mechanistically consistent with one another, in one population, measured by one instrument. That is coherence rather than replication. The Foundation presents it as coherence and asks the Department to weigh it as such. Appendices C.2 and C.8.

A smaller study published in May 2026 bears on the same pathway in a clinical population, and the Foundation includes it with its limitations stated rather than omitting it. Li and others followed 454 patients with hepatocellular carcinoma and compensated cirrhosis in a single Chinese city for twelve months, measuring light in each patient's bedroom with a handheld illuminometer between 23:00 and 04:30 on three occasions. Mean bedroom light above 50 lux was associated with increased risk of overt and minimal hepatic encephalopathy, with deterioration of liver function, with esophagogastric variceal rupture, and with disease-related mortality.

The Foundation does not place weight on that study for the proposition that light at night causes disease in the general population, and the reasons are set out at Appendix C.4. The population is narrow and seriously ill, the threshold of 50 lux is far above the level at which the cohort study described above found effects, and there is a plausible reverse-causation pathway that the authors do not address: hepatic encephalopathy disturbs the sleep-wake cycle, so a patient developing it may come to have more light in the bedroom at night rather than less. The Foundation identifies that difficulty itself because a reader who found it unaided would discount everything adjacent to it.

What the study does contribute is methodological, and it belongs with Part V.J. The investigators measured each participant's actual nighttime light exposure in the room where that person slept, repeatedly, with an inexpensive handheld instrument.

A third outcome study, published in January 2026, examined a different disease in the same cohort used by the cardiac study above. Chen and others followed 346,163 UK Biobank participants for a mean of 13.71 years, assigning outdoor artificial light at night from satellite data matched to each participant's residential address. Each standard deviation increment of exposure was associated with an 8 percent higher risk of incident ulcerative colitis (hazard ratio 1.084, 95% CI 1.023 to 1.149, $p < 0.001$), and the highest exposure level carried a 31 percent higher risk than the lowest (HR 1.309, 95% CI 1.12 to 1.529, $p < 0.001$). The association was non-linear on restricted cubic spline analysis and was stronger in women.

One feature of that result is worth noting for a reason unrelated to inflammatory bowel disease. No association was found with Crohn's disease (HR 1.044, 95% CI 0.83 to 1.308, $p = 0.71$), although the two conditions share the urban distribution and the socioeconomic gradient that make confounding the standard objection to studies of this kind. A confounder operating through

urbanicity or deprivation would be expected to move both. That it moved only one is some evidence, though not proof, that the association is not simply a map of where cities are.

The exposure measure is nonetheless the weakest element of that study and the Foundation says so. Satellite radiance at a residential address describes light leaving a neighborhood, not light reaching a person. The effect sizes are modest, and modest hazard ratios in observational work are the ones most vulnerable to residual confounding. Appendix C.5.

The melatonin pathway is also the hypothesized mechanism for the longest-standing question in this literature, which concerns breast cancer. The study described at Part V.J.4 and Appendix C.7 bears on it. Among 24,793 women followed in two pooled cohorts, outdoor light at night measured conventionally as brightness showed no significant association with breast cancer. A measure weighted by the capacity of the light to suppress melatonin, among women who reported light entering their rooms at night, was associated with a 1.53-fold hazard in the highest tertile against the lowest (95% CI 1.18 to 1.98). The Foundation presents that finding with the cautions set out at Appendix C.7, which are substantial, and relies on it principally for what it shows about measurement rather than for what it shows about risk.

The origin of that question should be identified, because this comment has described the literature on light at night without naming where it began. The hypothesis was advanced in 1987 by Richard G. Stevens, in a paper in the American Journal of Epidemiology titled Electric power use and breast cancer: a hypothesis. It proposed that the use of electric light at night, by suppressing nocturnal melatonin, might bear on breast cancer incidence. The Foundation identifies it for two reasons and neither is that the hypothesis has been established.

The first is chronological. The proposition that artificial light at night might have consequences for human health is not a recent contention, and it is not the Foundation’s. It was advanced in the peer-reviewed epidemiological literature thirty-nine years ago, and it has been under investigation continuously since. Part II.A records the agency’s determination of May 24, 2024 and the reliance it placed on a history of safety. The Foundation asks the Department to note that the question has had a published literature for the whole of the period in which light-emitting diode products were introduced and became dominant.

The second is that the hypothesis has since been tested at scale, and Appendix C.53 describes the test: a prospective cohort of 109,672 American women followed for twenty-four years, funded by three components of this Department and published in the journal of a fourth. The Foundation does not adopt the melatonin mechanism, for the reasons given above and at Appendix C.44, and does not need it. What it draws from the sequence is narrower: a hypothesis was published in 1987, it was investigated for three decades, the investigation produced results that the investigators themselves describe as requiring confirmation, and paragraph 360ii(a)(2) directs the Secretary to support exactly the research that would supply it.

One further study bears on mechanism rather than on risk, and the Foundation includes it for the mechanism alone. Yang and others, publishing in Clinical Epigenetics in July 2025, combined an observational analysis in 1,010 patients with an animal experiment. The human arm is weak and Appendix C.9 says so: it rests on 32 outcome events and returns an odds ratio whose confidence interval reaches down to 1.00. The Foundation does not rely on it.

The animal arm is a different matter. Dim light at night in mice produced global hypomethylation of DNA, and treatment with melatonin partially counteracted that effect. Metabolic profiling implicated ATP-binding cassette transporter proteins in the regulation of lipid metabolism under the same exposure.

The Foundation draws attention to the character of that finding rather than to its magnitude. The effects of optical radiation set out elsewhere in this Part are physiological: a retinal response, a hormonal response, a change in mitochondrial respiration. This one is epigenetic. It reports a change in the methylation state of the genome of an exposed animal, and a partial reversal of that

change by administering the hormone whose secretion light at night suppresses. Whether anything comparable occurs in humans at the exposures people actually receive is unknown, and the Foundation asserts nothing about it. That it is unknown is the point. Part V.L.

The studies set out above concern adults. One recent study measured the light exposure of children, and the Foundation brings it forward for the exposure data rather than for the association it reports.

Ding and others, publishing in Environmental Research in 2025, fitted 831 school-aged children in Chuzhou, Anhui Province, with personal light sensors for five days. The children averaged 8.53 years of age. The measured exposure was as follows: 490.1 minutes per day above 100 lux in daytime, and 311.2 minutes per night at or above 1 lux.

The Foundation asks the Department to hold that second figure against the recommendation described at Part V.J.4. The published guidance is that the sleep environment should be below 1 lux of melanopic equivalent daylight illuminance. These children were at or above 1 lux for an average of more than five hours every night. The measures are not identical, since the study reports illuminance and the recommendation is melanopic, and the Foundation does not treat them as interchangeable. The order of magnitude of the gap is nonetheless what the Department should notice, and it was measured on children rather than modeled.

The study also reports associations with body composition: a one percent increase in the proportion of time in daytime light at or above 100 lux, which is 14.4 minutes, was associated with a 3.10 percent decline in percentage body fat, while an additional 14.4 minutes above 1 lux at night was associated with a 3.49 percent increase, both at p less than 0.01. The Foundation places little weight on those associations and Appendix C.10 explains why: the design is cross-sectional, so exposure and outcome were measured at the same time, and a child who is heavier may plausibly spend less time outdoors and more time indoors at night. The direction of causation is not established by this design and the authors do not claim that it is.

What the study does establish is that the nocturnal light exposure of children can be measured directly, that it has been, and that in the population measured it stood far above the level the field recommends. No comparable measurement exists for children in the United States. Parts V.J, V.K and VII.

This subsection concerns the suppression of nocturnal melatonin and the disruption of circadian timing by light exposure, and in particular by the short-wavelength content described at Part V.B.1. The Foundation treats one document first, not because it is the most important in the literature, but because of what its date and its sponsorship establish.

1. The 2010 analysis prepared for ASSIST

Mark S. Rea, Aaron Smith, Andrew Bierman and Mariana G. Figueiro of the Lighting Research Center at Rensselaer Polytechnic Institute prepared for the Alliance for Solid-State Illumination Systems and Technologies a technical paper titled The potential of outdoor lighting for stimulating the human circadian system, dated May 13, 2010 and revised December 11, 2012. Part II.E.4 describes the consortium for which it was prepared.

The paper applied a published model of human circadian phototransduction to estimate melatonin suppression from four typical outdoor light sources under what it described as realistic exposure scenarios. Its result was that three of the four "would not meaningfully stimulate the human circadian system after one hour of exposure," while the fourth, identified as a 6900 K LED, was:

> "predicted to have a modest stimulating effect after a one–hour exposure (corresponding to 12 – 15% nocturnal melatonin suppression)."

The paper was candid about what it could not establish. In its own words, "there are several limitations to this analysis due to the uncertain causal relationship between retinal light exposure at night and human health."

The Foundation relies on that document for three propositions and for no more. It does not present a modest effect as a finding of injury, and it adopts the paper's own characterization of the effect and of its limits.

A quantitative estimate of nocturnal melatonin suppression attributable to a particular LED street lighting spectrum was available in 2010 and was revised in 2012.

It was produced for an industry consortium by a university research center. It was not produced by this Department, and the Foundation has found no federal counterpart to it.

Its authors identified the unresolved question as the causal relationship between nocturnal retinal exposure and human health. That is the question 21 U.S.C. § 360ii(a)(4) directs the Secretary to study and evaluate, and § 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research upon.

Fourteen years separate that paper from the determination of May 24, 2024 that no performance standard was necessary because of a long history of safety with respect to the visible wavelengths being emitted. The intervening period is the period in which the conversion of American street lighting to light-emitting diodes took place. Part IV.G.

G. Affective and Psychological Response

1. Scope of this subsection

This subsection concerns the affective and emotional responses described in Part I.G: wellbeing, agitation, fear, panic, and hopelessness. It does not concern the autonomic component of an acute stress response, which is addressed at subsection E.5, nor the circadian and hormonal mechanisms addressed at subsection F.

2. Light, circadian disruption, and mood — the established pathway

The route from light exposure to mood is not a conjecture of the Foundation's. It is a recognized area of inquiry with an identified mechanism, and it runs through the circadian system described at Part V.F rather than directly.

Stewart and Albrecht reviewed it in npj Biological Timing and Sleep in March 2025. The Foundation identifies the article as a review rather than as primary research, in accordance with the rule stated at Part V.A.1, and relies on it for what a review can establish: the state of expert synthesis. The authors summarize the position as follows:

> "Importantly, light affects our internal time-keeping system, the circadian clock, which regulates daily rhythms of biochemical and physiological processes, ultimately impacting mood and behaviour. The 24-h availability of light can have profound effects on our well-being, both physically and mentally, as seen in cases of jet lag and shift work."

The Foundation draws a narrow and specific use from that. This subsection is the one on which the comment must be most careful, because the evidence available to it in this domain is weaker than elsewhere in Part V, and because Part VII contains first-hand reports describing distress, agitation and worse. Those reports cannot establish causation. Part V.A.2 says so, and the Foundation does not retreat from it.

What this literature supplies is the thing those reports lack on their own: a biologically plausible route by which an affective response to light exposure could arise. Light reaches a non-visual pathway; that pathway sets circadian timing; circadian timing bears on mood. Each step is established independently of anything the Foundation says. Plausibility is not demonstration and the Foundation claims no more than plausibility here.

That is enough for the purpose this comment has. A recognized mechanism together with an accumulation of reports is the classic occasion for investigation, and 21 U.S.C. § 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure to electronic product radiation. It is not an occasion for a conclusion, and the Foundation asks the Department to reach none. Appendix C.12.

3. Discomfort, aversion, and the experience of glare

Discomfort glare is studied as a subjective response and is measured by rating scales. Part V.C.4 sets out that literature and its instruments.

The Foundation draws attention to what that establishes about method, because it answers an objection this Part attracts. Where a reported experience is said to be merely subjective and therefore outside the reach of a technical criterion, the answer is that the lighting field has treated exactly this class of effect by subjective report for decades, has built rating scales for it, and has accepted them as the recognized instrument. The literature at Part V.C.4 is therefore directly on point in two ways: it is evidence about discomfort, and it is evidence that subjective report is how discomfort is properly measured.

4. Sensory environments, distress, and sensory processing differences

Part V.E.3 sets out the neurological account of sensory processing differences and this subsection does not restate it. What it adds is the unit of analysis. The literature at Part V.E.3 concerns a response to an emission. The accounts at Appendix A frequently concern a response to an environment: a store, a classroom, a corridor, in which the lighting is one element of a setting that also contains sound, reflection, movement and crowding.

The distinction matters to this comment for a single reason, and the Foundation puts it as a limitation rather than as an argument. An emission criterion addresses one element of such a setting. It would not make a sensory environment tolerable to a person for whom the aggregate is the difficulty, and the Foundation does not suggest that it would. What a criterion would do is remove from the aggregate the one component that is a product characteristic, measurable, and within the authority of this Department. Part III.G sets out the techniques of minimization, of which shielding and diffusion address the character of the light in a space rather than its quantity.

The Foundation does not reproduce or cite individual accounts in this subsection. Some reports in this group contain material about the reporter's own distress that the Foundation has determined should not be quoted anywhere in this comment, and Part V.G.6 sets out separately, and with the care the subject requires, the one category of report the Foundation does address. Part VII.A.6 records the screening applied to the whole set.

5. What the incident reports describe [RFI Q3]

Part VII.B sets out what the reports describe, by category, and this subsection does not reproduce it. Its function is to place those accounts against whatever literature exists rather than to present them a second time.

The placement is this. For the ocular and glare responses at Part VII.B.1 there is an established literature, set out at Part V.C.3 and Part V.C.4. For headache and migraine at Part VII.B.2 there is an established literature at Part V.E.2. For photosensitive response at Part VII.B.3 there is an established literature at Part V.E.1 and a threshold framework. For the acute autonomic and panic responses at Part VII.B.4 the position is the one Part V.E.5 states: the Foundation has identified leads it has not obtained, and the accounts rest on report alone. Part V.G.7 states the three-way classification this Part applies.

6. Reports of hopelessness and suicidal ideation

Three of the accounts reproduced at Appendix A describe suicidal ideation, and two describe hopelessness. They describe more than one route by which it arose.

Some describe an accumulation: repeated seizures triggered by flashing or flickering sources, chronic ocular pain, or the progressive loss of the ability to drive after dark, to work, to shop, or to leave home, with no prospect of relief. Others describe something immediate. In those accounts an encounter with strobing or flashing sources, by day or at night and often without warning, produces an acute and overwhelming aversive state, and the thought of ending one's life presents itself as a means of escaping a stimulus from which there is no other escape.

Both routes are recognized in the medical literature in other contexts. Recurrent seizures are associated with elevated risk of depression and of suicide. Chronic pain is associated with both. So are loss of occupational function, loss of mobility, and exclusion from ordinary public life. And suicidal ideation arising as escape from an acute, overwhelming, and inescapable aversive state is a described clinical pattern, studied in connection with other sources of overwhelming distress. The accounts here do not describe a novel phenomenon. They describe known phenomena arising from a stimulus that has not been studied.

What distinguishes these accounts is not that the stimulus is light. It is the particular combination of spatial, spectral, and temporal characteristics set out at Part I.G: the radiance of the emitting surface, the number and arrangement of emitters in the field of view, the short-wavelength content, the modulation waveform and flash rate. No published work establishes which combinations of those characteristics are tolerable and which are not, because the parameter space has not been examined. That absence is the gap this comment asks the Department to address under 21 U.S.C. § 360ii(a)(4). It is not evidence that the combinations are benign.

What the Foundation asks the Department to take from these accounts is that they were made, that they were transmitted to the Center for Devices and Radiological Health, that the routes they describe are recognized routes, and that no federal body has examined either the reports or the stimulus characteristics that produced them.

7. What is established, what is plausible, and what rests on report alone

The notice asks that established evidence be distinguished from emerging findings and from areas of uncertainty. The Foundation closes this subsection by doing that for the affective and psychological material, in three statements.

Established. Light influences circadian regulation, and circadian disruption is associated with affective change. Part V.F sets out the circadian literature and Part V.G.2 the pathway.

Plausible and unstudied. That the acute responses described in this record follow from the spectral, spatial and temporal characteristics identified at Part I.G and treated at Part V.B. The mechanism is describable and the Foundation has located no study of it.

Resting on report alone. The specific acute experiences described at Part VII. The Foundation says so plainly, in the same terms it uses at Part V.A.3 for the literature as a whole, and Part VII.A.5 states the limitations of the reports before any use is made of them.

H. Occupational and Educational Exposure Settings

Two settings in which a person is present by necessity, for a fixed period, under lighting selected by somebody else. The Foundation treats them together because the feature they share is the one that matters: the exposure is compulsory and its duration is not the exposed person's to choose.

Occupational

Part II.H.10 sets out the position of the agency that administers occupational safety and health, and Part VII.J.3 sets out that nothing in the occupational framework requires any optical quantity to be monitored or any exposure record to be kept. A workplace may be measured for illuminance to establish that there is enough light; nothing requires it to be measured to establish that there is not too much.

What the record contains is reported rather than measured. Part VIII.B.6 records that thirty-two of the 593 accounts at Appendix A describe work or employment, and sets out the employment provision that reaches the setting. Part VI.E treats interior lighting in workplaces as a product class and Part VI.K records that a person employed at an entertainment venue is exposed for a shift, repeatedly, by occupational necessity, and does not choose the programming.

The characteristic that distinguishes occupational exposure from the rest of this Part is duration. Part III.E.3 treats cumulative exposure as a characteristic requiring a boundary, and the occupational case is where it bites: an exposure that would be unremarkable for ten minutes is a different quantity over two thousand hours a year. No federal instrument expresses an optical exposure in those terms, and Part V.J.5 treats the question of expressing optical exposure in the units used for radiofrequency exposure, where time-averaging is routine.

Educational

Part VI.E treats school lighting as a product class and Part VI.E.2 sets out the three features that distinguish a child's exposure to it: the longest compulsory exposure of any setting, the least lenticular filtering, as Part V.C.2.g records from the measured age-dependence of ocular transmission, and no capacity to consent or to avoid. Part VI.C.3 adds the school bus warning lamp, which the same children meet at close range twice a day. Part IX.L asks that this population be addressed expressly.

The Foundation identifies one gap specific to the educational setting. A school district procuring lighting specifies it by illuminance, efficacy, correlated color temperature and cost, which are the quantities the product literature carries, and Part VI.E.1 records that a district wishing to specify by source luminance or short-wavelength content could not, because the information is not published. Part IX.F.3 asks for the disclosure that would change that.

I. Environmental and Ecological Effects [RFI Q14]

This subsection answers question 14, and states its scope at the outset because the question invites a literature far larger than the comment can carry and the Foundation will not pretend to survey it. It addresses two characteristics of artificial light and not the whole of the question. The first is temporal modulation, the characteristic treated throughout Part V.D. The second is the presence of artificial light at night at all, taken up at the end of this subsection through ten studies: one of a disease vector, one of wild mammals, one of an amphibian, three of nocturnal moths, one of urban vegetation across four hundred and twenty-eight cities, one of a seabird, and two that are not about a species at all but about a mechanism and a product. Two of the moth studies are a matched pair from the same laboratory which reach opposite conclusions about the same proposed remedy. The third measured how much of its own subject the standard method of observation cannot see, and the answer was ninety-six percent. The study of urban vegetation is the only one in the comment that weighs this exposure against another environmental stressor. The study of the seabird is the only one whose exposure was specified in the subject's own visual terms as well as in human ones. The last two are placed last and read together: the ninth establishes the mechanism by which artificial light disrupts insect flight, and the tenth, which does not cite it, built a luminaire that removes the condition the mechanism requires and measured the result. Between them they bear more directly than anything else in this Part on what a performance standard would prescribe. The subsection then ends with a note on scope, stating that everything in it is terrestrial and setting out three things taken from a review of the marine literature. A final paper is not used as a study at all: the Foundation declines its findings, for reasons it states, and takes from it only the lighting recommendations its authors make and one error in its units. The large bodies of work on the intensity, the timing and the spectral content of artificial light at night are not surveyed here, and their absence is not a view about their weight.

Why modulation is the part of this question the Foundation can speak to

The reason is that the subject was identified as a gap by the people who study artificial light at night. The study described at Appendix C.94, published in 2014 by a group at the University of Exeter, states that research on the ecological effects of artificial light has "concentrated almost exclusively on the biological effects of the intensity, duration and, to a lesser extent, spectral signature of artificial light", and that another characteristic "has largely been overlooked", namely that the output of electric lamps flickers. The Foundation accordingly offers this subsection as an answer to the narrow part of question 14 on which a peer-reviewed primary source exists.

The measure, and what the collation found

Whether an animal perceives a modulated lamp as flashing or as steady is governed by its critical fusion frequency, which is the frequency at which a series of pulses ceases to be resolved as separate and is seen as a continuous stream. The authors assembled what they describe as the largest collation of such values to that date: 56 studies yielding 93 measurements for 81 species in 66 genera and 9 classes, admitting only peer-reviewed determinations accompanied by a full statement of method.

The range is wide. The lowest value was 6.7 hertz, for the cane toad. The highest was 400 hertz, for a fire beetle, which the Foundation presents as the extreme of the dataset rather than as a representative figure. The proportion above the frequency of a lamp on a 50 hertz supply is reported four ways: "16.1% of measurements, 13.5% of species, 16.6% of genera and 44.4% of classes". And the authors supply the conversion that matters to this Department: "It should be noted that a number of countries utilise a 60 Hz electrical supply and hence the flicker frequency with be higher at 120 Hz". The United States is such a country.

Two particulars bear on the urban and roadway environment. The pigeon, which the authors describe as "a very common urban bird that is likely to encounter high levels of artificial light", has "the highest CFF values recorded (143 Hz) of any vertebrate species and will easily be able to perceive flicker from artificial lights". And of insects, for which values exist for only twelve species, the range runs from 42.5 to 400 hertz, of which the authors say that "Given the vital role insects play in ecosystem functioning (e.g. pollination, decomposition), and as nutrition for other organisms, this depauperate knowledge base should give cause for concern".

What the Foundation does not take from this, which is most of what a reader might expect

The Foundation states the authors' own assessment of their evidence before drawing anything from it, and quotes it in full.

> "The evidence presented here suggests that impacts from the perception of the flicker of artificial light may be rather limited for most species studied thus far. There remains, however, a scarcity of data on CFFs for many taxa that are most likely to be affected, hence we suggest that the potential ecological effects should not be wholly dismissed".

Three further limits are the authors' and the Foundation adopts them without softening. The animals able to resolve this flicker are diurnal, so only species for which artificial light extends the day, or which are facultatively nocturnal, are candidates. Resolution falls with light intensity, which falls with distance, so perceptibility is a function of how close the animal is to the lamp: tsetse flies would resolve a flickering street lamp at 3 lux, which the authors describe as about the dimmest point between neighboring lamps, but honeybees and domestic chickens would need to be "closer than three metres to the light source in order to perceive the flicker", and chickens "will only be able to perceive flicker at light intensities exceeding the range likely to be produced by artificial lamps". And the evidence of effect, as distinct from perception, is thin: "Explicit studies of the biological effects of light flicker on animals remain scarce, and have focused on the efficacy of trapping devices for insects and on welfare issues for captive vertebrates".

The Foundation also states a distinction the paper does not need to make but a regulator does. Resolving a flicker is not being harmed by it. That a pigeon sees a street lamp as flashing rather

than steady is a fact about pigeon vision, and nothing in this literature converts it into an injury. The Foundation asserts no ecological harm and asks the Department to find none on this record.

What the Foundation does ask

Two things, both narrow. The first is that the Department record what the question's answer presently is, which is that the modulation of these products has not been studied as an ecological variable, that the measured temporal resolution of a substantial minority of species and of nearly half the classes examined exceeds the frequency at which mains-driven lamps modulate, and that the taxa the specialists identify as most likely to be affected are among those for which no measurements exist. The authors put that last point as a knowledge problem rather than as a finding, and so does the Foundation.

The second is that the Department notice the form of the authors' recommendation, which is the same form the Foundation urges throughout this comment: "Given the precautionary principle and that it is likely that in the future an increasing level of artificial light will come from lamps with a high flicker index, as incandescent bulbs are phased out, and replaced with fluorescent … and LED lamps, we suggest the impacts of flickering light on natural systems are given urgent attention". The authors do not claim to have shown harm. They identify a characteristic that is increasing, a mechanism by which it could matter, a set of species that could be affected, and an absence of data, and they ask that the question be studied. That is a request for study and not for restriction, and 21 U.S.C. § 360ii(a) directs this Secretary to conduct exactly such study.

A second characteristic, and the one place where this question reaches a human disease

Everything above concerns whether an animal can resolve a modulated lamp. The Foundation adds one study on a different characteristic, which is the presence of artificial light at night at all, and adds it for a reason of statutory relevance rather than ecological interest. Its subject is the principal mosquito vector of West Nile virus in the northern United States.

Fyie L.R., Meuti M.E., Sivakoff F., Fiorta M.A. and Gardiner M.M., Artificial light at night (ALAN) is a stronger inhibitor of overwintering dormancy than urban warming in mosquitoes, Journal of Applied Ecology, first published 18 May 2026, doi:10.1111/1365-2664.70407. Described at Appendix C.125.

What was done, and what was found

Culex pipiens f. pipiens females normally enter diapause in autumn in response to shortening day length. A female in diapause halts reproductive development, stops seeking hosts and ceases blood-feeding, and therefore cannot transmit a pathogen. The question the authors asked is whether ordinary residential lighting prevents that from happening.

Mosquito larvae were reared to adulthood in enclosures placed in the yards of private properties, schools and churches in Columbus, Ohio, across the autumns of 2022 and 2023. Each property carried two enclosures, one beneath a light fixture the owner had already installed and one in a dark spot on the same property. Temperature and illuminance were logged every thirty minutes in each enclosure. Diapause was then assessed in the laboratory by egg follicle length, by whether the female would take a blood meal, and by whether she produced offspring.

The central result is a contrast between two enclosures a few meters apart on the same property. Across both Octobers, every mosquito reared in the dark enclosures entered diapause. Of those reared beneath a porch or garage light, 41 percent did. In the dark enclosures in October not one female took a blood meal; beneath the lights, 29 percent did, and of those, nearly three quarters laid eggs and more than half produced living larvae. In September the ALAN-exposed females were roughly twice as likely to blood-feed as those in the dark, 70 percent against 37 percent.

The authors also report what the title states: the effect of the light exceeded the effect of urban warming, and in September overrode it. Temperature predicted diapause in the dark enclosures and

predicted nothing in the lit ones. Whatever the urban heat island was doing to these mosquitoes, the porch light was doing more.

The finding that corrects a proposition elsewhere in this comment

The Foundation places this next because it cuts against a line of argument that appears in this comment and in the Foundation's own advocacy, and because a comment that reported the convenient half of this paper would deserve to be discounted.

The lights in this study were the ones the property owners had already installed, and most of them were warm white at roughly 2,700 to 3,000 kelvin. The intensities were very low: a mean of 4.93 lux, a maximum of 19.07, and at some sites as little as 0.87 lux. Warm white light at under one lux was sufficient to prevent diapause. The authors state the consequence in their policy implications and the Foundation quotes it rather than softening it:

> "Low intensities of warm white ALAN were a stronger inhibitor of diapause initiation than urban warming, indicating that changes in brightness or light colour may not be sufficient to mitigate ecological impacts"

Two qualifications keep that from being the end of the spectral question, and the Foundation states both. The first is that these authors did not test spectrum. They deliberately excluded light color from their analyses, because the only relationship they detected between color and brightness was driven by a single unusually bright site. What they establish is that warm white light sufficed, not that spectrum is irrelevant. The second is that the authors themselves distinguish broad-spectrum warm white from narrow-band emission, and suggest that phosphor-converted amber or monochromatic sources may yet mitigate the effect, noting that moths and spider mites exposed to pure red light did enter diapause.

The distinction matters and the Foundation adopts it. A lamp of low correlated color temperature is not a narrow-band lamp. Warm white light is broad-spectrum light with a reduced blue fraction, and it retains blue content; the authors note that some warm white diodes carry distinct blue peaks absent from non-diode lamps of the same nominal color. So this study does not show that reducing short-wavelength content is pointless. It shows that reducing correlated color temperature and reducing brightness, which are the two mitigations most often proposed and the two most often conflated with reducing blue content, were together insufficient here. The Foundation will not again present a warmer correlated color temperature as an answer to a biological question without saying what spectrum the warmer lamp actually emits. Part V.B.3 and Part V.J.4 make the same point about metrics; this is the same error in the language of product specification.

What the study does not establish, stated before the use made of it

It establishes nothing about human health directly, and no part of the Foundation's submission requires that it should. The outcome measured is mosquito reproductive physiology. No human case was counted, no infection was measured, and vector competence was not tested. The step from a longer biting season to a greater incidence of West Nile virus in people is an inference, and the authors mark it as one: their paper reveals, in their words, a potential explanation for higher mosquito-borne disease risk in cities. The further proposition that light-exposed females may also be more susceptible to infection rests on three separate findings of other groups, one of which was obtained in males of a different ecotype. The Foundation does not assemble those into a chain and does not ask the Department to.

The study is also small in the places that matter most. Diapause was assessed across five to sixteen sites; blood-feeding and fecundity across five to seven. In September only two dark-treatment cages yielded blood-fed females, too few for the model, so a chi-square was used instead. Enclosures were lost to light malfunctions, animal interference and a logger failure, the enclosure design changed between the two years, and year was itself a significant predictor of blood-feeding. The mosquitoes came from a laboratory colony. It is one species in one city.

Why it is in a comment to this Department

For two reasons, neither of which is the one a reader might expect.

The first is statutory and narrow. Paragraph 360ii(a)(2) directs the Secretary to minimize two things, as Part II.D.4 sets out: the emissions of, and the exposure of people to, unnecessary electronic product radiation. The two objects are coordinate, and the first does not require a human receptor. This study is evidence about an emission. A porch light that prevents the principal West Nile vector in the northern United States from entering dormancy is emitting radiation that is doing work in the world beyond the visual task it was installed to serve, and the mitigations these authors recommend are shielding against light trespass and limiting duration by timer or motion sensor. Light trespass is one of the four categories Part II.D.3 identifies as instances of what the statute calls unnecessary. The Foundation offers this study as evidence bearing on that category, measured in a biological endpoint, and not as evidence of a human health effect.

The second is institutional, and it is a fact rather than an argument. This research was supported in part by a grant of the National Institutes of Health, numbered R01AI188567, together with a grant of the National Science Foundation and institutional funds. Part II.E records two other grants of this Department supporting research into the health effects of artificial light at night, and makes the observation that of the four verbs in paragraph (a)(2), the one being performed is the one requiring only money. This is a third grant and it is the most pointed of the three, because of what the research it paid for recommends. The authors' closing recommendation is addressed to bodies of a particular kind:

> "We recommend that mosquito control districts and public health departments consider extending mosquito surveillance and control efforts in the fall, especially in areas with significant light pollution and higher temperatures."

The Department of Health and Human Services is a public health department. It funded the research, the research recommends that public health departments account for light pollution, and the Foundation is aware of no action by any component of the Department in response. That is the same shape Part V.M describes three times in another country and Part II.E describes twice in this one: the question is reached, the money is spent, the recommendation is published, and nothing follows.

One further matter the Foundation records because its practice throughout this comment requires it. The authors note, on the authority of four other studies, that lower-income neighborhoods are more exposed to light pollution and to urban heat. Nothing in this comment should be capable of being read as an argument for reducing lighting in those neighborhoods without regard to what the residents want, and Part V.M states that position in terms. The Foundation records the distributional finding because it bears on where a federal characterization of this exposure would matter most, not because it supports any particular lighting decision.

The study that answers an objection this comment raised against itself

The second study is the one the Foundation regards as the most useful animal work in this comment, and the reason is methodological rather than ecological. Part V.A.3 sets out, from a review by investigators who conduct rodent studies of this exposure themselves, three grounds on which rodent evidence is indirect for a human. The first and largest is phase inversion: most laboratory rodents are nocturnal, so light at night falls in their active phase, while in a person it falls in the rest phase. That paragraph also recorded that no entry in this comment's appendix used a diurnal model, and called it a gap in the collection. This study closes it.

Vardi-Naim H., Janovsky G., Kronfeld-Schor N. and Wine Y., Artificial light at night disrupts immune rhythms in wild rodents under semi-natural conditions, Environmental Pollution, doi:10.1016/j.envpol.2026.127774. Described at Appendix C.126.

The design, and why its design is the point

Two closely related species of spiny mouse share rocky desert habitat in Israel and divide it by time: Acomys dimidiatus is nocturnal and Acomys russatus is diurnal. The investigators placed 160 animals, eighty of each species, in sixteen outdoor enclosures of one and a half by three meters, ten animals to an enclosure at an even sex ratio, where they could roam, interact and breed through the natural cycle of daylight, weather and season. Eight enclosures received artificial light at night and eight did not. The experiment ran about eight months, from December 2021 to August 2022, after an eight-week acclimation.

The exposure was characterized, which is why the Foundation can use it. It was a white light-emitting diode of approximately 6,000 kelvin correlated color temperature at an illuminance of 10 to 15 lux, measured at the entrances of the nesting shelters, with lower levels inside the shelters so that illumination across an enclosure was deliberately uneven. That is a blue-rich white diode at an illuminance of the same order as what a street lamp or a neighbor’s security lamp delivers to a bedroom window.

The Foundation notes the contrast with the mosquito study above, because the two together bracket the variable at issue. That study used warm white light of 2,700 to 3,000 kelvin at under one lux to nineteen lux. This one used cool white light of about 6,000 kelvin at 10 to 15 lux. Different spectra, overlapping intensities, effects in both.

What was found, reported in full because it is mixed

The cleanest result, and the one that holds in both species, concerns the timing of an immune response. Animals were immunized with keyhole limpet hemocyanin twice, fourteen days apart, some during their rest phase and some during their active phase. Under natural light, the ratio of the secondary to the primary antibody response was significantly higher in animals immunized during their rest phase, in both species. Under artificial light at night that difference disappeared in both species.

The Foundation asks the Department to notice the form of that result and not only its direction. The advantage attached to the rest phase, and it attached to the rest phase in the diurnal animal and in the nocturnal animal alike. It was therefore a property of circadian phase rather than of nocturnality. That is the finding that bears on Part V.A.3, because the standing objection to rodent evidence in this field is that light at night means something different to a nocturnal animal than to a person. Where an effect is indexed to the rest phase in both temporal niches, that objection does not apply to it.

The remaining rhythm results are split, and the Foundation sets out all four combinations rather than the two that are favorable.

- Circulating lymphocyte frequency in the diurnal species: a twenty-four-hour rhythm in the control animals and none detectable under artificial light at night. Disruption shown.
- Circulating lymphocyte frequency in the nocturnal species: a rhythm in both groups, and a formal comparison of models found no difference between them. No disruption shown.
- Fecal cortisol in the nocturnal species: a rhythm in both groups, but a significant treatment interaction, with reduced amplitude and a small phase shift. Disruption shown.
- Fecal cortisol in the diurnal species: no significant daily rhythm detected at all, in either group. Nothing to disrupt, and the authors note that this is contrary to earlier evidence of daily glucocorticoid variation in this species.

So of the four, two showed disruption, one showed none and one failed to detect the underlying rhythm. The paper’s title is supported by the antibody result and by two of the four rhythm comparisons, and the Foundation will not report it as though all four had run the same way.

A further complication the authors raise against their own mechanism deserves recording. Lymphocyte frequency peaked during the daytime in both species, which is the rest phase for only one of them, yet the antibody advantage followed the rest phase in both. The authors conclude that the trafficking of lymphocytes cannot by itself explain the antibody result, and hypothesize instead that lymphocytes may be more permissive to activation during the rest phase. They offer that as a hypothesis and the Foundation repeats it as one.

The survival result, and the weight it can carry

Animals exposed to artificial light at night died sooner. The Kaplan-Meier comparison gives a log-rank probability of 0.035 and the proportional hazards model gives a hazard ratio of 2.35, with an interval from 1.03 to 5.38 and a probability of 0.042, across eighty animals with twenty-four deaths and no difference between species or sexes.

The Foundation states what that figure will and will not bear, because a doubled hazard of death is the most arresting number in this subsection and the most easily overstated. The lower bound of the interval is 1.03, so the result is barely distinguishable from no effect. The authors could not determine any cause of death and say the result should be read as a fitness-related association and not as evidence of a pathological mechanism; in their earlier work in the same enclosures a subset of animals was examined and no clear pathological cause was identified. They attempted to model the enclosure as a random effect and the model would not converge, so the analysis treats eighty animals housed ten to an enclosure as independent, which overstates the precision of the interval rather than the direction of the effect. Their own retrospective sensitivity analysis puts the power to detect a hazard ratio of this size at about seventy-two percent. And the survival analysis was confined to the animals for whom a complete set of immune measurements existed, which is a restriction decided after the fact.

One further qualification matters more than any of those. The Foundation had taken this survival finding for a replication, and it is one, but not an independent one. The authors describe it as consistent with their own previous work in the same enclosure system with the same species. It is the same group confirming its own earlier result, which is worth considerably less than a second laboratory obtaining it, and the comment says so.

What it does not establish

No human effect. The animals are wild rodents and every endpoint is theirs. Melatonin, which is the mediator the mechanism is usually attributed to and the subject of Part V.F, was not measured, and the authors state that direct inference about melatonin-dependent mechanisms is therefore limited. Lymphocytes were identified by light-scatter morphology alone, because species-specific reagents do not exist for these animals, and the authors acknowledge that the gate may include other leukocytes. The physiological sampling was cross-sectional, each animal bled once, so the daily curves are assembled across animals rather than followed within them. And the enclosures are not the desert: the authors say so, noting that they limit pathogen diversity, predation and the unpredictability of resources, and call their approach a deliberate compromise.

The Foundation also records an analytical choice that bears on every result above. Values more than two standard deviations from their group mean were excluded as outliers. That is an aggressive rule, it was applied group by group, and in a study with these sample sizes it can affect which comparisons reach significance. The Foundation does not suggest it was applied in order to obtain the results, and notes that the authors disclosed it. It is recorded because a reader entitled to weigh the findings is entitled to know it.

Why it is in a comment to this Department

On the same narrow ground as the study before it, and on one further ground that this study supplies and the other does not.

The narrow ground is the emissions limb of paragraph 360ii(a)(2), set out at Part II.D.4, which directs the minimization of emissions of unnecessary electronic product radiation and does not require a human receptor. This is a characterized emission, a blue-rich white diode at a stated illuminance, producing measurable biological effect in a mammal. The Foundation offers it as evidence about the emission.

The further ground is mechanistic, and it is the reason this entry earns space in a comment about human health. The architecture through which the effect is proposed to run — retinal photoreception, the suprachiasmatic nucleus, melatonin and glucocorticoid output, and peripheral clocks in immune tissue — is the architecture Part V.F describes in human beings. The authors chose these species for that reason and say so, offering them as a model for the study of biological rhythms and of this exposure in diurnal mammals, including humans. Appendix C.84 records that photopigments of the opsin family are expressed in human B-cells and T-cells, which is a second and separate route by which light and immune function might be connected and which this study does not test.

The Foundation therefore does not ask the Department to find that artificial light at night impairs human immunity. It asks the Department to notice that a quantified dose of the emission at issue, in a mammal, measurably disorganized the timing of an adaptive immune response, and that the advantage lost was indexed to the rest phase in a diurnal animal as well as a nocturnal one. Whether the same holds in a person is a question for research, and paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support it.

One line of work the Foundation flags for the Department rather than relying on. Both this study and the mosquito study above cite, at second hand, findings by Kernbach and colleagues that artificial light at night raises the competence of a wild bird reservoir for West Nile virus and lengthens its infectious period. If those findings hold, then two halves of one transmission cycle have been separately associated with this exposure by independent groups: the vector's season at one end and the reservoir's infectiousness at the other. One of those two papers has since been obtained and is at Appendix C.145, and the Foundation reports at once that it does not run in the direction the sentence above invites. The other has not been obtained. The convergence is still stated as a reason for the Department to look and not as a finding.

The one of the two that has been obtained, and why it complicates rather than completes the picture

Kernbach, Martin, Unnasch, Hall, Jiang and Francis published in Proceedings of the Royal Society B in 2021 an analysis of the Florida Department of Health sentinel chicken surveillance program, which maintains caged flocks across the state and tests them monthly for antibodies to West Nile virus. Described at Appendix C.145. The analysis covered the months of June to December across four years, drawing on more than a thousand surveillance events at eighty sites and a hundred and five distinct coordinates.

Two findings, and the Foundation takes them in the order that is least comfortable for it. The first is the one that helps. Artificial light at night was the only one of the urbanization variables in the model with a strong effect. Impervious surface showed none. Human footprint showed none. Human population density was mixed and small. The second standing objection recorded at Part V.A.2 — that outdoor light at night is among the closest available proxies for urbanization and that the urbanization is doing the work — was tested here against three separate measures of urbanization entered in one model, and the light survived and they did not.

The Foundation states at once what that is not. It is not a second instance of the thing relied on at Part V.A.2, because the study relied on there is a human cohort of twenty-eight thousand people in which air pollution was measured and adjusted for, and this is a caged bird. An objection answered in a sentinel species is answered for that species. What it shows is that the objection is answerable, that it has now been answered twice in two literatures by two methods, and that the answer did not come out the way the objection predicts.

The second is the one that does not help, and the Foundation states it plainly because a comment that reported the first without the second would be doing the thing it criticizes. The relationship was not a straight line. Light was modeled as a second-order polynomial, and both the log and the squared terms carried the effect. Exposure risk was greatest at the lowest levels of artificial light, at radiance intensities below one in the units used, and declined toward the intermediately lit sites. The headline of the university press release that brought this study to the Foundation says light pollution drives increased risk. The curve in the paper says risk peaks in the faintly lit places and falls where the light is brighter.

Three things follow and the Foundation separates them. The first is that the proposition more light means more harm is false for this endpoint, and the comment does not advance it for any endpoint; Part V.A.2 has said throughout that a limit is a point chosen on a curve and that the curve has to be established rather than assumed. The second is that a standard which reduced intensity without knowing the shape of the curve could, for an endpoint of this kind, move an exposure toward the peak rather than away from it. The Foundation does not know whether that is a real risk here and neither does anybody else, which is the point. The third is the use the Foundation does make of it, and it is the strongest illustration in this comment of an argument made at Part V.A.2 from the other direction entirely: this shape could not have been found by comparing a lit place with an unlit one. It was found because somebody fitted a curve. A literature built from presence-and-absence comparisons would have reported either an effect or no effect and would have been wrong either way.

And the exposure variable belongs with the rest. It is not a measurement at the coop. It is the published world atlas of artificial night sky brightness at one-kilometer resolution, which is a modeled product derived from the same satellite radiometer whose limitations Part V.J.4 collects. The Foundation has added this entry to the census of entries at Part V.J.4 that take a satellite product as their own exposure variable, and notes that this is the first in which the outcome is a human notifiable disease in a sentinel species rather than a biological measure in a wild one.

A third study, on an endocrine organ this comment has already reached from the human end

The last of the three is the weakest and the Foundation says so before describing it. Its quantitative measures found nothing, its groups are of six animals and four, and it measured no hormone. It is here for one reason, which is the organ.

Ajduković M., Drobnjaković M., Šošić-Jurjević B., Vučić T., Petrović T. and Prokić M., Influence of Artificial Light at Night on Thyroid Gland Histology in Triturus Newts (Urodela, Salamandridae), Animals, volume 16, issue 3 (2026), article 483, doi:10.3390/ani16030483. Described at Appendix C.127.

Metamorphosed juvenile crested newts, bred in the laboratory from eggs of nine females taken from a wild population in Serbia, were divided into a group kept in natural darkness at night, below one tenth of a lux, and a group exposed at night to a white light-emitting diode of 6,000 kelvin at 30 lux, for sixty days. Both groups received about 450 lux of the same diode light by day, and the day length was adjusted weekly to follow the natural photoperiod from early September to late October. The thyroid glands were then examined by stereology and by immunohistochemical staining for thyroglobulin, the protein in which the gland stores its hormone precursor.

The authors state why they chose that exposure, and the Foundation notes it because this is now the third study in this subsection to characterize its light. They selected a diode source as the predominant outdoor light, an intensity of 30 lux as corresponding to what is perceived in public gardens and emitted by street lights, and a correlated color temperature of 6,000 kelvin as the one mostly used outdoors. Appendix C.126 used 6,000 kelvin at 10 to 15 lux and Appendix C.125 used 2,700 to 3,000 kelvin at under one lux to nineteen lux. Three independent groups, three stated exposures, all of them within the range a person encounters at a bedroom window.

What was found, with the nulls first

The stereological measurements, which are the quantitative part of the study, found no difference between the groups in anything. Not in the absolute volume of the gland, at a probability of 0.873. Not in the volume of the follicular epithelium, at 0.689. Not in the volume of the colloid, at 0.749. Not in the volume of the interstitium, at 0.936. Those are four null results and the Foundation reports them before the one positive result because that is the order in which the paper obtained them.

One measurement differed. The optical density of thyroglobulin immunostaining was higher in the light-exposed animals, at a probability of 0.030, which the authors read as accumulation of the protein at the apical surface of the follicular cells and therefore as a gland releasing less of it into circulation. Alongside that they describe, from representative micrographs, large colloid-filled follicles, a flattened epithelium and an absence of the resorption vacuoles that indicate active secretion. Those morphological observations were not quantified or counted. So the measures that were quantified were null, and the observations that carry the paper's interpretation were not quantified.

Three limits, one of which the Foundation regards as unresolved

First, the numbers. Six animals in each group for the stereology and four in each group for the immunohistochemistry. The authors explain that six is the minimum required for histological analysis and that Triturus ivanbureschi is strictly protected in Serbia under a named regulation, so the smallest possible number was used. The Foundation accepts that explanation entirely and does not accept that it changes what four animals per group can support.

Second, and this is the unresolved point. Ten images were analyzed for each of the eight animals in the immunohistochemical comparison. The methods do not state whether the significance test was performed across the eight animals or across the eighty images. The difference matters and is not a technicality: images taken from the same animal are not independent observations of the effect of a treatment applied to animals, and a test that treats them as independent will report a probability smaller than the design supports. The Foundation cannot tell from the paper which was done, and the single positive result in this study depends on the answer. Until it is resolved the comment states the result and does not rely on it.

Third, no hormone was measured. The authors say so themselves and give the reason: a juvenile newt is too small to yield enough blood for a reliable assay without pooling or a species-specific validated method. Thyroxine, triiodothyronine, thyroid-stimulating hormone and melatonin were all unmeasured. The hypofunctional state the paper describes is therefore an inference from the appearance of tissue, and the two mechanisms the authors propose, melatonin suppression and corticosterone, are offered as plausible pathways and not as findings. They also note that in amphibians the effect of light at night on circadian regulators is poorly understood, and cite work finding only slight effects on the melatonin signaling pathway in two frog species.

The authors are candid about magnitude in a way that cuts against any use of this paper for alarm, and the Foundation repeats it. They compare their findings to the same laboratory's earlier work exposing these newts to thiourea, a recognized endocrine disruptor, and state that the changes they saw from light are relatively subtle by comparison. Their own ranking places this exposure below a chemical disruptor in effect.

Why it is here, which is the pairing and not the finding

Appendix C.44 of this comment is a prospective cohort of 464,371 American adults in which the highest quintile of satellite-estimated light at night was associated with a 55 percent higher incidence of thyroid cancer, a hazard ratio of 1.55 with an interval of 1.18 to 2.02. That entry records two things about itself. The exposure is spectrally blind, for the reasons Part V.J.4 gives. And the mechanism the authors propose, running through melatonin, was hypothesized and not measured.

The entry also sets out at length the overdiagnosis objection that governs any thyroid cancer finding, and the Foundation does not withdraw it.

This newt study is the mirror image of that one. Its exposure is characterized to a stated spectrum and a stated illuminance. It measured a marker in the tissue of the organ itself. And it is six animals, with no hormone assay, in a species no part of this comment claims is a model for a person.

The Foundation submits the pairing and nothing more. The same endocrine organ is under investigation at both ends of this literature. At the human end there is a cohort large enough to detect an association and an exposure measurement that cannot say what the light was made of. At the animal end there is a characterized emission and a tissue measurement in a sample too small to settle anything. Neither end has what the other lacks, and no study the Foundation has found has both. That is a description of a research gap, and paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support the research that would close it, while paragraph 360ii(a)(4) directs the study and evaluation of emissions and conditions of exposure. The Foundation asks for nothing in this passage beyond that.

What this study does not establish should be said plainly, because the subject invites more than it supports. It establishes nothing about human thyroid function, nothing about human thyroid disease, and nothing about hormone concentrations in any animal. It does not establish that artificial light at night is an endocrine disruptor, a term the authors use as a category for what they are investigating rather than as a conclusion. And on its own quantified measures it established no difference at all.

The study that tests the remedies, and finds each of them wanting

The subsection ends with the strongest study in it. Everything before asks whether artificial light at night does something. This one asks the question a regulator has to answer, which is whether any of the things proposed to fix it work.

Briolat E.S., Galloway J.A.M., Cornelius E., Wright C.J., Bennie J., Gaston K.J. and Troscianko J., Severe and widespread reductions in night-time activity of nocturnal moths under modern artificial lighting spectra, Proceedings of the Royal Society B, volume 293, issue 2063 (2026), article 20252704, doi:10.1098/rspb.2025.2704, open access. Described at Appendix C.128.

The Foundation discloses a relationship before using the paper. Two of its authors, Jonathan Bennie and Kevin Gaston, are authors of the collation at Appendix C.94 on which the first half of this subsection rests, and both are co-authors of the satellite instrument paper relied on at Part V.J.4. The two halves of this subsection are therefore not independent of each other in authorship, and the same University of Exeter group appears three times in this comment. The Foundation states that here rather than leaving a reviewer to find it, and does not present the flicker material and the moth material as independent corroboration.

The design, which is why the result carries weight

Eight hundred and forty-three moths, of twenty-three species in three families, were tested individually over a hundred and twenty-four nights across two summers in Cornwall. Each animal spent a night in a small chamber, outdoors, under one of eight lighting conditions, filmed from above by infrared at one frame every ten seconds from the end of twilight until sunrise. Activity was scored as the proportion of frames in which the animal had moved. Moths were taken both by light trap and by hand net, deliberately, so that species with different attraction to light were represented. The analysis was run twice, once with species and family as random effects and once as a phylogenetic mixed model built on a tree inferred from nearly five thousand single-copy orthologous proteins from published genomes, and the two analyses agreed.

The lighting was characterized rather than described. Every treatment was set to ten lux at the chamber lid and calibrated with a spectroradiometer, and the composite treatments were matched to their broadband equivalents in human color space to a Euclidean distance below one. The eight

conditions were a dark control under the open sky; a white diode at a correlated color temperature of 5,986 kelvin; a narrowband amber diode at 1,621 kelvin; a broadband phosphor-converted amber diode at 1,743 kelvin; two composite lights made by combining three narrowband red, green and blue diodes to match the white and the broadband amber for a human observer; and the broadband amber at one lux and at a tenth of a lux.

One number in the methods is worth more to this comment than any other in the paper. The authors measured the natural night at their sites, a hundred and eleven times, and report a median illuminance of 0.0168 lux, with an interquartile range of 0.0102 to 0.0332 lux. That is the condition under which these animals evolved, measured with an instrument. The lowest treatment was about six times brighter than it and the standard treatment about six hundred times brighter. Part V.B.5 asks what the sources were under which human visual and circadian physiology developed; this is the same question answered for another taxon, with a figure attached.

What was found

Light suppressed activity, severely, and the median reduction per species at ten lux was as follows.

- Composite white, from red, green and blue diodes: 93 percent.
- Broad-spectrum white diode: 85 percent.
- Composite amber, from red, green and blue diodes: 82 percent.
- Broadband phosphor-converted amber diode: 73 percent.
- Narrowband amber diode: 57 percent.
- Broadband amber at one lux: 24 percent.

Every one of those except the broadband amber at a tenth of a lux differed significantly from the dark control, in both analyses. Depending on the treatment, between sixty-five and one hundred percent of the species tested were less active under light than in darkness.

The amber result, which corrects this comment for the third time

Part V.M records that the Foundation has twice had to amend its own framing of the amber question, once because a study it relied on had not analyzed spectrum at all and once because warm white light at under one lux was sufficient to prevent diapause in a mosquito. This study requires the third amendment, and it is the one that should settle the matter, because it is the only test the Foundation has found in which the candidate remedies were run against each other at a fixed intensity.

The result is neither of the two simple answers. Amber is not a solution: narrowband amber, which is the longest-wavelength and most spectrally restricted outdoor light anyone proposes, still cut activity by 57 percent at an intensity found beneath an ordinary street light. The authors put it plainly, that switching to amber lights would not mitigate the impacts of lighting on activity in many areas. But amber is not useless either, and a comment that reported only the first half would be doing what this one criticizes. Narrowband amber at 57 percent and broadband amber at 73 percent are meaningfully better than white at 85 percent and composite white at 93 percent, and the authors' own conclusion is that amber lighting deployed at the lowest possible intensity may have the least impact for nocturnal moths.

What this study establishes about spectral mitigation is two-sided, and the Foundation states both sides. Reducing short-wavelength content reduces the effect. It does not remove it. Two further studies in this subsection qualify that result in ways this one could not reach, the first by testing the same remedy against a different exposure regime and the second by testing the warmest lamp in general service. The Foundation therefore states its settled position once, at the end of the three moth studies, rather than here. What can be said here is that the remedy this study tested was tested properly and was found to be partial, and that the submission resting on it is about the structure of a standard rather than about any lamp.

A consequence for the instrument described at Part V.B.3

The Foundation draws one inference against material it has itself just put before the Department. Part V.B.3 sets out the Andalusian regulation now in force, which for the protected surroundings of astronomical observatories requires an amber source with an effective wavelength between 585 and 605 nanometers and a spectral width not exceeding 25 nanometers. That is a narrowband amber specification, and it is the most spectrally restrictive requirement the Foundation has located in any law.

The narrowband amber diode tested in this study is a lamp of that character, and at ten lux it suppressed moth activity by 57 percent. So the strictest spectral limit in force anywhere, applied at street-light intensity, would still be expected to produce a substantial biological effect in this taxon. The Foundation does not offer that as a criticism of the Andalusian rule, which was written to protect astronomical observation and achieves it. It offers it as the reason a spectral limit cannot stand alone: the quantity and the duration of the emission have to be limited too, and Part V.B.3 records that the same decree limits both. A standard that addressed spectrum only would, on this evidence, leave most of the effect in place.

The composite-light result, which is a proposed remedy failing

A specific mitigation has been proposed in the literature: that white light assembled from three narrowband diodes, red, green and blue, should be less harmful than broad-spectrum white light that looks identical to a person, because its emission overlaps less with the sensitivities of other animals. This study tested it directly and found no benefit. The composite white and the broadband white did not differ significantly, at a probability of 0.580, nor did the composite amber and the broadband amber, at 0.917. The composite white produced the largest suppression of any treatment.

The authors record that this contradicts recent findings in moths and in mosquitoes, and offer an explanation the Foundation regards as the most useful general proposition in the paper: that the earlier work measured attraction to light or flight past pulses of light, while this work measured continuous exposure, and that the attractiveness of a light is not a good proxy for its other effects. A lamp may draw fewer insects and still immobilize the ones that are near it. The Foundation asks the Department to carry that distinction into any assessment it commissions, because the same error is available in the human case: a lamp that is judged acceptable on one endpoint has not been assessed on the others.

Intensity, skyglow, and a result that runs the other way

Lowering the intensity helped but did not reliably clear the effect. In the main experiment the broadband amber at one lux and below was not significantly different from natural darkness once phylogeny was accounted for. But a second experiment on five species found significant suppression under white light at one lux and under broadband amber at one lux, and species-level comparisons showed many species still affected at these levels, including under white light at a tenth of a lux, which the authors describe as similar to skyglow. Since skyglow is far more widespread than direct lighting, that is the finding with the largest geographic reach and the least evidence behind it, and the Foundation reports it as the authors do, as a reason for further investigation.

One set of results runs clearly against the general picture and the Foundation reports it because candor requires it and because it bears on how confidently anyone should legislate from this. Several species became markedly more active under the dimmest amber light, not less. Under broadband amber at a tenth of a lux the peppered moth increased its activity by 618 percent relative to darkness, and three other species by between 119 and 166 percent. Under broadband amber at one lux the peppered moth increased by 240 percent. The direction of effect at low intensities is therefore not uniform across species, and a mitigation that suppresses activity in most species while greatly increasing it in others is not obviously benign. Nothing in this comment should be read as asserting that the biological consequences of these lamps are understood.

Two findings that bear on other parts of this comment

The first concerns part-night lighting, which Part V.M examines at length because three British jurisdictions switched their street lights off at or around midnight and the Foundation relies on what followed. These authors observe that most insects reach lights within three hours after sunset, that the same is true of early-emerging bats, and conclude that switch-offs would need to be earlier than midnight to provide effective mitigation. That is the second independent arrival at the same point in this comment: Appendix C.124 records that the household survey in the largest part-night lighting study found no measurable change in residents' self-reported sleep, and the Foundation noted there that a midnight switch-off leaves the evening exposure window, which is the biologically consequential one, untouched. Two literatures, two taxa, one conclusion about timing.

The second is methodological and the Foundation flags it because it bears on the reliability of a whole literature. Moths caught in light traps were less active than moths caught by hand net, and in one species the control activity of trap-caught animals was 89 percent lower than that of net-caught animals, which would make the apparent effect of light smaller than it is. The authors state the consequence: using artificial light to collect the animals whose response to artificial light is then measured can mask the effect being studied. Part V.A.2 sets out how this comment grades evidence; this is a selection mechanism of a kind that grading does not capture, and the Foundation records it as a caution applying to the insect literature generally and not to this paper, which tested for it.

What it does not establish

The authors state the governing limitation themselves and the Foundation adopts it without softening: the moths could not escape the light or seek refuge from it. An animal in a chamber of a few centimeters under a lamp has nowhere dark to go, and a moth in a hedgerow may. The authors offer in support only the observation that moths are known to remain at lights for long periods, sometimes through the following day, and call that anecdotal. Until the experiment is done where the animal can leave, the magnitude of these figures belongs to the apparatus as well as to the light.

Three further limits. Activity is a proxy and not a fitness endpoint: nothing in this study measures reproduction, feeding, predation or survival, and the link to the population declines the paper invokes is an inference the authors mark as one. The animals were introduced after twilight had ended, so the paper cannot say whether light delays the onset of activity, which may be where the effect matters most. And these are twenty-three common and widespread British species in three families of larger moths, not a sample of Lepidoptera.

And it establishes nothing whatever about human health. No part of the Foundation's submission requires that it should. Its place in this comment is as evidence about an emission and about the adequacy of proposed remedies, which is the subject of Part IX.

Why it is here

On the emissions limb of paragraph 360ii(a)(2), as Part II.D.4 construes it, and for one thing more. The Foundation has asked the Department throughout this comment to characterize four properties of these products: their spectral content, their quantity, their geometry and their duration. The usual objection is that the first of those is the one that matters and that a shift to warmer or narrower spectra disposes of the question. This study is the most direct evidence the Foundation has found that it does not. At a fixed intensity, every spectrum tested produced a large effect, the best of them leaving more than half of it in place, and a composite spectrum engineered for the purpose produced no benefit at all. Spectrum, intensity and duration each mattered and none was sufficient alone. That is an argument for characterizing all four, which is what paragraph 360ii(a)(4) directs and what Part IX requests.

A fifth study, on headlamps, and the pair it forms with the fourth

This study is here for two reasons. It is the only study in this comment that applies an ecological method to the product class on which the Foundation has done the most work, which is vehicle lighting. And read against the moth study at Appendix C.128, which immediately precedes it, it

yields the opposite answer on the same proposed remedy, which required the Foundation to refine for a fourth time what it says about spectral mitigation.

Fabusova M., Gaston K.J. and Troscianko J., Pulsed artificial light at night alters moth flight behaviour, Biology Letters, volume 20, issue 11 (2024), article 20240403, open access. Described at Appendix C.132. Two of its three authors are authors of the study at Appendix C.128, and the disclosure made there about the recurrence of this group applies here.

The exposure, which is larger than anything else in this subsection

Four hundred and twenty-eight wild-caught moths of sixty-four species in seven families were each dark-adapted for at least ten minutes, then released while exposed to a single ten-second pulse of light at one meter, and their first behavior recorded. Four light treatments were used, matched in correlated color temperature and in intensity to human vision by finding metameric pairs: a cool phosphor-converted diode at 5,664 kelvin, a warm phosphor-converted diode at 3,102 kelvin, a cool composite diode of red, green and blue at 5,661 kelvin, and a warm composite at 3,222 kelvin. A dark control was also run.

The illuminance of each treatment was between about 430 and 465 lux. The Foundation draws attention to that figure because it is of a different order from everything else in this subsection. The other four studies used light at under one lux, at ten to fifteen lux, at ten lux and at thirty lux. This one used something near four hundred and fifty. The reason is the subject: the authors state that vehicle headlamps form horizontally focused beams typically an order of magnitude more intense than static street lighting, and they cite an estimate that seventy percent or more of the land area of Great Britain may be affected to some degree by light from road vehicles.

The authors also took their animals by hand net under a red headtorch, expressly to avoid the sampling bias that light traps introduce. The study at Appendix C.128 later measured that bias and found it substantial. The Foundation notes the precaution because it was taken before the problem was quantified.

The mechanism, which is the same mechanism this comment argues about human drivers

The authors set out why a pulse should matter more to an insect than to a person, and the Foundation records it because Part V.C makes the human half of the same argument. A vertebrate pupil constricts in about a second. Insects have no pupil of that kind; they adapt by migrating screening pigment within the optical units, a process that can take over thirty minutes to reverse, and which has been found to operate more slowly at night than by day. An animal with a thirty-minute recovery constant, struck by a beam of several hundred lux for ten seconds, is in a different position from a driver whose pupil closes in a second and whose recovery Part V.C.3 measures in seconds.

The Foundation does not offer the insect case as evidence about human recovery, which Part V.C treats on its own evidence. It offers the parallel as the reason a single exposure metric cannot serve both, and as the reason the duration of a pulse is a characteristic of the emission that paragraph 360ii(a)(4) directs the Secretary to evaluate.

What was found

The clearest result is the comparison with darkness. Released in the dark, 86 percent of moths flew directly upward, which the authors read as the normal escape response. Released into a pulse of light, an average of 37 percent did. The pulse replaced the ordinary response with a range of others.

On which light was worst, the Foundation reports the three tests separately because they do not all point the same way.

- Erratic flight alone was most frequent under the cool phosphor-converted diode but the effect was not significant on any test: neither color temperature, nor spectrum, nor their interaction, each at a probability of 0.350.
- Flight into the light was significantly predicted by color temperature, being more frequent under cool lights of either spectrum, at a probability of 0.002. Spectrum alone did not predict it.
- The two combined, which the authors treat as the harmful class, showed a significant interaction between color temperature and spectrum at a probability of 0.006, and were most pronounced under the cool phosphor-converted diode. The authors give the effect sizes: harmful responses were 1.8 times more likely under that lamp than under the other three, and 25.5 times more likely than in darkness.

Moths also responded fastest under the cool phosphor-converted diode, about twelve seconds faster than under the others, against a mean latency across treatments of 21.45 seconds. And there was no detectable difference between taxonomic families, which the authors note is contrary to studies of attraction to static lights and suggests the result may extend beyond the sixty-four species tested.

The pair, and the fourth refinement of what this comment says about spectrum

Part V.I has already recorded that the Foundation's position on spectral mitigation has been corrected three times. This study requires a fourth correction, and it is the most useful of the four because it does not subtract from the position but qualifies the circumstances in which it holds.

The study at Appendix C.128 tested composite lights made from three narrowband diodes against broad-spectrum lights matched to them for human vision, under continuous exposure at ten lux, and found no benefit whatever: probabilities of 0.580 and 0.917, with the composite white in fact the worst treatment of all. This study tested the same proposed remedy, against a single intense pulse, and found that it helped: the harmful class of responses turned on an interaction in which the cool phosphor-converted lamp was worst, and the authors conclude that lower color temperature or composite alternatives are likely to provide benefits.

Two studies, the same laboratory, two of the same authors, the same county, the same proposed remedy, opposite answers. The later study names this one as the contrasting finding and supplies the explanation, which the Foundation adopts: the earlier work measured a response to a brief pulse while the later measured continuous exposure through a whole night, and the attractiveness or immediate effect of a light is not a good proxy for what it does over hours.

The refinement this pair supplies is therefore about exposure regimes and not about amber. Whether a spectral change helps at all depends on the regime against which it is tested: against a brief intense pulse a composite or warmer spectrum reduced the most harmful immediate responses, and against continuous exposure at street-lighting intensity it did not measurably help at all. A mitigation validated against one regime therefore cannot be assumed to work against another, and a standard that prescribes a spectrum without specifying the exposure regime it is meant to address has not said enough to be assessed. The Foundation carries that refinement forward into the settled position stated at the end of the next study and states no separate position here.

What the authors say about human beings, which the Foundation records with care

The paper closes on a proposition about people, and the Foundation reports it as the authors framed it rather than as it would prefer. Noting that the blue peak of phosphor-converted diodes has been associated with decreasing alertness in older drivers, they write that they "can speculate that changing the spectral composition of car headlights by reducing the blue peak will likely be associated with beneficial changes to road safety for moths and humans alike."

Three ecologists, in a conservation collection of a biology journal, writing about insects, reach a conclusion about the spectral composition of motor vehicle headlamps and human road safety. The Foundation notes the convergence with its own position at Part VI.B and then states plainly what the

sentence is and is not. It is speculation, and the authors label it so. It is outside their field. It rests on two cited studies of human pupillary response and alertness which the Foundation has not read. It is not evidence of anything about human drivers and the Foundation does not offer it as such. What it is worth is this: the proposition that the blue content of headlamps is worth reducing is now reached independently by investigators with no interest in the Foundation's position and no connection to the American regulatory dispute, on their way to a different conclusion about a different taxon.

What it does not establish

The light did not move. The authors say so: the source was static and the pulses were intended to simulate a passing headlamp encountered at close range. A real headlamp approaches, brightens, sweeps and recedes, and arrives with noise and moving air. The exposure was a single pulse, where a moth beside a road receives many at traffic frequency. Only the first behavior within two minutes was recorded: nothing about survival, reproduction, collision or energy expenditure was measured, and the harm is inferred from the character of the response rather than observed. The animals were handled and released from a pot, and the authors list an escape response to handling among the mechanisms that could confound or supersede the others. The mechanism was not determined and the authors say it cannot be from behavioral data alone. The control arm was forty-two animals and was not balanced across treatments. And the erratic flight result, which the abstract leads with, was not statistically significant on its own; the significant findings are flight into the light and the combined class.

It establishes nothing about human health. Its place in this comment is as evidence about an emission of a product class, and about the inadequacy of a spectral prescription that does not specify the exposure regime.

A sixth study, which measured how much of the problem the instrument cannot see

The Foundation asks the Department to read this study before the others in this subsection if it reads only one. Its subject is moths, and it is the third and last of the moth studies. Its importance is that it quantified the blindness of the method by which almost everything known about this exposure has been learned.

Degen J., Storms M., Lee C.B. and nine co-authors, the last being Degen T., Shedding light with harmonic radar: Unveiling the hidden impacts of streetlights on moth flight behavior, Proceedings of the National Academy of Sciences, volume 121, number 42 (8 October 2024), article e2401215121. Described at Appendix C.135.

The design, which is the reason the finding was available to be made

Ninety-five flights of ninety-four individual moths were tracked by harmonic radar on an open pasture near Großseelheim, Germany, in June and July 2018. A transponder weighing 10.5 milligrams was fixed to the thorax; it carries no battery, being powered by the radar beam, and returns the beam at twice the transmitted frequency, which permits a position fix every three seconds out to a kilometer. Six high-pressure sodium streetlights on three-and-a-half-meter poles were arranged in a circle of eighty-five meter radius with the release point at the center, their light cones not overlapping. Moths were released one at a time, with the lights on or off on alternating nights, and tracked until the signal was lost for ten minutes.

What that apparatus permits is the observation of the whole flight, inside and outside the lit area. Every previous method — the light trap, the capture and recapture, the observation of the lamp itself — can only record an animal that came to a light. The radar records the animals that did not.

The finding

Every moth tested had been caught using light, which is to say every moth tested was known in advance to respond to light by approaching it. The authors state the consequence for their sample plainly: it "might not be representative for the whole population." They expected most of these animals to fly to a streetlight.

Of the fifty released with the lights on, two flew to a streetlight. Four percent. Those two showed the behavior the literature describes, circling the lamp and falling to the ground. Twenty-eight individuals entered the twenty-three meter radius within which a lamp of this type is believed to capture a moth; twenty-four of them flew out again and continued. Six individuals, twelve percent, passed within ten meters of a burning streetlight without interrupting their flight — a distance at which the authors had separately confirmed, by releasing seven privet hawk moths ten meters from a lamp, that every animal circles and crashes.

And yet the lights changed the flights. Turning them on significantly increased the tortuosity of flight in both groups studied, which is to say the flights became less efficient: in hawk moths when the moon was above the horizon, in lappet moths when it was below. In lappet moths the circle of six lamps acted as a barrier the animals were significantly prevented from crossing when the lights were on and the moon was not visible, at a probability of 0.039.

Why this is the most useful study in this Part

Because the effect was in the ninety-six percent. The animals that arrive at the lamp are the ones the method sees, and they were a twenty-fifth of the animals affected. The authors draw the conclusion themselves, and the Foundation adopts it without enlargement: "light-trap catches might underestimate the impact of ALAN since only individuals that fly toward the light source are sampled," and the observation of moths at streetlights "might only concern a small fraction of individuals that pass a streetlight in free-flight." Their own framing of the question is the one the Foundation would put to the Department: how well can light traps placed at the lamp post reflect the real impact of streetlights?

This is the seventh time in this comment that the Foundation has had to report that the instrument used to observe this exposure cannot see it. The first six concern the satellite radiometers whose spectral band begins at five hundred nanometers and which are therefore blind to the emission that has grown fastest; those are collected at Part V.J.4. This one concerns a different instrument, in a different discipline, measuring a different subject. The Foundation draws attention to the pattern rather than to any single instance of it, because the pattern is the answer to question 7 and question 8. The methods by which this exposure has been observed were not built to measure it, and in the one case where somebody built an instrument that could and then compared the two, the established method was shown to be recording four percent of what was happening.

The Foundation asks the Department to take the specific consequence rather than the general sentiment. A performance standard under section 360kk must prescribe an emission characteristic, and an emission characteristic must be measured. Where the Department finds the published literature reporting an effect, it must ask what instrument produced the observation and what that instrument is capable of recording, because the answer in this field has repeatedly been that the instrument records a fraction. That is a reason to measure, which is what paragraph 360ii(a)(4) directs, and it is a reason not to treat the absence of a recorded effect as evidence of absence.

The lamp, which is the fifth and strongest demonstration of the spectral point

The lamps were high-pressure sodium at 2,000 kelvin. The authors note that lamps of this type "are considered to be 'insect-friendly' because of the spectral composition of their light emissions."

Two thousand kelvin is warmer than any white diode sold as a mitigation and warmer than the three thousand kelvin ceiling the ecological literature recommends, including the recommendation the Foundation reproduces from the paper that closes this subsection. Sodium light is close to monochromatic and is the lamp the field itself nominates as the least harmful in general service. It fragmented the landscape. It made the flights of two families of moths measurably less efficient.

The Foundation accordingly states its position on spectral mitigation here, once, and asks that this paragraph govern every place in this comment where the subject arises. Eight studies in this subsection bear on it and they are consistent with one another once two qualifications are stated. First, reducing short-wavelength content reduces some effects and not others. In one study collected

here a warmer source was statistically indistinguishable from darkness on the two endpoints it measured, in a living animal; that is the fifth occasion on which this position has had to be amended, the study is set out below, and three features of it govern how much it can carry. In every other study a reduction in short-wavelength content left an effect in place. A modeling study is the second qualification and is set out below also: under a near-monochromatic sodium source the modeled chromatic contrast between a camouflaged snail and its background fell below the threshold at which any of three modeled predators could discriminate it, and those authors record that in the absence of color a predator uses luminance contrast, which they did not model. Second, whether it helps at all depends on the exposure regime against which it is tested, a composite spectrum having helped against a brief intense pulse and not against continuous exposure at street-lighting intensity, so that a mitigation validated against one regime cannot be assumed to work against another. Third, a lamp of low correlated color temperature is not a narrow-band lamp: warm white is broad-spectrum light with a reduced blue fraction and it retains a blue peak, measured at 455 nanometers in a lamp sold as 3,000 kelvin, and Part V.B.3 sets that point out at length. Fourth, the lamp at the amber end of the range actually deployed — sodium at 2,000 kelvin, nominated by the field itself as insect-friendly — still produced a barrier across a landscape. Fifth, it follows that a spectral change is a mitigation and not an answer, and that anyone who offers one as a reason not to limit the quantity, the direction or the duration of an emission offers a partial measure as a complete one.

The consequence for a performance standard is specific, and the Foundation asks the Department to take the consequence rather than the sentiment. A standard under section 360kk that prescribed a correlated color temperature would prescribe a quantity that does not determine the emission it is being used to control, and a standard that prescribed a spectrum without specifying the exposure regime it addresses would not have said enough to be assessed. If the Department intends to regulate spectral content, it should prescribe the spectral content: a limit on radiant power within a stated wavelength interval, or an index computed from the spectral power distribution of the kind the Andalusian instrument described at Appendix D.2 employs. Part IX.G.1 already lists those quantities and Part IX.J already asks the Department to state that lumens, watts and correlated color temperature do not describe the spectral content of a source. This subsection is the evidentiary basis for requests the comment has already made, and it does not enlarge them.

The authors place one limit on this which the Foundation reports and does not evade. They expressly decline to generalize to light-emitting diodes: sodium lamps are being replaced worldwide, diodes “can vary considerably in spectrum and intensity,” and the authors write that the repeatability of their results “will need to be specifically investigated for the different LEDs in the future.” So this study does not establish that a diode fragments a landscape. It establishes that the lamp nominated as insect-friendly does. The Foundation observes, marking the inference as its own, that the direction of that result is unfavorable to the lamp that replaced it rather than favorable, and that the burden of showing otherwise lies with whoever proposes the replacement.

The question the settled position invites, which is whether to go further and use red

If moving a lamp toward the long-wavelength end reduces the effect without removing it, the obvious question is what happens at the end of the range. Several European authorities have begun requiring red light in or near protected areas, principally to protect bats. The Foundation does not ask this Department to prescribe red light anywhere, and sets out here why it does not.

Durmus D., Jägerbrand A.K. and Tengelin M.N., Research note: Red light to mitigate light pollution: Is it possible to balance functionality and ecological impact?, Lighting Research and Technology, volume 56, issue 3 (2024). Described at Appendix D.7. The Foundation identifies what this document is before using it: a research note and mini review, which its authors describe as a qualitative synthesis of pertinent literature. It reports no original measurement and no original experiment, and every empirical claim in it is taken from a source the Foundation cites to that source or records as an acquisition. It is used here as a statement of informed opinion from within lighting engineering, and the comment does not treat it as evidence.

What the ordering in the record actually is

On insect attraction, and only on that, the ordering follows wavelength and the studies collected in this subsection agree on it. White is worst, amber is better, and red is better still. At Appendix C.128 narrowband amber suppressed moth activity by 57 percent against 85 and 93 percent for the two white treatments. At Appendix C.136 bringing a tailored luminaire from 2,700 to 2,000 kelvin took the catch from half the conventional figure to a third. At Appendix C.133 shearwaters offered blue against red at matched brightness chose red, at probabilities of 0.003 and 0.00052. And in three separate studies the investigators handled their animals under red light precisely because they regarded it as close to darkness for the taxon in hand.

So the answer to the narrow question is yes. The answer to the question that matters is no, and the Foundation sets out four reasons, three of them the authors' and one its own.

Why red is not the answer

- The bat evidence, which is the reason red is being required, does not support a general rule. The authors report that two species of pipistrelle show increased activity under red light during migration, which is a positive phototactic response, while light-averse species of Rhinolophus, Myotis and Plecotus may avoid it. In the one controlled experiment they cite, activity fell under every color tested and fell least under red. The responses are, in their words, species-specific and shaped by ecological context.
- A spectrum chosen because a species cannot see it may make that species easier to eat. The authors put the point as the creation of unintentional ecological traps for animals unable to detect the light, raising their vulnerability to predation and so potentially raising mortality in the very populations the measure was meant to protect. The Foundation has not seen that consideration anywhere else in this literature and regards it as the most important sentence in the document.
- Red is not neutral for animals whose peak sensitivity lies elsewhere, because they can still detect it. The authors report that red light can disrupt the magnetic orientation of migratory birds, producing disorientation and circling at the source with a consequent collision risk, and that in one controlled experiment red and white light advanced the onset of activity in blue tits to a greater extent than green did. On that endpoint red behaved like white.
- And the Foundation adds the point that follows from the study described immediately above. A red luminaire that is unshielded still sends light where it is not wanted. Nothing about the spectrum of an emission constrains its direction, and the direction was the characteristic that brought insect attraction to the level of darkness while a fivefold reduction in quantity did not. Substituting red for white is a change in the characteristic that mattered least of the ones tested.

The two human costs, which bear on parts of this comment already written

The Foundation reports these because they are the reasons it will not ask for red light, and because each lands on an argument the comment makes elsewhere.

The first is visual function. Narrowband red gives poor color rendering, which the authors say can hinder accurate identification of objects including faces, compromise visual acuity and color discrimination, and reduce local contrast; they add that under extremely chromatic sources chromatic adaptation breaks down, so that a person cannot fully adapt to the lighting at all, and that red light reduces subjective ratings of visual comfort. Part V.M records that where the public has been asked, the preference is not for amber but for a warm correlated color temperature combined with good color rendering, which narrow-band sources do not provide. Red is worse on that axis than amber, and the Foundation will not ask this Department to recommend a lamp under which a pedestrian cannot identify a face.

The second is power. Red sits far down the photopic and scotopic sensitivity functions, so a red source needs more radiant power for the same visual effect. The authors give a figure from a

commercially available streetlight marketed for light pollution mitigation: it delivers about 50 percent less luminous flux than a white luminaire drawing comparable power. Part IV.G sets out the federal lamp efficiency framework administered under the Energy Policy and Conservation Act, and the Foundation notes the collision plainly. A spectral requirement that halves luminous efficacy runs against a federal efficiency standard, and a shielding requirement does so too, since the authors of Appendix C.136 state that they sacrificed efficiency to their shielding. The Department should expect that conflict and should raise it with the Department of Energy under the liaison duty of paragraph 360ii(a)(3) and (a)(6) rather than discover it later.

What the Foundation takes from it

The authors conclude that advocating red light is well-intentioned, that its effectiveness in mitigating ecological impacts remains uncertain, and that caution is warranted against its use as a universal solution. They then write the sentence the Foundation adopts: it is also possible that very little or no light is more beneficial than red light outdoors.

That is the position of this comment, reached independently by three lighting researchers, and it is why the Foundation asks for limits on quantity, direction and duration rather than for a color. A change of color moves the harm between species and imposes costs on the people using the road. Less light, aimed where it is needed, for as long as it is needed, does not. The request Part IX makes is accordingly a request about the quantity, the geometry and the timing of an emission, and it does not ask the Department to prescribe a spectrum at all; where the comment discusses spectral content it asks only that it be measured and disclosed, which is the request at Part IX.F.

Two further results, one of which does not help the Foundation

First, the geometry understated the real case, and the authors say so. Their lamps stood eighty-five meters apart, which is much farther than ordinary street lighting; they give European pole spacing for roads as twenty-five to forty-five meters, and conclude that the barrier effect "would be even stronger with the typical streetlight design." An experiment that understates its exposure and still finds an effect is the useful kind.

Second, and against the Foundation's interest: the authors looked for an effect of skyglow on flight direction and did not find one. The brightest sectors of their sky were the ones carrying skyglow from named towns, and the moths did not fly toward them; nor did they fly toward the moon when the moon was brightest. The Foundation reports this because it has elsewhere in this comment treated diffuse sky brightness as an exposure, and this study found that the diffuse component did not steer these animals while the local point source changed their flights. Two qualifications keep that from being more than it is. Failing to find a directional preference is not the same as finding no effect, and the authors tested direction only. And the result sits comfortably with the comment's own emphasis, since the thing that mattered here was the emission of a product at close range rather than the diffuse sum of many products at a distance. Part V.J.4 should be conformed to this rather than left to imply more than the record carries.

What it does not establish

Every tested animal was male; the authors caught almost no females, so nothing here speaks to the sex that lays the eggs, which matters because the inference the authors draw is about reproductive success. Every tested animal was caught using light, so the behavioral results describe a phototactic subsample even though that selection makes the four percent figure stronger rather than weaker. The radar cannot resolve altitude, and altitude is the authors' own explanation both for the twelve percent who passed close by and for the difference between the two families; they call for three-dimensional tracking and state that the proof is not available with present methods. The tortuosity analyses rest on thirty-one hawk moths and thirty-two lappet moths after exclusions, with cells the authors describe as small and unbalanced. The choice of which tortuosity index to use for each family depends on an assumption about which family was native to the field, which the authors support but do not test. The twenty-three meter attraction radius is taken from earlier work and was not measured here. A flight ended where the signal was lost, which may mean the animal landed,

flew too high, shed the transponder or was eaten. And the one individual flown twice is an anecdote in which both variables changed at once.

It establishes nothing about human health and the Foundation does not offer it for that. Its place is on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, in the measurement argument at Part V.J, and in the spectral position above.

A seventh study, which weighs this exposure against one the Government already takes seriously

This study is the only one in the comment that puts artificial light at night beside another environmental stressor and asks which matters more. The stressor it chose for the comparison is the urban heat island, and the answer it reports is the reason the Foundation includes it.

Wang L., Meng L., Richardson A.D., Hölker F., Li H., Mao J., Longcore T., Xia J. and She D., Artificial light at night outweighs temperature in lengthening urban growing seasons, Nature Cities, volume 2 (2025), pages 506 to 517, open access. Described at Appendix C.131.

What was done

Four hundred and twenty-eight cities of the Northern Hemisphere, from 2014 to 2020. For each city the authors divided the area into ten concentric bands by the proportion of impervious surface, from the outermost rural band to the urban center, and then measured four things in each band: satellite light at night, near-surface air temperature, the date on which vegetation greenness began to increase in spring, and the date on which it began to decrease in autumn. The separation of the two drivers was attempted by partial correlation, each computed while holding the other constant, with the difference between the two coefficients tested for each city. The spatial pattern was then checked against a thirty-meter phenology product for sixty-two cities in the continental United States, including a version with lawns and other developed open space excluded.

The gradient itself is the first result and it bears on everything after. Across the ten bands, light at night rose from 3.1 to 53.3 nanowatts per square centimeter per steradian, an increase of roughly seventeen times, and the rise was exponential, most of it concentrated in the last three bands. Air temperature over the same gradient rose from 10.7 to 11.5 degrees Celsius, which is eight tenths of a degree, and most of that occurred between the first band and the second. The two stressors have very different shapes across a city.

What was found

In 378 of the 428 cities, the growing season lengthened toward the center: spring onset advanced and autumn senescence was delayed. Averaged across all cities, spring onset was 6.4 days earlier and autumn senescence 7.1 days later in the urban half of the gradient than the rural half.

On which driver accounts for it, the answer differs between the two ends of the season and the Foundation states both rather than the title.

- For spring onset the two are comparable. The partial correlation with light was minus 0.37 and with temperature minus 0.33. Where the two differed significantly, light was dominant in 135 cities and temperature in 144. Neither wins.
- For autumn senescence the two are not comparable. The partial correlation with light was plus 0.38 and with temperature minus 0.03. Senescence was positively correlated with light in 310 cities, while its relationship with temperature was inconsistent in direction, negative in 134 cities and positive in 118. Across the seven climate zones examined, the light coefficient averaged 0.49 and the temperature coefficient 0.003, and light outweighed temperature in every zone.

So the finding in the title holds for the end of the growing season, where it is emphatic, and does not hold for the beginning, where the two drivers are of similar strength. The Foundation reports it that way and asks that it not be cited more broadly than that.

One further figure the Foundation notes because of who is reading. Of the three continents examined, North American cities were the brightest, at 30.1 nanowatts per square centimeter per steradian in spring against 23.6 for Europe and 20.8 for Asia.

The comparison the Foundation asks the Department to draw, which is not about plants

The urban heat island is a recognized environmental health hazard in the United States. It has federal attention, interagency programs, surveillance, heat action plans and public guidance addressed to it. The Foundation makes no criticism of any of that and does not suggest that heat deserves less.

What it asks the Department to notice is the comparison. In four hundred and twenty-eight cities, measured over seven years with the same satellites and the same method, the environmental variable with the larger and more consistent effect on the measured outcome was not the heat. It was the light. And of the two, the one with a federal program is the heat.

The Foundation states the limits of that comparison immediately, because it is rhetorically attractive and could be overdrawn. The outcome measured is the timing of vegetation growth, not a human outcome, and nothing follows from it about the relative importance of heat and light to human health, where the evidence on heat is incomparably stronger. The two variables have very different ranges across the gradient the study uses, light varying seventeenfold and temperature by less than a degree, and the Foundation's own view is that a comparison of correlation magnitudes between variables of such unequal range is not straightforwardly a comparison of importance; that criticism is the Foundation's and is not addressed by the authors. And a single observational study does not settle anything.

What survives is narrower and still useful. It is no longer open to say that artificial light at night is too small a variable to warrant federal attention when a peer-reviewed study of four hundred and twenty-eight cities finds it outweighing the urban heat island on the outcome it measured. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research. The comparison is a reason to begin.

The pathway to a human outcome, which the Foundation records as a lead and not a finding

The authors identify consequences of the shift they measured, and one of them is the first route from this exposure to a clinical endpoint that the Foundation has encountered in this subsection. They write that earlier leaf-out and later senescence driven by light may increase the risk of frost damage, disrupt plant and pollinator interactions, and lead to an earlier occurrence of pollen allergy symptoms. For the last of these they cite a study in a journal of the American Medical Association association reporting an association between changes in the timing of spring onset and asthma hospitalization in Maryland.

The Foundation sets out the chain and then says what is missing from it. Light at night is associated with an advance in the start of the growing season of about six days. The start of the growing season is when wind-pollinated trees release pollen. And a change in the timing of spring onset has been associated with asthma hospitalization in one American state. Each link is measured, which distinguishes this from the chains the Foundation declined earlier in this comment. What is missing is any study joining them: no one has measured whether light at night is associated with pollen season timing, or with allergy or asthma presentations, and the Foundation does not assert that it is.

It submits instead that this is precisely the research paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support, and that it is unusually tractable. The exposure is already measured by satellite for the whole country. Pollen counts are already collected. Asthma presentations are already recorded. The question is whether anyone has put the three series beside each other, and so far as the Foundation can establish, no one has.

The Foundation adds one qualification to the scope of that request, because the chain described above concerns one pollen season and there are two. The study the authors cite concerns the onset of spring and the wind-pollinated trees that release pollen when the growing season begins. A second and independent route runs through the late-summer weed pollens, of which common ragweed is the principal allergen in North America and whose season does not overlap the tree season at all. Whether artificial light at night bears on the second route is not something the Foundation asserts, and it has examined one study on the question and declined to rely on it. The point here is narrower and concerns the design of the research rather than its result: a study scoped to spring phenology would not detect an effect on the late-summer season, and the two seasons are monitored separately by the same networks. The Foundation asks that any study undertaken under paragraph 360ii(a)(2) cover both rather than one.

What it does not establish, and the measurement problem it shares

It is observational and spatial. Light and temperature both rise toward a city center, and so do many things the model does not contain: carbon dioxide, ozone, nitrogen oxides, particulate deposition, soil compaction, irrigation and drainage. The authors address species composition, noting that cities carry more non-native plantings and validating their result against a thirty-meter dataset with lawns excluded, but they do not address the atmospheric or soil variables. Partial correlation separates light from temperature. It does not separate either from anything absent.

And the exposure is the same instrument this comment has criticized five times. The authors state the limitation themselves, and add a refinement that is specific to plants and that the Foundation had not previously seen. Plants sense light through several photoreceptor families: phytochrome responds to red and far-red light between roughly 620 and 1,000 nanometers, while phototropins and cryptochromes respond mainly to blue. The satellite band runs from 500 to 900 nanometers. It therefore covers much of the range to which one photoreceptor family responds and is blind to the range to which the others do. The authors call for a sensor capable of capturing a broader spectrum, particularly in the blue. Their defense of their own result is that the conversion to light-emitting diodes probably occurred at about the same time across each urban region, so that the spectral change is roughly common to all bands of their gradient. The Foundation records that this is an assumption which the authors state as one and do not test.

It establishes nothing about human health. The outcome is the greenness of vegetation observed from orbit.

An eighth study, which specified its exposure in the subject's visual system and in a human's, and in which the two did not agree

This is the last of the studies the Foundation relies on in this subsection, and it is here for a reason that has nothing to do with its subject. Its investigators characterized their light twice: once in the photometric unit a person would use, and once in the receptor space of the animal they were testing. The two characterizations do not describe the same stimulus. That is the central proposition of Part V.J.4, demonstrated by investigators who were not arguing for it.

Atchoi E., Mitkus M., Machado B., Medeiros V., Garcia S., Juliano M., Bried J. and Rodríguez A., Do seabirds dream of artificial lights? Understanding light preferences of Procellariiformes, Journal of Experimental Biology, volume 227, issue 19 (2024), article jeb247665. Described at Appendix C.133.

The design

The subject is the Cory's shearwater, Calonectris borealis, whose largest population breeds in the Azores and whose fledglings leave the burrow at night in late October and early November. About six percent of fledglings are grounded each year in what the literature calls fallout events, in which birds come down in lit urban areas and cannot resume flight; a rescue campaign on Faial has collected them every year since 1995.

One hundred and thirty-one rescued fledglings and eighty-four adults from a colony were each given a single trial in a plywood maze, 100 by 50 by 40 centimeters, painted matte black and divided into two arms with a light above each. A bird was held under a dark box for one minute, then released, and its arm entry, choice and latency recorded; a trial ended after ten minutes if the bird did not move. Three treatments: one arm white and one dark; one arm blue and one red; and a control with both arms dark.

The exposure, which is the part that matters

The white arm was a named commercial product, a warm-white diode strip at 3,000 kelvin, with measured spectral peaks at 455 and 625.2 nanometers, delivering 175 lux at the bird's starting position. The dark arms measured below 0.1 lux. The Foundation notes in passing that 0.1 lux is a ceiling and not a measurement, and that the moth study at Appendix C.128 measured the natural night sky at a median of 0.0168 lux, so a dark arm specified as below 0.1 lux is specified loosely by the standard this appendix now has available.

The blue and red arms were single-peak diodes at approximately 450 and 620 nanometers. Here the investigators did something no other study in this appendix did. Rather than matching the two stimuli in human photometric terms, they modeled the visual system of a shearwater and matched them in it: the two arms were set to differ by about four percent in achromatic contrast, which is to say they were very nearly equally bright to the bird, while differing by about 60.7 just-noticeable differences in chromatic contrast, which is to say they were about as distinguishable in color as two stimuli can be. The investigators also report what those same two stimuli measure in human photopic units: 75 lux for the blue arm and 120 lux for the red.

The Foundation asks the Department to hold those two statements together. Two light sources that are within four percent of each other in the brightness channel of the animal being tested differ by a factor of 1.6 when measured in lux. The discrepancy is not an error by anyone. It is what the photopic luminosity function is: a weighting derived from human observers, which assigns to each wavelength the value it has for human vision and no other. Applied to a bird it returns a number, and the number is not about the bird.

Part V.J.4 makes this argument and supports it by showing what is lost when the spectrum is discarded. This study supplies the demonstration directly, and in the direction that matters for a performance standard. A limit expressed in lux is a limit expressed in a human weighting. For the purposes of section 360kk that is not a defect, because the statute is concerned with people and the Foundation has said throughout that the Department should regulate in the units in which human exposure is assessed. The point is narrower and it cuts the other way: the Department cannot read the ecological literature, or answer question 14, by converting its exposures into lux and comparing them, because lux is not the quantity those studies are about. Any synthesis of this literature that proceeds by reducing every exposure to illuminance will produce comparisons that are arithmetically sound and biologically empty.

What was found

The birds avoided the light, and avoided the shorter wavelength.

- Fledglings entered an arm in 101 of 131 trials, 77 percent, against 45 of 84 for adults, 54 percent; Fisher exact probability below 0.001, odds ratio 2.88. In the control both arms being dark, every fledgling made a choice; adults did in 70 percent of trials.
- Offered white against dark, fledglings chose the dark arm in 77 percent of the trials in which they chose, binomial probability 0.009. Adults chose dark in 66 percent, which was not significant at 0.3; the authors calculate that between 176 and 305 adults would have been needed to resolve it.
- Offered blue against red at equal brightness to the bird, both ages chose red: fledglings at a probability of 0.003, adults at 0.00052. Only one adult chose blue.

- In the control there was no side bias in either age group, at 0.627 and 0.115, which is the check that makes the other two results interpretable.
- Fledglings took longer than adults to choose, probability below 0.01, and both groups were fastest in the control. Within each treatment, however, the latency comparisons between the two arms were all null.

What the authors concluded, and what they expressly did not

The authors do not claim that these birds were attracted to the light. They claim the opposite, and the distinction is theirs: at close range the birds were "apparently disoriented by the stimuli rather than being behaviourally attracted to them." Their summary of the white treatment is that "artificial light appears to impair the fledglings' ability to exit the unknown lit environment," and of the whole experiment that "the presence of a close-range artificial light can be disruptive to Cory's shearwater fledglings."

They also report a negative result against their own hypothesis, which the Foundation records because it is the kind of reporting that makes the rest credible. Fallout falls overwhelmingly on fledglings rather than adults, and the obvious explanation would be that the two ages behave differently toward light. They do not: the choices did not differ significantly between ages, and the authors therefore write that "behavioural differences cannot account for the age bias observed in fallouts." Their alternative, that the fledgling visual system is still immature, is offered as a hypothesis and the Foundation reports it as one.

What it does not establish

It is not a model of fallout and the authors say so: a two-armed maze at close range is not the circumstance in which a bird flying at night encounters a lit town. The samples within treatments are small, the choice results resting on roughly two to four dozen birds each, and the adult arm is underpowered by the authors' own calculation. The white stimulus was not isoluminant with the blue and red pair, so the two experiments cannot be compared to each other on intensity. The visual model was built on the spectral sensitivities of a different species, the wedge-tailed shearwater, and not on the species tested. The fledglings had already been grounded by urban light, handled, ringed, measured and held in boxes before testing, so they were not naive to the exposure; the authors raise this themselves, argue from earlier work that it is unlikely to have skewed the result, and recommend testing unexposed birds. And the tested fledglings were selected for mass at or above 660 grams and averaged 820 grams against 766 for the rescued population as a whole, so they were the fitter part of a group that had already been injured by the exposure.

It establishes nothing about human health, and the Foundation does not offer it for that. Its place is on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, and in the measurement argument above.

One further bearing, on the spectral question settled earlier in this subsection

The white lamp here was 3,000 kelvin, which is at the warm end of what is sold as a mitigation. It has a measured peak at 455 nanometers. The fledglings avoided it. Taken with the mosquito study at Appendix C.125, where lamps at 2,700 to 3,000 kelvin and under one lux did not prevent the effect, and with the two moth studies at Appendices C.128 and C.132, this is the fourth independent demonstration in this subsection that a low correlated color temperature is not a narrow spectrum. Warm white is broad-spectrum light with a reduced blue fraction, and it retains a blue peak. The Foundation repeats the position stated at the end of the moth pair and does not restate it here.

A ninth study, which found that insects are not attracted to light at all

Fabian S.T., Sondhi Y., Allen P.E., Theobald J.C. and Lin H.-T., Why flying insects gather at artificial light, Nature Communications, volume 15 (2024), article 689, open access. Described at Appendix C.137.

This study and the one that follows it are placed last and should be read together. This one establishes why artificial light disrupts insect flight. The next one, whose authors cite this work, built a luminaire that removes the condition this mechanism requires, and measured what happened. The Foundation knows of no other pair in this literature in which the mechanism and the remedy were established independently and agree.

What was done

Four hundred and seventy-seven stereo-videographic recordings of wild insects flying near artificial light were made in Costa Rica at 500 frames per second under infrared illumination, which the investigators took to be invisible to the subjects. In the laboratory, eight infrared motion-capture cameras tracked a three-marker frame glued to the thorax of individual insects flying freely in a two-meter tent around a light source, resolving the orientation of the animal's back as well as its position, to a marker residual of about a quarter of a millimeter. Five hundred and thirty-eight continuous flight trajectories were recorded across four species: two dragonflies, which are diurnal and not associated with light trapping, and three moths. Separate experiments reversed the direction of the light, tested insects under two centimeters in length, switched between two lights while an insect was circling one of them, and simulated the proposed mechanism in an agent-based model.

What was found, which displaces the standard account

The insects did not fly toward the light. Their velocity vectors concentrated at right angles to the direction of the source, in every species tested, at probabilities below 0.001. In darkness and under a diffuse overhead light the same effect was absent, at probabilities of 0.36 and 0.65, which establishes that it was the point source and not the enclosure.

What the insects did instead was tilt their backs toward the light. The investigators measured this as the alignment between the animal's dorsal axis and the direction of the source, on a scale running from minus one to one. With the light on the values were 0.84, 0.79, 0.82 and 0.82 across the four species. With the light off, 0.17. Body bank angles rose correspondingly, median values moving from between about 9 and 20 degrees under control conditions to between about 29 and 48 degrees near a point source, all at probabilities below 0.001.

That behavior is the dorsal light response, a conserved reflex by which a flying insect keeps its back to the brightest part of its visual field. Throughout the evolutionary history of insect flight the brightest region has been the sky, so the reflex is a reliable way of determining which way is up. Most small insects cannot glide and have no passive stability, and the mechanosensory systems available to them measure rates of rotation rather than absolute attitude. The brightest region of the visual field is how they know where up is.

A bright lamp at close range is therefore not an attraction. It is a false vertical. An insect obeying the reflex banks toward it, and because flying animals accelerate in a direction fixed relative to the body, banking turns the flight path. The result is continuous steering around the source. The three behaviors the investigators recorded in the field follow from it: orbiting at a stable bank, stalling into a climb when the animal faces away from the lamp, and inverting into a dive when it passes over the lamp. All three appeared in ten orders of insect and in under two percent of recordings made in the dark.

The decisive experiment, which concerns direction and not quantity

The investigators shone an ultraviolet lamp downward onto a white sheet laid on the ground, which is the classical method of trapping insects. The insects inverted, tumbled and crashed. They then took the same lamp and shone it upward onto a sheet stretched overhead, producing a diffuse canopy resembling the sky. The insects flew normally beneath it, on various paths, and did not cluster. The same lamp, the same intensity, the same spectrum: reversing the direction from which the light arrived was the difference between normal flight and crashing.

The effect held for small insects. From thirteen families in six orders, every taxon tested except one flew upward stably under a diffuse ultraviolet ceiling and none could maintain flight with the same light coming from below, tilting and inverting shortly after takeoff. Measured across trajectories, path tortuosity near a point source had a median of 3.21 against 1.21 under the diffuse canopy, and insects turned preferentially toward the light near a point source at a probability below 0.001 and not at all under the canopy.

The Foundation asks the Department to hold that result beside the request Part IX makes. The variable that determined whether these animals could fly was the direction of the emission. Not its quantity, which was unchanged, and not its spectrum, which was unchanged.

The four explanations this displaces

- Escape to the light, in which the insect flies at the lamp as it would at a gap in foliage. Refuted: the animals flew orthogonally to the source and rarely toward it.
- A corrupted celestial compass, in which the insect mistakes the lamp for the moon. Refuted by an experiment the Foundation regards as elegant. An animal holding a compass bearing must keep the light on the same side of its body. When the investigators switched between two lamps while an insect was circling one, the insect changed the side it presented to the light in 25 of 37 trials, and three animals reversed direction on the same lamp with no switch at all. The simulated compass model also failed quantitatively: its agents escaped the light, at a median range change of 1.75 meters per second away from the source, where the real animals and the dorsal-tilting agents did not escape.
- Thermal radiation. Already refuted, and refuted again by the observation that diodes emit negligible infrared and trap insects in vast numbers.
- Blinding by a light brighter than a dark-adapted eye can handle. Refuted by the regularity of the behavior: a blinded animal does not produce three reproducible motifs that a four-parameter controller reproduces in simulation.

On the last of those the Foundation enters a caution of its own, because the comment relies at Part V.C on the proposition that a high-luminance source impairs human vision and recovery. Nothing here bears on that. What these investigators refuted is blinding as the explanation of a particular insect behavior in the immediate vicinity of a lamp. The mechanism they propose is a visual reflex that requires the animal to see the light rather than to be blinded by it, and it is specific to flight attitude in a taxon with no pupil. It is not evidence about people, and the comment does not offer it as any.

Why this bears on a performance standard, and the three entries it ties together

The authors state the mitigation their mechanism implies in one sentence, and the Foundation quotes it because of the words in it: “reducing unnecessary, unshielded, upward-facing lights and ground reflections can mitigate the impact on flying insects at night, when skylight cannot compete with artificial sources.”

Four things in that sentence. Unnecessary. Unshielded. Upward-facing. Ground reflections. The first is a judgment about quantity, the second and third about direction, and the fourth about a characteristic of the installation rather than of the lamp. The Foundation observes, marking the observation as its own, that the adjective these authors reached for first is the adjective Congress used in paragraph 360ii(a)(2). They are not invoking the statute and do not know of it. They arrived at the word because it is the right word for light that is emitted without a purpose that requires it.

The mechanism also explains three results the comment already carries, and the Foundation sets out the connections because each was previously recorded as a finding without an explanation.

- It explains why the luminaire described in the next study worked. Confining the emission to the target area and shielding the aperture removes the bright point above the horizontal that subverts the reflex. It also explains why dimming that luminaire fivefold did not work:

reducing the quantity of a point source leaves it a point source, and the reflex responds to the brightest direction rather than to an absolute level.

- It explains the figure at Appendix C.135, where radar tracking found that four percent of light-caught moths terminated their flights at a streetlight while the lights significantly altered the paths of the rest. Insects steering around a lamp are not arriving at it. A trap at the lamp post records the small fraction whose steering ends there. These authors reach the same conclusion from the other direction, observing that only two of fifty moths released eighty-five meters from a light ended their flights there, and inferring that artificial lights may trap passing insects rather than draw them from a distance.
- It supplies the mechanism for a recommendation the comment reproduced at Appendix C.134 and expressly said it did not address: that coastal construction use non-reflective, dark-colored materials. A reflective surface under a luminaire returns light upward from below the animal, which is the configuration these investigators showed to be the most disruptive of all. Reflectance is therefore not a refinement of the direction variable but part of it, and the Foundation now has a reason to say so.

One further matter, which the Foundation records without argument. This work was funded in part by two agencies of the United States: the National Science Foundation and the Air Force Office of Scientific Research, together with the European Research Council and several private foundations. The mechanism by which artificial light at night disrupts the flight of insects was therefore established with American federal money, in the same years in which the agency holding the electronic product radiation authority declined to evaluate the emission on the ground that existing mitigations are effective. The Foundation draws no inference about any individual and makes no complaint about the funding, which was well spent. It asks the Department to notice where the work is being done and under whose appropriations, and to treat that as a matter for the liaison duty of paragraph 360ii(a)(3) and (a)(6) rather than as a coincidence.

What it does not establish

It establishes nothing about human health and the Foundation does not offer it for that. Within its own subject the limits are these. The field classification of the three motifs was made by eye and the authors call it somewhat subjective, providing the original videos for verification. The field dataset is biased toward large insects by the requirement that a subject reflect enough infrared to be tracked: the authors state that most insects present at their light were under a centimeter while the mean size in their data was 29 millimeters, and that clear-winged butterflies showed the response but could not be digitized at all. Wind could not be excluded and true airspeed could not be estimated. The laboratory work rests on four species with between two and twelve individuals each, with markers glued to the thorax after immobilization on ice and no formal control for the marker beyond the absence of visible difference. Wavelength was not systematically studied and the authors say so, although the flies they tested tipped and crashed over ultraviolet light and not over white. Range was not tested at all, which is the most important limit: the mechanism is established at close range and the authors expressly do not claim it explains arrival from a distance. Two taxa were immune, three oleander hawkmoths across seventy-one trajectories and wild vinegar flies, and the authors cannot say why, noting the oddity that oleander hawkmoths are readily trapped by lights in the field. And the authors state plainly that they do not understand why insects do not tilt toward the moon or toward a low sun, which is an unexplained gap at the center of their own account.

No fitness, reproductive or population endpoint was measured. The Foundation offers the study on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, and for the proposition that among the characteristics of an emission, the direction is the one that governed this effect.

A tenth study, which changed the product rather than the practice, and which is the closest thing in this Part to the evidence a performance standard would rest on

Dietenberger M., Jechow A., Kalinkat G., Schroer S., Saathoff B. and Hölker F., Reducing the fatal attraction of nocturnal insects using tailored and shielded road lights, Communications Biology, volume 7 (2024), article 671, open access. Described at Appendix C.136.

The Foundation places this study last and asks the Department to read it with Part II.G rather than only with this subsection. Everything else in Part V.I reports that an exposure produced an effect. This one took a product, changed one characteristic of its emission, held the others fixed, installed it on real streets, and measured whether the effect went away. That is the form of evidence on which a performance standard rests, and it is the only study in this comment that has it.

What was changed, and what was held constant

The characteristic changed was the spatial distribution of the emission. Working with a manufacturer, the investigators designed luminaires whose optics confine the light to the target area and whose added shielding suppresses emission at high angles at the point where the radiation leaves the fixture, so that the luminaire is close to invisible from outside the lit area. Each was designed for its own site from the measured geometry of that site — road width, mounting height, pole spacing — then validated after installation and dimmed to match the illuminance of the fixture it replaced.

What was held constant is what makes the study usable. The illuminance on the ground was matched. The correlated color temperature was matched at the site where the comparison was like for like. And compliance with the European road lighting standard was maintained throughout, which the authors state in terms: the light field was tailored "without compromising human safety standards." The Foundation draws attention to that because the objection it most often meets is that any limit on an outdoor luminaire trades against the safety of the people using the road. Here the limit was imposed and the road lighting standard was still met.

The result, which establishes a hierarchy among the four characteristics this comment asks the Department to regulate

At the controlled site in a dark-sky reserve, twelve lit luminaires were compared with twelve permanently unlit ones six hundred meters away, with flight interception traps on all twenty-four, monthly from March to October for four years. Three lit configurations ran in succession.

- Conventional diodes at 30.6 lux attracted 7.7 times as many insects as the unlit controls.
- The same luminaires dimmed by 82 percent, to 5.6 lux, attracted 5.4 times as many. Against the high-illuminance treatment the reduction was not statistically significant, at a probability of 0.812.
- The tailored and shielded luminaires, at essentially the same illuminance as the dimmed ones, 5.2 lux, attracted 1.3 times as many as the unlit controls. The reduction was significant below 0.001, and in pairwise comparison the tailored luminaires were not significantly different from any dark control.

A fivefold reduction in quantity did not measurably help. Confining the same quantity to where it was wanted brought the catch to the level of no lighting at all. The Foundation states the proposition that follows, and states its limits in the next paragraph but one. On this evidence the direction of an emission is not one mitigation among four. For this endpoint it was the one that worked, and the quantity reduction that is ordinarily offered first did not.

The result then survived transfer out of the experimental field. At three municipal sites beside nature reserves — urban, suburban and rural, spanning a wide range of sky brightness — the replacement luminaires attracted roughly half as many insects as the existing street lighting, at probabilities below 0.001, below 0.001, and 0.005. These were ordinary streets under real traffic.

Three findings on spectrum, which confirm the position settled earlier in this subsection

The design separated the spatial question from the spectral one, and the Foundation reports all three results because together they are the cleanest confirmation of the settled position in this comment.

- At the urban site the correlated color temperature was held at 4,000 kelvin on both sides of the comparison. The reduction still occurred. So the benefit was spatial and not spectral.
- At the other two sites the replacement raised the color temperature, from sodium at 2,000 kelvin to diodes at 2,700 kelvin. The reduction still occurred, which the authors note is "not a matter of course, because a higher CCT is expected to increase insect attraction." A geometry change overcame a spectral change in the wrong direction.
- A further control fitted amber film inside the tailored luminaires to bring them to 2,000 kelvin at the same illuminance. The catch fell further, to a third of the conventional figure against a half at 2,700 kelvin. So the spectral change did add a benefit, on top of the spatial one, and the authors say it "could constitute an additional optimization."

That is the settled position of this comment, demonstrated within a single experiment: a spectral change is a real mitigation and it is not the mitigation that did the work. The Foundation asks the Department to note the order in which the two appear here. The geometry change moved the catch from seven-and-a-half times the dark control to one-and-a-third. The spectral change then improved a figure that was already near the floor.

Why this belongs with Part II.G, and what it shows about a duty not discharged

Part II.G sets out paragraph 360ii(a)(5), which directs the Secretary to develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation. Part II.G.3 lists the techniques that exist for roadway lighting and includes full-cutoff optics and shielding among them, and Part II.G.3 then states the position this comment takes: the techniques have been developed, and what is absent is the federal development, testing and evaluation of their effectiveness.

This study is that evaluation, performed for one technique on that list, and it was paid for by a government. The work was funded by the German Federal Agency for Nature Conservation with resources from the federal environment ministry, and at the municipal sites by a regional council. A national conservation agency commissioned the design of a luminaire, had prototypes manufactured, installed them on public streets in three municipalities and in a dark-sky reserve, measured the emission with a goniophotometer and a spectroradiometer, ran flight interception traps for four years, and published the result with its data and code.

The Foundation offers that as the answer to question 5.0, which repeats the language of paragraph (a)(5) almost verbatim. The Department has asked what procedures and techniques for minimizing exposure exist and how effective they are. Here is what the exercise looks like when it is carried out. It is not expensive by the standards of federal research, it does not require any contested finding about injury, and it produces a number that purchasers and specifiers can act on without any standard being prescribed at all, which is what Part II.G.4 and Part IX.J ask for. The Foundation does not suggest that this Department should have studied German insects. It asks the Department to notice that the method is available, that another government used it, and that the quantity it isolated — the spatial distribution of a luminaire's emission — is an emission characteristic within the meaning of section 360kk and a characteristic of the product rather than of its operation by anyone.

That last point is the one the Foundation most wants the Department to take. Part IX has been careful throughout to ask for what this chapter reaches and not more: the Foundation does not ask the Department to tell a city when to switch off a streetlight, because that is the city's decision about operating a product it owns. Shielding is different in kind. A cutoff is manufactured into the

luminaire. It is present when the fixture leaves the factory, it is testable on a goniophotometer before anything is installed, and it does not depend on anyone's subsequent conduct. Of everything in Part V, this is the characteristic that sits most squarely within what a performance standard can prescribe, and this study is the evidence that prescribing it would do something.

What it does not establish, including the part that limits the use the Foundation can make of it

The most important limit is that the study does not say what to prescribe. The luminaires were tailored individually to each site and the shielding was fine-tuned until it met the criteria, and the published text gives no cutoff angle, no upward light output ratio and no luminous intensity distribution. Goniophotometric measurements were made and sit in a supplementary table the Foundation has not obtained. So this study establishes that confining an emission works; it does not supply the number that a standard would have to state. The Foundation records that gap rather than passing over it, because the whole of its submission is that a performance standard must prescribe a measurable characteristic, and a comment cannot demand a number while relying on a study that does not contain one.

The dimming null must not be overread, and the authors say so themselves: a further reduction of intensity, they write, could have produced a measurable effect, and a threshold is hard to predict because it will vary between taxa. The null is a null for 5.6 lux against 30.6 lux in this setting. It is not a finding that quantity does not matter, and this comment continues to ask for limits on quantity. What it supports is an order of priority, not an exemption.

Three further limits. At the controlled site the three lit treatments ran in successive years rather than simultaneously, so treatment is confounded with year; the authors address this with mixed models carrying temperature, wind and precipitation, and with the fact that the unlit controls caught almost exactly the same number of insects in each period, 430, 397 and 421, which is the strongest internal evidence in the study. At the municipal sites there were no dark controls at all, because the authorities would not permit the street lighting to be switched off under real traffic; the authors state that limitation and state that the community-dispersion results would probably have reached significance at all three sites had a dark control been available. And insects were identified only to order or suborder.

Finally, two things the Foundation records because they cut in opposite directions. The prototypes were not optimized for energy efficiency, which the authors say was sacrificed to the shielding — a trade the Department should expect to meet, given the federal lamp efficiency framework described at Part IV.G. And the catch in a trap at a luminaire measures the insects that came to the luminaire; citing the radar study at Appendix C.135, these authors write that the number caught "represents only a fraction of the insects affected." That is the eighth attestation in this comment that the instrument cannot see the whole of the exposure, and here it means the reductions reported are more likely to understate the benefit of the shielding than to overstate it.

It establishes nothing about human health. The Foundation offers it on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, as an evaluation of a technique under paragraph (a)(5), and as evidence that the characteristic Part IX asks to have prescribed is the characteristic that governs.

The strongest population evidence in this subsection, and the one study that counted the animals where they live

Every study in this subsection so far measures what an individual animal does: where it flies, how it banks, whether it feeds, how it orients, whether it can be seen. One measures how many there are. It is the strongest evidence in this collection that this emission reduces a wild population, and it was designed around the measurement problem that Part V.J.4 collects rather than inheriting it.

Boyes D.H., Evans D.M., Fox R., Parsons M.S. and Pocock M.J.O., Street lighting has detrimental impacts on local insect populations, Science Advances, volume 7, issue 35 (2021), article eabi8322,

doi 10.1126/sciadv.abi8322, open access. Described at Appendix C.142. The authors declare no competing interests. The work was funded by the Natural Environment Research Council through a doctoral training partnership and by an industrial studentship with Butterfly Conservation, a conservation charity of which two of the five authors are staff; the Foundation records that in the same spirit in which it records every other interest in this comment.

The design decision, which is why the Foundation leads with it

The standard way to sample moths is a light trap. These investigators did not use one, and they say in terms why: light traps, in their words, "lead to biases when comparing assemblages from lit and unlit areas." They sampled caterpillars instead, by beating hedgerows in daylight and sweeping grass margins at night. A caterpillar does not fly to anything. It is where it hatched, so counting caterpillars counts the population rather than the population's response to the person counting it. Part V.J.4 collects two papers that disclosed the light-trap bias while using the method. This is the first group in this comment that designed it out.

The sites were twenty-six matched pairs and one triplet in Oxfordshire, Buckinghamshire and Berkshire. Street-lighting datasets obtained from nine local authorities and a national highways body by freedom of information request were overlaid on satellite imagery; more than five hundred candidate locations were examined by street view, one hundred and fifty-three were visited in person, and the survivors were pairs in which the lit and unlit sections "appeared identical, except for the presence of ALAN." Lit and unlit transects were at least sixty meters apart, median one hundred and eighteen. According to the authorities' own records the lit sections had carried the same lamp type for at least five years and often for decades. Every site was visited between two and four in the morning to confirm that no part-night lighting or dimming was in operation.

Three independent measures, and the same ordering in each

Abundance first. In hedgerows, from 1,656 caterpillars beaten over twenty-five visits to thirteen matched pairs, there were fewer caterpillars on the lit side at every site, an overall reduction of 47 percent. In grass margins, from 822 caterpillars collected over sixty-four visits to fifteen sites, the overall reduction was 33 percent.

Then the same figures by lamp, which is the cleanest spectral comparison in this subsection:

- Hedgerows: 52 percent fewer under light-emitting diodes and 41 percent fewer under high-pressure sodium, both at a probability below 0.001.
- Grass margins: 43 percent fewer under light-emitting diodes at a probability of 0.02; 24 percent fewer under high-pressure sodium, not significant at 0.20; and 11 percent fewer under low-pressure sodium, not significant at 0.78.

And the reason that ordering is not an artifact of brightness: the mean illuminance of the sodium transects and the diode transects did not differ statistically, in either habitat, at probabilities of 0.34 and 0.85. The lamps differed in composition and not in measured quantity. That is a controlled spectral comparison in the field, at matched illuminance, on a population endpoint, and the Foundation has no other.

The second measure is mass. Caterpillars on lit transects were heavier. The effect was significant under diodes in both habitats, at probabilities below 0.001 and of 0.04; mixed under high-pressure sodium, at 0.007 and 0.10; and absent under low-pressure sodium, at 0.60. The authors read it as accelerated development under stress, consistent with laboratory work on two noctuid species, and note that earlier pupation is predicted to be deleterious to adult fitness. The Foundation reports that reading as the authors' own and returns to its ambiguity below.

The third is a manipulative experiment, and it is separate from the rest. Lighting rigs four meters high carrying either diodes or high-pressure sodium were erected in grass margins with no history of lighting, switched on an hour before sunset, with sampling between one and two hours after dusk, across nine visits. Nocturnal caterpillars normally climb grass stems at night to feed. Fewer were

found under the diode light than under no light, at a probability of 0.03. Under high-pressure sodium the difference was not significant, at 0.58. Generators were placed fifty meters away so that noise, vibration and fumes could not account for it.

The finding that bears most on the structure of this comment

The authors then say something that unsettles the way this field has measured its own subject, and the Foundation quotes it rather than paraphrasing:

> "Our findings also reveal that the number of adult insects attracted to different lighting technologies may not serve as a suitable proxy for their ecological impact, as has often been previously assumed."

The reasoning is set out immediately after it. A published meta-analysis reports that light-emitting diodes attract similar numbers of moths to sodium lamps, or slightly fewer, from which diodes would be expected to be the less damaging. At these sites the diodes were the more damaging, on every one of the three measures above. The authors draw the inference carefully and the Foundation adopts it at the same strength: this "could suggest that flight-to-light behavior is not the principal mechanism via which moth populations are negatively affected by ALAN," a hypothesis they say requires further confirmation.

Read with three studies already in this subsection, that proposition closes a circle. Appendix C.135 tracked individual moths by radar and found that four percent of those already selected for flying toward light terminated their flights at a lamp. Appendix C.136 states that the number caught in a trap at a light source represents only a fraction of the insects affected. Appendix C.137 supplies the mechanism of the flight itself. This study adds the last step: the quantity the field has been measuring for decades, moths at a lamp, may not rank lighting technologies in the order of their effect on moth populations, and at these sites it ranked them backwards. A mitigation chosen on the attraction evidence is a mitigation chosen on a proxy that the people who measured the population say may not be one.

The admission about the unit, which Part V.J.4 takes as its tenth

The exposure here is better characterized than in most of this subsection. Illuminance was measured with a named hand-held meter of stated resolution, at five points along each transect, on overcast nights or at the new moon, pointed upward at the height the caterpillar occupies: one and a quarter meters in hedgerows and a quarter of a meter in grass. Lit hedgerows averaged 5.7 lux and lit grass margins 2.2 lux; unlit transects were estimated below 0.01 lux and every one of them read the meter's minimum. And then the authors say this:

> "An important caveat is that lux is based on human vision, and thus potentially ecologically relevant spectral information can be omitted when using this unit. Identical measurements of lux may not correspond to the same illumination as perceived by a caterpillar. Despite these shortcomings, lux is the SI unit for light intensity and continues to be used by ecologists and urban planners alike due to its convenience."

Part V.J.4 adds that to the instances it collects and explains why it matters that this one concerns a meter in a hedge rather than a radiometer in orbit. The short point here is that the investigators who produced the strongest population result in this comment state in their methods section that the unit in which they expressed the exposure cannot carry the information the result is about, and that they used it because it is the convenient one.

What it does not establish, including the part that runs against this comment

The Foundation reports the authors' own scaling conclusion before anything else, because it is the opposite of the inference a reader might draw from the effect sizes. Using the actual distribution of streetlights rather than an assumption about major roads, they estimate that 1.1 percent of the land area of their study region is directly lit above one lux once road surfaces and urban land are excluded: 15.5 percent of suburban land, 0.23 percent of arable land and 0.68 percent of

broadleaved woodland. From that they conclude that direct illumination by streetlights "has probably been a minor contributor to long-term national moth declines to date; however, our results show that it can be a very substantial local factor." The Foundation adopts that sentence whole. Nothing in this comment asserts that this emission is a principal cause of insect decline, and this study, which is the best evidence it has, says it is not.

Five further limits. The design is not randomized: the treatments are existing streetlights, and the authors say so. Lit transects were often at junctions and may have had more traffic noise, nitrogen oxides or headlight glare; the authors expect the influence of those factors to have been minor, which is an expectation rather than a measurement, although they did test and exclude differences in botanical composition, verge management and surrounding urbanization. The low-pressure sodium figures rest on two transects and establish nothing. The mass finding is ambiguous even on the authors' account, who offer accelerated development under stress and local acclimation as competing explanations and note that it sits awkwardly with their own short-term result. And the short-term experiment used a brighter and bluer lamp than the field sites, 25.3 lux at about 5,000 kelvin against 2.2 lux at 2,700 to 4,000 kelvin, so the two arms are not matched and the authors identify that as one explanation for the apparent conflict between them.

It establishes nothing about human health and is not offered for any. The Foundation offers it on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, and as the clearest demonstration available to this comment that the spectral composition of a lamp changes what it does to a population at a quantity of light that is held constant.

The one study in which a spectral change did remove the effect, and why the position above stands

The position stated earlier in this subsection records that in no study collected here did a reduction in short-wavelength content remove an effect. One study qualifies that. The Foundation places it here, before the last two papers, and states the qualification precisely, because a careless reading of this study would overstate the comment's own case in the one direction in which it has been most careful.

McMahon O., Smyth T. and Davies T.W., Broad spectrum artificial light at night increases the conspicuousness of camouflaged prey, Journal of Applied Ecology (2022), doi 10.1111/1365-2664.14146, first published 25 March 2022. Described at Appendix C.141. The authors declare no conflict of interest. The work was supported by the Natural Environment Research Council under grant NE/S003533/2. Smyth and Davies are two of the ten authors of the marine review described at Appendix D.7, and the handling editor of this paper is a co-author of the other marine review there. The Foundation records the overlap rather than leaving it to be found.

What was done, and the first thing to say is that no animal was exposed to anything. Sixty-seven littorinid snails of two species were collected from bladder wrack at Whitsand Bay in southwest England in May 2020 and the reflectance of their shells was measured with a spectrometer between 350 and 750 nanometers; two measurements of the seaweed were averaged to give a background. Published photoreceptor peak sensitivities were taken for three predators: the herring gull, tetrachromatic, hunting from the air; the common blenny, trichromatic, in water; and the green shore crab, dichromatic, in water. Hyperspectral irradiance measured at ground level under real urban installations in Cornwall supplied the illuminants for four lamp types, with sunlight and full moonlight as natural references. For the two aquatic predators the light was carried through three meters of seawater by a radiative transfer model. A standard receptor-noise model of chromatic discrimination then computed, for each of thirty-six combinations, the color distance between snail and background in units of just noticeable difference.

The result in one sentence. Under low-pressure sodium all three color morphs fell below one just noticeable difference for all three predators, which is the threshold below which prey cannot be told from its background at all; under high-pressure sodium, metal halide and light-emitting diode

lighting the threshold was exceeded. Yellow morphs were affected most, which the authors attribute to the greater difference between their reflectance and that of the seaweed.

The mechanism, which this comment did not previously have

Everything else in this subsection concerns light that attracts, suppresses, disorients or shifts a clock. This concerns light that supplies information. Color vision requires more than one wavelength. A near-monochromatic lamp cannot support it and a broad-spectrum lamp can, so replacing the first with the second returns to the night a sensory channel that belonged to the day. The injury, if it is one, is not that there is more light. It is that the light carries information that was not available at that hour, and the organism on the losing side of the exchange is the one whose defense was its appearance. The authors put it as the encroachment of light that enables color-guided behaviors previously possible only during the daytime.

The qualification, stated before any use is made of the study

The model computes chromatic contrast and nothing else. The authors state what follows from that, and the Foundation quotes them because the sentence is the whole of the limitation:

> "In the absence of colour however, nocturnal predators will use luminance contrast perception."

Under the narrow-band lamp the prey became indiscriminable by color. It did not become invisible, and this study did not model whether it became harder to see. The authors go on to recommend, as their own next step, a review of the color vision systems of the nocturnal predators in a given ecosystem in order to identify the wavelengths that minimize luminance contrast between prey and background — which is to say that they treat the question their model leaves open as the operative one.

The position stated earlier therefore stands, and the Foundation amends only the first of its five propositions. A reduction in short-wavelength content removed a modeled effect, in a model of one mechanism, with the authors recording that a second mechanism remains and was not modeled. For the separate question whether any study has removed an effect measured in a living animal, see the movement immediately following.

The one study in which a warmer lamp was indistinguishable from darkness, and the three reasons it cannot carry what it appears to

Alaasam V.J., Duncan R., Casagrande S., Davies S., Sidher A., Seymoure B., Shen Y., Zhang Y. and Ouyang J.Q., Light at night disrupts nocturnal rest and elevates glucocorticoids at cool color temperatures, Journal of Experimental Zoology Part A, volume 329 (2018), pages 465 to 472. Described at Appendix C.148. Twenty-four captive zebra finches, eight to a group, exposed for about two weeks at night to a commercial diode strip sold as 5,000 kelvin, to one sold as 3,000 kelvin, or to no light at all. Birds under the cooler lamp became more active at night, peaking after about nine days, and showed a within-individual rise in corticosterone. Birds under the warmer lamp differed from the unlit controls on neither measure.

That is the first result in this appendix in which reducing short-wavelength content removed an effect in a living animal, and the Foundation states it as such and amends its settled position accordingly. It then states three features of the study which bear on how much the result can carry, and the second of them changes what the result is about.

The first is sample size. Eight animals a group, with no power calculation reported. A failure to distinguish the warmer lamp from darkness in groups of eight is weak evidence that no difference exists, and the Foundation does not convert it into one.

The second is the unit in which the two lamps were equalized, and it is the reason this study belongs as much to Part I.G as to this subsection. The two treatments were standardized to 0.3 lux, measured at perch height with a handheld consumer light meter. Lux is weighted to human photopic vision.

Two lamps set to the same lux therefore do not deliver the same radiant energy, and the cooler lamp at 0.3 lux necessarily delivered more energy at short wavelengths than the warmer lamp at 0.3 lux. The exposure contrast in this experiment was in that sense produced by the choice of standardizing quantity. The authors read the result as an effect of color temperature and recommend 3,000 kelvin over 5,000 kelvin. The more exact reading is that at equal human-perceived brightness the source with more short-wavelength content produced the effect, which is what the authors themselves propose as the mechanism when they attribute it to non-visual photoreceptors more sensitive to short wavelengths. The Foundation is not criticizing the inference. It is observing that the study does not show a 3,000 kelvin lamp to be safe at an exposure matched in any radiometric quantity, and that nothing in it rehabilitates correlated color temperature as a descriptor.

The third is what was measured and for how long. Two endpoints, nocturnal activity and a glucocorticoid, over about two weeks, in birds bred in captivity which the authors state had presumably never experienced light at night of any kind. Body condition and food intake did not change in any group, so the difference that was found is a difference in behavior and in a hormone and not in any fitness measure. The authors add two cautions of their own against their own recommendation: that a longer exposure might produce pathology, and that the activity peak had begun to decline, which they say may indicate acclimation. They add two more about the warmer lamp itself, that light at 3,000 kelvin may still attract insects and that long-wavelength light at higher intensities may have other consequences.

Taken together, the proposition the Foundation can state is this. In one experiment, on two non-fitness endpoints, in eight captive birds a group, at an illuminance of three tenths of a lux, a warmer commercial lamp was indistinguishable from darkness. That is a real qualification to the first of the five propositions above and the Foundation has amended it. It is not a demonstration that warmer lamps are safe, it is not a demonstration about color temperature as distinct from spectral content, and it sits beside the moth experiment at Appendix C.128, in which every spectrum tested at a fixed intensity produced a large effect, and the rodent study at Appendix C.146, in which a lamp emitting only between 550 and 650 nanometers suppressed foraging out to forty meters.

And one fact about this paper that belongs to Part II rather than to Part V

The copy the Foundation read is an author manuscript bearing the heading HHS Public Access, deposited in PubMed Central under the public access policy of the Department of Health and Human Services because the work was funded by the National Institute of General Medical Sciences of the National Institutes of Health under grant P20 GM103650. One co-author was supported by a National Park Service Natural Sounds and Night Skies Division postdoctoral fellowship. The Foundation sets that out plainly and without complaint. An operating division of this Department funded an experiment on whether the color temperature of a commercial light-emitting diode alters nocturnal rest and glucocorticoid output in a vertebrate; the resulting manuscript is held in the Department's own repository; and the authors concluded with a lighting recommendation. The Department is therefore not approaching this subject without a record of its own. Part II.H records federal engagement with this exposure largely as absence, and this is engagement.

A second qualification, which the Foundation regards as the more useful of the two

The threshold of detectability was also exceeded under sunlight and under a full moon. These snails are discriminable in nature. Low-pressure sodium is therefore the outlier in the set and not the natural baseline, and the proposition this study establishes is not that broad-spectrum lighting creates a condition unknown to the organism. It is that broad-spectrum lighting reproduces, on every night and across the whole of a lit shore, a condition that nature produces on a few nights a month and in no fixed place.

That is a claim about the duration and the extent of an exposure rather than about its kind, and it is a better claim for this comment than the headline suggests, because duration and extent are among the characteristics Part IX asks the Department to characterize. It is also the same shape as the finding at Appendix C.128, where the measured natural night sky was a median of 0.0168 lux and

more than half of the measured change occurred below full-moon illuminance. In both cases the relevant comparison is not between light and darkness. It is between the lit night and the range the organism evolved in, which includes a bright phase it gets for a few nights and then loses again.

What the Foundation does not take, and four features of the modeling that bear on its weight

It takes no assertion that predation increased, that any snail was eaten, or that any population changed in structure. Nothing was observed. The authors are explicit that conspicuousness does not necessarily scale linearly with color distance and that behavioral work is needed to establish the level of just noticeable difference at which prey actually become conspicuous, which they place beyond the scope of the paper. The passages about selective predation, altered population structure and the genetic composition of polymorphic populations are the authors' inference from the model and the Foundation does not adopt them.

Four features of the modeling belong with any use of it, and Appendix C.141 sets them out at length. No spectral sensitivity measured in a herring gull was available, and the authors assembled that visual model from published sensitivities within its family, describing it as the best possible approximation. The shore crab's photoreceptor proportions were unavailable and were set to the value that maximizes its ability to discriminate color. The authors state that statistical comparison between the three predators cannot be made. And the two darker morphs may not be two: the ordination showed no clear separation between olive and brown, and the authors write that these may in fact be a single dark morph.

One convergence of vocabulary is recorded and no authority is claimed from it. The authors close by asking that habitats be protected from "unnecessary exposure to artificial light." That is the phrase paragraph 360ii(a)(2) uses, arrived at independently, in a journal of applied ecology, by authors with no interest in this proceeding.

A diurnal animal, and the one study in this subsection whose emitter was not a light-emitting diode

Every animal in this subsection so far is active at night or at twilight, and every lamp in it is one that is sold for outdoor lighting now. One study is different on both counts. The Foundation states the second difference before the finding, because it governs what the study may be used for.

Parlin A.F., Stratton S.M. and Guerra P.A., Oriented migratory flight at night: consequences of nighttime light pollution for monarch butterflies, iScience, volume 25, issue 5 (2022), article 104310, open access. Described at Appendix C.140. The authors declare no competing interests. The animals were wild monarch butterflies caught during the fall migrations of 2019 and 2020 at a field station of the University of Cincinnati in southwest Ohio.

The emitter was a full-spectrum halogen bulb of 250 watts and 4,000 lumens, with ultraviolet A and B content, in a work light on a tripod. That is not a light-emitting diode, and the Foundation does not offer this study as evidence about light-emitting diode products. What the investigators did was tie their source to the deployed stock by intensity rather than by composition: using a manufacturer's own floodlight tool they computed the illuminance their source produced at four distances against three named light-emitting diode floodlights at 3,000 kelvin, and they state that their source is orders of magnitude less bright than much of the lighting found outdoors at night. So the exposure is realistic in quantity and is not a diode in spectrum. This is evidence about light at night. It is not evidence about one lamp technology against another and nothing below should be read as though it were.

What was done. Monarchs navigate by a time-compensated sun compass: they hold the sun at a bearing and correct for its movement across the sky using timing information from a circadian clock in their antennae. Wild fall monarchs were tethered in a flight simulator in a dark room and the lamp was placed where the sun would have been. In daytime trials the lamp substituted for the sun completely. Given a morning lamp position the animals oriented southwest at 231 degrees (Rayleigh

r 0.725, p 0.0012, n 13); given an afternoon position, at 217 degrees (r 0.747, p below 0.001, n 13). The two did not differ from each other, and neither differed from previously published observations of free-flying fall monarchs outdoors under clear skies. Animals held on a light-dark cycle delayed by six hours shifted their heading by 97 degrees, which is what a clock-driven compass predicts and what a compass without a clock would not do.

Then the night trials, which are the point. Seventy-eight monarchs were placed in the simulator in darkness at three times in their night cycle. In the dark they were quiescent, as monarchs are at night in the laboratory and in the wild. When the lamp was switched on, 96 percent of them — 75 of 78 — flew immediately. Forty-seven of those sustained flight long enough to meet the analysis criterion and 42 of the 47 flew directionally.

The direction is what told the investigators what the light had done. Light early in the night, at the fifteenth hour of the cycle, produced a group heading of 15 degrees with the lamp held to the right: afternoon behavior, which is a phase delay. Light in the middle and at the end of the night, at the eighteenth and twenty-first hours, produced headings of 233 and 232 degrees with the lamp held to the left: morning behavior, which is a phase advance. A fourth condition at the eighteenth hour with the lamp moved to an afternoon position gave 296 degrees, the animals still holding it to their left. All four group vectors were significant at or below 0.01.

Four things the Foundation takes, the weakest stated first

The weakest is the clock. No molecular measurement was made. The investigators read the phase shift off the flight direction and matched the pattern across the night to a published mathematical model of the antennal clock. That is a legitimate inference and it is not a measurement, and the Foundation does not describe this study as having measured a circadian perturbation. What it measured is flight direction, and the direction behaved as a shifted clock would require.

The second is the immediacy, and it is what the Foundation most wants the Department to notice. There was no acclimation period, no accumulating dose and no gradient. Animals quiescent in darkness flew within the time it took to switch on a lamp, and nineteen of every twenty did. Everything else in this subsection is a change in a rate, a count, a tortuosity or a proportion, measured across nights or across a season. This is a switch. The Foundation does not generalize from one insect to any other organism and does not need to. It records that the dose-response relationships Part V.A.2 says this field has not built will not all be the same shape, and that at least one endpoint in at least one species responds to a lamp of ordinary outdoor intensity as a step rather than as a gradient.

The third is the mechanism, and it is a short-wavelength mechanism that the study did not test. In the monarch antennal clock the absence of light drives transcription of cryptochrome 2, timeless and period; in the presence of light, cryptochrome 1 — which these authors describe as a blue-light circadian photoreceptor — degrades the timeless protein and allows the other two to enter the nucleus and repress transcription. The light-sensitive step in this animal’s clock is mediated by a receptor the authors identify as blue-sensitive. The Foundation states clearly that the study did not vary wavelength and tested nothing about it: the lamp was broad spectrum and there was one of it. The mechanism is recorded because Part V.B.1 and the settled spectral position of this subsection rest on the proposition that short wavelengths are not interchangeable with long ones for biological purposes, and this is another photoreceptor family in this comment for which that is so.

The Foundation also states what it declines to infer from that, because the inference is available and it does not make it. It would be easy to argue that if the clock step is blue-driven, then a light-emitting diode of equal illuminance, having more short-wavelength content than a halogen, would produce at least as large a response. That is an inference and not a finding, and it is not clean in either direction: the halogen used here carried ultraviolet A and B, which most white diodes do not. The honest statement is that this experiment does not compare technologies and that the comparison has not been made in this species.

The fourth is where it happened. This is a United States study of a United States population, by investigators at a United States university, on animals caught in Ohio during two actual fall migrations, and the authors place the exposure on the migratory corridors of the eastern seaboard, the Great Lakes region, the Midwestern central flyway, Texas and Mexico. Nearly all of the ecological evidence in this subsection was produced in Europe. The Foundation offers this one for the narrow proposition that the phenomenon is not a European one, and for no more than that.

One convergence of vocabulary belongs with it. The study is about light trespass, which the authors define as light cast where it is unwanted or not needed at night, emanating from buildings and streetlamps. Part I of this comment takes that category from CIE 150:2017, where it sits beside glare, uplight, skyglow, over-illumination and clutter, and Part II.H.3 identifies those categories as the subject of paragraph 360ii(a)(2) named in another vocabulary. Here is a peer-reviewed ecological study that took one of those engineering categories as its independent variable and found a response to it. The Foundation offers that as a convergence and not as an authority.

What it does not establish, including the part that limits it most

Monarchs are not known to fly at night during the fall migration, and the authors say so plainly: there are no documented reports of it, and fall night temperatures are often too low to sustain flight. The behavior demonstrated is therefore not a behavior anyone has observed in the wild. The authors' claim is about the clock rather than about the flight, with the flight serving as the readout, and they add that an animal roosting beside a streetlight may have its clock shifted without flying anywhere. They offer the urban heat island effect and warming nights as reasons the behavioral consequence could become real, and they cite records of nocturnal flight in other migratory nymphalid butterflies. The Foundation reports the authors' position and does not adopt the forecast.

Three further limits. The flight was tethered and virtual rather than free. Across all trials in the study 39 percent of animals flew at all, 112 of 287, so the analyzed sample is a minority selected by willingness to fly; the authors state the figure and compare it to other work using the same apparatus. And the illuminance or irradiance at the animal is not stated in the body of the paper: the measurements were made, with a light meter and with a spectrometer, and they are in supplementary material the Foundation has not obtained. The entry at Appendix C.140 records that as an outstanding acquisition and the Foundation does not state an exposure level for this study until it has it.

It establishes nothing about human health and is not offered for any. The Foundation offers it on the emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it. One further element of the study, an analysis of where monarch roosts lie in relation to lighting, is taken up at Part V.J.4 rather than here, because of the instrument it used.

A final paper, whose findings the Foundation declines and whose recommendations it does not

Grillo F., Marrone A., Gauci A. and Deidun A., Maltese Coastline Never Sleeps: The Effects of Artificial Light at Night (ALAN) on the Local Infralittoral Assemblages—A Case Study, Journal of Marine Science and Engineering, volume 12, issue 9 (2024), article 1602, open access. Described at Appendix C.134, where the entry is built in the inverted form the Foundation uses when it takes something from a paper other than its result.

The study put a baited underwater video camera on the seabed at two locations in a harbor on the north coast of Malta, one beside a ferry quay and one on a rocky reef, and recorded one-hour samples under three lighting conditions produced by dive torches: high-intensity white, low-intensity white, and red. Eighteen samples in total, in August 2023, three per combination. Nearly twenty-four thousand animal counts resulted, of which eighty percent were a single species of bogue.

Why the Foundation does not rely on the findings

The reasons are set out at Appendix C.134 and summarized here. There was no dark control: the red treatment served as what the authors themselves call a pseudo-control, so every one of the eighteen samples had a lamp burning, and the study compares three lights to one another rather than any light to darkness. The camera was baited, so a preference for the bright treatment cannot be separated from the ability to find bait under it, and the authors report that the fish exploited the bait bag specifically on illuminated nights. The two locations differ in seabed, in wind exposure, in boat traffic and in being or not being a harbor, so the site contrast is not a light contrast. There were three replicates per cell. The claim that light mattered more than habitat is supported by comparing probability values rather than variance components, which is not a comparison of magnitude. The diversity index showed no effect of light at all. And the authors disclose that the species making up eighty percent of all counts was undercounted in the high-light treatment, for a reason connected to the treatment.

The Foundation states this plainly because it has been asked to assist the Department in weighing a literature, and a literature is weighed by reading it rather than by counting it. A paper that reaches a congenial conclusion on a design that cannot support it is of no use to the Department, and citing it would invite the Department to discount what else the Foundation has put forward.

The first thing the Foundation does take: a specification written by marine scientists which is the same specification this comment asks for

The paper's recommendations are not a finding and do not depend on its design. They are the authors' statement, as marine ecologists, of what coastal lighting should be required to do. The Foundation sets them out because they are organized by the same four characteristics of an emission that Part VI and Part IX are organized by, and because they were written by people who had never heard of this comment.

- Direction. Full cut-off fixtures aimed downward, achieving what the authors specify as a zero percent Upward Light Output Ratio. That is a numerical limit on an emission characteristic, of exactly the form section 360kk requires a performance standard to take.
- Quantity. That light intensity be limited to what is strictly necessary for safety and operational purposes.
- Containment. That lighting be focused on specific areas, preventing overflow into ecologically fragile regions, into the sky, and — the authors' own words in a paper about fish — into nearby residences.
- Duration. That schedules be used to dim or switch lighting off during periods of inactivity.
- Spectrum. That lighting be selected with a correlated color temperature below 3,000 kelvin.
- And a sixth the comment does not presently address: that reflected light be reduced by using non-reflective, dark-colored materials in coastal construction.

Four of those six are the four characteristics of an emission that this comment asks the Department to regulate, arrived at independently, in a marine engineering journal, by authors with no interest in the American statute. The Foundation offers that convergence for what it is worth, which is not evidence of a health effect but is evidence that the characteristics it has selected are the characteristics practitioners in the field actually reach for. The fifth of them is the reason this paper closes the subsection.

The second thing: the field recommends below 3,000 kelvin, and the studies in this very subsection show that below 3,000 kelvin is not enough

What this subsection establishes, from five independent studies, is that it is a partial measure offered as a complete one.

- Appendix C.125. Lamps at 2,700 to 3,000 kelvin, at under one lux, did not prevent the loss of diapause in the mosquito. The authors wrote that changes in brightness or light color may not be sufficient to mitigate ecological impacts.
- Appendix C.133. The lamp the shearwater fledglings avoided was 3,000 kelvin. Its measured spectral peak was at 455 nanometers.
- Appendix C.128. Reducing short-wavelength content reduced moth activity suppression from 93 and 85 percent to 82, 73 and 57 percent. It did not remove it, and at low intensity some species increased their activity under amber rather than decreasing it.
- Appendix C.132. The same remedy, tested against a brief intense pulse rather than continuous exposure, did help — which is why the Foundation's position is about exposure regimes and not about amber.
- Appendix C.135. High-pressure sodium at 2,000 kelvin, the lamp the field nominates as insect-friendly and warmer than anything the recommendation contemplates, produced a barrier across a landscape and reduced flight efficiency in two families of moths.

The position this bears on is the settled one stated at the end of the moth studies above, and the Foundation does not restate it here. What this paper adds is an illustration of it. The field recommends a correlated color temperature below 3,000 kelvin. The field's own data, in five studies collected here, show that lamps at or below 3,000 kelvin produce the effects the recommendation is meant to prevent. The reason is set out at Part V.B.3: correlated color temperature is a single number describing a resemblance to a blackbody, and two lamps sharing it can differ substantially in the quantity that matters.

The consequence for a performance standard is stated with the settled position above and is not repeated. The Foundation notes here only that the ecological literature, by recommending the convenient number in place of the quantity that governs, illustrates the problem rather than solving it.

The third thing: how the two study sites were characterized

The paper reports the ambient light at each location as a photometer reading in lumens: zero at the reef, eighty at the harbor, rising to one hundred and forty-five when charter boats passed.

The lumen is a unit of luminous flux. It measures the light leaving a source, integrated over all directions. It is not a measure of light arriving anywhere, and a photometer placed at a point does not read it. What such an instrument reads is an illuminance, in lumens per square meter, which is the lux. The same methods section uses the lumen correctly a few paragraphs later, when it gives the maximum output of the dive torches as 2,600 lumens, because that is a source quantity. So the two sites, whose difference in light is the entire premise of the comparison, are characterized in a unit that cannot express the difference.

The Foundation records this without any suggestion that it was deliberate or that these authors are unusual. It records it because Part V.B.3 and Part V.J.4 argue that the exposure information the Department needs does not exist in usable form in this literature, and because the argument is better made with an example than with an adjective. Here is a peer-reviewed study in the field, published in 2024, whose two experimental sites are specified in the wrong physical quantity, printed three times, alongside a correct use of the same unit. And here, at Appendix C.133, is a study from the same year that characterized its light in two receptor spaces and reported the spectral peaks of its lamp to a tenth of a nanometer. The Department is being asked to build a standard on a body of work with that range of practice in it. That is the problem, and the remedy is the one Part IX asks for: that the Department measure, in stated units, under a stated procedure, and publish what it measures.

A closing note on what this subsection omits, and three things taken from a review of it

Everything above is terrestrial except in four particulars, which the Foundation names so that the statement is accurate: a seabird at its land colony at Appendix C.133, the inverted Maltese entry at Appendix C.134 whose findings the Foundation declines, the model of an intertidal shore at Appendix C.141, and the field experiment in a Polynesian lagoon at Appendix C.144, which is set out at the end of this note. Beyond those four, the literature of the sea is represented in this comment by two reviews and by nothing else. That is a limit of the Foundation's reading and not a judgment about the sea, and because question 14 asks about ecological effects without qualification the Foundation states the omission rather than leaving it to be noticed.

Fobert E.K., Miller C.R., Swearer S.E. and Mayer-Pinto M., The impacts of artificial light at night on the ecology of temperate and tropical reefs, Philosophical Transactions of the Royal Society B, volume 378, issue 1892 (2023), article 20220362, open access, in a theme issue on light pollution in complex ecological systems. Described at Appendix D.7. It is a review article and not a study: it reports no original measurement, states that it has no additional data, and is organized around what the authors expect rather than what they found. The Foundation does not treat it as evidence and declines its system-level framework, which the authors themselves frame as potential scenarios. It takes three things from it, each of which the authors took from somewhere else and each of which is recorded as an acquisition.

First, the extent of the exposure in water, which the comment had nothing on

The review collects four figures. About 22 percent of the world's coastal regions experience some degree of light pollution. Biologically important artificial light reaches more than 75 percent of the seafloor near coastal developments. Approximately 1.6 million square kilometers of coastal sea are exposed at a depth of ten meters. And biologically important levels are estimated to reach 70 meters down from skyglow and 100 meters from waterside street lighting.

The Foundation reports those as the review reports them, which is at second hand from four primary papers it has not read. They are recorded here because the comment has no other statement of how far this exposure extends below a water surface, and because the last of them is a statement about a product: waterside street lighting, delivering a biologically significant emission one hundred meters down.

Second, a spectral mechanism the comment did not have

The review states the physical point plainly: short wavelengths penetrate deeper through the water column, and many marine organisms are sensitive to short wavelengths because of the environment in which they evolved. The consequence is that the transition to light-emitting diodes increases the reach of the exposure and not merely its spectral content.

That is a different argument from any the comment has made about spectrum, and the Foundation identifies the difference. Elsewhere the comment argues that a shift toward short wavelengths changes what an emission does to a receptor, and that the instruments and descriptors in use cannot express the shift. Here the shift changes how far the emission travels. A diode and a sodium lamp of equal output do not illuminate the same volume of water. The settled position at the end of the moth studies is unaffected, because this is not a claim that a spectral change would be a sufficient remedy; it is a claim that the spectral change already made has enlarged the exposed volume.

Third, the lowest effect thresholds anywhere in this comment

Three figures, again at second hand, and the Foundation sets them against the only measurement of natural darkness it holds.

- Embryos of the common clownfish failed to hatch under artificial light at approximately 15 lux.
- Daily rhythms of the Pacific oyster were disrupted at intensities as low as 0.1 lux.

- Hatching of the sergeant major, a damselfish, was inhibited at light intensities as low as 0.03 lux.

The moth study at Appendix C.128 measured the ambient night at its field sites one hundred and eleven times and found a median of 0.0168 lux. The lowest figure above is therefore about twice that ambient figure, which as Part V.I now records is itself one to two orders of magnitude brighter than a moonless natural sky. The Foundation draws no biological conclusion from that comparison, which is between a laboratory threshold in one taxon and a field measurement in another country. It draws a measurement conclusion, and it is the same one Part V.J.4 draws: an effect threshold of three hundredths of a lux lies below the resolution of nearly every instrument the literature in this comment has used, and far below anything a satellite radiometer can see. If thresholds of that order are real, the Department cannot find them in the published record. It would have to measure.

What the Foundation does not take

Three things. The system-level framework, including the four mechanisms and the three scenarios in which the authors suggest novel ecosystems could arise, which is a research agenda and is offered as one. The example of diversity collapse through spawning desynchronization, because the study behind it attributed the desynchronization to temperature and the authors here offer light only as something that could interfere comparably. And the route from reef collapse to human beings through fisheries, which the authors mention as an ecosystem service and which the Foundation declines for the reason given twice already in this subsection: the construction of paragraph 360ii(a)(2) adopted at Part II.D.4 does not run an effect on another species through to a person, and the limb the comment relies on is engaged by the emission itself.

What the review does supply, beyond the three items above, is the ninth attestation collected at Part V.J.4 that the instrument cannot see the exposure, and it is the most severe of the nine because in the marine case the act of observing introduces the thing observed. The authors also close with a sentence the Foundation adopts without alteration: that light pollution is largely an unregulated environmental stressor globally. They are describing the world. This comment is about one statute that was enacted to address it and has not been used.

A second review of the same subject, published a year earlier, and what it adds

There is a second review of artificial light in the sea, by ten authors, and the Foundation adds it here rather than in a subsection of its own because it covers the same ground. Marangoni, Davies, Smyth, Rodríguez, Hamann, Duarte, Pendoley, Berge, Maggi and Levy, Impacts of artificial light at night in marine ecosystems — a review, Global Change Biology, volume 28, issue 18 (2022), pages 5346 to 5367. Described at Appendix D.7. The authors declare no competing interests. It is a review and the Foundation treats it as one: it reports no original measurement and its data statement records that no new data were created or analyzed.

It is not independent confirmation of the figures above, and the Foundation says so before taking anything from it. Three of the four exposure-extent figures in the preceding paragraphs trace to primary papers of which Davies is an author, and Smyth of one of them; Davies and Smyth are two of the ten authors of this review. The figures are therefore being repeated by some of the people who produced them. That is ordinary in a field this small and it is not a criticism of anyone. It is the reason the Foundation does not describe the agreement between the two reviews as corroboration.

What it does supply, first, is the definition of a term the paragraphs above quote without defining. “Biologically important” artificial light, in those figures, is not a judgment by the people who drew the maps. It is the minimum irradiance of white light that elicits diel vertical migration in female Calanus copepods, measured in an earlier experiment and then used as the criterion for the global depth maps. The Foundation records that because it is an instance of the thing Part IX asks for and has had almost no example of: a threshold defined by a measured response in a named organism, and then applied as a mapping criterion rather than asserted. Whether a copepod is the right organism on which to set a criterion for a whole ocean is a separate question and the Foundation does not answer it. The structure is the right structure.

Second, the extent of the exposure with depth, and one figure the comment did not have. Approximately 1.9 million square kilometers of the world's coastal seas are exposed at one meter depth, 1.6 million at ten meters and 840,000 at twenty meters. The most exposed regions are given as the Mediterranean, the Red Sea and Persian Gulf, and the seas of southeast Asia. And 20 percent of the world's contiguous Marine Protected Areas are exposed across 100 percent of their range. All of these are at second hand.

Third, the ninth attestation gets a measurement, and the red-light question gets an answer

The review devotes a box of its own to how research activity creates the bias it is trying to measure. It records that the optical instruments used to count plankton and fish at depth — it names five of them — all require an external light source; that red light has been recommended for marine surveys on the assumption that most species react to it less than to shorter wavelengths; and that two studies supported the assumption, finding that mesopelagic fish avoid white, blue and green light but not red. It then records that the assumption was contradicted.

Geoffroy and others, in 2021, mounted echosounders on a hull above probes carrying lights of different colors and found that pelagic organisms in Arctic and temperate regions strongly avoid artificial light, including visible red light at 575 to 700 nanometers. The density of organisms fell by as much as 99 percent. The distance of avoidance ran from 23 to 94 meters from the source, varying with color, with irradiance and possibly with the species present. The light levels were 11 to 18 microwatts per square centimeter.

Three things follow and the Foundation separates them. The first is that the ninth attestation collected at Part V.J.4 is no longer only the proposition that observing disturbs what is observed. The disturbance has been measured, it is very large, and it reaches tens of meters. The count at Part V.J.4 is unchanged, because this is the same attestation better quantified and not a new one.

The second is that this answers, for one environment, a question put to the Foundation during the preparation of this comment: whether red light is a remedy. In the sea it is not. The Foundation has declined to ask for red light anywhere in Part IX, and the reasons recorded at Appendix D.7 for the terrestrial case are now joined by a measured avoidance response in the pelagic case. The narrow proposition about insect attraction is unaffected and is stated where it belongs.

The third is that a measurement of avoidance distance in meters, at a stated irradiance in radiometric units, for three stated colors, is the shape of the relationship Part IX.C asks the Secretary to establish. It exists, in an environment where almost nothing else does, and it was produced incidentally by investigators trying to stop their own instruments from corrupting their own surveys.

Fourth, what the review says about regulation, and two cautions against this comment's own direction

The Foundation reports the regulatory statement because it is made by ten specialists in a peer-reviewed journal and because this comment has no comparable survey. The review records that a few countries — it names Spain, in Catalonia; Chile; France; and Italy, in Piedmont — are trying to establish laws regulating light pollution, and that most of the documents that address the subject are guidelines, codes or standards issued by regulators, advisory committees, non-governmental organizations or professional bodies "with no legal basis for enforcement of recommendations." It adds that many of the professional guidance documents are addressed to lighting engineers and designers, give little detail on management for the protection of sensitive receptors, and "must be purchased at a substantial cost." And it records that guidance for the marine environment "does not currently exist" in the English-language literature at all.

The United States is not among the four, with a qualification the Foundation has had to add to this sentence and sets out at the end of this subsection: one American State does impose an enforceable lighting condition for a biological purpose, in an instrument too narrow for a survey of this kind to

have caught. The Foundation does not offer the general absence as an indictment of any agency and does not need to. It offers it as the state of the world against which section 360kk is to be read. A performance standard is enforceable and a guideline is not; a standard published by the Secretary appears in the Code of Federal Regulations and costs nothing to read, while the specification the review identifies as the relevant professional document must be bought. Those are the two differences between what section 360kk authorizes and what the field presently has.

Two cautions run the other way and the Foundation states them in the same place. The first is that the guidelines this review endorses recommend a case-by-case approach to assessment, management and mitigation, on the express ground that specific assessment trigger values are difficult to set across the range of variables involved. The Foundation asks for a numerical performance standard, which is the opposite approach, and it does not pretend the two can be reconciled by argument. It states the distinction instead. A case-by-case assessment is what an environmental regulator does about an installation in a place. A performance standard is what section 360kk does about a product in commerce. The first is not available to the Department and the second is the authority it holds.

The second caution is narrower and sharper. On sea turtles the review states that the thresholds of concern for both wavelength and intensity are likely to vary within and among species, and it identifies all seven species of marine turtle as affected. A threshold that varies within a species cannot be met by one number chosen for that species. The Foundation's answer is the one it gives throughout and it is not a rebuttal: a performance standard does not have to be the threshold of the most sensitive organism, and nothing in section 360kk requires it to be. It has to be a stated quantity that a product either meets or does not. Determining what quantity is the work that paragraph 360ii(a)(4) assigns to the Secretary and that the Foundation asks to have done.

Fifth, a ranked priority, and what the review concedes about its own evidence base

The review sets out six best-practice rules for outdoor lighting design — begin with natural darkness and add light only for a purpose; use adaptive controls over timing, intensity and color; light only the object or area intended; use the lowest intensity appropriate to the task; use non-reflective, dark-colored surfaces; and use lights with reduced or filtered blue, violet and ultraviolet wavelengths — and then ranks them. "Of these, the most important is avoiding short wavelength blue light due to its ubiquitous visibility across a wide range of taxa, as well as its higher capacity to penetrate the water column." The Foundation reports both halves of that sentence. The ranking supports the priority Part IX gives to spectral content. The second of the two stated reasons is specific to water and does not transfer to land, and the comment does not transfer it.

The review concedes twice that its evidence base is not at environmentally realistic intensities, and the Foundation records both concessions because they bear on every figure in it. In introducing the biological sections the authors state that many of the short-term experiments they collect used "high ALAN levels (not considered environmental realistic)" and offer them as a step toward understanding mechanism rather than as estimates of effect in the field. On sandy beaches they state that the intensities used in some studies were those measured under the light source in the promenade area, which "could be higher than those occurring in the intertidal area," and they rebut the concern with unpublished data of one of their own authors. Neither concession discredits the review. Both describe the condition of a young literature, and it is the same condition Part V.A.2 describes for the terrestrial work.

And the findings in it do not all run one way. The Foundation sets out the exceptions because a reader given only the review's summary would not know they were there. Within this one document: a beach study found the locomotor activity of an amphipod no different between a lit and an unlit beach; another found no effect on the growth rate of an isopod and an increase in its absorption efficiency; the microbial community of a coral remained stable under artificial light; a study of juvenile bonefish and a study of a seagrass fish assemblage found almost no effect; the Atlantic dog whelk forages more under artificial light rather than less, which is the opposite of what the Chilean abalone does; artificial light increased the biomass and the photosynthetic efficiency of intertidal

microphytobenthos; and little penguins preferred lit paths to dark ones in reaching their nests. The Foundation does not treat that heterogeneity as evidence of safety, and the review does not either. It treats it as the reason a single threshold applied across taxa is not presently derivable from this literature, which is the proposition Part V.A.3 states and the reason the request in this comment is for research rather than for a number.

One further thing the review contains is taken up at Part V.J.4 rather than here, because it concerns measurement and not the sea: a box in which the authors state that there is no agreed unit for the quantity this whole literature reports.

And one primary study in the sea, which is the only long-term field experiment anywhere in this comment

The two documents above are reviews. One primary study belongs with them, and the Foundation sets it out at length because its design is rare and its endpoint is the one this comment has least of. Schligler J., Cortese D., Beldade R., Swearer S.E. and Mills S.C., Long-term exposure to artificial light at night in the wild decreases survival and growth of a coral reef fish, Proceedings of the Royal Society B, volume 288 (2021), article 20210454, doi 10.1098/rspb.2021.0454. Described at Appendix C.144. The authors declare no competing interests. Ethical approval was granted by the animal ethics committee of the French national research agency under a stated permit number.

What was done. In the lagoon of Moorea, French Polynesia, three subtidal fringing reef sites exposed to long-standing shore lighting from streetlights and hotels were each paired with a nearby site of comparable depth and reef structure lit only by the moon. Forty-two territories were created, each consisting of one healthy magnificent sea anemone collected from the northern lagoon and randomly distributed. Forty-two laboratory-reared juvenile orange-fin anemonefish, raised from eggs collected from about fifty wild breeding pairs, were weighed, photographed and measured, and then placed singly into the anemones: twenty-four in the dark territories and eighteen in the lit ones, with no difference in size between the groups. The species lives in obligate mutualism with its anemone and cannot leave it without exposing itself to predation, which is why these authors chose it. Survival and growth were then monitored over a mean of twenty and a half months.

The exposure was measured in both kinds of unit, which is rare enough in this comment to be worth stating on its own. Illuminance in lux and photosynthetically active radiation in watts per square meter were recorded at the depth of the anemones, sixty centimeters, with a named instrument, in triplicate, at one location in each of the six sites, after moonrise, on twelve nights spanning the four lunar phases across four months: two hundred and sixteen measurements. Lit territories averaged 4.3 lux and control territories 0.03 lux, a factor of one hundred and forty-three. The three lit sites differed significantly from one another, at 0.9, 2.3 and 8.9 lux. The control sites did not differ from one another at all.

Two things about that exposure matter to this comment more than the finding does

The first is that the authors say their levels are low. They write that the illuminances measured are representative of what shallow fringing reefs receive under street lighting and hotel lighting, that these are considerably lower than those produced by the light-emitting diode lighting used at ports, and that the impacts of artificial light in coastal marine ecosystems "could be greater than observed in the present study."

The second is the control figure. Three hundredths of a lux is a measured natural nighttime illuminance, taken underwater at sixty centimeters with a radiometric instrument, across four lunar phases. Appendix C.128 measured the night at its field sites in Cornwall, England one hundred and eleven times and found a median of 0.0168 lux. The Foundation had set those two figures beside each other as agreeing measurements of natural darkness, and has had to withdraw that characterization. The point Part V.A.2 makes, that a dose-response relationship for this exposure must extend below the illuminance of a natural night, stands; but these two numbers do not establish where a natural night is.

What the two figures are not. They are not measurements of the same quantity and neither is a measurement of a pristine natural night. The lagoon figure is an average across four lunar phases, so it contains moonlight by construction. The Cornwall figure is the ambient night at two sites on a university campus in a populated county, taken with an instrument whose stated sensitivity is 0.005 lux, so it sits about three times above the floor of its own detector. A clear moonless night sky, lit only by starlight, galactic light and airglow, is conventionally placed on the order of a thousandth of a lux, and the analysis at Appendix C.147 places the moonless natural level at between one ten-thousandth and one thousandth of a lux. Both figures above are therefore one to two orders of magnitude brighter than an unlit sky, and their agreement with one another corroborates nothing.

The Foundation states the correction because it made the error and because the corrected version is the stronger point. What these two studies measured is the darkest condition available to field investigators working where people live. If that condition is ten to a hundred times brighter than a natural moonless night, then the dark controls in this literature are not dark, every effect reported against them is an effect measured against an already-lit baseline, and the part of the dose-response relationship lying between a natural night and a field control has been examined by nobody. These figures do not show where a natural night is. They show how far from one the experiments have been conducted.

The findings, with the weakest stated first because the abstract does not

Survival. The fish in the lit territories had lower survival, by 36 percent. The probability attaching to that comparison is 0.055, and the authors accordingly write that survival "tends to be lower." The abstract reports the 36 percent without the probability. The Foundation reports both, and treats the survival result as suggestive rather than established, which is what its authors call it in their own Results.

Growth. Three measures and one of them significant. Height, 15 percent lower, at a probability of 0.036. Weight, 51 percent lower, at 0.074, which the authors again describe as a tendency. Length, 21 percent lower, at 0.251 and not significant. The abstract gives a single figure of 44 percent for growth. The Foundation has not been able to reconstruct that number from the three reported values, whose arithmetic mean is 29 percent, and records the discrepancy for verification rather than relying on either figure.

And the counts behind those percentages are very small. Of the forty-two fish, twenty-one were present at twelve to seventeen months (fifteen control and six lit) and fifteen at eighteen to twenty-three months (twelve control and three lit). The growth comparison in the final period rests on three exposed animals. The Foundation is not disparaging the study. It is a twenty-month field experiment in a lagoon, it could not have been done another way, and it is the only one of its kind in this comment. The Foundation states the counts because a reader given the abstract's percentages without them would be misled about what they rest on.

The authors' own competing explanation, which the Foundation adopts as it adopted the same move at Appendix C.138

They write that the difference in growth "may be due to phenotypic plasticity in morphology in response to ALAN and may be adaptive," that it may represent a reallocation of resources rather than a deficit, and that a lower growth rate in height "may therefore be the optimal strategy for anemonefish exposed to ALAN," facilitating escape from predation. Whether such plasticity is adaptive in the long term, they say, remains unknown. This comment does not assert that the growth difference is an injury, for the same reason it does not assert it of the eye-size difference in songbirds at Appendix C.138: the investigators themselves put adaptation forward as a competing reading, and a commenter who suppressed that would be doing something the Foundation has criticized others for.

Three further limits

The fish could move, and absence was scored as death. The authors address this: they report the distances between anemones within a treatment and between treatments, and they cite a study finding that this species is the most mobile of six anemonefishes tested, with 13 percent changing host anemone within four months. But at the first site the control and lit territories were 8.6 meters apart, which is within the range of movement the same paragraph describes, and one new recruit appeared on a lit territory during the study, so immigration occurred. Individual identity was confirmed photographically at every visit from the shape and length of the white stripes, which is the right control and does not remove the difficulty that a fish which left is indistinguishable from a fish which died.

The anemones themselves were lost in numbers. Seven control anemones and seven lit anemones were gone by the end; the authors describe that as an equal number, and in count it is, though as a proportion it is 29.1 percent against 38.8 percent. Seven fish were removed from the survival analysis because both fish and anemone were absent and the cause could not be attributed.

And the lit territories were systematically closer to shore than the control territories, at every site: seventeen to twenty-nine meters against forty-six to three hundred and twenty-two. The authors argue that other coastal stressors are unlikely to explain their results because the design spans three sites differing in exposure to those stressors, which answers variation between sites and does not directly answer the systematic difference in distance from the shore within them. The Foundation records the observation and does not press it, because the supplementary figure that maps the territories would be needed to say anything further and has not been obtained.

What the Foundation takes is accordingly narrow and, it submits, worth having. A field experiment ran for twenty months in the sea, at an illuminance the authors call representative and low, against a measured natural control of three hundredths of a lux, and the exposed animals grew less in one of three dimensions with the other two pointing the same way, and died more often at a probability just above the conventional threshold. Nothing in it concerns human health and the Foundation offers it on the emissions limb of paragraph 360ii(a)(2) alone, together with the two natural-darkness figures, which are the most useful thing in it.

Last in this subsection, the one enforceable American lighting rule written for a biological purpose that the Foundation has found, and how narrow it is

The survey above records four countries attempting to legislate on light pollution and does not name the United States. That is accurate as a statement about general light pollution law. It is not the whole picture, and the Foundation corrects it here rather than leaving a sentence in the comment that a reader with State regulatory experience would know to be incomplete. At least one American State already requires outdoor lighting to be low in intensity and shielded, for the express purpose of protecting an animal, as an enforceable condition and not as guidance.

The instrument is the hydraulic code of the State of Washington, administered by the Washington Department of Fish and Wildlife. Washington Administrative Code section 220-660-140 governs residential and public recreational docks, piers, ramps, floats, watercraft lifts and buoys in fresh water. Subsection (3)(d) provides that if artificial nighttime lighting is used in the design, the applicant is to use low-intensity lights that are located and shielded, and the stated purpose of the requirement is to prevent light from attracting fish, unless there are safety constraints. A second provision in the same section, subsection (7)(f), directs that to avoid attracting fish to lights at night, impact pile driving be limited to daylight hours whenever feasible.

The Foundation states the limits of that instrument before its use, and they are severe. It is a condition attaching to a permit for one narrow class of in-water construction in one State, not a rule about lamps and not a rule of general application; it reaches the designer of a dock and not the manufacturer of a luminaire. The protected subject is a fish and not a person. The operative term, low-intensity, is not defined in the provision, no illuminance, luminance, radiance or spectral quantity appears in it, and nothing in it states how an inspector is to decide whether a given light

complies. And the whole requirement yields to unspecified safety constraints, on the face of the subsection, with no standard governing when that exception is available.

What the Foundation takes from it is therefore not that the problem is solved anywhere. It is three narrower things. First, that an American regulator has already decided, in binding text, that artificial nighttime lighting is a thing to be limited in intensity and directed by shielding when a biological receptor is present, which is the premise Part IX proceeds from and which is here conceded rather than argued. Second, that the drafter stopped exactly where this comment says the Federal gap lies: the duty is stated and the number is missing, because no instrument of general application supplies one. A State permit writer who wanted to know what low-intensity means has nowhere in the Code of Federal Regulations to look. That is the work paragraph 360ii(a)(5) directs the Secretary to do and section 360kk gives the Secretary power to complete, and it would be done once federally rather than improvised in every State permit. Third, that a safety carve-out with no standard attached is the same device Part VI.C examines in the vehicle lamp setting, and it behaves the same way: it swallows the rule unless something tells the decision-maker how much light safety actually requires.

The Foundation came to that provision through a document it does not otherwise rely on and describes at Appendix D.1: an interim briefing memorandum of March 10, 2020 on artificial lighting and salmon, prepared for the Salmon Recovery Council of the Lake Washington, Cedar and Sammamish watershed forum, an interjurisdictional body administered through King County, Washington. The memorandum is a staff summary rather than research; its two most arresting figures are drawn from an unpublished presentation to its own technical committee; and it repeats a proposition about the atmospheric behavior of blue light that this comment has declined at Part II.D.4 on the authority of the people who measure skyglow. The entry sets all of that out. The Foundation notes it here because the regulation is verifiable primary law whatever the memorandum is worth, and because the memorandum is the reason the Foundation looked.

One further thing in that line of work belongs in this subsection rather than in the appendix, and it tells against the direction a reader might expect the Foundation to take it. The same watershed forum commissioned field research, and the final report delivered to it in April 2025 by a university wetland ecosystem team does not report a simple gradient of fish abundance with light. On the account the Foundation has of it, juvenile salmon densities were highest both at the brightly lit residential sites and at the dark reference sites and lowest at the brightly lit commercial sites, and water depth mattered more to their distribution than lighting did. The Foundation has not read that report, has only a description of it, builds nothing on it and states it anyway, because the 2020 memorandum is the kind of document a comment can quote confidently and the research that followed it is the kind that makes confident quotation unwise. Obtaining that report is recorded as a priority at the appendix entry.

J. Exposure Assessment Methods and Their Limitations [RFI Q7, Q8]

This subsection concerns how exposure is measured, and the Foundation begins with what is known about its scale, because the scale bears directly on the duty stated at Part II.D.

Guo, Liu, Kyba and others, publishing in Environment International in 2026, merged two satellite datasets into a single time series to estimate the human population exposed to outdoor artificial light at night, and projected forward under standard socioeconomic scenarios. They found that the population exposed to outdoor light emissions rose from 4.3 billion in 2000 to 6.3 billion in 2020, with 88 percent of that growth occurring in areas of medium to high light emission. For the high-emission areas, which are predominantly urban, 73 percent of the increase was attributable to population growth and migration. For the medium-emission areas, which are predominantly suburban, the increase in radiance itself accounted for the larger share, 63 percent. They project that by 2050 nearly 70 percent of further growth will occur in medium to high emission areas, and conclude that “Preparation for potential increased disease burden and actions to reduce light growth are therefore advisable.”

The Foundation offers that study for the purpose identified at Part II.D rather than as evidence of any health effect. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, development, training and operational activities to minimize the emissions of and the exposure of people to unnecessary electronic product radiation. The paragraph speaks of emissions and of exposure, and a duty to minimize a quantity presupposes knowing what the quantity is.

The quantity is being tracked. It is being tracked by academic researchers working from satellite radiance data, published in the peer-reviewed literature, at global scale, with projections to 2050 and an express recommendation that action be taken to reduce the growth. What does not exist is any federal measurement of what a person in the United States is exposed to, any federal inventory of the emitting products, and any federal baseline against which a minimization duty could be assessed. The Foundation asked the Department to establish such a baseline at Part II.D.6, and renews that request at Part IX.C.

The limits of satellite radiometry are real and the Foundation states them. These data measure light radiated upward and detected from orbit, which is a proxy for what reaches a person at ground level and not a measurement of it. They describe outdoor light and say nothing about interior exposure, which for most people is the larger part of the total. They do not identify the technology producing the light. Appendix C.3 sets out the study in full.

One further point belongs in this subsection, and it answers an objection rather than making a claim. It might be said that individual optical exposure cannot practicably be measured, and that this is why the federal record contains no measurement of it. The premise is not correct. The study described at Appendix C.4 measured nighttime light in the bedrooms of 454 individual participants, on three separate occasions each, using a handheld illuminometer costing on the order of tens of dollars. Whatever else may be said about that study, and Part V.F says a good deal, it establishes that direct measurement of a person's nighttime optical exposure is neither technically difficult nor expensive.

The absence of such measurement in the United States is therefore not explained by its difficulty.

Those limits are themselves the argument of this subsection. The best available description of how much artificial light the human population is exposed to comes from instruments in orbit, because no instrument on the ground is systematically collecting it.

1. Instruments and measurands currently available

a. Source geometry, apparent source size, and retinal irradiance

A further difficulty attaches to the characterization of a finished luminaire rather than of a component, and the Foundation states it here because it determines what a photometric file can be taken to describe. The optical study at Appendix C.88 designed, built and measured two secondary optics, each converting the output of the same named light-emitting diode into uniform illumination of a defined area, and each achieving over 95 percent uniformity on the authors' stated measure. The finding was that the two differed not in what they achieved but in how securely they held it: "the uniformity produced by the freeform lens reduces abruptly compared with the CDTIRO when some parameters such as size and the position of the light source are changed."

What follows is a proposition about the object of measurement. The distribution a luminaire delivers is a property of the emitter and the optic taken together, and for at least one common class of optic it is not robust to a change in the size or the position of the emitter. A photometric file describes the pairing that was measured. It does not follow that it describes a unit built with an emitter of slightly different dimensions, or with the same emitter mounted slightly differently, and the manufacturer document at Appendix D.3 supplies the reason such substitutions are unremarkable: two components may carry the same reported half width and distribute their output differently. The Foundation states the limit of this point as the source states it. The

degradation is described as abrupt and is not quantified anywhere in that paper, and the Foundation does not assert a magnitude. What it asserts is that the quantity is sensitive to a variable that no reporting convention examined in this comment records.

2. Laboratory measurement versus real-world exposure conditions

A measurement of an optical emission is a measurement under conditions, and changing the conditions changes the number. This subsection sets out the difference between the conditions under which these products are measured and the conditions under which people meet them, because several requests in this comment depend on the distinction.

Four differences, each of which has been identified elsewhere in this Part and is collected here.

Geometry. Irradiance is referred to a surface, so its value depends entirely on where the surface is placed, and Part III.D.6 records that a criterion expressed in it is uninterpretable without a stated measurement geometry. A laboratory measurement fixes the geometry by convention. A person meets the product at whatever geometry the installation and their own posture produce.

Motion. A laboratory presentation is static. A headlamp approaches, a beacon is passed, a display is traversed, and Part III.D.9 treats movement through space as a characteristic requiring a boundary. Part V.D.2 sets out the stroboscopic and phantom-array effects, which exist only because the source or the eye is moving, and which no static measurement produces.

Multiplicity. Part V.J.3 sets out the single-emitter design of the instruments and Part III.D.8 treats the number of emitters during exposure. A measurement of one luminaire does not describe a field of view containing twenty.

Adaptation. The eye that meets a source at night against a dark field is in a different state from the eye in a laboratory, and Part V.D.1 and Part V.C.3 set out why that state is the condition under which glare and straylight do their work.

Two consequences follow for the requests this comment makes. The first is for the Department: Part IX.C asks that the evaluation directed by paragraph 360ii(a)(4) be conducted under the conditions in which the product is actually met rather than under static laboratory presentation, and this subsection is the ground of that request. The second is for everybody else: Part VIII.E.3 establishes that a public entity which acquired an instrument would still not know under what conditions to use it, because no federal document states the conditions, and Part VIII.D.3 establishes that the resulting number could not be evaluated in any event.

3. Multi-emitter exposure, and the single-emitter design of the existing literature

a. Multiple high-radiance images on the retina

That proposition is now supported from the industry rather than asserted against it. The manufacturer white paper described at Appendix D.3 and at Part V.C.4.f addresses the same point under the name pixelation, and states it in terms the Foundation could not improve on. It identifies as the difficulty “the inadequacy of the photometric measurements that assumes the source is a single point. Instead, it is an array of closely spaced sources: very small high luminance zones separated by low luminance zones.” It continues: “The current photometrics for glare assumes a single source of luminance and so requires only a snippet of information — a measurement taken from one spot facing this single point source. Of course, a LED luminaire contains multiple light sources within that single luminaire, so it’s obvious that new metrics are needed to take account of this.”

And on what the measurement discards: “A photometric measure uses a light sensor to collect the light from multiple LED sources as if the light has been emitted from a point source of light where distance is irrelevant. In other words, the photometry cuts down the luminaire’s details to one pixel of information.” The document observes that glare calculations then compare one pixel per

luminaire against the background, while the person sees every variation of intensity within the optic.

The Foundation records that the same document proposes the remedy it identifies at subsection g below, namely imaging rather than single-point measurement: it notes that high-resolution digital cameras now permit radiant imaging of every point in the field, and that this could quantify what people actually experience. That is a measurement capability, which is the subject of § 360ii(a)(5), and it exists.

A measured result for an array rather than a single emitter bears on this subsection, and the Foundation records it because it is the only one it has. Appendix C.86 describes near-field goniometric measurement of a task lamp carrying twenty-one discrete light-emitting diode modules mounted on flat surfaces. The measured distribution was not the distribution of a single emitter enlarged. The author reports a weighted Lambertian and attributes the departure from the single-emitter form to three properties of the array: the number of elements, their coarser spacing, and the greater size of the emitting plane. Her conclusion is that "the Lambertian LIDs are indeed weighted according to the x and y dimensions of the flat LED sources", and she notes that the measurement would reveal more asymmetry at higher angular resolution than she used.

The Foundation does not overstate what that shows. The measurement was of luminous intensity distribution in relative units, reported in candelas per kilolumen, and the author states that the magnitudes were not tied to her analytic solution. It is not a measurement of what an array deposits on a retina. What it establishes is the proposition this subsection needs and the single-emitter literature cannot supply: the emission of a multi-emitter assembly differs in shape from that of its elements, in a manner that depends on the geometry of the assembly, and a measurement that averages across the aperture records none of it.

The optical side of the same point is reported at Appendix C.88. Where refractive optics of the kind used on roadway luminaires are placed close together, they obstruct one another: on the authors' account "it is necessary to provide a gap between them in order to keep uniformity of illumination. Otherwise the lenses act like obstacles and uniformity deteriorates." An array is therefore not the sum of its elements on the optical side any more than on the photometric side, and the spacing of the elements is a variable that governs what the assembly emits. The Foundation notes that the quantity degraded in that study is uniformity of an illuminated surface rather than anything about an observer, and offers it only for the proposition that elements of an array interact.

A further matter belongs here and it changes the character of the deficiency this subsection describes. The manufacturer document at Appendix D.3 and Part V.C.4.f proposes imaging measurement as the remedy for single-point photometry. A second manufacturer, in the document described at Appendix D.3, reports that the measurement is already being made. Designers are instructed to "use ray files of the LEDs which contain near field information," and the manufacturer states that it "offers measured ray data for all LEDs and all standard programs."

The Foundation asks the Department to note precisely what that is. A near-field ray file records where on the emitting surface each ray departs and in what direction. It is the characterization that a single photometric reading taken at a distance discards, and it is the characterization that would permit the number, position and intensity of the retinal images described at paragraph b above to be computed rather than estimated. On the manufacturer's own account it is measured for every device in its range and supplied to its customers in the file formats of the standard optical design packages.

Three consequences follow, and the Foundation separates them because they bear on different parts of this comment. The first is that the deficiency identified in this Part is not that the measurement is infeasible, that the instruments do not exist, or that nobody performs it. It is performed, per product, as a commercial routine, by at least one major manufacturer on its own statement. The second is that what has not happened is its entry into any public or regulatory

channel: the Foundation has located no federal requirement that such data be produced, no federal repository that holds it, and no evidence in the public record that any federal body has asked for it. The third is the statutory one. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from industry. The information the study required by paragraph (a)(4) would need is in the hands of industry, in a measured and standardized form, and is distributed to anyone with a commercial reason to ask for it.

4. Photometric reporting as a limitation of the existing literature

A limitation runs through the whole of the literature described in this Part, and the Foundation brings it forward here because it determines what that literature can and cannot be used for.

The studies of artificial light and human health characterize exposure in one of three ways, and all three are blind to the same thing.

Satellite radiance at the residential address. The coarsest. It measures light radiated upward from a neighborhood, in broadband units, as a proxy for what a person living there receives. The ulcerative colitis study at Appendix C.5 uses this method.

Wrist-worn light sensors. Better, because the instrument is on the person. The sensor records illuminance in lux, a photometric quantity weighted by the photopic luminous efficiency function. The cardiac study at Appendix C.2 uses this method.

Direct measurement with an illuminometer in the room where the person sleeps. The most precise of the three as to place and time, and still a reading in lux. The study at Appendix C.4 uses this method.

Each of the three is photometric or broadband. None is spectral. A reading of 3 lux, or 50 lux, or a satellite radiance value, says how much light there was as the standard observer's eye would weigh it. It does not say what the light was made of. Two exposures reported as identical in these units may differ entirely in the short-wavelength content that Part V.C identifies as bearing on the retina and Part V.F identifies as bearing on circadian timing, and in the long-wavelength content that Part V.B.6 identifies as bearing on mitochondrial function.

What the satellite instrument can and cannot see

The first of those three methods requires a further statement, because to call it broadband understates the difficulty. A broadband instrument is one that cannot distinguish one spectrum from another. The instrument on which this literature depends does something different. Its sensitivity band begins above the emission peak of the products with which this comment is concerned.

Kyba and others, publishing in Science Advances in 2017, reported the first analysis of the calibrated satellite radiometer from which the global record of artificial light at night is now derived, and described the instrument in these terms:

> "This sensor provides the first-ever global calibrated nighttime radiance measurements in a spectral band of 500 to 900 nm, which is close to the visible band, with a much higher radiometric sensitivity than the DMSP, and at a spatial resolution of near 750 m."

The band begins at 500 nanometers. The emission peak of a phosphor-converted white light-emitting diode lies between approximately 450 and 470 nanometers, as Part V.B.1 describes. The authors state the consequence in terms the Foundation need not paraphrase:

> "So-called 'white' LEDs emit a portion of their light at wavelengths below 500 nm (blue), where the DNB is effectively blind."

What follows from that is the material point, and the Foundation asks the Department to read the next two passages together.

> "This means that a street light transition from (orange) high-pressure sodium lamps to (white) LEDs in which surface luminance is held constant results in a decrease in the radiance observed by DNB."
>
> "…whereas decreases in city center radiance in the DNB band likely indicate absolute energy reductions, white LED transitions will often increase the skyglow experienced on the ground…"

The instrument does not merely under-record the conversion to light-emitting diode street lighting. For a conversion at constant surface luminance it records the conversion as a reduction, while the quantity to which a person standing on the ground is exposed increases. The authors observed that pattern in the data. Many large cities showed falling radiance at the center alongside rising radiance in outlying areas, and the authors attribute the fall at the center to "the sensor's lack of sensitivity to light in the range of 400 to 500 nm." They add that the rise in scattered skyglow "would be considerably more noticeable if the DNB was sensitive to light below 500 nm," the clear sky scattering short wavelengths preferentially.

Three consequences follow. The Foundation states first the one that runs against its own appendix.

At least fifteen of the one hundred and fifty-three entries collected in Appendix C take satellite radiance as their own exposure variable: C.3, C.5, C.9, C.16, C.17, C.22, C.31, C.33, C.37, C.43, C.44, C.129, C.138, C.145 and C.147. The last two are refinements of the category rather than plain instances: neither uses raw radiance, each using instead a published product modeled from it, which inherits the band limitation of the instrument and adds a modeling step on top of it. Appendix C.147 adds a second modeling step, converting the modeled sky brightness into a predicted illuminance at the ground. The last of those is a refinement of the category rather than a plain instance: its exposure variable is not raw radiance but a published atlas of night sky brightness modeled from it, which inherits the band limitation of the instrument and adds a modeling step on top of it. Two further entries, C.14 and C.35, are reviews of literatures composed substantially of such studies. The denominator has been conformed to the present size of the appendix and must be conformed again whenever an entry is added, which has now been missed on four occasions and was found stale again when Appendix C.143 was added; the list itself has not been re-audited.129 records that task and it remains outstanding. Appendices C.139 and C.143 are not among the thirteen and are not candidates for the list: it has no outcome variable, being a study of the instrument rather than a study conducted through it, though it does use the satellite product to calibrate its intensities and to mask its maps.

> The same fact forecloses the contrary inference. If that literature cannot establish an effect attributable to the emission of light-emitting diode products, neither can it establish the absence of one. A review of the published literature on artificial light at night and human health, of the kind the response of May 24, 2024 states the agency commissioned and relied upon, will have drawn substantially on studies whose exposure instrument cannot detect the wavelengths in question. That is not a criticism of whoever conducted the review. It is a statement of what the available literature is capable of showing, in either direction, and it is the reason the Foundation asks for measurement rather than for a further review.

The field has now conceded the point in print

When this comment was first drafted the proposition above was the Foundation's inference from the instrument description. It is no longer only that. The authors of the exposure study at Appendix C.3, which is one of the thirteen entries just named and the one this comment relies on for the size of the exposed population, state the difficulty themselves among their limitations, and state the consequence for their own numbers.

> "Both DMSP/OLS and VIIRS/DNB have limited sensitivity to short-wavelength (blue) light below 500 nm, which is the spectral range most strongly associated with non-visual physiological effects such as circadian disruption."

They add that blue-rich emission has increased substantially with the adoption of solid-state lighting, that satellite radiance accordingly underestimates both the visual and the non-visual exposure burden, especially where the conversion to light-emitting diode lighting is rapid, and then state the conclusion that governs how this comment uses their figures:

> "Consequently, the ALAN exposure estimates presented in this study should be interpreted as conservative lower-bound estimates, and the actual environmental and biological light burden may be greater than indicated by satellite observations alone."

Three things follow, and the Foundation puts the unhelpful one in the middle rather than at the end.

The first is that the exposure figures this comment reports from that study are a floor. The Foundation is not defending them as estimates of the biologically relevant exposure and does not need to. The authors have said they are lower bounds, and a duty to minimize a quantity is not discharged by leaving the only available measurement of it below the true value and unimproved.

The second runs against the Foundation. The same authors identify a second reason the satellite record may mislead, and it has nothing to do with spectrum. The conversion to light-emitting diode lighting is commonly accompanied by better shielding and a changed angular distribution, which reduces direct uplight. They state that this may weaken the relationship between ground-level illumination and the radiance a satellite observes, and introduces further uncertainty into long-term trend analysis. The Foundation accepts that and states the consequence plainly: the direction of the ground-level trend is not established by this record. Better shielding at constant or rising ground illuminance would show in these data as a reduction. So would a genuine reduction. The instrument cannot tell the Department which it is looking at, and neither can the Foundation.

The third is the request, and it is modest because the second point makes it so. The Foundation does not ask the Department to find that ground-level exposure is rising. It asks the Department to notice that the only continuous national measurement of this emission cannot answer the question in either direction, that its own authors say so, and that paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. An instrument that is blind to the wavelengths at issue and confounded by the optics of the fixture is not that evaluation. It is the reason one is needed.

> The remedy was identified by the same authors in the same paper: "From a remote sensing perspective, the situation could be greatly improved if nighttime satellites had color sensitivity." Nine years have passed and the Foundation is aware of no federal program to provide it. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. A measurement convention whose band excludes the wavelengths at issue is not a characterization of the emission.

The remedy was not supplied. What was built instead, and what it measured

Five years after the instrument paper, three of its authors — Sánchez de Miguel, Bennie and Gaston — published in the same journal the work that the sentence just quoted anticipates. No satellite carrying color sensitivity had been launched, so they used the only color imagery of the night side of Earth that exists in quantity: photographs taken out of the windows of the International Space Station by astronauts, with ordinary digital single-lens reflex cameras. The study is at Appendix C.139. The Foundation takes four things from it and declines the rest.

The first is the specification of the instruments, stated independently of the 2017 paper and more completely:

> "the key satellite sensors have been panchromatic, providing no information on the spectral composition of artificial light at night (ALAN), and while the bandwidths have been broad, they have also been insensitive to the blue part of the visible spectrum (380 to 450 nm); the Defense Meteorological Program/Operational Line-Scan System (DMSP/OLS) was sensitive from 450 to 1000 nm, and the Suomi-National Polar-Orbiting Partnership/Visible and

> Infrared Imaging Radiometer Suite–Day/Night Band (SNPP/VIIRS-DNB) and NOAA20 VIIRS-DNB are sensitive from 480 to 920 nm."

Two numbers in that passage are worth separating. The interval the authors name as the one to which the sensors are insensitive runs up to 450 nanometers, which is the lower edge of the emission peak of the phosphor-converted white light-emitting diode as Part V.B.1 describes it. The nominal lower limit of the band of the instrument now in service is 480 nanometers, which lies above the whole of that peak. The 2017 paper gave the band as 500 to 900 nanometers and said the sensor was "effectively blind" below 500. These are compatible statements about different things — the nominal limits of a band, and the wavelength below which its response has fallen to nothing of use — and the Foundation reports both rather than harmonizing them. What neither permits is the view that the instrument records what a white diode emits at its peak.

The authors state the consequence in a single sentence:

> "satellite-borne imagery may provide a poor or limited quantitative indicator of the exposure to environmental risks associated with ALAN, as shifts toward potentially harmful lower-wavelength emissions are masked by the low sensitivity of the sensors at these wavelengths."

The second thing the Foundation takes is that the masking has now been measured rather than inferred. The authors built two composite color maps of Europe from calibrated astronaut photographs, one for 2012 to 2013 and one for 2014 to 2020, at five-hundred-meter resolution across twenty-six countries, and compared them. They conclude:

> "We have demonstrated that one consequence of this shift in the spectral composition of artificial nighttime lighting emissions has been a marked progressive underestimation in the intensity of those emissions as determined by the principal satellite platform used for this purpose (SNPP/VIIRS-DNB)."

The word to notice is "progressive". The error is not a constant that could be calibrated away once and for all. It grows as the conversion proceeds, which means that a time series assembled from this instrument carries a bias that increases along the series, in the direction of understating the change. The authors add that the same radiance values are used to estimate population density and urbanization, economic activity, the extent of wilderness and the effects of the coronavirus pandemic. The Foundation does not pursue those uses and notes only that the defect is not confined to lighting research.

The third bears on Part IX, and it is the reason this paper is worth more to the Foundation than its findings. Having recovered the spectral information, the authors re-expressed their maps as indices of biological consequence: a melatonin suppression index, a star light index, and an index of the phototactic response of moths, each computed from the color ratios through published response curves, and each mapped across the continent and reported country by country. Part IX.G.1 asks that a performance standard prescribe the spectral characteristics of the emission, and Part IX.J asks the Department to state that lumens, watts and correlated color temperature do not describe spectral content. The objection to be expected is that no practicable spectral measure exists at scale. It does. One has been computed for a continent, at five-hundred-meter resolution, from imagery that cost nothing to acquire.

The fourth is the authors' own statement about whether the short-wavelength content is necessary to the technology. On the benefits claimed for it:

> "The benefits of LED technology do not rest principally in the ability to produce broad white light emissions (this is also achievable with other technologies)."

And on how the emission came to have the composition it has:

> "the increased use of LEDs in public lighting has also led to intentional shifts in the spectral composition of the associated emissions, with these often becoming whiter, with the intention of providing improved color rendering for human vision."

That is a statement by investigators in the field that the characteristic at issue is a design choice made for an identified reason, and not an inherent property of the emitter. It answers the objection that a standard addressed to short-wavelength content would be a standard against light-emitting diodes. It would be a standard against one design decision, which the people who study the emission say was taken deliberately and is not required by the technology.

Four qualifications belong with all of that, and the Foundation states them here rather than leaving them to the appendix. The camera is not a spectrometer: it has three broad channels, and the spectra are inferred from two color ratios by synthetic photometry against the known emission spectra of lamp types. The three indices are not three findings; they are deterministic re-expressions of the same two ratios, and the paper's own statistics show it, because the Kruskal-Wallis statistic reported for the green-to-red ratio, for the melatonin suppression index derived from it and for the star light index derived from it is the same number to two decimal places, a monotone transformation of a variable leaving its ranks unchanged. One reported percentage cannot be reconciled with the medians printed beside it, and Appendix C.139 sets out which. And the composite maps are masked using the very satellite product whose blindness is the paper's subject, at a threshold of half a nanowatt per square centimeter per steradian, so the corrective map cannot see lighting that the criticized instrument cannot see.

None of the four disturbs the use made of the paper here, and the Foundation says why rather than asking the Department to take it on trust. The band limits are instrument specifications and not results: they do not depend on the camera, the statistics or the mask, and can be checked against the sensor documentation without reference to this paper at all. The demonstration that an index of spectral consequence can be computed and mapped is a demonstration rather than an estimate, and it survives an error in any particular figure. And the direction of the spectral shift is established by the color ratios, which the authors state in their Methods are the better-determined quantity, rather than by the absolute intensities, which they state are the worse.

One note on the arithmetic of what follows. This paper is not an eleventh instance in the list below. The instances in that list are investigators who used the instrument to measure something else and either disclosed or did not disclose that it could not see what they were studying. These authors set out to measure the blindness itself. The paper is the source for the list and not a member of it.

What the blindness does to the record itself, and what it does to the only long-run number for this country

The same five authors published a year earlier the companion to the work just described, and the Foundation takes it out of chronological order because its subject is not a map but the time series. Sánchez de Miguel A., Bennie J., Rosenfeld E., Dzurjak S. and Gaston K.J., First estimation of global trends in nocturnal power emissions reveals acceleration of light pollution, Remote Sensing, volume 13, issue 16 (2021), article 3311, open access under a Creative Commons Attribution license. Described at Appendix C.143. The authors declare no conflict of interest and the work carries the same research council grant as the mapping study.

What they did was assemble a global, country-by-country series of satellite-detectable emitted power from 1992 to 2017 by reconciling three mutually incompatible datasets — the uncalibrated Defense Meteorological Satellite Program archive, whose values are digital numbers between one and sixty-three that saturate in any bright city; the radiance-calibrated subset of that archive, which exists for only eight years; and the Visible Infrared Imaging Radiometer Suite — and anchoring all three to a ground truth, which was the recorded electricity consumption of municipal street lighting in seventy-five Italian provinces. They then modeled what the sensors could not see.

The headline, as they state it, is that satellite-detectable light increased by at least 49 percent over the twenty-five years. For the part the sensors miss they give a projection: a global total in the blue band of 513 megawatts in 2017, which would be 806 megawatts if forty percent of lighting were diodes at 3,000 kelvin and 1,294 megawatts at 4,000 kelvin. From those they derive the figure in

their abstract, that the true increase in radiance in the visible spectrum "may be as high as globally 270% and 400% on specific regions."

The Foundation relies on the 49 percent and declines to lean on the 270. The larger figure depends on an assumed rate of conversion taken from a Spanish manufacturers' association and on an assumed color temperature for the lamps that replaced the old ones, and the authors offer it as a bound on uncertainty rather than as a measurement. The 49 percent is what the instruments recorded. Everything the Foundation takes from this paper is available without the larger number, and a comment that leaned on it would be relying on a modeled quantity where a measured one was at hand.

The finding that bears on the United States

At the continental scale the authors report persistent growth in detected light in Asia, South America, Oceania and Africa; a rise in Europe that levelled off around 2010; and this:

> "in North America it appears to be in decline."

They then qualify it, and the Foundation asks the Department to read the two sentences together rather than separately:

> "any conclusions as to the apparent levelling off or decrease in lighting intensity in Europe and North America should be treated with caution as the shifting spectral distribution of light towards blue-rich LEDs is likely to mask the effects of increases."

The only continuous multi-decadal measurement of this emission over the United States shows it falling. The investigators who constructed that measurement say the fall should be treated with caution, because the instrument is becoming blind to the technology that replaced the one it was calibrated against. A Department that took the national trend at face value would be relying on a number its own authors disclaim, and the direction of the error is the one that most favors doing nothing.

This is not an inference the Foundation constructed. The beginning of this subsection quotes the 2017 instrument paper for the mechanism: a conversion from sodium lamps to diodes at constant surface luminance "results in a decrease in the radiance observed by DNB." That was a prediction about what the instrument would do. This is the continental observation of its having been done, by three of the same authors, four years later.

How large the artifact can be, how the 2017 authors described their own headline figures, and what they found for the United States

The Foundation has since read the 2017 instrument paper in full and takes three further statements from it. They bear on the passage above and the Foundation sets them out here rather than at the head of this subsection, because together they answer the question a reader of that passage will ask, which is how much of an apparent decline the instrument could manufacture on its own.

The first is a magnitude. The authors state that a decrease of about thirty percent in recorded radiance could be produced by a complete conversion from high-pressure sodium to diode lighting rather than by any reduction in visible light at all. That is the artifact quantified by the people who built the measurement. The comment has until now been able to say only that the instrument would record a decrease where none had occurred; it can now say how large a false decrease is available, and thirty percent is larger than any national change reported in the period.

The second is the authors' own characterization of their headline numbers, and it is the sentence this subsection would choose if it could choose only one: "The measurements of change in lighting reported here are therefore actually lower bounds on the increase of lighting in the human visual range." The paper reports that the artificially lit surface of the Earth grew by 2.2 percent a year from 2012 to 2016, that total radiance grew by 1.8 percent a year, and that continuously lit areas

brightened by 2.2 percent a year. Those are the figures in general circulation. Their authors describe them as lower bounds.

The third runs against this comment and is the reason the first two matter. Among the few countries in which lighting was stable rather than growing over the period, the authors name some of the world's brightest, and the United States is on that list, with Italy, the Netherlands and Spain. Read alone, that is a finding that American outdoor light was not increasing during the four years in which American street lighting was converting to diodes. The Foundation does not suppress it and does not accept it, and the ground for not accepting it is the authors' own: the instrument is blind below five hundred nanometers, a complete conversion can manufacture a thirty percent apparent decrease, and the reported figures are lower bounds. A measurement that cannot see the new technology will report stability in the country doing the converting.

That is now the second satellite analysis in this subsection to find American or North American light flat or falling, and the second whose own authors supply the reason to distrust the finding. The Foundation draws no conclusion about whether American outdoor light rose or fell between 2012 and 2016. It draws the conclusion this subsection exists for: that the question cannot be answered from the satellite record, that the two published answers are in the direction least favorable to this comment, that in each case the investigators say so themselves, and that paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions rather than to adopt the only number that happens to exist.

Two further matters, which bear on arguments made elsewhere in this comment

The first is the share of the emission that comes from street lighting, which this comment has never been able to state for the United States and which these authors decline to state for anywhere. They write that the proportion is "unclear and debated in the literature" and likely to vary between countries and cities, and they give a published range that runs from 12 percent in Flagstaff, Arizona to nearly 100 percent in Spain. That is an eightfold spread between two developed countries. Set it beside the volunteer count at Appendix C.130, where streetlights in dense German urban areas were outnumbered by other sources by a factor of five to seven, and beside the observatory review at Appendix D.7, which supplies the Flagstaff end of the same range. Three sources now say the same thing: the streetlight share is small in some places, dominant in others, and not known for this one. The Foundation does not assume a figure for the United States and asks the Department not to either.

The second is the hour. The older satellite passed at about half past nine in the evening and the present one passes between midnight and two in the morning, so the two instruments do not measure the same night. These authors build two separate series for that reason, recalibrating each sensor against the other for 2012, the one year in which both operated. The Foundation notes the consequence rather than the method: the difference between an evening series and a post-midnight series is itself a measurement of how much lighting is switched off or dimmed between those hours, and it is the only measurement of that quantity at national scale that this comment has encountered. It bears on any request addressed to the duration of an emission, and the authors report that the gap is large in Europe, North America, Asia and Oceania and much smaller in South America and Africa.

One sentence from the abstract is adopted without alteration, because it is the whole of what this comment needs on the efficiency question at Part IV.G: "there is limited evidence that advances in lighting technology have led to decreased emissions."

What the Foundation does not take

The global calibration rests on one country. The entire series, for every nation on Earth, is anchored to the recorded street-lighting electricity consumption of seventy-five Italian provinces, chosen because that is where the historical provincial data exist. The authors are explicit about it and validate the result against national figures for eleven other countries, which is the right thing to do and is not the same as calibrating on them. The Foundation reports the direction of travel and not

the magnitude for any particular country outside that validation set, and it does not report a figure for the United States at all, because none is given and the authors' own caution forbids inferring one from the continental curve.

Nor does the Foundation adopt the authors' further claim that the transition to solid-state lighting "actually resulted in a dramatic rise in that consumption compared with that which had previously been occurring." That is a statement about energy consumption rather than about emission, it is supported by a citation the Foundation has not been able to match to the proposition, and the comment does not need it. What the comment needs is the measured direction of the emission and the authors' statement that the apparent decline in North America is probably an artifact of the instrument. Both are in the paper.

The difficulty had reached the health-effects literature by 2018. Argys, Averett and Yang, publishing in the Southern Economic Journal in 2020, examined skyglow and birth outcomes and declined to use satellite data, writing that satellites "are not sensitive to the blue part of the visible spectrum of light… such as that emitted by Light-Emitting Diode (LED) streetlights" and that "satellite images may fail to capture the skyglow added by LED streetlights, a growing source of light pollution." In its place they used a citizen-science dataset in which the sensor is the unaided human eye, recorded as the faintest star an observer can see. The Foundation does not rely on the findings of that study and does not include it in Appendix C. It relies on the methodological fact alone, which is this. By 2018 investigators working on this question had concluded that the best available measure of the exposure was volunteers counting stars, because no instrument in orbit could see the part of the spectrum they required.

The authors of the ulcerative colitis study state the point against their own result. Among the limitations they identify is that wavelength-specific effects could not be differentiated. That is not a defect of their study. It is a defect of the measurement conventions available to them, and every research group in this field inherits it.

And a fifth attestation, from the journal where it costs most to make

The Foundation adds one more, because of where it appears and because the paper that makes the admission is wholly dependent on the instrument it is admitting about. Johnston, Kim and Harris, publishing in Nature Climate Change in November 2025, combined satellite light measurements with carbon flux observations from eighty-six eddy covariance towers in North America and Europe. Described at Appendix C.129. Their statement about the instrument is made among the limitations of their own analysis:

> The available nighttime light satellite products used here, being the Visible Infrared Imaging Radiometer Suite and the Defense Meteorological Satellite Program, "are coarse in spatial resolution, are insensitive to blue light emitted by white light-emitting diode (LED) lighting and cannot fully capture local heterogeneity in ALAN exposure at flux tower sites."

And on the exposure variable itself they go further than any other source in this comment. Their measure is not calibrated radiance. It is a harmonized digital number, an index, and they state that such values "represent relative radiance indices and cannot be directly converted into absolute illuminance units such as lux, as they do not capture spectral composition or ground-level variability", and that the categories built from them "should thus be interpreted as relative exposure gradients rather than specific ecological thresholds".

The pattern, stated once and counted, with the three kinds of blindness distinguished

The Foundation has now had to report ten times in this comment that the instrument used to observe this exposure cannot record it. It collects the instances here so that they are counted once rather than remarked on each time they arise, and so that the Department can see that the difficulty is a property of the field and not of any paper.

- Kyba and nine co-authors, Science Advances, 2017. The instrument paper. The Day/Night Band records a spectral band of 500 to 900 nanometers, and the authors state that white diodes emit a portion of their light below 500 nanometers, "where the DNB is effectively blind." They give the consequence: a conversion from sodium to diode lighting at constant surface luminance produces a decrease in the radiance the instrument records.
- Guo, Liu, Kyba and others, Environment International, 2026. Appendix C.3. Both the sensors used have "limited sensitivity to short-wavelength (blue) light below 500 nm," and the authors therefore label their own global exposure figures conservative lower-bound estimates.
- Argys, Averett and Yang, Southern Economic Journal, 2020. The economists who declined to use satellite data for birth outcomes at all, rather than use it and qualify it.
- The ulcerative colitis analysis at Appendix C.5. Among its own limitations, that wavelength-specific effects could not be differentiated.
- Johnston, Kim and Harris, Nature Climate Change, 2025. Appendix C.129. The products used are "insensitive to blue light emitted by white light-emitting diode (LED) lighting," and the digital numbers that carry the exposure variable "cannot be directly converted into absolute illuminance units such as lux."
- Wang, Meng, Richardson and others, Nature Cities, 2025. Appendix C.131, taken up at Part V.I. The same band, with a refinement specific to plants: the band covers much of the range to which phytochrome responds, roughly 620 to 1,000 nanometers, and is blind to the blue to which phototropins and cryptochromes respond. The instrument is therefore blind in a way that is not uniform across the biology.
- Degen and eleven co-authors, Proceedings of the National Academy of Sciences, 2024. Appendix C.135, taken up at Part V.I. Different in kind, and the only one in which the shortfall was measured.
- Dietenberger, Jechow, Kalinkat and others, Communications Biology, 2024. Appendix C.136, taken up at Part V.I. Citing the radar study immediately above, these authors write that the number of insects caught in traps at a light source "represents only a fraction of the insects affected." It matters which way that cuts: their own measured reductions are therefore more likely to understate the benefit of shielding than to overstate it.
- Fobert, Miller, Swearer and Mayer-Pinto, Philosophical Transactions of the Royal Society B, 2023. Appendix D.7. Different in kind again, and the most severe. Reviewing the marine literature, these authors state that any nocturnal sampling method which introduces artificial light into the sampling environment will alter the outcome, and report work finding that light from a large vessel, or even from a headlamp on a small open boat, induces an avoidance response in the pelagic community to a depth of more than eighty meters.
- Boyes, Evans, Fox, Parsons and Pocock, Science Advances, 2021. Appendix C.142, taken up at Part V.I. Different again, and the one that forecloses the obvious answer to the first six. Having measured the exposure at their field sites with a hand-held photometer at the height of a caterpillar, these authors write that "lux is based on human vision, and thus potentially ecologically relevant spectral information can be omitted when using this unit," that identical readings in lux may not correspond to the same illumination as the animal perceives it, and that they used the unit anyway because it is the SI unit and is convenient.

These are three failures and not one, and the Foundation asks the Department not to run them together.

The first six concern a radiometer whose spectral band excludes the wavelengths at issue. That is an instrumental blindness: the quantity exists, the instrument does not record it, and the error is in a known direction, because the emission the band excludes is the one that has grown fastest. The tenth is of the same kind in a different instrument and at the opposite end of the scale, and the Foundation separates it for that reason. It is a hand-held photometer held at the height of a

caterpillar in an English hedge, whose weighting function discounts rather than excludes the short wavelengths, and whose users say so in the methods section of the study that depends on it. It matters because it forecloses the obvious answer to the first six. If the satellite cannot see the emission, measure it at the ground; the people who measured it at the ground report that the unit they had to use cannot carry the information either.

The seventh and eighth concern a biological sampling method, the light trap set at the lamp post, which can by construction record only those animals that flew to the lamp. That is a selection blindness: the instrument records a subset defined by the very response under study, and says nothing about the rest.

The ninth is the one the Department should find most difficult, because it cannot be corrected by a better instrument. In the marine case the act of observing introduces the exposure. A nocturnal survey needs light to see by, and the light it brings disturbs the community it came to measure, to a depth of eighty meters from a headlamp on a small boat. There is no version of that measurement which leaves the subject undisturbed, so the marine literature is constrained not by the resolution of its instruments but by the physics of looking.

The seventh is the most useful of the ten because it is the only one where someone built an instrument that could see both and compared them. Tracking individual moths by radar inside and outside the lit area, the investigators found that four percent of animals already selected for flying toward light terminated their flights at a streetlight, while the lights significantly altered the flight paths of the others and barred one family from crossing a lit circle. The established method was recording four percent of what was occurring. The Foundation does not extrapolate that ratio to any other instrument, and does not need to. What the nine have in common is narrower and harder to answer: in this field the blind spot of the instrument has repeatedly coincided with the thing at issue, and the coincidence has been identified by the investigators themselves rather than by any critic of theirs.

Eight research groups, ten papers, eight journals, three disciplines, and the same admission in each: the measurement on which the study of this exposure principally rests cannot see what is at issue. The consequence the Foundation draws from it is set out immediately below and is not repeated elsewhere; where this pattern is mentioned in Part V.I or in the appendices it is mentioned by reference to this passage.

The Foundation draws the consequence it has drawn throughout and adds one. The consequence throughout is that paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and that a measurement convention which excludes the wavelengths at issue is not a characterization of the emission. The addition is this. A quantity that cannot be converted into any physical unit cannot be the basis of a performance standard under section 360kk, which requires that a standard prescribe an emission characteristic. The absence of a usable national measurement is therefore not merely a gap in knowledge. It is the specific obstacle standing between this Department and the instrument Congress gave it.

A tenth and an eleventh instance, which make no admission, and what the difference tells the Department

Every one of the ten above is an admission. In each case the investigators identified the limitation in their own work, and the Foundation has been able to quote them doing it. That is to the credit of the field and it is also the reason the pattern was visible at all. This subsection would be incomplete without an instance in which the limitation is present and is not identified, because the difference between the two cases determines how carefully the Department must read. There are two, and the Foundation takes them in turn.

Jones T.M., Llamas A.P. and Phillips J.N., Phenotypic signatures of urbanization? Resident, but not migratory, songbird eye size varies with urban-associated light pollution levels, Global Change Biology, volume 29 (2023), first published 20 September 2023. Described at Appendix C.138.

Five hundred and two breeding songbirds of four species were caught, measured and released at nine sites across San Antonio, Texas. In the two species resident year-round, eye size was negatively associated with light pollution and with daytime brightness, and birds in the urban core had smaller eyes than those at the edge. In the two migratory species there was no such association. Body size showed no effect of urbanization in any species once a difference in age structure was accounted for. The finding on eye size is novel and the Foundation does not dispute it.

The exposure variable was taken from a public online light pollution map, using its 2021 product from the Visible Infrared Imaging Radiometer Suite, in radiance units, sampled at one point per tenth of a square kilometer and averaged to a single value for each site.

That is the instrument described at the beginning of this subsection. Its spectral band begins at five hundred nanometers, and the emission of a white light-emitting diode below that wavelength is the part it cannot record. A study of eye morphology is a study of a visual system, and the wavelengths the instrument omits are not incidental to a visual system. The authors do not mention the limitation.

A second limitation compounds it, and this one the authors do state. Across their nine sites, light pollution and daytime brightness were correlated at 0.96, which they describe and which led them to decline to put both variables in the same model. Their own summary attributes the finding to light levels comprising both daytime brightness arising from urban development and artificial light at night. So the association is with a composite of nighttime satellite radiance and daytime openness which the design cannot separate, measured at night by an instrument blind to the wavelengths that matter most to an eye.

What the Foundation is not saying

That the investigators did anything improper. The satellite product they used is the standard exposure proxy in this field, it is freely available, and using it is ordinary and reasonable practice. Several of the ten papers above used the same product. The observation is about the practice and not about these authors, and the Foundation would make it of any study in the collection that did the same, including those whose findings favor its position.

The two consequences, which are the reason this instance is here

First, the Department cannot rely on this literature to disclose the limits of its own exposure variables. Ten papers identified the problem and two did not, and nothing on the face of either of those two papers would alert a reader to it. A Department reading this literature to find a number would have to open the methods of every study, establish which instrument produced the exposure variable, and determine for itself what that instrument can record. The Foundation has done that for the entries in Appendix C and reports the result at the census above: at least thirteen of them rest on satellite radiance.

Second, this is the specific reason paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, rather than to collect what others have studied. A literature cannot be made usable by being read more carefully if the measurements in it were never of the right quantity. The duty is to measure, and the reason for the duty is on display here.

What survives the criticism, which the Foundation records in fairness

The comparison between the resident and the migratory species does not depend on the absolute accuracy of the exposure metric. It depends only on the rank ordering of the nine sites, and on the fact that the same metric was applied to all four species. Both groups were measured against the same imperfect yardstick; only one showed the association. That contrast is therefore more robust than the dose-response coefficient, and it bears on a characteristic this comment asks the Department to regulate. The species exposed all year showed the association and the species exposed for part of the year did not, which is a statement about duration of exposure. The

Foundation records it as suggestive and not as established, because the authors offer an alternative explanation of their own: migratory birds may face conflicting selective pressures across their annual cycle, and the younger migrants found in the urban core may have fledged elsewhere entirely. Appendix C.138 sets out both.

The eleventh, in a different discipline, with a sharper mismatch and a milder consequence

The tenth instance stood alone when it was written and it does not now. Parlin, Stratton and Guerra, publishing in iScience in 2022 and described at Appendix C.140 and at Part V.I, established in a flight simulator that a lamp switched on at night makes quiescent migratory monarch butterflies fly immediately, and in a direction that reveals a shift in their circadian clock. Having established that indoors, the authors asked whether monarchs encounter such lighting in the field. They answered it with the Day/Night Band of the Visible Infrared Imaging Radiometer Suite, taking the monthly cloud-free composites for 2012 to 2020 and extracting a radiance value, in nanowatts per square centimeter per steradian, at each volunteer-reported roost location.

That is the instrument this subsection began with, and the mismatch here is sharper than in the tenth instance. In the songbird study the subject was eye morphology, so the omitted wavelengths were relevant to a visual system in general. Here the mechanism the authors themselves identify is specific. The light-sensitive step in the monarch's antennal clock is mediated by cryptochrome 1, which the same paper describes as a blue-light circadian photoreceptor. The exposure variable chosen to show that these animals meet the relevant light is a band that begins above the blue. The authors do not mention it.

The difference in kind from the tenth is stated so that the two are not treated as equivalent, because they are not. In the songbird study the satellite product supplied the exposure variable of the finding, and the finding was an association with it. Here it supplies a supplementary demonstration that roosts occur in lit places, presented in a supplementary figure, and none of the paper's conclusions depends on it. The limitation is the same. Its consequence is milder.

What the Foundation is not saying is what it was not saying about the tenth. That the investigators did anything improper. The product is the standard proxy; the question they put to it was whether these animals roost where there is light, which is a question of presence rather than of dose; and for a question of presence a band-limited instrument is a conservative one, because it can only understate how much of the relevant light is there. The Foundation would make the same observation of a study whose findings favored it, and in this comment it has.

The consequence is the one the tenth instance established and this one confirms. Two papers now, in different disciplines, in different journals, four years apart, used the same band-limited product without noting what it omits, in studies whose own subjects were a visual system and a blue-light photoreceptor respectively. The ten admissions collected above remain ten and remain to the credit of the field. What the eleventh adds is that the practice of not noticing is not a single lapse. A Department reading this literature for a number cannot rely on the literature to tell it when the number is wrong, and that is the whole of the point.

A twelfth instance, of a third kind, in which the investigators did everything this subsection asks for and the animal still outran the instrument

The eleven instances above divide into two kinds: ten in which investigators identified the spectral limitation of their own measurement, and two in which the limitation was present and was not identified. A third kind exists and the Foundation sets it out last, because it is the only one that tells the Department what happens when the measurement is done properly.

Shier D.M., Bird A.K. and Wang T.B., Effects of artificial light at night on the foraging behavior of an endangered nocturnal mammal, Environmental Pollution, volume 263 (2020), article 114566. Described at Appendix C.146. The subject is the Stephens' kangaroo rat, a nocturnal rodent listed as

endangered under the Endangered Species Act, studied in southern California by investigators at a zoological society and two campuses of the University of California.

These investigators did not use a lux meter and said why. “We measured vector irradiance (mW/cm2) rather than lux, as lux measurements are weighted according to human visual spectral sensitivity.” The instrument was a spectroradiometer covering 190 to 1,110 nanometers with a cooled silicon charge-coupled detector and an ultraviolet-to-near-infrared cosine receptor, calibrated for irradiance against calibration lamps traceable to the National Institute of Standards and Technology. It was mounted on a tripod eight centimeters above the ground, facing the source, which the authors state is where the measurement reflects the illumination the animal would experience. Three measurements were averaged at each of ten points. That is a radiometric measurement, at a biologically relevant height and perspective, with a nationally traceable calibration, in the field, by field biologists, in 2020. Every element of the specification the Australian guidelines set out, and which Part IX asks the Secretary to establish, was met here by a team studying a rodent.

And the finding that matters to this subsection is what happened next

The experiment placed ten baited foraging trays five meters apart in a line running away from a light on a three-meter pole, and scored whether the animals emptied each tray. The lights were two consumer products, identified by manufacturer: a solar flood light of one hundred and eight diodes rated at 756 lumens emitting between 400 and 700 nanometers, and a yellow compact fluorescent bug light rated at 300 lumens emitting between 550 and 650 nanometers. Then this:

> “Light intensity from the bug and flood lights, as measured by vector irradiance, decreased with distance from the artificial light source up to 25 m, at which point light was no longer detected. Yet, our results showed significant effects of artificial lighting on SKR foraging up to 40 m from the bug light and 50 m from the flood light.”

The animals responded at twice the distance at which the instrument could detect that there was any light at all. The authors state the two available readings of that and decline to choose between them: either the spectroradiometer was not sensitive enough beyond twenty-five meters, or “the effects of ALAN on SKR extend beyond the point at which light in the form of irradiance, is measurable.” They add the consequence for method, which is the sentence this subsection takes: that the results “suggest that effects of sky glow on behavior may extend beyond those of irradiance, and highlight the need to measure both irradiance and radiance to understand the effects of ALAN on a species’ behavioral ecology.”

The Foundation draws three consequences and keeps them apart.

First, this is not an instance of the pattern collected above and is not added to the count. Nothing here was spectrally blind. The measurement captured 190 to 1,110 nanometers, which is wider than the range any instrument in this subsection has reached, and the authors rejected the photopic unit on the record. What failed was sensitivity at low levels, which is a different defect, and it is the defect the Australian guidelines identify when they state that optimal methods will have “the sensitivity to detect and measure change at the low light levels represented by artificial light skyglow.” This comment has argued that the field measures the wrong quantity. This study shows that measuring the right quantity is necessary and not sufficient.

Second, it disposes of the objection that the measurement Part IX asks for cannot be performed outside a laboratory. It was performed, with a traceable calibration, at the height of a rodent’s eye, by a conservation research team on a field site, and the authors published the instrument, the geometry, the number of replicates and the data. The Foundation has spent this subsection establishing that the literature does not do this. One study did it, and the reason the Department should notice is that the study is ordinary: a small team, commercial instruments, a public dataset.

Third, and this is the part that bears on what a standard could achieve, the relationship the Department is asked to establish was not bounded by this experiment. The arrays were fifty meters

long and the flood-light effect reached the furthest tray, so the authors write that the impact "may extend into habitat beyond 50 m from the light source as we found significant effects all way to the furthest patches." The home range core of this species averages thirty meters. A single consumer flood light on a three-meter pole therefore altered the foraging behavior of an endangered mammal across a distance larger than its entire core home range, and the far end of the relationship was never reached. That is the shape of the dose-response this comment asks the Secretary to establish, in the one study that tried to measure it, and the answer came back open at one end.

One qualification the Foundation records because it runs against the convenience of the passage above. The same authors also converted their irradiance figures to lux, by assuming all the energy lay at 555 nanometers, and state the reason: to allow comparison with other studies. A team that had just explained in print why lux is the wrong unit nonetheless had to produce a lux figure so that its work could be read alongside everyone else's, and the conversion they used is a crude one that the choice of a single wavelength makes approximate. The Foundation does not criticize the decision. It reports it as the clearest demonstration in this subsection of the cost of having no agreed unit: the pressure to report the wrong quantity is exerted by the literature itself, on investigators who have identified the problem and solved it for their own purposes.

A thirteenth instance, of a fourth kind, in which the emission is not characterized at all

The twelve instances above divide into three kinds: an instrument that cannot see the wavelengths at issue and investigators who say so; an instrument that cannot see them and investigators who do not; and an instrument that saw the right quantity and ran out of sensitivity before the animal ran out of response. A fourth kind exists and the Foundation sets it out because it is the simplest and the most common condition in this literature.

Van Doren B.M., Horton K.G., Dokter A.M., Klinck H., Elbin S.B. and Farnsworth A., High-intensity urban light installation dramatically alters nocturnal bird migration, Proceedings of the National Academy of Sciences, volume 114 (2017), pages 11175 to 11180. Described at Appendix C.150 and set out at Part V.I, where its finding is used. It is among the best-designed studies in this comment. Seven years of weather surveillance radar and acoustic recording at a single installation whose operators switch it off and on, with the biological response measured in both states, at two radar elevations, with a simulation to test the mechanism, and with effect sizes and probabilities reported throughout.

The Foundation has read it and can find in it no lumen, no candela, no lux, no irradiance, no radiance, no wattage and no spectrum for the light source. The word intensity appears in the title and in a comparison with another installation, and nowhere as a quantity. The exposure variable is whether the lights were on.

That is not a criticism of the investigators, and the Foundation states why in the same terms it has used throughout this subsection. They are ornithologists studying birds at four kilometers with radar, the installation is not theirs to measure, and the on-and-off design is what gives the study its strength. The observation is about the state of the record. The Department is being asked by many parties to act on this literature, and the best-controlled field study in this comment of a real American lighting installation does not say how much light the installation emits. A performance standard under section 360kk must prescribe an emission characteristic. Nothing in this study could be converted into one, and the comment relies on it for the shape of the response and for the reversibility rather than for any number a standard could use.

A fourteenth instance, of a fifth kind, in which a spectral explanation is offered and no spectrum is measured

The four kinds above concern what an instrument could or could not see. The fifth concerns what is said about a spectrum when no instrument was pointed at it, and the Foundation sets it out last because it is the condition in which most of this literature reasons.

The two bat experiments described at Appendices C.152 and C.153 are by the same three authors, on the same species, in consecutive field seasons. The earlier used high-pressure sodium luminaires, the later used white light-emitting diode luminaires, and both characterized the exposure in lux measured with the same model of handheld illuminance meter. Neither publishes a spectral power distribution for either lamp, and neither reports a correlated color temperature for the diodes, which are described as cool white and by product name. The later paper then explains one of its own findings spectrally. Having recorded no increase in the feeding activity of two pipistrelle species at the lights, it attributes that to the spectral content of the diodes, reasoning that they emit little ultraviolet and are therefore less attractive to the insects bats feed on, and it adds that although the diodes emit white light they are comparable with high-pressure sodium in spectral content for that reason.

The Foundation makes three observations and no accusation. The reasoning is sound and the general proposition about ultraviolet is correct; this is not an error. The support for it is the published properties of two lamp classes and the entomological literature, not a measurement of the two luminaires that produced the results, which is a different kind of support and the paper does not distinguish them. And the claim is confined to the ultraviolet, while the difference between a cool white diode and a sodium lamp is largest in the blue, which is the part of the spectrum at issue in almost everything else in this comment and is not addressed.

The Foundation records this instance for one reason. In Part V.A.2 it relies on the comparison between these two experiments, and that comparison would be far stronger if the Department could be told what the two lamps actually emitted. It cannot, because nobody measured. Paragraph 360ii(a)(4) directs the Secretary to plan and conduct research into the effects of electronic product radiation, and the first thing such a program would do that the existing literature does not is record the emission.

What the instrument cannot tell the Department, counted by hand

Everything above concerns what the satellite cannot see. One project set out to establish what is actually there, by sending people out to count it, and the result bears on the structure of this comment as much as on the measurement question.

Team Nachtlichter, Citizen science illuminates the nature of city lights, Nature Cities, volume 2 (2025), pages 496 to 505, open access. Described at Appendix C.130. The authorship is collective and the Foundation states it as published.

In the autumn of 2021, 258 registered participants walked 3,868 transects in 4,409 surveys and classified 234,044 individual light sources into eighteen categories, covering about twenty-two square kilometers in thirty-three communities, mostly in Germany. The transects were laid out to cover the publicly accessible area of specified satellite pixels completely. Participants completed mandatory online training, and variability between observers counting the same street was estimated at ten to twenty percent, which the authors note is similar to the month-to-month variability of the satellite sensor itself. Streetlight counts were checked against municipal databases and agreed to better than seven percent in three cities; in two others the hand counts were forty and ninety percent higher, because they included streetlights on private roads that the public databases omit.

The composition of the light, which runs against this comment's own emphasis

The Foundation reports the principal finding first and then states what it costs the Foundation.

- Private windows were the most frequently observed light source, ahead of streetlights and commercial windows.
- In dense urban areas, lights used for advertising outnumbered streetlights. In the early evening there was roughly one illuminated sign and one commercial window for every streetlight.

- Late at night the streetlight share rises as signs and windows go dark, but streetlights remained outnumbered by other sources by a factor of about five to seven in dense areas.
- Extrapolated nationally, approximately 78 million individual light sources, plus or minus 3 million, remain illuminated at midnight across the mainland of Germany, and about 2.52 million in Berlin. Against that, the authors give published estimates of nine to nine and a half million public streetlights in the country.

Part VI.D of this comment treats roadway lighting at length and Part VI.J treats signage. If these proportions hold anywhere outside Germany, the emphasis of this comment, and of the literature it draws on, follows the availability of records rather than the distribution of the emission. The authors say so about lighting policy generally: street lighting has been the dominant focus because public authorities own those lights and, with geographic information systems, have records of them. The Foundation records that its own treatment is subject to the same criticism, and that the finding cuts in favor of the attention it gives signage at Part VI.J, which on this evidence is not a marginal product class but one that outnumbers street lighting in city centers.

The most common source is the one the Foundation has not addressed at all, and it names the gap rather than leaving it. A private window is not a light source. It is an aperture, and what passes through it is the emission of a lamp indoors. On the construction of paragraph 360ii(a)(2) that Part II.D.4 sets out, that lamp is an electronic product and what reaches a person outside the building is its emission, no differently from a lamp mounted on the outside of the same wall. The Foundation does not ask the Department to regulate curtains. It observes that the single most numerous contributor to the outdoor light environment is a product class this comment treats only as interior lighting at Part VI.E and Part VI.G, and that the Department should know this before accepting any characterization of outdoor light that begins and ends with street lighting.

Shielding and brightness, which are two of the four variables Part IX asks to have characterized

The participants recorded the emission direction, apparent brightness and color of what they counted, and the results speak to the geometry variable more directly than anything else in this comment.

- German streetlights were largely controlled: forty-eight percent fully shielded and forty-nine percent partially shielded.
- Lights mounted on the sides of buildings were not: only twenty-nine percent fully shielded, and twenty-six percent unshielded.
- Floodlights were worst. Fifty-eight percent were unshielded, which the authors state implies upward rather than downward lighting, and in continuous urban fabric the unshielded fraction was seventy percent.
- On brightness, twenty-four percent of bollards were reported bright, which the authors read as indicating glare or a mismatch with the surroundings; and in commercial and industrial areas over a quarter of signs were reported as exceptionally bright.

The authors draw from that last figure a conclusion this comment makes at Part VI.J.6 and has not previously been able to attribute to anyone else: that the reported brightness of signs is consistent with earlier research finding signs often much brighter than is recommended or appropriate, and that this "may reflect a need to update regulations about glare as the existing guidelines predate the use of highly luminous LEDs by several decades."

What the project failed to do, which limits what the Foundation may take from it

The authors attempted to convert their inventory into a radiometric model, by fitting weights representing how much a single light of each type contributes to the radiance an overhead sensor records. They tried it against three datasets of increasing resolution: the satellite day-night band at 750 meters, a higher-resolution satellite at 10 meters, and aerial photographs at about one meter. It

failed in every case. The fitted parameters were unphysical, assigning larger weights to small signs than to large ones, and the authors report that regardless of what they tried the procedure never returned physically meaningful results.

Two consequences. The translation the paper does offer, that a German satellite pixel at midnight corresponds to about 219 lights per square kilometer per unit of radiance, plus or minus 11, is a bulk statistical relationship and not a physical model; it is country-specific, the same figure outside Germany being about 120; and it converts radiance into a count of lamps, not into any measure of what reaches a person. And the failure is itself evidence for the proposition this subsection advances. If a complete hand inventory of every visible light in a satellite pixel, combined with imagery at one-meter resolution, cannot be made to reproduce the radiance that pixel reports, then the radiance is not a characterization of the emission in any sense a performance standard could use.

A federal prediction, and what was measured afterwards

The Foundation separates the following because it concerns this Government and not a foreign one, and because it is the only item in this subsection that does.

The paper records that in 2017 a report of a Department of Energy national laboratory concluded that widespread conversion to light-emitting diode street lighting was likely to decrease skyglow. It then records what was measured over the period during which much of that conversion occurred, 2011 to 2022, which was an increase of roughly ten percent a year. The authors write that whether existing approaches failed because private lighting was neglected or for other reasons is an open question, but that it is "at least clear that existing policy results in increasing light growth."

The Foundation states four qualifications before it states the point. It has not read the 2017 report and takes its conclusion from this paper's description. The ten percent figure is not radiometry: it is derived from citizen-science observations of how many stars are visible to the unaided eye, converted to an equivalent rate of sky brightening, and it is in tension with the two percent a year that late-night satellite observation reports over a similar period — a discrepancy of a factor of five which these authors suggest may itself be explained by changes in the type, color and direction of lights active at different times of night. The conversion to light-emitting diodes was not the only thing that changed in those years. And a prediction that proves wrong is not thereby shown to have been unreasonable when made.

What survives all four is this. A national laboratory of the United States made a quantitative prediction in 2017 about an environmental consequence of a federal efficiency policy, Part IV.G describes that policy, the best available subsequent measurement points the other way by a large margin, and the Foundation is aware of no federal reassessment of the prediction. That is the same structure Part V.M describes in a British city and Part II.E describes in this Department: a quantified benefit asserted in advance, and not checked afterwards by the body that asserted it. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other Federal departments and agencies with related interests. This is such information, and the Foundation asks whether it was received.

What it does not establish

No health effect, and it addresses none. No radiometry whatever: a count is not a measurement of emission, and the apparent brightness categories are a participant's judgment, the authors noting that signs of twenty and of a hundred candelas per square meter would both likely be recorded as normal in a bright area. The composition findings are German and the authors say the radiance relationship appears specific to Germany. Areas with high-rise buildings and private industrial parks were not surveyed. Lights not visible from public space, in back yards, courtyards and on rooftops, were not counted, so the inventory undercounts. And the contribution of vehicle headlamps, which is the subject of Part VI.B, remains, in the authors' words, unknown.

Its place in this comment is accordingly narrow and, the Foundation submits, important. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This is what the beginning of such a characterization looks like. It was performed by volunteers, in one country, over one autumn, at a cost the Foundation would guess to be a small fraction of a single federal study, and no American counterpart to it exists.

Two consequences follow, and the second is the one this comment turns on.

The literature can establish that exposure to artificial light at night is associated with disease. It cannot establish which light. The epidemiology is therefore capable of justifying concern and incapable, by itself, of specifying a remedy.

A performance standard must specify an emission characteristic. It must say what a product may emit, in what quantity, at what wavelengths, with what temporal structure. A body of evidence expressed entirely in photometric units cannot supply that specification, however large it becomes. Adding another cohort study in lux will not produce a number that a standard could use.

That is why the Foundation asks for study rather than for a standard, and why the two requests are not interchangeable. The gap between the existing literature and a prescribable standard is a measurement gap, and it will not close on its own. No individual research group can retrofit spectral exposure assessment onto a cohort recruited twenty years ago. A federal research program can specify spectral exposure assessment at the outset, and 21 U.S.C. § 360ii(a)(2) and (a)(4) direct the Secretary to conduct one. Parts IX.H.3 and IX.H.6.

The field's own verdict on its exposure assessment

The preceding paragraphs state a criticism of a body of scientific literature, and a criticism of that kind is worth more when it comes from inside the field than when it comes from a commenter. It comes from inside the field.

Palomar-Cros and others published in Science of the Total Environment in December 2024 a systematic review and meta-analysis of artificial light at night and cancer incidence across multiple cancer sites. The authors searched six databases, two trial registries and Google Scholar from inception to April 17, 2024, screened 9,835 records, and included 28 studies comprising 2,508,807 individuals. Twenty studies of breast cancer, covering 731,493 individuals, supported a quantitative synthesis. Higher outdoor artificial light at night was associated with breast cancer risk, with a pooled relative risk of 1.12 (95 percent confidence interval 1.03 to 1.23). The association for indoor light was positive but not statistically significant, 1.07 (0.95 to 1.21). Appendix C.14 sets out the review in full, including the findings for the other cancer sites and the reasons for caution.

The Foundation offers it here for the sentence with which the authors qualify their own principal finding. Having reported the association, they state that most of the included studies relied on satellite images of very low resolution, between one and five kilometers, drawn from the Defense Meteorological Satellite Program, and, in the authors' own words, "without information on color of light." They conclude that future studies with better exposure assessment are needed.

That is the proposition of this subsection, stated by the authors of the most comprehensive synthesis of this literature yet published, among whom are investigators of considerable standing in cancer epidemiology. The Foundation did not have to construct the argument. The field has reached the limit of what broadband satellite radiometry can tell it, and says so.

Two things follow, and the Foundation separates them carefully because they point in different directions.

The first is a caution against overreading the review. An instrument that carries no information about the color of light cannot distinguish a warm low-correlated-color-temperature source from a blue-rich one. It follows that this body of evidence, whatever it shows about the quantity of

outdoor light, is silent on the question this comment actually asks. It cannot be cited for any proposition about light-emitting diode products as against the sources they replaced, and the Foundation does not cite it for one. Twenty studies and 731,493 individuals do not answer the question of which light, because none of them measured it.

The second is what that silence costs. A performance standard under § 360kk must specify what a product may emit. The largest body of evidence bearing on artificial light and human health has been assembled from an instrument that cannot see the characteristic a standard would have to govern. That is not a reason to doubt the evidence. It is a reason to doubt that more of the same evidence will ever produce a prescribable number, which is what the Foundation has said throughout and what the authors of this review, in their own terms, confirm.

Read together with the study described in the next paragraphs, the pattern is consistent. Measured without regard to spectrum and at kilometer resolution, the association across twenty studies is 1.12. Measured with spectral weighting at thirty-meter resolution in a single study, within the subgroup reporting light entering the sleeping room, it is 1.53. The Foundation does not present those figures as comparable, because they are not: different populations, different designs, different exposure definitions, and the second arising in an exploratory subgroup. What the juxtaposition illustrates is the proposition that the choice of measurand is not neutral, and that the conventional choice is the one that discards the variable a standard would act upon.

One qualification is necessary, and it sharpens the point rather than softening it. A spectral metric does exist. The International Commission on Illumination has standardized melanopic equivalent daylight illuminance, which weights an exposure by the sensitivity of the retinal pathway that governs non-visual responses rather than by the photopic function. Quantitative recommendations expressed in that metric have been published: a melanopic equivalent daylight illuminance above 250 lux during the day, below 10 lux in the pre-sleep environment, and below 1 lux in the sleep environment.

So the instrument exists and the thresholds have been proposed. What has not happened is the application of either to the large cohorts in which health outcomes are actually measured. The studies at Appendices C.2, C.4 and C.5 report photopic lux, satellite radiance and illuminance respectively, and none reports a melanopic quantity. The expert consensus described at Part V.L identifies this as one of its nine gaps, under the heading of inconsistent exposure descriptors and metrics, and reports that real-world exposure data indicate both daytime and pre-sleep exposure fall largely outside the published recommendations.

That is a more precise statement of the difficulty than the absence of a metric would be, and a worse one for the present position. The field is not waiting for someone to invent a way of expressing spectral exposure. It has one. What is absent is the infrastructure to apply it at population scale, and the coordination that would require.

The one study that resolved wavelength, and what happened when it did

The claim in the preceding paragraphs requires one further qualification, and it is the most important fact in this subsection. Wavelength-resolved exposure assessment has been attempted in a human health study. It was done once, recently, and it changed the answer.

Quinn and others, publishing in Environment International in November 2025, pooled two cohorts comprising 24,793 women with 674 breast cancer cases. Rather than using the conventional broadband satellite product, they estimated outdoor light at residential addresses from photographs taken from the International Space Station, at approximately 30-meter resolution. Because those photographs carry color information, the investigators were able to derive three distinct exposure measures: average visual radiance, which is brightness in the conventional sense; a melatonin suppression index, which weights the light by the extent to which its spectral composition suppresses melatonin; and the product of the two, which they term average impact.

The result is the point. No statistically significant association was observed in the overall study population on any measure. Among women who reported light entering their rooms while sleeping, the spectrally weighted measure was significantly associated with breast cancer overall and across each subtype examined, with those in the highest tertile of average impact carrying a 1.53-fold hazard against the lowest (95% CI 1.18 to 1.98). The authors conclude that both intensity and wavelength of light should be considered when evaluating exposure to artificial light at night.

The Foundation is careful about what that demonstrates, because the positive finding arises in a subgroup and the authors describe that analysis as exploratory. A subgroup result among several exposure measures and several disease subtypes is not a secure finding, and Appendix C.7 sets out the reasons for caution at length. The Foundation does not assert that light at night at the levels studied causes breast cancer.

What the study does establish does not depend on the subgroup finding replicating, and it is this. A spectrally weighted exposure measure can be constructed from available data. It has been constructed. And in the one study that constructed one, the choice of measurand was not neutral: brightness and spectral weighting did not return the same answer. That is an empirical demonstration of the proposition this subsection advances, and it comes from the literature rather than from the Foundation.

The conclusion the Foundation draws is accordingly narrow and, it submits, difficult to resist. Nearly the whole of the epidemiology measures light in units that discard the information about spectral composition. The one study that retained that information found that retaining it mattered. Whether its particular finding survives replication is exactly the sort of question that 21 U.S.C. § 360ii(a)(2) directs the Secretary to support research upon, and § 360ii(a)(4) directs the Secretary to study and evaluate.

The same limitation in the laboratory literature, and an audit of which studies escape it

The preceding paragraphs concern the epidemiological literature, where exposure is assessed by satellite radiance, by a worn sensor or by a meter in a room. The same limitation appears in the laboratory literature, by a different route, and the Foundation states it as a characteristic of the evidence base rather than as a criticism of the investigators. A cell-biology or animal study is designed to establish whether a mechanism operates. It is not designed to establish an exposure-response relationship, and its exposure is therefore reported to whatever precision the experiment required rather than to the precision a standard would require.

Two quantities are needed before any reported exposure can be compared with a limit of the kind described at Part V.C.2: the spectral distribution, and a level in radiometric units or in photometric units together with enough spectral information to convert. Either one alone is insufficient, and the insufficiency is not marginal. Because the photopic weighting function is small and steeply varying across the short wavelengths, a level reported in lux for a source whose spectrum is not given cannot be converted into the blue-light weighted quantity the framework uses, and the error in assuming otherwise runs to one or two orders of magnitude. Appendix C.66 records a worked instance.

The Foundation has audited the studies collected during the preparation of the retinal subsections of this Part, and reports the result in both directions. Among those studies, the following report exposure in terms from which the blue content can be recovered:

- C.63 – spectral distributions for a white phosphor-converted source and for monochromatic blue, green and red arms, with the exposure apparatus built and characterized by a national building science laboratory.
- C.65 – a single stated wavelength of 470 nanometers with a stated illuminance, which permits conversion because the source is substantially monochromatic.

C.60 – exposure in radiometric units at a stated wavelength, for both the environmental measurement and the applied dose.

C.59 – spectroradiometric measurement performed under the procedure of the governing standard, with the aperture and integration time stated.

C.62 – luminance in candelas per square meter with correlated color temperatures stated for each condition.

C.69 – irradiance in milliwatts per square centimeter at a stated peak wavelength, with photon flux density also given, and with the control arm matched on irradiance and differing only in spectrum. The best-specified exposure in this group.

C.75 – retinal radiant exposure dose in joules per square centimeter, computed from the measured radiance of the source with the ocular transmittance of the animal taken into account, together with the source luminance and radiance and a named commercial lamp model. This is the only exposure in the appendix reported in the same unit as the exposure limit, and it is therefore the only one that can be placed directly against it. The computation depends on an assumed pupil diameter, which the entry discusses.

C.76 – corneal irradiance in microwatts per square centimeter measured at the exposure position for each of three monochromatic arms matched to within one percent of each other, with the peak wavelength of each stated, the spectral power distribution of the white source characterized, the control irradiance given, and a dedicated author responsible for the photometry and radiometry. The best-characterized exposure in the appendix. It is radiometric and wavelength-resolved, so the blue content is recoverable; the paper does not itself convert to retinal dose or compare against the exposure limit.

C.70 – illuminance with correlated color temperature and manufacturer part numbers for every lamp, which is more than most studies give and still not sufficient on its own; the spectral power distributions exist but are in a supplementary figure the Foundation has not obtained. Classified here as recoverable in principle and not yet recovered.

The following do not:

C.61 – a stated wavelength with no irradiance reported anywhere in the paper, the illumination having been the imaging light of a microscope rather than a designed exposure.

C.66 – illuminance in lux at three levels, with the peak wavelength of the diodes not stated. This is the combination from which nothing can be recovered.

C.68 – neither quantity available to the Foundation, the article being closed access with no accessible version and the abstract reporting no exposure conditions.

The division is not a ranking of the studies by quality. Two of the three in the second group are published in journals of standing and one reports a mechanism established through genetic and pharmacological interruption. The division is a ranking by one property only: whether the reported exposure can be placed against a numerical limit. That property is what a standard-setting record requires and what the present literature, taken as a whole, does not supply.

The same inconsistency has been identified from within the field. The review at Appendix C.67, surveying the human clinical literature, reports that research groups have defined the mesopic condition anywhere from 0.1 to 50 lux and that the wavelength and stimulus duration used for experimental exposure vary between studies, and gives that inconsistency as among the reasons the literature is difficult to interpret. A body of work whose exposure specifications differ by more than two orders of magnitude between laboratories cannot be synthesized into a dose-response relationship, however many studies it contains.

The Foundation draws the conclusion that bears on the request made in this comment. The absence of a standardized exposure specification is not only a limitation of the literature; it is a

function the Secretary's authority under 21 U.S.C. § 360ii(a) exists to perform. Paragraph (a)(2) directs the planning and conduct of research and testing relating to electronic product radiation, and paragraph (a)(4) the study and evaluation of emissions and conditions of exposure. A specification of how optical exposure is to be characterized and reported, issued or adopted federally, would make the next decade of this literature comparable in a way that the last two decades are not. That is a request for study and for a reporting convention, and it is a smaller request than a performance standard.

The field's own verdict on its unit of measurement, which is more specific than the verdict above

The verdict just quoted, from the cancer meta-analysis, concerns the resolution of one instrument and its blindness to color. There is a second, published in 2022, and it concerns the unit itself. It appears in a box of its own in a review of artificial light in marine ecosystems by ten authors, described at Appendix D.7 and taken up at Part V.I, and the box is headed "Challenges in measuring artificial light in biological studies."

The Foundation quotes it at length because paraphrase would weaken it and because what it says is what this subsection says. On the state of the practice:

> "Measuring light for ecological studies is still undefined and is poorly understood by biologists who have used a wide range of techniques and instruments to measure light at scales ranging from a few centimeters to tens of kilometers. The wide range of instruments employed typically use different measurement systems and units, which means study results cannot be confidently compared. There is currently no globally recognized standard method, or agreed unit of measurement, for monitoring biologically active light…"

On the instrument in general use:

> "Commercial lux meters only quantify light that is within the CIE curve … and exclude light wavelengths that fall outside of the CIE curve."
>
> "Photometric detectors have reduced sensitivity to wavelengths below 450 nm (blue light) or above 650 nm (red light). Consequently, photometric instruments commonly used to quantify light in biological studies, such as lux meters, do not account for the blue light that is most visible to biological receptors."

And on where the instrument came from:

> "Lux meters are further limited in that they were designed for use in measuring light in buildings, have poor sensitivity to low light levels and cannot detect sky glow or dim light in a field setting. Finally, they do not provide any spectral information…"

Four propositions are stated there, and each of the four is a proposition this comment reached from its own reasoning before it had this source. That the photopic weighting discards the short wavelengths at issue. That the units in use are not commensurable across studies, so the results cannot be pooled, which is what the audit immediately above found by a different route. That the instrument on which this literature depends was designed for architectural use and is unsuited to field measurement at low levels. And that there is no agreed unit for the quantity. The Foundation did not construct any of the four, and it does not need to be believed about them.

The demonstration inside the document, which the Foundation reports as a characteristic of the field and not as a fault of the authors

The review then demonstrates its own proposition, in a way its authors cannot have intended and which the Foundation reports because it is the clearest illustration in this comment of why the measurement has to be performed by someone with the authority to standardize it. Having stated in a box that lux cannot measure biologically active light, that photometric detectors are insensitive below 450 nanometers, and that no agreed unit exists, the review reports the exposure of essentially every study it collects in lux. Two hundred lux, one hundred and twenty, one hundred, ninety-seven

down to eleven, eighty, seventy, sixty, fifty down to forty, forty down to thirty, thirty, twenty-seven, twenty, fifteen, five, four and three tenths, two tenths, one tenth. Across the whole review the Foundation counts two exposures reported in radiometric or quantum terms, and both are in the pelagic sections: an irradiance of eleven to eighteen microwatts per square centimeter in the avoidance experiment, and a surface measurement of 2.2 micromoles of photons per square meter per second from shipboard lighting.

That is not a criticism of these authors, and the Foundation states why in the same terms it used about the satellite product. The investigators whose work the review collects reported what their instruments gave them, and the instrument in general use gives lux. The review's own box explains the reason: there is no agreed unit. A field cannot report in a unit that does not exist. The shortfall is therefore not a shortfall of diligence on anyone's part. It is the absence of a standard, and the establishment of measurement standards for an emission of this kind is the thing that 21 U.S.C. § 360ii(a)(4) directs the Secretary to do and that § 360kk requires before any emission limit can be written at all.

The review asks for it, in terms the Foundation adopts without alteration. Among the questions it lists for future research is this:

> "What are the best practice techniques to monitor and measure biologically meaningful (i.e., radiometric as opposed to photometric) light, both underwater and on land, at both fine (meters) and broad (kilometers) scales?"

The parenthesis is the authors'. Radiometric as opposed to photometric is the distinction Part V.J.5 draws and the distinction on which the requests at Part IX depend. One further question of theirs belongs beside it:

> "What are the thresholds (intensity, wavelength, exposure time) that elicit biological responses in marine species?"

Intensity, wavelength and exposure time are three of the four emission characteristics Part IX asks to have characterized. The fourth, the spatial distribution of the emission, this review addresses as a design recommendation rather than as a research question. The Foundation adds nothing to any of this. The consequence is the one already drawn twice in this subsection and is not drawn a third time.

The document that review points to, which is a national government's attempt at the answer, and what it found

The research question quoted immediately above asks what the best practice techniques are for measuring biologically meaningful light. The review that asks it cites, for a fuller treatment, a document of the Commonwealth of Australia. The Foundation recorded that document as an acquisition target of the first rank and has now obtained it. Department of Climate Change, Energy, the Environment and Water, National Light Pollution Guidelines for Wildlife, version 2.0, May 2023, Canberra. Described at Appendix D.1. It is published under a Creative Commons Attribution 4.0 International license and costs nothing, which bears on a contrast drawn at Part V.I. Its technical appendices were drafted by practitioners in this field, and among the named technical reviewers are two investigators who appear elsewhere in this comment.

What makes this document different from everything else collected in this subsection is its purpose. The eleven instances above are investigators noting a limitation in their own methods. This is a national government instructing the people who will do the measuring. It therefore does not merely concede the limitation. It surveys the available instruments one by one, states what each can and cannot do, tabulates the answers, and recommends against the two instruments on which almost all of the literature in Appendix C depends.

On the satellite products, which supply the exposure variable in fourteen entries of Appendix C, the guidelines state that maps derived from satellite-collected information have limited value in

quantifying light for wildlife; that the images measure light after it has passed through the atmosphere and been subject to scattering and absorption, and do not give an accurate representation of the light visible at ground level; that annual composite images are assembled from images collected under different atmospheric conditions and so cannot be used to quantify light confidently within or between years; and, in terms this comment has had to establish for itself from instrument specifications, that "the most commonly used instrument (VIIRS DNB) is not sensitive to blue light, so light in this part of the spectrum is undersampled." The recommendation that follows is not a caveat. It is that remote sensing products are "currently not an appropriate approach for measuring light as part of a wildlife monitoring program, as they do not accurately quantify light as observed from the ground, they underestimate the blue content of light, and results are not repeatable due to environmental conditions."

On the lux meter, which is the instrument of the terrestrial literature as the satellite is of the remote-sensing literature, the conclusion is the same and is expressed as a prohibition rather than a qualification. "Commercial lux and luminance meters are not appropriate for the measurement of light in wildlife monitoring programs, because they have low sensitivity and low accuracy at low light levels." The guidelines add that more expensive tailored devices do not cure the defect, because the objection is not to the quality of the instrument but to the quantity it measures.

On the sky quality meter, which is the instrument of the dark-sky measurement community and the source of most of the night-sky brightness figures in public circulation, the guidelines report two things the Foundation had not previously established and would not have asserted without a source. The first is that the instrument does not do what it is designed to do: "Although the SQM is designed to have a photopic response, it is generally more sensitive to shorter wavelengths (that is, blue) than a truly photopic response, but this will depend on the individual instrument." The second is a calibration result. Instrument accuracy is reported by its maker at about ten percent, but a calibration study of a group of these instruments found errors ranging from negative sixteen percent to positive twenty percent, and the guidelines state that the long-term stability of these meters has not been established. An instrument whose spectral response varies by unit and whose error spans thirty-six percentage points across units is not a basis for a national criterion, and the Foundation says so about an instrument that its own allies in this field rely on.

And on the American unit, in the glossary, in one sentence: the footcandle "is not appropriate for understanding how animals perceive light." Part VI.J.6 records that the only operative American brightness criterion the Foundation can identify for digital billboards is expressed in footcandles above ambient.

The table, which the Foundation reproduces in words because it is the most compact statement of this subsection's thesis that exists anywhere

The guidelines tabulate eight measurement techniques against ten attributes. The account that follows is taken from the formatted table in the published document and not from a reading of running text. One column is headed by the question whether the instrument measures biologically relevant light. For satellite imagery the entry is no. For the sky quality meter the entry is no, with a footnote recording some sensitivity to short blue wavelengths and none to long orange and red ones. For the telephone application the entry is no. For the lux meter the entry is no. For the three imaging systems — the all-sky transmission monitor, the digital camera with a fish-eye lens, and the National Park Service all-sky mosaic — the entry in each case is that calibration is required. For one instrument, a field spectroradiometer built to detect aerosols at night, the entry is yes.

Two further columns complete the picture and the Foundation sets them out because each disposes of an answer that might otherwise be made. The first is the column asking whether the instrument is commercially available. For the one instrument that measures the relevant quantity, the entry is no; the running text adds that the prototype is no longer in operation. So the instrument that can do the job cannot be bought, and the question is not one of budget: the table prices it at seven thousand dollars, against twenty thousand for an all-sky mosaic that cannot do the job without calibration. The second is the column asking whether the instrument detects skyglow at all. For the lux meter the

entry is no. The instrument that supplies the exposure figure in most of the terrestrial literature in Appendix C is recorded by this government as unable to detect the phenomenon and as not measuring the right quantity when it does measure.

One entry in that table bears directly on an appendix entry in this comment. Satellite imagery is recorded as detecting skyglow, with a two-word footnote attached to that entry: “Via modelling.” Appendix C.145 takes as its exposure variable a published atlas of night sky brightness modeled from satellite radiance, and Part V.J.4 records that entry as a refinement of the satellite category rather than a plain instance of it because the modeling step is added to the instrument limitation. The Australian table makes the same distinction in a footnote of four words.

Of eight techniques surveyed by a national government, four cannot measure the quantity at issue, three can do so only if separately calibrated by a specialist for each deployment, and the one that does it directly cannot be purchased and is no longer running. That is the state of the measurement art as a government found it in 2023, and it is stated twice in the document in general terms: “There is currently no globally recognised standard method for monitoring light for wildlife,” and “Currently there are no generally agreed methods for measuring biologically relevant light for wildlife or for quantifying skyglow.” The table itself is not original to the guidelines; it is modified from a published review, which is recorded here because the proposition is therefore not one government’s view of the field but the field’s view of itself, adopted by a government.

The guidelines also state what a method would have to do, and the Foundation sets the specification out because it is the closest thing to drafting language that exists for the request at Part IX. A method should be reasonably priced, repeatable, accessible and deployable; should capture the whole visual field to which the subject may be exposed, generally horizon to horizon; should be “capable of quantifying all wavelengths of light equally (radiometric), including at least 380 nm to 780 nm, or capable of being calibrated over the range of wavelengths of relevance for the species of interest”; should be sensitive enough to detect change at the low levels that skyglow represents; and should distinguish individual point sources locally from skyglow across tens of kilometers. Every element of that specification is within the competence paragraph 360ii(a)(5) confers, and none of it has been performed by any agency of the United States.

On modeling, the guidelines are equally direct and the Foundation records it because Part V.J.1 discusses the substitution of models for measurement. Most commercially available light modeling software is weighted to the photopic curve and therefore does not account for the wavelengths to which most wildlife is sensitive; a second class of limitation is the inability of such models to carry atmospheric conditions, topography, other light sources, luminaire spectra and viewing geometry, which the guidelines say would require a complexity science and technology have not yet delivered.

And the sentence in that document which is the most serious thing said anywhere in this comment against what the Foundation asks for

The Foundation places it here, in the subsection that relies on this document most heavily, rather than in a part of the comment where it would be less noticed. Having set out the problem the preceding paragraphs describe, the Australian guidelines decline to solve it in the way this comment asks the Secretary to solve it. In their introduction: “It is not possible to set prescriptive limits on lighting. Instead, these guidelines take an outcomes approach to assessing and mitigating the effect of artificial light on wildlife.” And in the appendix on modeling: “it is not possible to objectively estimate how much artificial light is going to cause an impact on a particular species, or age class, over a given distance and under variable environmental conditions.”

That is the second time in this Part that the people who do this work have said that the thing the Foundation asks for cannot be done. The first is recorded at Part V.I, where the marine review endorses guidelines recommending a case-by-case approach on the express ground that assessment trigger values are difficult to set. The Foundation does not argue either of them away, and a comment that buried them would deserve to be discounted entire. It states three distinctions and then states what survives them.

The first distinction is the subject. These guidelines govern the assessment of individual developments against listed species under a national environmental statute, across a continent, for taxa ranging from marine turtles to bats to ecological communities. A prescriptive limit in that setting would have to be a single number good for every species in every habitat, and the Foundation agrees that no such number exists. Section 360kk authorizes something different: a performance standard on the emission of an electronic product, which is a statement about what a manufactured article may emit and not a statement about what any organism can tolerate.

The second distinction is the one the document itself draws by its conduct, and it is the Foundation's principal answer. This document declines to prescribe a biological threshold and prescribes a great deal about the emission. It directs that a lighting design include spectral power distribution curves for all planned lighting types. It specifies what a measurement method must be capable of, down to a wavelength range. It tabulates, for five separate taxa, which commercial luminaire types are less disruptive and which are to be avoided. It records a filtered sodium source defined by the exclusion of wavelengths below a stated figure. It states that correlated color temperature does not disclose the blue content of a lamp and that "The only way to determine whether the spectral content of a light source is appropriate for use near sensitive wildlife is to consider the spectral curve." Every one of those is a prescription about the emitting article rather than about the receptor. That is the architecture of Part IX and it is the architecture of the first limb of paragraph 360ii(a)(2): a duty to minimize radiation that serves no purpose does not wait upon proof that the radiation is harmful.

The third distinction is narrow and the Foundation does not lean on it. The guidelines were written to be administered by assessors examining particular projects, and an outcomes approach is what such a reader can use. A performance standard is written for a manufacturer and is a different instrument addressed to a different person.

What survives the three is real and the Foundation states it without softening. The reason the guidelines give — that biological response varies by species, by location and by environmental conditions — is true of human beings as well, and Part V records variation by age, by ocular media, by photosensitive condition and by circadian phase. The Foundation's answer is the one it gives throughout and it is a choice rather than a refutation: a performance standard does not have to be set at the threshold of the most sensitive individual, any more than the performance standards already in 21 C.F.R. part 1040 are. It has to be set, published, and capable of being measured. The Australian document is the Foundation's best evidence that the measuring is the part nobody has done, and the Foundation notes that it took a national government and two years of revision to produce an outcomes approach, which is a larger undertaking than anything paragraph 360ii(a)(5) would require of the Secretary to produce a measurement method.

One further thing in the same document the Foundation declines, for completeness and because the pattern now has three instances. The guidelines state that short-wavelength light scatters more readily than long-wavelength light, contributing more to skyglow. Part II.D.4 declines that formulation on the authority of the people who measure skyglow, and the reasons are given there. The Foundation records that the simplified claim now appears in a peer-reviewed review, in a regional watershed memorandum in the United States, and in a national government guideline, which is the clearest demonstration it has that a proposition about the physics of this emission can propagate through official guidance without being checked. That is an argument for paragraph 360ii(a)(4) and not against this document.

5. Expressing optical exposure in the units used for radiofrequency exposure

This is the subsection that ties this Part to the notice, and the Foundation puts it as simply as the arithmetic allows.

Radiofrequency exposure limits are expressed in watts per square meter. Optical irradiance is expressed in watts per square meter. The quantities are the same quantity, and the instruments that measure them differ in spectral range rather than in kind.

Two consequences follow. A research program that reported optical exposure radiometrically, as Part IX.C.1 asks, would produce data directly comparable with the radiofrequency exposure literature this Department is assembling under this notice. And it would permit a single exposure framework across the non-ionizing spectrum, rather than two vocabularies that cannot be reconciled: one expressed in power per unit area and one expressed in units weighted to human brightness perception, which Part V.J.4 establishes is what the optical literature has largely used.

K. The Three Expert Assessments on Which Reliance Is Placed [RFI Q5]

Question 5 of the request for information asks what national and international frameworks federal health agencies should consider. For light-emitting diode products the practical answer is three documents, and this subsection sets out what each is, what each concluded, what condition each attached to its conclusion, and what each stated it could not conclude. The Foundation treats them together because they are the basis on which this question is presently taken to be settled, because the second cites the first, and because the first and second share an author.

The Foundation states first what it does not contend, because the contrary claim is available and the chronology forecloses it. It does not contend that these documents brought about the replacement of incandescent and halogen lighting by light-emitting diode products in the United States. That replacement was driven by the federal energy policy described at Part IV.G, beginning with the Energy Independence and Security Act of 2007, and by June 2018, when the earliest of the three was adopted, the transition was already far advanced, as the adoption figures at Part II.D.4 record. Neither of the first two bodies has authority over lighting policy in the United States in any event: one is an advisory committee of the European Commission and the other is a registered non-profit association. The Foundation imputes no motive to any author of any of the three.

What the Foundation contends concerns the present. These are the documents relied upon now, when the question is whether the subject warrants examination. The remainder of this subsection is therefore addressed to what they say, and principally to what they say about their own limits. Part V.A.2 records the weight the Foundation accords assessments of this kind: they establish what expert bodies have concluded and recommended, and they are evidence of the state of expert opinion rather than primary evidence of effect.

1. The three documents identified

a. The SCHEER Opinion, June 2018

Scientific Committee on Health, Environmental and Emerging Risks, Opinion on Potential risks to human health of Light Emitting Diodes (LEDs), adopted at the Committee's ninth plenary meeting on 5 and 6 June 2018 and cited by the Committee as of 6 June 2018. Published by the European Union, 2018; ISSN 2467-4559; ISBN 978-92-76-00197-3; doi 10.2875/605415. Ninety-two pages. The Committee is one of two non-food scientific committees advising the European Commission, and the Opinion was prepared in answer to four terms of reference put to it by the Commission, directed to the hazards of LED emission in the general population, the dose-response relationship, and the risks associated with LED displays and with LED lamps in the general population and in vulnerable and susceptible populations.

The Opinion names its working group. Of the Committee: Rodica Mariana Ion, Ana Proykova as Chair, and Theodoros Samaras. As external experts: Ellen Bruzell, Jean-François Doré, Massimo Nicolò, John O'Hagan as Rapporteur, Celia Sánchez-Ramos, and Linda van Kerkhof. The Opinion records no minority opinion. Declarations of interest are not reproduced in the document; it states that all declarations of working group members and supporting experts are available on a Commission webpage, which it identifies.

b. The ICNIRP statement, 2020

International Commission on Non-Ionizing Radiation Protection, Light-Emitting Diodes (LEDs): Implications for Safety, Health Physics, volume 118, number 5, pages 549 to 561, 2020. The Foundation identifies it as a statement rather than as guidelines, and the distinction matters: the Commission's exposure limits for incoherent optical radiation are a separate and earlier instrument, described at Part V.C.2, and this document does not amend them. Among the collaborators the statement names are Sharon A. Miller and John O'Hagan, the latter identified as of the Commission's Scientific Expert Group and of Public Health England. The statement cites the SCHEER Opinion described above.

c. The IEA 4E assessment, October 2024

Martinsons and others, Solid State Lighting: Review of Health Effects, published by the International Energy Agency's 4E Solid State Lighting Annex in October 2024. Part V.C.2.f treats this document where it bears on the exposure limit, Part V.C.4 where it bears on discomfort glare and Part V.D where it bears on temporal light modulation. This subsection is concerned only with its place among the three and with the chronology.

2. The chronology, and the authorship common to two of the three

The Foundation sets out the sequence and declines to characterize it.

From 2012 onward, as the 2024 assessment reports and as Part V.C.2.f quotes, several independent research teams reported retinal damage below the exposure limit of the International Commission on Non-Ionizing Radiation Protection, using more sensitive detection techniques and different animal models including rats and living macaques.

On 5 and 6 June 2018 the SCHEER adopted its Opinion. Its Rapporteur was John O'Hagan.

In 2020 the International Commission on Non-Ionizing Radiation Protection published its statement on light-emitting diodes. John O'Hagan is among the named collaborators. The statement cites the 2018 SCHEER Opinion.

On May 24, 2024 the Center for Devices and Radiological Health issued the Final Response described at Part II.A, disposing of four citizen petitions concerning visible light emitted by LED products.

In October 2024 the IEA 4E Solid State Lighting Annex published the review described above, which reports that there is currently no consensus between the lighting community and many retinal experts about the need to revise the exposure limit on which the two earlier documents rest.

Two further facts about the 2018 Opinion belong in this sequence, and the Foundation states them as facts about the document rather than as criticism of any person. The Opinion relies on work of its own Rapporteur for substantive content. Its conclusion about exposure from screens is attributed in terms: O'Hagan and others, 2016, assessed emissions from various screens and concluded that exposure levels were below ten percent of the relevant limit. Figure 3 of the Opinion, comparing the emission spectra of a sixty-watt incandescent lamp and an equivalent-lumen LED lamp, is attributed to the same 2016 work. Figures 10 and 11, showing the temporal modulation of a domestic LED installation and the spectra of LED lighting in a kitchen, are attributed to John O'Hagan, 2017, and no publication is given for them.

The Foundation draws no inference from that and asks the Department to draw none. Rapporteurs are appointed for their expertise in the subject, and an expert's own measurements are an ordinary reason to appoint one. The facts are stated because the three documents are put forward as independent corroboration of one another, and the Department should know that the first and second share a contributor and that the first relies in part on that contributor's own unpublished measurements.

3. The condition attached to the safety conclusion, and what the condition rests on

The SCHEER conclusion is stated three times in the Opinion and is conditioned in each. In the abstract:

> "The Committee concluded that there is no evidence of direct adverse health effects from LEDs emission in normal use (lamps and displays) by the general healthy population."

In answer to the first term of reference:

> "The SCHEER concludes that the available scientific research does not provide evidence for health hazards associated with LEDs when the total exposure is below the ICNIRP exposure limits. However, reversible biological effects in terms of flicker, dazzle, distraction and glare may occur."

And in answer to the second:

> "If the exposure is below ICNIRP exposure limits, the SCHEER is not aware of any risk of damage to the eye and skin."

The Opinion then states what those limits are derived from, and the Foundation asks the Department to read this sentence against the three above:

> "The ICNIRP guidelines are based on observed eye or skin injury after experimental exposure of primates and rodents, and on information from human accidents. Reduction factors are used in setting the exposure limits for humans when animal studies are used."

The limits are constructed from observed injury in acute exposures of animals and from human accidents. The Opinion elsewhere states, in its identification of research needs:

> "In general there is a lack of knowledge regarding the injury threshold for effects from long term chronic exposure."

The Foundation states the consequence without embellishment. The safety conclusion of the 2018 Opinion is that the research does not evidence hazard below a limit, where the limit was constructed from acute injury and where the same document records that the chronic injury threshold is not known. That is not an error of reasoning and the Foundation does not call it one. It is a conclusion about a question narrower than the one the Department is now asking. A finding of no evidence of hazard below an acute-injury limit is not a finding about chronic exposure, and the Opinion does not claim otherwise.

The 2024 assessment then reports, as Part V.C.2.f sets out, that the limit itself has been contradicted in the published literature since 2012 and that no consensus exists on revising it. The Foundation does not assert that the limit is wrong, which it is not competent to determine. It asserts that a conclusion conditioned on a limit is worth what the limit is worth, and that whether this limit is settled is a question on which the most recent of the three documents reports there to be no consensus.

One further matter belongs to this subsection, and the Foundation places it here because it bears on the condition rather than on the conclusion. The Opinion states that reversible biological effects in terms of flicker, dazzle, distraction and glare may occur, and states separately that it is not aware of any risk of damage to the eye and skin where exposure is below the limits. Both statements may be true together. The question the Foundation asks the Department to consider is how far apart they are.

That distance has been measured, for a different emitting technology, by the research community that regulates it. Appendix C.87 and Part V.C.3 describe exposure limits for visual impairment derived from human subject experiments by authors at the United Kingdom defence research laboratory and the United States Air Force, and proposed for incorporation into international laser safety standards. Those limits are expressed in the same units as the injury limits and can

therefore be set directly against them. At night, an exposure sufficient to obscure 40 degrees of the visual field sits about one thousand seven hundred times below the injury limit for a ten-second exposure, and the mildest impairment the framework recognizes sits about one millionth of the way to it. The ratios are the Foundation's arithmetic on published values and the underlying numbers are set out at Appendix C.87.

The Foundation draws no conclusion about light-emitting diodes from laser values and does not invite one. The inference it does draw concerns the structure of the condition. Where a safety conclusion is conditioned on exposure below a limit, and the limit is constructed from observed injury, the conclusion carries no information about effects that occur far below that limit. The Opinion names four such effects in the same sentence as the condition. For the one emitting technology where the distance between the injury limit and the onset of impairment has been quantified, the distance is three orders of magnitude in darkness. The Foundation does not assert that the distance is the same here. It asserts that nobody has measured it here, that the Opinion's own sentence indicates it is not zero, and that measuring it is precisely the study paragraph 360ii(a)(4) directs.

4. What the 2018 Opinion states it could not conclude

The Foundation sets out the following in the Opinion's own words, because each corresponds to a request made in this comment and because the correspondence is closer than the Foundation would have dared to assert on its own authority.

> "The search of the literature for long-term impact of LED emission on human health did not identify studies investigating the healthy general population." The headline conclusion is that there is no evidence of adverse health effects in the general healthy population. The literature search found no studies of that population. Part V.A.2 makes the same point about the determination of May 24, 2024 and about the finding that the quality of the evidence was low.

> "Although there are no reliable data to be used for risk assessment of eye-safety of life-time usage of LED light sources, there might be some concern on the potential negative consequences of LED emissions particularly in a susceptible population which already present early signs of pathologic senescence of the macula."

> "There is insufficient knowledge about the actual exposure of people to optical radiation from LED sources and the total exposure from all optical radiation sources – information about the exposure of the general healthy population is needed for assessing the potential health effects." That is the baseline the Foundation requests at Part II.D.6 and again at Part IX.C, and the absence Part V.J describes.

> "Cumulative exposure over a twenty-four hour time period should be considered, and further research should be done into the reported effects of long-term, low-level exposure on age-related macular degeneration." Part V.C.2.c and Part V.C.2.d describe the absence of any cumulative framework for this waveband. The Opinion recommends the thing the Foundation says has not been done.

> "Reliable information on the dose-response relationship for adverse health effects for the healthy general public is not available in the scientific literature for all wavelengths emitted by LED devices." And, on the possibility of supplying one: "Since LED emission characteristics like exposure patterns and spectra (wavelength-dependent intensity) vary from one emitter to another, it is not possible to predict the profile of the dose-response function for a general LED emitter." The Foundation draws attention to the reason given. It is the variability of the products, which is a fact about what is in commerce and is the subject of the characterization request at Part IX.C.

> And the statement that sits least comfortably beside the conclusion, in the same answer to the same term of reference: "Animal experiments and in vitro studies suggest that cumulative

blue light exposure below the levels causing acute effects can also induce photochemical retinal damage."

The Foundation is careful with the last of those. The Opinion elsewhere discounts that body of work, stating that the conclusions of the cellular and animal studies "derive from results obtained either using exposure conditions that are difficult to relate to human exposures or using exposure levels greater than those likely to be achieved with LED lighting systems in practice." That is a fair criticism and it is the same criticism the Foundation makes of its own appendix at Part V.A.2, paragraph on mechanistic and in vitro studies. The Foundation does not offer the sentence as establishing that cumulative exposure at ordinary levels damages the retina. It offers it as the Committee's own statement that the mechanism is not confined to acute exposure, which is the premise of the research request rather than of a finding.

5. What the 2018 Opinion states that bears on a performance standard

Four passages in the Opinion bear on the statutory questions in Part II rather than on the science, and the Foundation brings them forward because they are findings of an expert body about products in commerce.

On temporal light modulation: "There appear to be no technical reasons why LED lamps need to produce time-modulate emissions, since many models do not." Section 360kk(a)(2) directs that a performance standard be technically achievable. A finding that there is no technical reason for a characteristic, because products without it are already on the market, is a finding of technical achievability in substance if not in those words. Part II.G.3 and Part V.D.

On the purchaser's ability to avoid it: "It is not possible for consumers to identify which LED lamps exhibit TLM and which do not at the point of purchase." The Opinion adds that some LED lamps have modulation of almost one hundred percent, and that "A small number of people report adverse health effects such as migraine or headaches." Part V.E.2 addresses that population. The disclosure point bears on Part IX.

On luminaire design: "Some sources available on the market incorporate 'point' LED sources without diffusers, which can cause glare if viewed. This was also reported to be a concern with some LED street lights." Part V.B.2 sets out why the presence or absence of a diffuser governs the radiance of a product and therefore the irradiance delivered to the retina, and why enlarging the emitting aperture is the available remedy.

On vehicle lighting, where the Committee uses its own voice: "The SCHEER is concerned about the high luminance sources used on some vehicles, particularly daylight running LED lights that remain on without dimming at night. Current examples appear to be blue-rich, which increases glare and scattering, particularly for older observers. These running lights are a greater glare source in fog than more traditional vehicle lighting." Part VI.B and the citizen petitions described at Part IV concern vehicle lighting. The Foundation notes that the reduction of intensity at night is among the available techniques listed at Part II.G.3.

One further passage identifies a regulatory gap in terms: "There is a European standard for electronic toys that limits the emission of optical radiation from toys" but "The standard does not take into account a product that is not a toy, which may be given to a child to use (for example smartphones or tablets)." The Foundation offers that as an illustration of the point made at Part II.C: a standard addressed to a product category leaves uncovered the same emission from a product outside the category.

That passage can now be taken further than the Opinion took it, and the Foundation does so because the Opinion's criticism turns out to understate the position. The Committee treated the existence of the toy standard as settled and identified the gap as one of scope: the standard does

not reach a product that is not a toy but is given to a child. That is a sound observation. It is not the whole of the problem.

In July 2026 the results of a three-year market surveillance campaign under that standard were published. Of fifty toys purchased anonymously from French retailers and tested by accredited laboratories, thirty percent contained at least one light-emitting diode that failed the eye safety limits of the standard, and approximately eighty-seven percent of the failures were failures of the blue light hazard limit. Appendix C.59 and Part V.C.2.k. One of the authors of the 2024 intergovernmental review described at subsection 1, and one of the external experts of the 2012 predecessor Opinion described at subsection 9, are among the authors of that study.

The Foundation draws a narrow conclusion and states its limits. The study concerns the French market and a European standard that has no application in the United States, and its sample was not statistically representative. It does not establish a non-compliance rate anywhere, and the Foundation asserts none. What it establishes is that the existence of a standard addressed to a product category is not the same thing as compliance by the products in that category, and that where a national authority has looked, it has found a substantial proportion of marketed products exceeding the limits. A comment that relied on the presence of a standard as evidence of safety would be relying on the wrong fact, and so would a determination that did the same.

6. Two statements in the Opinion that tell against the Foundation

The Foundation brings forward the two passages most adverse to its position, because a reviewer will find them and because each admits of an answer.

The first is a comparison with the lamp the light-emitting diode replaced. Having reported that the blue-light-weighted radiance from screens is below ten percent of the photochemical retinal hazard limit, the Opinion adds: “For a comparison, 14% of that limit corresponds to a mid-range incandescent lamp.” On that measure a screen is less hazardous than an incandescent lamp, and the Opinion states elsewhere that for the same color temperature the blue component of an LED lamp is similar to that of an incandescent lamp.

The Foundation accepts the figures and disputes what follows from them. The quantity compared is the blue-light hazard weighted radiance, which is an acute photochemical injury metric built on the weighting function described at Part V.C.2.a. A comparison expressed in that quantity establishes that neither source approaches the acute injury threshold. It establishes nothing about circadian response, for which the relevant weighting is the melanopic one described at Part V.F; nothing about discomfort or disability glare, for which the relevant quantity is luminance and the relevant variable is the geometry treated at Part V.B.2; nothing about temporal modulation, which an incandescent filament does not produce at the depths recorded for some LED lamps; and nothing about the long-wavelength content that Part V.B.6 identifies and that the Opinion itself raises when it notes that the infrared and possibly ultraviolet emission of an LED lamp “may be greatly reduced or absent (in comparison with other types of lamps), which might influence (positively or negatively) the normal human physiology.”

The second adverse passage is broader: “For many people, exposure to natural optical radiation will predominate, i.e. exposure to optical radiation from LEDs is likely to be insignificant compared with the exposure to natural light outdoors.”

One measurement bears on that passage and the Foundation brings it forward because it is the only quantification of the comparison the Foundation has located. The study at Appendix C.63 reports that the French agency for food, environmental and occupational health safety, in a 2019 report on new lighting technologies, carried out measurements in real-life conditions and concluded that artificial lighting adds up to 50 percent of the phototoxic dose received from natural lighting, rising to 200 percent where only cool light-emitting diode sources are used, with screens among the largest artificial contributors.

If those figures hold, the Opinion's characterization does not. An increment of half the natural dose is not insignificant, and a doubling is not an increment at all. The Foundation states the qualification with the figure: it has not obtained the 2019 report, the figures are taken at second hand from a paper citing it, the measurements are French, and the comparison is of phototoxic dose weighted by the hazard function whose adequacy Part V.C.2.f questions. The report must be obtained and read before the comparison is filed. But the Foundation records now that a national health agency appears to have made the measurement that the Opinion's sentence assumes the answer to, and to have reached the opposite conclusion.

The Foundation accepts that as to total daily radiant exposure and denies its relevance to the questions this comment raises. The proposition is about aggregate dose. The circadian argument at Part V.F is not about aggregate dose but about light at a time of day when the natural stimulus is absent, and the Opinion concedes that point separately when it states that normal use of LEDs or LED-illuminated screens in the evening can perturb the circadian system. The glare and discomfort argument at Part V.C.4 is about the luminance of a source in the field of view against a given background, not about how much light the person received that day. And the exposure that matters for the photophobic population described at Part V.E.2 is the exposure present, not the exposure summed. Sunlight is a large quantity of light that almost no one looks at directly; the products at issue are smaller quantities of light arranged to be looked at.

7. What the three documents establish, and what they do not

The Foundation states its position on the three as a whole.

They establish that expert bodies have examined the question and have not found evidence of adverse health effects from LED products in normal use by the general healthy population at exposures below the international limits. The Foundation does not dispute that and does not ask the Department to disregard it.

They do not establish that such effects are absent, and none of them says they are. The 2018 Opinion says the literature search identified no studies of the population about which it concluded, that no reliable data exist for lifetime eye-safety assessment, that the actual exposure of people is insufficiently known, and that the chronic injury threshold is not known. The 2024 assessment says there is no consensus on whether the limit the conclusion is conditioned on requires revision.

They are European and intergovernmental documents. None of them is a performance standard, none has force of law in the United States, and none purports to discharge any duty of the Secretary. Part I.E records their status in the framework table.

The use the Foundation makes of them is accordingly narrow and, it submits, difficult to resist. Each of the three identifies, in its own words, research that has not been performed and measurement that has not been made. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research to minimize exposure to unnecessary electronic product radiation, and paragraph 360ii(a)(4) to study and evaluate emissions and conditions of exposure. The three documents on which reliance is placed are, read in their own terms, a list of the work those paragraphs direct and that has not been done. Part V.L sets out the gaps as the field states them.

8. A contribution of the 2018 Opinion to Part V.B.2

One passage of the Opinion is quoted here because it corroborates the optical conventions on which Part V.B.2 relies, from an institutional source and independently of the Foundation's own arithmetic. In answer to the third term of reference:

> "Evaluating the retinal blue light hazard effectively requires taking account of the irradiance of the retinal image of the source viewed. For momentary viewing, the retinal image subtends the same angle as does the source. With increasing exposure time, the retinal image is spread over an increasingly large area of the retina due to eye movement (saccades) and task-determined

> movement, resulting in a corresponding reduction in retinal radiant exposure at any given point on the retina. A time-dependent function of the angular subtense of the retinal image for exposures from 0.25 sec (aversion response time) to 10,000 sec is defined, ranging from 1.7 mrad (taken as the smallest image formed on the retina) to 100 mrad."

That passage states, in an assessment adopted by a scientific committee of the European Commission, that the quantity governing the retinal hazard is the irradiance of the retinal image; that the smallest image the eye forms corresponds to an angular subtense of 1.7 milliradians; that the upper bound of the averaging field is 100 milliradians; that the aversion response time is taken as 0.25 second; and that the framework extends to 10,000 seconds and no further. Part V.B.2 relies on the first three of those values and Part V.C.2.c on the last. The passage also supplies the reason the averaging angle grows with duration, which is the spreading of the image by saccadic and task-determined eye movement.

One divergence between that passage and the guidelines it describes must be recorded, because Part V.B.2 was built on the Opinion's figures and has since been corrected. The Opinion gives the smallest image formed on the retina as 1.7 milliradians and the averaging range as 1.7 to 100 milliradians. The guidelines of 2013, obtained and set out at Appendix D.1, give the minimum angular subtense as 1.5 milliradians corresponding to a retinal spot of 25 micrometers, and give the averaging field for the photochemical hazard as 11 milliradians for exposures of 100 seconds or less, rising to 110 milliradians at 10,000 seconds. Neither of the Opinion's two figures appears in the 2013 guidelines. The Foundation does not know the explanation and does not speculate beyond noting the likely one, which is that the Opinion of 2018 describes the guidelines of 1997 rather than those of 2013. Part V.B.2 now uses the values in the 2013 guidelines and states that it does. The Foundation draws no inference adverse to the Opinion from the discrepancy and records it because a comment that corrected its own figures while leaving its source uncorrected would be concealing the reason for the change.

Two observations follow, and the Foundation separates them from the quotation. The first is that the Opinion's own treatment of screen exposure was carried out in terms of source radiance, and the Opinion states the consequence: "Since the assessment was carried out in terms of source radiance, the assessment conclusion was made independent of viewing distance." The proposition advanced at Part V.B.2, that retinal exposure from a resolved source does not diminish with distance, is therefore not a contention of the Foundation's against the expert bodies. It is the convention those bodies apply, stated by them.

The second is that the aversion response time of 0.25 second is the interval the framework assumes a person requires to look away. Part V.C.2 addresses the weight the guidance places on the aversion response. A framework whose shortest exposure is the time taken to avert the eye is a framework for sources a person encounters once and turns from, which is not the condition of exposure described at Part VI.

9. The predecessor opinions, and what they already stated

The three documents identified at subsection 1 are the documents on which reliance was placed. They are not, however, the beginning of institutional assessment of this subject, and the Foundation sets out what came before them because the earlier record bears on how the later documents should be read.

The committee that adopted the 2018 Opinion was itself a successor. Before its reconstitution the corresponding body was the Scientific Committee on Emerging and Newly Identified Health Risks, and that committee adopted two Opinions bearing on this subject. Both are listed at Appendix D.1.

The Opinion of September 23, 2008

The first, titled Light Sensitivity, was adopted at the committee's 26th Plenary on September 23, 2008. Its mandate was narrow and is worth stating because of who prompted it: the Commission

asked the committee to determine whether the claims of light-sensitive citizens' associations, that energy-saving lamps aggravated their symptoms, were justified on the evidence; if so, which lamp characteristics were responsible; and how large the affected population was.

Three of its findings bear on this comment, and two of them cut against positions the Foundation has seen advanced in this field.

- Of the candidate mechanisms, only ultraviolet and blue light were identified as a potential risk factor. As to the others the committee stated that "No evidence was found that would indicate that either EMF or flicker could be a significant contributor." It further stated that there is no scientific evidence that fluorescent lamps, including compact fluorescent lamps, induce seizures.
- On blue light the committee found that compact fluorescent lamps "could create a risk of blue light over-exposure contributing to some retinal damage" when used close to the eye, and that "Blue light may be harmful to those with retinal diseases." The second of those is graded at the committee's evidence level B.
- On the sufficiency of the record the committee stated that "There is a need for additional experimental and epidemiological studies before final conclusions can be drawn."

Light-emitting diodes are not mentioned in that Opinion. The European assessment of this subject began in 2008 on fluorescent lamps, before the light-emitting diode was a general illumination product, which is a fact about the age of the inquiry rather than a criticism of it.

The Opinion of March 19, 2012

The second, titled Health Effects of Artificial Light, was adopted at the 17th Plenary on March 19, 2012. It is the direct predecessor of the 2018 Opinion, and four of its statements are material here.

- On the adequacy of its own evidence base as to this technology: "LEDs were under-represented in the present analysis of lamps."
- On the classification question treated at Part V.C.2.k: "Further consideration also needs to be given to the risk classification of high power LEDs." The committee records that industry data placed a 6,000 K high-power diode in the Exempt Group, but only when it was analysed as a small source. The Foundation asks the Department to notice that the group assignment turned on the analytical treatment of the source geometry, which is the point Part V.C.2.k makes about the 11 milliradian criterion.
- On what a low risk group does and does not establish, which is the argument at Part V.C.2.c in the committee's own words: the Exempt Group classification should not be taken to imply adequate protection of the general population as a whole from long-term effects. The committee also stated that there is no evidence that artificial light from lamps in the Exempt Group or Risk Group 1 would cause any acute damage to the human eye. The word is acute, and the two statements together are the acute-to-chronic division this comment describes throughout.
- On the distance at which diode products should be assessed, the committee stated that their retinal hazards need further assessment at 20 centimeters, since diode luminaires can be used at that distance in the home. That is the 200 millimeter reference distance discussed at Part V.C.2.k, identified by a European scientific committee in 2012 as requiring further work.

The 2012 Opinion also addressed light at night, stating that exposure while awake may be associated with an increased risk of breast cancer, and adding that such effects are associated with light in general without any specific correlation to a given lighting technology. Part II.E.6 and Appendix C.58 describe the state of that literature in the same period. Its research-gap list includes items this comment asks for independently: emission data across lamp types, a personal exposure database, and risk group categories that account for chronic effects.

Authorship continuity, and a link to Appendix C

The membership of the two working groups overlaps substantially and overlaps again with the literature appraised in Appendix C. Professor Mats-Olof Mattsson was rapporteur in 2008 and chair and rapporteur in 2012. Dr. Thomas Jung chaired in 2008 and served in 2012. Dr. Frank de Gruijl and Professor Harry Moseley served as external experts on both. Professor James Ferguson served as an external expert on both, and Professor Francine Behar-Cohen joined for 2012.

One of those names appears in this comment already. The 2016 review at Appendix C.55, which supplies the spectral design criterion this comment relies on and which limits its own safety conclusion to exposures of days to weeks, is co-authored by Ferguson. The Foundation draws the same narrow point it draws at Part V.A.1: the body of expert assessment and the body of primary literature on this subject are produced by a small and overlapping group of people. That is a feature of the field rather than a criticism of any individual, and it bears on how much independent corroboration a reader should take the agreement of these documents to represent.

What the Foundation draws from the predecessor opinions

Three things, each a matter of record.

First, the European assessment lineage runs 2008, 2012, 2018, and the 2024 intergovernmental review described at subsection 1 continues it. Four documents across sixteen years, from bodies constituted to advise on emerging health risks. Over the same period the Foundation has identified no assessment of this kind by any United States body, and the single North American assessment it has located is the 2013 Canadian evidence brief at Appendix D.1. Part II.E.4.

Second, the questions this comment puts to the Department were identified by the predecessor committee in 2012 and have not been closed since. The risk classification of high-power diodes needed further consideration. The Exempt Group did not imply protection against long-term effects. Diode products needed assessment at the distance at which they are actually used. Emission data across lamp types were lacking and a personal exposure database did not exist. Fourteen years later the Foundation is asking for the same four things, and Part V.L records that the 2024 review still reports the central limit to be unsettled.

Third, and the Foundation states this because it bears on its own credibility, the 2008 Opinion examined and rejected two mechanisms that are frequently asserted in this area. It found no evidence that electromagnetic fields or flicker from the lamps at issue were significant contributors to the symptoms reported to it, and no evidence that those lamps induce seizures. This comment does not advance either proposition. Its case concerns the optical emission of light-emitting diode products in the visible band, the quantities by which that emission is measured, and the absence of any federal determination about it. Part V.C.4 treats temporal light modulation on its own evidence and in its own terms, and Part I.A states the standard this comment holds itself to.

L. Research Gaps and Priorities [RFI Q16]

The gaps set out in this subsection are not the Foundation's alone. The report described at Part V.C.2.f, the work of national research and radiation protection bodies rather than of a party to this proceeding, identifies gaps corresponding to several of them, and where that is so it is noted below. The Foundation offers that correspondence because a research agenda proposed by a respondent carries less weight than the same agenda proposed independently by the bodies that study the question.

In January 2026 an expert consensus on exactly this question was published in BMC Medicine. Thirteen experts drawn from academia, public health, radiation protection and occupational health institutions convened a workshop and consultation process, and set out the research gaps and priorities for ocular light and optical radiation exposure as a determinant of health. Their framing sentence is the one the Foundation asks the Department to read first:

> Light exposure over 24 h is a modifiable environmental influence on human physiology and behavior with significant implications for health and well-being, yet the field lacks coordinated research infrastructure, standardized methodologies, and translational pathways.

They identified nine critical gaps, which they state as follows:

Gap 1: Lack of standardized measurement tools.

Gap 2: Inadequate exposure estimation infrastructure.

Gap 3: Lack of consistent exposure descriptors and exposure metrics.

Gap 4: Absence of core outcome standards.

Gap 5: Limited dose–response evidence.

Gap 6: Limited evidence on intervention effectiveness.

Gap 7: Poor characterization of globally representative and vulnerable populations.

Gap 8: Fragmented data harmonization and sharing.

Gap 9: Limited integration of non-visual effects of light into public health frameworks.

The Foundation did not devise that list and had no part in producing it. It sets the list beside the statute, and asks the Department to notice the correspondence.

Gaps 1, 2 and 3 concern measurement: the tools, the infrastructure for estimating exposure, and the descriptors and metrics. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. Paragraph 360ii(a)(6)(A) directs consultation with other Federal departments and agencies on techniques, equipment and programs for testing and evaluating electronic product radiation.

Gaps 4 and 5 concern outcome standards and dose-response. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research. Part V.C.2.c sets out what the absence of dose-response evidence beyond the acute range means for the one exposure limit that exists.

Gap 6 concerns intervention effectiveness. Paragraph 360ii(a)(5) directs the Secretary to develop, test, and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation. The correspondence here is not approximate. It is the same subject in the same words.

Gap 7 concerns vulnerable populations and windows of vulnerability. Part VII identifies the populations in question, and § 360kk(a)(1)(A) requires the Secretary to consider the latest available scientific and medical data in the field.

Gap 8 concerns data harmonization and sharing. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other Federal and State agencies, professional organizations, industry and labor associations and other organizations.

Gap 9 concerns integration into public health frameworks. That is the electronic product radiation control program itself, which § 360ii(a) directs the Secretary to establish and carry out.

One word deserves particular attention. The consensus states that the field lacks coordinated research infrastructure. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate, and support research. The verb the experts reached for is in the statute.

The Foundation puts the conclusion of this subsection as plainly as it can. Thirteen independent experts, publishing in a peer-reviewed medical journal in January 2026, described a research agenda for optical radiation exposure as a determinant of human health. That agenda is, provision by provision, the program Congress enacted in 1968 and assigned to the Secretary of Health and

Human Services. What is missing in the United States is not a plan. A plan exists, in statute, and has existed for fifty-eight years. What is missing is its execution as to this radiation.

The subsections that follow identify the gaps the Foundation would add to that list, drawn from the particular products and exposures this comment concerns.

1. Multi-emitter and real-world exposure conditions

The nine gaps set out above concern light exposure as a whole. The Foundation adds this one because every instrument and every exposure limit in the field is built around a single source, and the exposure this comment concerns is rarely from one.

Part V.J.3 sets out the single-emitter design of the available instruments and Part III.D.8 treats the number of emitters during exposure as a characteristic requiring a boundary. Question 15 of the notice raises it. What is not known is how exposures from multiple simultaneous sources combine for any of the responses at Part V.C, Part V.D or Part V.E: whether they add, whether the most intense source governs, and whether the answer differs between a photochemical response and a temporal one. Until that is known, a criterion expressed per luminaire cannot be converted into a statement about what a person in a street receives.

2. Radiometric characterization of products in common use

No federal inventory records what the products in commerce actually emit, expressed radiometrically. Part V.J.4 establishes that the existing literature reports exposures photometrically, in units weighted to the visual response, which discards the information needed for every non-visual response this Part treats. Part II.D.6 sets out the absence of the baseline and Part IX.C asks for it.

The gap the Foundation adds is narrower than the request. It is that nobody knows the distribution. Even for the best-studied class, there is no published account of the range of spectral power distributions, source luminances and modulation depths across the products actually on sale in the United States. The 2018 Opinion described at Part V.K.4 gives the variability of the products as its reason for being unable to predict a dose-response function for a general emitter. The variability is therefore not an obstacle to be regretted; it is a measurable property of the market that nobody has measured.

3. Response-specific weighting functions beyond the visual

The weighting functions in general use are the photopic function for light as seen, and the blue light hazard function for photochemical retinal injury. Part V.C.2 sets out the second and Part V.B.3 the limits of the first.

The gap is that the responses this comment concerns are not confined to either. Migraine, photophobia, the trigeminal pathway at Part V.E.4, the melanopsin-mediated pathway, circadian disruption at Part V.F, and the autonomic responses at Part V.E.5 each have a wavelength dependence of their own, and for most of them no agreed weighting function exists. Part IX.C.4 asks that the weighting appropriate to each response studied be adopted rather than a single function applied to all of them. Appendix C records one study indicating that the tissues containing receptors responsive to optical radiation extend beyond the eye, which if correct means the enumeration of responses is itself incomplete.

4. Temporal characteristics below and above the flicker fusion threshold

Part V.D sets out temporal light modulation and Part V.D.3 the recommended practice that addresses it. The gap the Foundation adds has two halves, divided by the frequency at which modulation ceases to be visible.

Below that frequency, what is in dispute is not whether an effect exists but what bounds it: Part V.D.1 sets out modulation depth and frequency, and Part VIII.D.4 records that a visible alarm operating at three hertz and full modulation exceeds the recommended practice by a factor of twenty while

complying with the accessibility framework. Above it, the stroboscopic and phantom-array effects at Part V.D.2 are produced by modulation nobody can see, which means a person cannot know they are exposed to it, cannot attribute an effect to it, and cannot avoid it. Part III.E.2 treats rise and decay times, which are the characteristic that distinguishes a pulse that is abrupt from one that is not, and for which the Foundation has located no federal specification anywhere.

5. Populations identified in Part VII as disproportionately affected

The seventh of the nine gaps concerns globally representative and vulnerable populations. The Foundation adds the particular form the gap takes in this record. Part VII.A.4 records the self-identified condition categories of the 593 reporters at Appendix A, and Part VII.K treats the group. Those categories are what people wrote about themselves on a web form. They are not a sampling frame, not a case definition, and not a population.

So the gap is not merely that the populations are poorly characterized. It is that nobody has enumerated them. No federal body has stated which populations are differently sensitive to optical radiation, which are differently exposed to it, or how many people are in either category, and Part VIII.C.3 establishes that a public entity attempting to identify the populations affected by its own installations runs into the same absence. Part IX.C.6 asks that these populations be studied and Part IX.L that they be addressed expressly in whatever the Department publishes.

6. Longitudinal and cumulative exposure

The last gap the Foundation adds is duration. Part III.E.3 treats cumulative exposure as a characteristic requiring a boundary, and Part V.H sets out the settings in which the exposure is compulsory and repeated.

What is absent is any longitudinal study of the exposure this comment concerns. The literature at Part V is overwhelmingly of acute exposure: a subject is exposed for minutes or hours and a response is measured. The exposure that began with the transition described at Part IV.G is of a different kind, being continuous, nightly and lifelong for the populations at Part IX.L, and no study of it over years exists because the transition is itself recent. Part II.D.6 establishes that there is no exposure baseline from which such a study could even begin, which is the gap Part IX.C asks be closed first.

M. Crime, Safety, and the Benefits Claimed for Outdoor Lighting

Every other subsection of this Part concerns what light does to people. This one concerns a claim made on the other side of the ledger, and the Foundation includes it because a benefit asserted but not delivered changes what the Department is weighing.

Why this belongs in a comment to this Department

The products described in Part VI are installed, and their spectral and photometric characteristics chosen, on a stated justification. For outdoor lighting that justification is public safety, and within it the reduction of crime is the component most often quantified and most often used to carry the cost. Broad-spectrum white sources are selected over the narrow-band orange sources they replaced partly on that ground.

The Foundation does not ask the Department to regulate crime, and it does not suggest that the Department has any competence in criminology. The relevance is narrower and it is one of structure. If a spectral choice carries a biological cost, the question whether it also carries the safety benefit asserted for it is part of the same assessment, and the body assessing the biological side is entitled to know what is on the other. Where the asserted benefit is not found, a biological cost of any size stands unoffset. That is the whole of the Foundation's argument in this subsection and it does not extend further.

A correction the Foundation makes to its own framing

It would be convenient for this comment if the evidence showed that broad-spectrum white street lighting increases crime. The Foundation has examined the question and that is not what the evidence shows, and it says so here rather than allowing the implication to stand anywhere else in the comment. What the best available evidence shows is a null: no detectable change in crime in either direction. The Foundation relies on the null and claims nothing beyond it.

The study

Marchant P.R. and Norman P.D., To Determine if Changing to White Light Street Lamps Reduces Crime: A Multilevel Longitudinal Analysis of Crime Occurrence during the Relighting of Leeds, a UK City, Applied Spatial Analysis and Policy, volume 18, article 77 (2025), open access, described at Appendix C.118.

The Foundation discloses two things at once. The authors declare competing interests in unusually direct terms: the first states that he "has concerns about light pollution affecting astronomical observations and biodiversity, so has been motivated to examine the claims of benefit for increased public lighting" and that he "has previously published work critical of claims of substantial public safety benefit from increasing lighting"; the second states a concern that public money may be wasted on schemes with no proof they achieve their purpose. The Foundation discloses that as it disclosed the dark-sky interest at Appendix C.117 and the advocacy commission at Appendix C.114. And the study records that no funding was sought or obtained for it.

Against those interests the Foundation sets the study's procedural discipline, which exceeds anything else in this comment. It is a confirmatory study following a plan fixed in advance. The protocol was sent to three named independent custodians before the analysis began, one of them at a German geosciences research center and two of them professors at British universities, and is published with the paper. The modeled data are published with it, so the analysis is reproducible, which the authors note is not true of the studies they criticize. The manuscript was written to the reporting guideline for cohort studies.

What was done

Between 2005 and 2013 the city of Leeds replaced substantially the whole of its street lighting, installing 78,189 new white lamps in place of predominantly orange ones. The authors modeled weekly police recorded crime in all 107 of the city's middle-layer super output areas across 456 consecutive weeks. The period yielded 679,452 recorded crimes, of which 471,374 could be assigned to darkness or daylight: 221,644 in darkness and 249,730 in daylight.

The design is the feature that matters. Because the areas were relit at different times, at different rates and to different extents, each area serves as a comparison for the others at any given week, and the underlying trend in crime unrelated to lighting is absorbed by a polynomial in time fitted separately by area. The authors record that the order of installation was determined by the convenience of the contractor working outward from two depots and not by the level of crime in any area, which removes the regression-to-the-mean problem that afflicts studies where the worst areas are lit first. Overdispersion, which they argue is the central statistical error in the earlier literature, is modeled directly.

The result

Three measures, each a percentage change from the start to the finish of the relighting, with ninety-five percent confidence intervals:

- Daylight-adjusted darkness crime, which is the ratio of darkness to daylight crime and the study's principal measure: an increase of 2 percent, confidence interval minus 3 to plus 7 percent.
- Darkness crime unadjusted: an increase of 3 percent, confidence interval minus 1 to plus 8 percent.

- Round-the-clock crime, being darkness and daylight summed: an increase of 3 percent, confidence interval 0 to plus 6 percent.

The authors state the conclusion in their abstract: "no evidence was found for an improvement (or detriment) in the city's level of crime by relighting, contrary to the substantial reduction anticipated by the city council." The point estimates sit slightly on the side of more crime and none of them is distinguishable from zero. The Foundation does not present them as showing harm. What the confidence intervals establish is that an effect of the size claimed for this intervention can be excluded.

What had been claimed

The size of the claim is what gives the null its force, and it was stated in a public document. The city's outline business case for public funding asserted that "The research suggests reduction in crime rates attributable to improved lighting of over 25%. We believe that a reduction of 20% in night-time crime only is a reasonable assumption in the context of Leeds." On that assumption the case put the net present value accruing from crime benefits alone at £109,049,000 and the benefit to cost ratio for the project at 3.75.

A twenty percent reduction was assumed, and a confidence interval of minus three to plus seven percent was found. The Foundation asks the Department to note the shape of that, because it is the shape this comment describes elsewhere in other subject matter: a quantified benefit asserted in advance on a literature that was not examined, used to justify a change to the optical characteristics of an installed product class, and not checked afterwards by the body that asserted it.

That the result is not isolated

The Foundation records the surrounding literature as the study reports it, in each case noting that it has not read these sources itself.

- The national evaluation of street lighting projects for the United States Department of Justice, Tien and others (1979), found no crime reduction benefit.
- A Home Office crime prevention unit paper, Atkins and others (1991), could detect no crime prevention benefit from street lighting.
- The report to the United States Congress, Preventing Crime: What Works, What Doesn't, What's Promising (1997), stated in its chapter on preventing crime at places that "We can have very little confidence that improved lighting prevents crime, particularly since we do not know if offenders use lighting to their advantage."
- The LANTERNS study, funded by the United Kingdom's national health research institute at a cost the present authors give as £414,315.32, used data from 62 of the 174 local authorities of England and Wales and several million crime reports. For the change to white light specifically it found a crime rate ratio of 0.89 with a confidence interval of 0.77 to 1.03, which includes no effect. The Foundation has since read that study and no longer relies on this second-hand account of it. It is set out at the end of this subsection and at Appendix C.124, where the figure above is confirmed and where the characterization its own authors placed on it, which is weak evidence of a reduction rather than an absence of effect, is reported.

The third of those is worth isolating. The sentence reported to Congress in 1997 identifies the possibility that offenders use lighting to their advantage, and records that it is not known whether they do. Twenty-nine years later the Foundation is unable to identify any federal body that has resolved it. The lighting of the public realm has been converted in the interval.

The study that found the opposite, recorded in full

One body of work found a benefit, and the Foundation sets it out because it is the only randomized evidence in the field. Chalfin and others, reporting in 2017, 2019 and 2021, randomly allocated additional lighting across New York City public housing developments and concluded that it was

associated with fewer night-time crimes. That is a stronger design than anything else in this subsection and the Foundation does not diminish it.

The qualification is about what was installed. The present authors record that the intervention used lighting towers of six hundred thousand lumens, against standard outdoor lighting which they give as running typically between five thousand and thirty-five thousand lumens. The treatment was therefore something on the order of twenty to a hundred times a normal street light, deployed for six months. Whatever that study establishes about saturating a housing development with light, it does not bear on the question in this subsection, which is whether changing the spectrum of ordinary street lighting from orange to white delivers a safety benefit. The present authors also note that the analysis involved extensive covariate selection, which places it in an exploratory rather than a confirmatory frame, and that no protocol is available.

A pattern the Foundation notes without imputing motive

The literature on which the Leeds business case relied traces to work carried out at a British university in the nineteen-nineties which the present authors record was "funded by Urbis Lighting Company". That work was then carried into a Home Office research study and three successive meta-analyses, and from there into the business cases of authorities seeking public money to relight their cities.

The Foundation states that as a fact about provenance and draws no inference about any person. It notes only that the structure is the same one Part VI.J.6 describes in another product class: the technical basis for a public decision about the optical characteristics of a lighting product, produced under funding from the industry that sells it, and never independently tested by a body with a health mandate. The Foundation does not say the conclusions were wrong because of the funding. It says that where this pattern appears, independent verification is what is missing, and that supplying it is a public function.

What this subsection establishes, and what it does not

It establishes nothing about health. No study discussed here measured any biological, visual or physiological endpoint; the outcome throughout is recorded crime. It establishes nothing about light-emitting diodes specifically: the Leeds conversion ran from 2005 to 2013 and the lamps are described as white and broad-spectrum, not as diodes, and the Foundation does not represent this as a study of the products at Part VI.D. And it does not establish that white light increases crime.

What it establishes is that the principal safety benefit claimed for converting street lighting from narrow-band orange to broad-spectrum white was not delivered in the one city where the whole conversion was measured against a pre-registered plan, and was not detected in the largest multi-authority study either. The consequence for this comment is stated at Part IX: where the Department weighs a biological question about the spectral content of outdoor lighting, it should not assume that a countervailing safety benefit exists, because on the evidence the Foundation has been able to find, it has not been demonstrated.

A second study, which points both ways and shows why the question is hard

Lee J., Leitner M. and Paulus G., Spatiotemporal Analysis of Nighttime Crimes in Vienna, Austria, ISPRS International Journal of Geo-Information, volume 13, number 7, article 247 (2024), open access, described at Appendix C.119. The first two authors are of Louisiana State University and the third of the Carinthia University of Applied Sciences. The work was supported by the Austrian Marshall Plan Foundation and the authors declare no conflicts of interest.

The Foundation includes this study for a narrower purpose than the one above and states the purpose first, because the study contains findings on both sides and the Foundation relies on neither as proof of anything. It is included because it shows what the evidence actually looks like when the question is examined carefully, and because its authors say so.

What was done

The authors analyzed 522,880 reported crimes in Vienna from 2014 to 2019, of which 128,322 fell within four types occurring at night: assault, theft, burglary and robbery. Night was defined as the period from civil dusk to civil dawn, computed for each day. Two measures of light were used: the density of streetlights, from an open government dataset, and the median brightness recorded from orbit by the day-night band of the Visible Infrared Imaging Radiometer Suite, on a grid of 3,106 cells of five hundred meters. Ordinary least squares and geographically weighted regressions were run, univariate and multivariate, with socioeconomic and infrastructure variables.

The finding that favors the Foundation, and its limits

The regressions came out one way. In the authors' words from their conclusions: the analysis "shows a mostly positive relationship between streetlight density or NTL values with nighttime crimes. This means that brighter areas lead to a statistically significant increase in nighttime crimes". In the univariate results every coefficient was positive, for both measures of light and all four crime types.

The Foundation does not present that as evidence that lighting causes crime, and the Department should not read it so. The study is cross-sectional: it compares places at a moment rather than the same place before and after a change. Bright places are busy places, with more people, more premises and more property, and the authors identify the confounding directly. They note that "brighter areas have higher chances to observe and report crime incidents", which is a reporting effect rather than an effect on crime, and they report from the literature the observation that areas with more streetlights have higher crime rates because those areas overlap with higher rates of human activity. A positive correlation between light and recorded crime is what one would expect whether or not light makes any difference to offending.

The finding that runs the other way, which the Foundation states in the same place

The same paper reports that in 2017 Vienna replaced older hanging lamps with light-emitting diodes under a municipal program, and that the largest single-year fall in nighttime crime in the series followed. Between 2016 and 2017 nighttime theft fell by about 26.6 percent, robbery by about 27.0 percent, burglary by about 18.9 percent and assault by about 9.4 percent. The authors write that the change "may have contributed to a substantial decrease in nighttime criminal activities".

That is adverse to the position this comment takes and the Foundation reports it without qualification before offering any comment on it. It is also, on the authors' own account, the second-best supported of the two findings in their paper: they describe the descriptive result and the regression result as seeming "to contradict" one another, and they do not resolve the contradiction.

The Foundation offers one observation about the descriptive finding, and offers it as a methodological point rather than a dispute about Vienna. A fall in crime in the year after an intervention, with no control and no counterfactual, in a city where the paper separately records "a gradual decrease in nighttime crime incidents" across the whole six-year series, is the uncontrolled before-and-after inference that the preceding study was written to criticize. The Foundation applies that criticism evenhandedly. It declines to rely on the Vienna before-and-after comparison for the same reason it declines to rely on the before-and-after studies that reported benefits, and it declines to rely on the Vienna correlations for the reasons given above.

What the authors conclude, which is what the Foundation takes from the paper

They conclude that the relationship is unresolved, and they identify the specific tension:

> "there appears to be an interesting balance between better lighting to identify opportunities to commit a crime and better lighting to increase the risk of detection/apprehension. This seemingly contradictory effect that increasing lighting has on crime is yet another valuable avenue for future research."

And of the seasonal pattern, in which the brightest months in Vienna are also months of high recorded crime, they write that this "suggests that increased lighting may not be a simple deterrent to crime".

That is the proposition the Foundation advances in this subsection and it is the whole of it. The idea that more outdoor light produces less crime is treated in public decision-making as settled. It is not settled. The largest pre-registered study of a complete municipal conversion found no effect; the largest multi-authority study found no effect; a report to Congress in 1997 recorded that it was not known whether offenders use lighting to their advantage; and a careful spatial analysis published in 2024 produces results its own authors describe as contradictory and unresolved. The Foundation asks the Department not to treat the proposition as established, in either direction, and in particular not to treat it as a reason why the optical characteristics of outdoor lighting need not be examined for biological effect.

Fear of the dark is real, and the Foundation does not argue with it

A comment that treated fear of the dark as an error to be corrected would deserve to be ignored, and would also be wrong. The Foundation does not ask anyone to feel safe in a place where they do not. Its position in this subsection concerns what quantity of light the evidence actually supports, and the evidence on perceived safety turns out to point in the same direction as the evidence on recorded crime.

The Foundation takes the following from a commentary at Appendix D.1 and states its character first: it is a signed essay by a lighting consultancy, not research, and the Foundation uses it for the sources it collects rather than for any finding of its own. The consultancy works in the field of light pollution, which is an interest, disclosed here as this comment discloses the interests at Appendices C.114, C.117 and C.118.

Two propositions in it bear on this subsection and both are taken from work the Foundation has not read and must obtain. The first concerns how much light is needed for a person to feel safe. In an experimental study placing volunteers in nighttime streets in several Israeli cities under varied lighting, feelings of safety are reported to rise fastest in going from no light to low intensity, and then to level off rapidly as light is increased further. If that holds, the subjective justification for outdoor lighting is satisfied at low light levels and is not advanced by high ones. The essay adds, and the Foundation records it as an assertion rather than a finding, that high light levels can make people feel as though they are in a spotlight and so feel more exposed rather than less.

That matters to the question before the Department because it separates two things that are usually run together. A person's need to see and to be seen is real and is met at modest luminances. The luminances actually installed, measured in Part VI at hundreds and thousands of candelas per square meter, are not explained by it. Whatever is driving those values, on this evidence it is not the amount of light a person needs in order to feel safe.

The second proposition is displacement. Work reported there on British streets is summarized as finding that the absence of street lighting "may prevent theft from vehicles, but there is a danger of offenses being temporally or spatially displaced". The Foundation records that because it cuts against a simple reading of the null results above: an intervention may move offending in time or place without changing the total, and a study measuring one area may miss that. It is a reason for caution about all the results in this subsection, including the ones the Foundation relies on.

How the statistician whose work this subsection rests on puts it

The essay quotes the author of the Leeds study directly, and the Foundation reproduces both passages because they state the position more compactly than the papers do. On the state of the literature:

> "Studies which purport to show large lighting benefit for public safety tend to be of poor scientific and statistical quality, done by those with poor scientific and statistical

> background. [Even] better quality, large temporal- and spatial-scale studies are unable to detect any public safety lighting benefit."

And on the relationship between the feeling and the fact:

> "It is hardly surprising that human beings are uneasy about the dark as we are a daytime species" — but "[our] unease does not mean that a less brightly lit night is dangerous in terms of both crime and road traffic collisions."

That is the distinction this subsection exists to draw, and the Foundation adopts it. The unease is real. The inference from the unease to the necessity of the installed luminances is what the evidence does not support, and it is that inference, rather than the unease, that the Foundation asks the Department not to adopt when it comes to weigh the biological question.

How much light a person needs in order to feel safe, measured

The passage above reports, from a commentary, that the subjective benefit of outdoor lighting saturates at low levels, and records that the Foundation did not know at what level. It has now obtained the study and this passage replaces that account and supplies the figure.

Svechkina A., Trop T. and Portnov B.A., How Much Lighting is Required to Feel Safe When Walking Through the Streets at Night?, Sustainability, volume 12, number 8 (2020), article 3133, open access, described at Appendix C.122. Department of Natural Resources and Environmental Management, University of Haifa. Funded by the Israel Science Foundation. The authors declare no conflict of interest.

What was done

One hundred and six people walked designated routes through ten residential neighborhoods in three Israeli cities after dark, and at each of 257 marked points reported how safe they felt, on a four-point scale, through a mobile application that would not accept a reading unless the satellite position matched the designated point and the time was between thirty minutes after sunset and midnight. Seven thousand two hundred and fifty-five individual assessments were collected.

At the same points the illuminance was measured instrumentally with a chroma-meter, following the measurement methodology of the International Commission on Illumination, in three ways: horizontally at ground level, vertically in the direction of walking at a height of 1.5 meters, which is the illuminance on the observer's face, and vertically across an arc of about one hundred and twenty degrees. The Foundation draws attention to the design, because it is the kind of study the comment asks for elsewhere: a reported human response and an instrumental measurement of the optical quantity, taken at the same place at the same time.

The measured levels were ordinary. The horizontal average was 18.52 lux, the panoramic 11.92 and the directional 11.37, which the authors note is close to the 15 lux recommended by that Commission.

The finding

Feeling of safety rose with illuminance, significantly and positively, in every model. The Foundation reports that first because it is the authors' first finding and because this comment does not dispute that light at night helps people feel safe.

The shape of the relationship is the finding that matters. Taking the logarithm of the illuminance improved the fit of the model from an R-squared of 0.13 to one of 0.32, which the authors say "indicates that the relationship between FoS and illumination is, in fact, non-linear", and that "there are diminishing FoS returns, as increasing illumination to high levels leads to smaller and smaller improvements". Their conclusion states the level:

> "our analysis indicates that reasonably high assessment of FoS may occur at relatively low illumination levels of 5–10 Lux, and that increasing illumination levels beyond this threshold may result only in a minor rise in FoS levels."

And they name the belief that this displaces: "This result confirms that the conclusion 'the brighter—the better' is a common misconception, which may lead to unnecessary energy waste."

Five to ten lux is the figure this comment has lacked. It is an illuminance at the point where the person is standing rather than a luminance of a source, and the two are not interchangeable, as Part V.B.2 explains. But it is a measured answer to the question what quantity of light the subjective justification for outdoor lighting actually requires, and it is a small one.

That the requirement is not the same everywhere

The authors also found that the illuminance needed to reach a given feeling of safety differed markedly between cities: to reach the sample average, about 5.67 lux sufficed in Haifa while about 24.46 lux was needed in Be'er Sheba. They attribute the difference to the socio-economic position and recorded crime of the latter city and to the stronger daylight its residents are accustomed to, and they draw the conclusion that a "one-size-fits-all" approach to night lighting is "another misconception".

The Foundation records that because it cuts against any proposal to fix a single number nationally, including its own. What people need differs by place and by population. It does not disturb the central finding, which is that in all three cities the response curve flattened: the authors report "leveling-off of the FoS response curves" for all of them.

What this study does not say, including about spectrum

The Foundation states two limits, the second of which is important to a proposition this comment might otherwise be tempted to make.

First, the study measures a reported feeling, not safety. It is not evidence about crime, and the Foundation does not offer it as such.

Second, and this is the one to be careful about: the study says nothing about the color of the light. The authors selected their sites on a design that deliberately crossed high and low illumination with predominantly short-wavelength and predominantly long-wavelength sources, so both kinds are present in the sample. But they then analyzed illuminance alone. They state that of the attributes their observers rated, only illuminance and feeling of safety were used, and that light temperature, glare and uniformity "are meant to be investigated in follow up studies". Their limitations section repeats it: the analysis "solely focuses on illuminance" and follow-up studies should look into light temperature and the rest.

So this study does not show that amber or other long-wavelength light delivers the same feeling of safety as short-wavelength light at the same illuminance. The Foundation has not found a study that shows it, and does not assert it. What can be said is narrower and still useful: the diminishing returns reported here hold across a sample containing both spectral types, and the authors themselves set the spectral question down as unanswered and in need of work. The Foundation adopts that as one of the research questions it asks the Department to put in hand.

The Foundation notes one thing the authors do say about spectrum, in their introduction and on the authority of other work rather than their own data: that the evidence of adverse effects of short-wavelength outdoor lighting on circadian rhythm and melatonin secretion in people and wildlife "cannot be ignored", while the health and ecological impacts of long-wavelength light "appear to be less severe". That is a statement about health and not about perceived safety, and the two have not been joined by measurement. Joining them is precisely the work that is missing.

A fourth consideration, which concerns the quality of light rather than its quantity

The passage above establishes how much light is needed for a person to feel safe. A separate body of work addresses what kind, and the Foundation brings it forward with its weakness stated first: the account the Foundation has is an explanatory article in The Conversation of 28 May 2019 by researchers describing their own work, catalogued at Appendix D.1. The underlying research, by Plan International Australia, the XYX Lab at Monash University and the engineering consultancy Arup, has not been obtained. No statistical detail is given in the article: no sample description beyond a count of sites, no measures of uncertainty, no method of analysis. The Foundation reports it as a signpost to work that must be obtained, not as a finding it relies on.

The subject is the perceived safety of young women in Melbourne, analyzed across more than eighty locations the women themselves identified as unsafe, with lighting measured at those locations.

The finding on quantity, and the reason the Foundation does not rely on it

The authors report that higher light levels were associated with being perceived as less safe, not more: that sites with higher light levels "are more likely to be perceived as unsafe sites" and that "the average light level across these sites was twice what was measured across safe sites".

The Foundation does not advance that as evidence that brighter lighting makes people feel less safe, and the Department should not read it so. The comparison is between places, not within a place before and after a change. The locations women identify as unsafe are disproportionately the busy, central, transit-adjacent places where harassment occurs, and those are also the places cities light most heavily. The association is exactly as likely to arise from that as from any effect of light on feeling. This is the same objection the Foundation makes at Appendix C.119 to the Vienna correlations, and it applies here with the same force and against its own interest. The Foundation records the finding and declines to use it.

The findings on the character of the light, which are the useful part

Three propositions in the article do bear on the question this comment puts, and the Foundation sets them out as reported.

The first is about uniformity and glare. The authors report that "consistent and layered lighting – where there are multiple light sources and where surfaces with different reflective values are taken into consideration – makes women feel most safe", and that this "reduces the 'floodlit effect', the sharp drop-off of light beyond the path, and the potential for glare and contrast to blind and disorientate". The two named mechanisms, glare and contrast, are the subject of Part V.C and Part VI.B.1. What is described is a lighting design that is dimmer in the bright places and better distributed, and it is reported as the design that reassures.

The second is about spectrum, and it is the first source the Foundation has found that addresses it: that "the human visual spectrum reacts better to warm light", that the data from the young women "showed how sensitive they are to cool white light with regard to feeling safe in cities", and that "Spaces with warmer colour temperatures are perceived as safer places". The article records that urban light-emitting diodes are mostly 4000 kelvin cool white or above.

The third qualifies the second and the Foundation gives it equal weight, because it corrects a position this comment might otherwise have taken. The same research found that the women did not want the old orange lamps back. The article reports that the lowest color rendering came from sodium luminaires "that make everything look overly yellow", and that the women "preferred a high-quality LED light that enabled them to distinguish shapes and colour, helping to create a sense of safety".

So the reported preference is not for amber light and not for a return to low-pressure sodium. It is for a warm correlated color temperature combined with good color rendering, which is a property narrow-band amber sources do not have. The Foundation states that plainly because the distinction matters to any recommendation it makes: a person who cannot distinguish shapes and colors does

not feel safe either, and a spectral recommendation framed simply as less blue would not capture what this research reports. What it reports is a combination — lower correlated color temperature, high color rendering, better uniformity, less glare — and the Foundation adopts that formulation rather than a simpler one.

And a measurement point, reached from a third direction

The authors close on the instrument, and the Foundation records it because the same observation now arrives from three unrelated fields. They write that illuminance, the light falling on a surface, "is the only unit of measurement required to comply with the P Categories of the Australian Standards", and that on their results other metrics "such as luminance (light bouncing off a surface and hitting the observer's eye) should be considered too".

Part V.B.2 makes that argument from optics. Part VI.J.6 makes it about the criterion governing electronic billboards, which is expressed in illuminance at a distance and cannot constrain what reaches the retina. Here it is made by lighting engineers about a national roadway and public space standard, on the ground that illuminance does not describe what the eye actually receives. Three fields, three instruments, one quantity missing from all of them.

What a police force told its own oversight body

Everything above in this subsection is research. This is not. It is an operational report by a police force to the authority that oversees it, and the Foundation brings it forward for that reason rather than for its method, which is weak.

Essex Police, 108/16 Update on Part-Night Lighting, version 2.4, reported to the Office of the Police, Fire and Crime Commissioner for Essex for the meeting of 30 November 2017, approved 16 November 2017, author Matt Robbins on behalf of the chief officer. Marked official. Described at Appendix D.1.

Essex County Council switched its street lights off between one and five in the morning across twelve districts, after piloting from 2007, with the arrangement formally introduced on 30 March 2015. The force compared crime, anti-social behavior and killed-or-seriously-injured collisions in the districts that adopted it against two districts that did not. Its executive summary states:

> "There is no evidence of a relationship between PNL and levels of crime, ASB or KSIs in areas where PNL was adopted, when compared with control areas that never took up the initiative. The findings from this report support previous research conducted by Essex Police, as well as that of a national, independent study."

The national study referred to is the multi-authority study discussed above, to which the report records that Essex Police contributed data.

Why the Foundation does not treat this as evidence

The method is a comparison of raw percentages between two periods, with two unmatched districts serving as controls. There is no regression, no adjustment for anything, no confidence interval and no test of significance. It is the uncontrolled before-and-after design that the studies above were written to criticize, and the Foundation applies that criticism here as it has applied it to the Vienna comparison and to the business case that prompted the Leeds work.

The report's own figures bear that out. Over the shorter comparison window crime between one and five in the morning rose 8.2 percent in the districts that switched off and 18.4 percent in those that did not; over the longer window the same measure rose 18.5 percent in the switched-off districts and 10.3 percent in the others. The two windows point in opposite directions and the report does not reconcile them. It also records that crime rose at every other hour of the day as well, and that crime had risen across Essex and nationally.

Its own list of caveats is more damaging still, and the Foundation reproduces the decisive one. The force states that it cannot tell from its records which offenses happened outdoors: many offenses

included in the analysis "may therefore have been committed within premises". A street lamp cannot affect a crime committed indoors. The force also records that it does not know which streets within each district were switched off, so that offenses in town centers, where the lights stayed on, are inside the figures. And the collision counts are too small to carry percentages: two against six, three against nine, with the report twice noting that low numbers skew the comparison.

The Foundation therefore takes no number from this document. What it takes is the position of the body that produced it.

The two things it does establish

The first is institutional. A police force, examining its own data about its own county, across several analyses over several years, told its own commissioner that it could find no relationship between switching street lights off and crime, and recorded that "There are no current plans for future analysis in this area given the findings from multiple analyses over different time periods". That is not a finding about light. It is the operational position of the kind of body most likely to assert a link, stated in a document written for internal purposes rather than for publication.

The second is an absence, and it is the reason this document belongs in a comment to this Department. The report carries a standard set of headings for the implications of what it describes. Under equality and human rights it records no identified impact. And under health and safety it records, in full:

> "There are no identified implications with regards health and safety."

An entire county changed the lighting of its public realm. The police force examined the consequences and reported to its oversight body under a heading expressly directed to health. The entry is empty. The Foundation does not suggest that the force should have found something; identifying the health consequences of changing the optical environment of a county is not the function of a police force and it has no competence to do it. The point is that the heading existed, the question was formally asked, and no body with the competence to answer it was anywhere in the process. That is the condition this comment describes: decisions about the optical radiation to which whole populations are exposed are taken by authorities whose remit is traffic, crime and cost, with the health box ticked empty because there is nobody to fill it in.

The other half of the safety claim, which is road collisions

This subsection is titled crime and safety and has so far concerned only crime. The same investigators applied the same method, to the same city, over the same period, to road traffic collisions, and the Foundation records the result because collision reduction is the other justification offered for converting street lighting to white sources, and because it is the justification that bears on Part VI.D.

The account below is taken from a short feature by the same two authors in Significance, the magazine of the Royal Statistical Society and the American Statistical Association, described at Appendix D.7. The Foundation states its character: it is signed commentary summarizing the authors' own research, not the research itself, and the underlying papers have not been read.

In Leeds, across the same 456 weeks and 107 areas, nearly 14,000 collisions in daylight and over 5,000 in darkness were reported. The confidence interval for the effect of the relighting on the daylight adjusted darkness collision rate runs from about a 20 percent reduction to about a 10 percent increase. Null. Combined with a companion study of the relighting of Birmingham, the authors report that the interval narrows and "moves in the direction of harm", to a 16 percent reduction to a 12 percent increase.

And the multi-authority study already described in this subsection returned the same answer on collisions as on crime. Its white light conversion covered 15,833 kilometers of road across 62 local authorities, and the authors report its collision interval as a 7 percent reduction to a 9 percent increase. In their words, that study "found all its results to be null, despite its extensive data, both for

lighting reductions and for whitening, for all the investigations of lighting's effect on both RTCs and crime".

The authors state the limit of their own result and the Foundation adopts the statement rather than overreading them: "Not being able to detect any effect is, of course, not the same as there being zero effect. Also, of course, the result is consistent with either a little benefit or a little detriment."

Why the Foundation puts this before a health agency

The authors offer an explanation for how a conversion of this size proceeds on evidence this thin, and it is the reason this subsection exists in a comment to this Department. They write that lighting research is often done by people with a technical background but without professional statistical support, and draw the comparison themselves:

> "such work, although having potentially large consequences for both public finances and the environment, does not get the same level of checking as much of that done, for example, in health care. Also, some of those public servants assessing lighting proposals are likely to be ill-equipped to make satisfactory judgements on any purportedly scientific evidence with which they are presented, as they are unlikely to have sufficient scientific/statistical background to spot flaws."

The comparison is to health care, and it is the authors' own. The Foundation does not contend that street lighting should be regulated as a medical device. It contends that the optical emission of these products is electronic product radiation within the meaning of the statute discussed at Part II, that Congress assigned the biological consequences of such radiation to this Department, and that the passage above describes exactly what happens to a technical question about optical radiation when no body with that mandate is engaged with it.

Their conclusion is one sentence and the Foundation rests this subsection on it: "The more recent results from the large-scale, better-quality research mentioned above may suggest that the high levels of lighting currently used may not be justified."

Where this subsection hands over

The same authors identify what the costs are that the absent benefit fails to offset, and in doing so they name the two properties this comment has been concerned with throughout. They write that the costs of lighting are not only financial, that the effects on biodiversity are considerable, and then:

> "White light is comprised of all the colours of the rainbow. Other organisms with which we share our planet have different responses to the various wavelengths of light radiation. The blue component of white light is thought to be particularly damaging because it signals daytime."

And on intensity, in a sentence that answers the commonest reply to any complaint about modern luminaires: "Although the design of modern lamps allows the directionality of emitted light to be better controlled, the increasing brightness means more light is scattered from surfaces into the environment." Better optical control does not compensate for more output, because what is controlled is the direction of the beam and not the light that leaves every surface the beam lands on.

Spectrum and intensity: the two quantities. The authors are writing about other organisms, and Part V.I takes up that question. The Foundation's submission is that the same two quantities govern the effects on people set out in the rest of this Part, and that the agency charged with the second of those is this one.

The limits of what the Foundation claims, stated plainly

A reader may be tempted to assemble the material in this subsection into a stronger proposition than it supports, and the Foundation forecloses that here. The evidence set out above establishes that the claimed safety benefits of brighter and whiter outdoor lighting have not been demonstrated. It does not establish that such lighting increases crime, and it does not establish that it increases

collisions. The correlational study at Appendix C.119 cannot bear that weight and the Foundation has said so there.

Nor does the Foundation assert that it knows the correct quantity or spectrum of outdoor light. There is reason to think an optimum exists below current practice: the perceived-safety evidence reported above suggests the subjective benefit saturates at low levels, while the biological and ecological costs described in this Part scale with intensity and with short-wavelength content. If both halves of that hold, then increasing output past the saturation point adds cost without adding benefit. The Foundation advances that as the reason the question should be studied and a limit set, not as a finding it has made. Identifying where the optimum lies, and in what quantities it should be expressed, is the work the Foundation asks the Department to put in hand at Part IX.

The collision study read at source, and what the city relied on

The preceding passage reports the road collision results from a magazine feature by their authors. The Foundation has now obtained the study itself and this passage replaces that account. Marchant P.R. and Norman P.D., To determine if changing to white light street lamps improves road safety: A multilevel longitudinal analysis of road traffic collisions during the relighting of Leeds, a UK city, Applied Spatial Analysis and Policy, volume 15 (2022), pages 1583 to 1608, open access, described at Appendix C.120. The protocol was lodged with the same three named custodians on 5 August 2016 and the analysis dataset is published in a public repository.

The figures, stated precisely

Across the same 456 weeks and 107 areas, 13,977 collisions in daylight and 5,302 in darkness were recorded. The measure is the daylight adjusted darkness collision rate ratio, which is the factor by which the ratio of darkness to daylight collisions is multiplied by a given amount of relighting.

- For each one hundred replaced lamps, the ratio is 0.990 with a ninety-five percent confidence interval of 0.971 to 1.010, being a 3 percent reduction to a 1 percent increase.
- For a typical area, which received about seven hundred lamps, the ratio is 0.934 with an interval of 0.816 to 1.070, being an 18 percent reduction to a 7 percent increase.
- Modeled instead on the fraction of the relighting completed, full relighting of an area gives 0.920 with an interval of 0.776 to 1.09, being a 22 percent reduction to a 9 percent increase.

The authors noticed an anomalous pattern in the official collision data for 2012 and 2013 and repeated the analysis on a series truncated at the end of 2011, which they describe as the more trustworthy. That gives 0.993 with an interval of 0.971 to 1.015 per hundred lamps, and for a typical area an 18 percent reduction to an 11 percent increase. Their own summary of the range is that it “resides somewhere between a 20% reduction to a 10% increase”. Every interval includes no change.

Combined with the companion study of Birmingham in a fixed-effect meta-analysis, a typical area gives 0.952 with an interval of 0.838 to 1.082 using the full Leeds series, and 0.971 with an interval of 0.842 to 1.119 using the truncated one. The second of those is the figure reported in the preceding passage as a 16 percent reduction to a 12 percent increase, and the Foundation notes that the full-series combination gives a 16 percent reduction to an 8 percent increase. Both are in the paper and the comment should not quote one without knowing which it is.

The multi-authority study gave a collision rate ratio of 1.01 with an interval of 0.93 to 1.09 for conversion to white light across 15,833 kilometers of road, against about 2,800 kilometers in Leeds. For the region containing Leeds alone it gave 0.96 with an interval of 0.81 to 1.15.

What the city put forward, and what those documents actually said

This is the material the Foundation most wishes to place before the Department, because it is a documented account of how a public body came to spend a large sum on an optical intervention, and it is checkable.

The city's bid asserted: "Nationally, there is evidence that good street lighting can reduce night-time road accidents by between 15 and 35% (source – Institution of Lighting Engineers, also TRL reports 586 and 929)." The authors examined both reports.

Of the first, Sabey and Johnson (1973), a controlled before-and-after study of trunk road sites, they write that it is "surprising that this study was referenced by Leeds in its bid to acquire new street lighting, as it showed variable effect on safety and none were statistically significant for the roads on which there were 30, 40 and 50 miles per hour (mph) speed limits". Only roads with a seventy mile per hour limit showed a statistically significant effect. The authors add that roads of fifty miles per hour and below "form the bulk of those in Leeds and indeed other UK cities".

Of the second, Scott (1980), the authors state that its design is cross-sectional, comparing different roads having different lighting levels, and that such a design "allows many confounding factors to mislead". The Foundation notes that this is the same objection it records at Appendix C.119 against the Vienna correlations, applied here to a study relied on for the opposite conclusion.

And then the fact that the Foundation regards as decisive about that second report. A systematic review of street lighting for preventing road traffic injuries was carried out under the auspices of the Cochrane Collaboration. It identified 145 potentially relevant studies and included seventeen. It found no randomized controlled trials at all; all seventeen were controlled before-and-after studies; the collision counts in them were mostly under one hundred; none was at the scale of a city; and the review records that "the methodological quality of the included studies was generally poor". The present authors then state:

> "Note the Cochrane Review did not include the study report 929 (Scott, 1980), used to justify the Leeds relighting scheme, because of its poor methodological design."

So of the two technical reports named in the bid, one showed no statistically significant effect on the class of road that makes up most of the city, and the other was excluded from the systematic review of this very question on grounds of poor design. The Foundation does not suggest that anyone misled anyone. It observes that this is what the evidentiary basis for a major optical intervention looked like when somebody with statistical training went back and read it, and that nobody with such training had been required to read it at the time.

The authors reach the same conclusion in their own terms: "the evidential basis, for the claim that changing street lighting would improve road safety, was weak".

Three things in the paper that qualify it, which the Foundation records

First, the authors disclose two departures from their own protocol: the focus on the daylight adjusted darkness rate is described as a variation from the outcomes the protocol specified, though the specified outcomes are also reported, and an analysis at a smaller spatial scale that the protocol contemplated was not done, for want of time. The Foundation has praised the procedural discipline of this group's work and it reports the deviations in the same breath. They are disclosed in the paper, which is the point of lodging a protocol.

Second, the authors identify a suspect pattern in official national collision data for 2012 and 2013 and handle it by analyzing both the full and the truncated series rather than choosing one. The Foundation reports both above for the same reason.

Third, and this is a finding about darkness that runs in an uncomfortable direction, the paper reports that while daylight collisions across the city fell markedly over the period, collisions in darkness stayed roughly constant, so that the darkness to daylight ratio was rising throughout, independently of any lighting change. The authors suggest increased night-time road use or increased risky behavior at night as possible causes and do not resolve it. The Foundation records it because a comment arguing that darkness is not dangerous must not pass over a measured, unexplained rise in the relative collision burden of darkness. Nothing in the paper attributes that rise to lighting, and nothing in it shows that more or whiter lighting would have arrested it.

What happened where lights were switched off

Every study so far in this subsection asks whether adding or whitening light reduces crime, and finds that it cannot be shown to. This one asks the question from the other end, on data fine enough to answer it street by street, and the Foundation gives it the space it does because its central result is the strongest empirical finding against the proposition this subsection examines.

Tompson L., Steinbach R., Johnson S.D., Teh C.S., Perkins C., Edwards P. and Armstrong B., Absence of Street Lighting May Prevent Vehicle Crime, but Spatial and Temporal Displacement Remains a Concern, Journal of Quantitative Criminology, volume 39 (2023), pages 603 to 623, open access, described at Appendix C.121. The authors are of the University of Waikato, University College London, the London School of Hygiene and Tropical Medicine and other bodies. Funded by the National Institute for Health Research under the same grant as the multi-authority study discussed above. The authors declare no conflict of interest.

What was done

Ten years of police recorded crime from the Thames Valley force area, April 2004 to September 2013, comprising 283,275 offenses: residential burglary, robbery, theft of vehicles, theft from vehicles and violence. The street network was divided into 33,804 segments. Of those, 815 had their lights switched off between midnight and six, 1,315 were dimmed, and 958 had orange sodium lamps replaced with white light. Crimes were classified to night or day by civil twilight. Analysis was by conditional Poisson regression in a controlled interrupted time series, so that each segment serves as its own control and anything constant about a street drops out.

Two features make this the most sensitive test in this subsection. The unit is the street segment rather than an administrative area, and the authors modeled the streets immediately adjoining each treated street separately, which is what allows displacement to be seen at all. The multi-authority study at Appendix C.118 could not do this; these authors note that it was confined to area-level data and could not separate night from day.

The result

Switching the lights off at midnight was associated with less crime, not more. On the streets where it was done, after adjusting for daytime crime, night-time crime of all kinds fell, with a rate ratio of 0.74 and a confidence interval of 0.63 to 0.87, and theft from vehicles fell further, 0.56 with an interval of 0.41 to 0.78.

Measured across the whole day rather than at night only, the same streets show total crime at 0.81 with an interval of 0.75 to 0.88, burglary at 0.75 with an interval of 0.65 to 0.85, and violence at 0.83 with an interval of 0.71 to 0.97. And the adjoining streets, over the whole day, also showed reductions: total crime 0.83 with an interval of 0.76 to 0.89 and violence 0.75 with an interval of 0.64 to 0.89.

Taking the treated streets and their neighbors together, which is the measure of what the intervention did to the local network as a whole, the authors report a net reduction: total crime 0.83 with an interval of 0.79 to 0.88, burglary 0.85, theft from vehicles 0.90, and violence 0.79 with an interval of 0.70 to 0.88.

The Foundation states the proposition carefully. On these data, in this force area, over ten years and across thirty-three thousand street segments, turning the street lights off for the second half of the night was followed by less recorded crime, and the reduction survived when the surrounding streets were counted in.

The finding in the title, which the Foundation does not omit

The study is named for its qualification and the Foundation gives it equal prominence. One offense moved. Theft from vehicles fell sharply on the unlit streets and rose on the adjoining lit ones, with a rate ratio of 1.55 and an interval of 1.14 to 2.11, and the authors report that the reduction and the

increase were equal in magnitude. Night-time crime of all kinds on adjoining streets rose by about eighteen percent, 1.18 with an interval of 1.02 to 1.38, driven by that one offense.

Dimming shows the same thing displaced in time rather than space: night-time vehicle crime fell relative to daytime, but theft from vehicles across the whole day rose, and the net figure for dimming on treated and adjoining streets together is an increase, 1.16 with an interval of 1.04 to 1.29.

So the honest statement of this study is not that darkness prevents crime. It is that the effect depends on the offense, that for one offense the problem moved next door, and that for the network as a whole the balance was nonetheless favorable.

The mechanism the authors identify, which is the point of this subsection

The reasoning is about what a thief needs in order to work. Quoting a study of rural electrification, the authors note that "lighting illuminates objects (i.e., objects of value)". An offender walking a dark street cannot see which cars hold anything worth taking, cannot judge the security of a vehicle, and cannot remove fittings or search an interior without producing a light of his own, which announces him. They conclude:

> "The findings of this study suggest that the mechanism by which street lighting has been proposed to reduce crime—increased visibility at night—may be one that can also increase vehicle crime. This speaks to the inherent specificity in the opportunity structure of different crimes; environmental features make some types of crime more likely whilst simultaneously making other types of crime less likely."

That is the sentence the Foundation places before the Department. The mechanism asserted to justify lighting the public realm — that visibility deters offending — is shown by these authors to work in both directions, because the offender needs to see as much as the guardian does. It is not a reason to make the country dark. It is a reason why the proposition that more light is more safety cannot be assumed, and must not be the ground on which a health authority declines to examine the emission.

What this study says about white light specifically

Three findings, and the Foundation reports all three because the third runs against it.

- At night, which is when an optical effect would have to appear, there was no evidence that white light was associated with a change in any crime type examined.
- On streets adjoining those converted to white light, night-time crime overall fell slightly, 0.87 with an interval of 0.77 to 0.99, driven by violence at 0.74 with an interval of 0.61 to 0.91.
- Measured across the whole day, white light was associated with a reduction in total crime, 0.91 with an interval of 0.83 to 0.99, driven by burglary at 0.72 with an interval of 0.62 to 0.83; and the net figure for burglary on treated and adjoining streets together is 0.84 with an interval of 0.77 to 0.92.

The third is a crime reduction associated with white light and the Foundation does not minimize it. It does draw attention to what the authors make of it, because the explanation decides what follows for this comment. A benefit appearing across the whole day and not at night cannot be a visibility effect, since the lamps are off in daylight. The authors therefore attribute it to community cohesion: that replacing the lamps is read by residents as investment in the neighborhood, which prompts the informal social control that reduces crime. They had predicted in advance that a visibility mechanism would show itself at night and a cohesion mechanism would show itself equally by day and night, and the pattern they found is the second.

If that is right, the benefit attaches to the fact of the municipal improvement and not to the spectrum of the lamp. A signal of investment could be sent by any visible improvement, at any correlated color temperature, at any luminance. Nothing in this result requires the short-wavelength content whose

biological effects the rest of this Part describes. The Foundation does not assert that the authors' explanation is correct; it asserts that on their own data the white light benefit did not appear in the place where an optical mechanism would have put it.

The limitations, including one the Foundation regards as serious

The authors record that the lights chosen for switching off were selected under published exemption criteria: lights at major junctions, in town centers with closed-circuit television or night-time activity, where lighting was needed to reduce road accidents, and where crime might increase through reduced lighting, were all exempt. The authors rely on this to show that the changes were not made in response to crime, which supports treating them as exogenous.

The Foundation records the other side of the same fact. The streets that had their lights turned off were, by the design of the criteria, the streets least likely to suffer from it. The authors acknowledge the related possibility that part-night lighting may have been applied to streets with the lowest pedestrian traffic after midnight, and that the switch-off may itself have deterred people from walking or parking there, reducing the opportunity for crime by reducing the targets. They were unable to test it. The result above should therefore not be read as showing what would happen if a city switched off every light, which is not what was done and not what the Foundation proposes.

The same question asked of three hundred thousand broken lamps

The comment has recorded twice that the only randomized evidence in this field found a benefit from adding light, and has qualified it by noting what was installed. The lead author of that study has since examined the question the other way round, on a scale that dwarfs everything else in this subsection, and the Foundation sets out what he found.

Chalfin A., Kaplan J. and LaForest M., Street Light Outages, Public Safety and Crime Displacement: Evidence from Chicago, described at Appendix C.123. The first two authors are of the University of Pennsylvania and the third of the University of Chicago. The Foundation has read the manuscript posted by the first author's department and notes that a version appears to have been published subsequently under a different title.

The design, which is the reason the Foundation reports it at length

Street lights fail and are repaired. The authors use nearly three hundred thousand outages in Chicago over an eight-year period, affecting nearly fifty thousand street segments, giving about one hundred and forty million observations. Because the date on which an outage begins is known only when a resident reports it, but the date of repair is recorded precisely, they compare crime in the days immediately before a repair with crime in the days immediately after. The result is close to a regression discontinuity in time, and it tests the effect of a sudden, involuntary, local loss of light.

The scale permits two things no other study here can do. It separates major outages, where more than two lamps on a segment are dark, from minor ones. And it has the power to measure what happens on the streets within five hundred feet. The authors also run placebo tests on daytime crimes and on indoor night-time crimes, neither of which should respond to a street lamp, and report that neither does.

What happened where the lights went out

On the street where the lamps were dark, during a major outage, index crimes rose by two percent, violent crimes by one and property crimes by one, none of it statistically significant, with a confidence interval for index crimes running from minus three to plus six percent. The authors state the reading themselves:

> "The most reasonable interpretation of these results is that street light outages do not appreciably impact crime in the short-term on affected street segments."

Where one or two lamps only were out, there was nothing at all: the authors report coefficients "uniformly small and of mixed sign" for both the affected street and its neighbors, and conclude that "ambient lighting has a non-linear effect on crime". Losing a little light did not register.

The Foundation asks the Department to weigh the source of that null. It is not from a critic of street lighting. It is from the author of the one experiment in this field that found a crime reduction from adding light, working on a hundred and forty million observations, and reporting that removing light from a street did not appreciably change crime on it.

What happened next door, which the Foundation reports with equal prominence

Crime rose on the surrounding streets. Index crimes on segments within five hundred feet rose about three percent during an outage, violent crimes about two and property crimes about three, each significant at the conventional level because of the size of the data. Robberies on adjacent segments rose about seven percent, with a confidence interval of 0.6 to 13.4 percent. Motor vehicle theft is the exception to the pattern: it rose about nine percent on the dark street itself and about six percent next door, though neither quite reached significance.

The authors conclude that street light outages "compromise public safety in ways that can have downstream effects on an entire community", and calibrate the magnitude: a six to seven percent rise in robberies and vehicle thefts is, they say, what one would expect from reducing a city's police force by between five and fifteen percent. The Foundation reports that without qualification. It is an adverse finding and it is from a large and careful study.

The mechanism, and the distinction on which this passage turns

The authors explain the pattern by the movement of people rather than by the behavior of offenders alone. A robbery requires a victim to be present. If a street goes dark, people avoid walking down it, so there are fewer people to rob there and more on the next street. A vehicle theft requires no victim to be present, and a car parked in daylight cannot move when the lamp above it fails, so vehicle theft rises where the darkness is. The authors put it as the general principle that the effects of place-based measures "can be mediated and indeed shaped to a considerable degree by the behavior of potential victims".

The Foundation draws the distinction that follows, and it governs how this study and the one at Appendix C.121 should be read together. Displacement of this kind requires a gradient. What moved people and offending in Chicago was not darkness but the difference between one dark street and a lit street fifty yards away; and in the English study the same thing happened, theft from vehicles moving from the unlit street to the lit one beside it. Those authors said so in terms, observing that where the coverage of a lighting change is more extensive such spillover is less likely, because an offender would have to seek out an unfamiliar area instead of walking round the corner.

A broken lamp on one street is therefore not a model of a lighting standard. It is a model of an anomaly. What these two studies establish together is that a sharp local differential in lighting moves crime toward the lit side; what neither of them tests, and what no study the Foundation has found tests, is a uniform reduction in luminance or in short-wavelength content applied across a whole jurisdiction, where there is no better-lit street to move to. That is the measure this comment is concerned with, and the Foundation says plainly that it is untested rather than claiming support these studies do not give it.

A finding about who suffers outages, which the Foundation records because it must

The authors report that higher-crime areas of Chicago suffer more street light outages and that those outages take longer to repair than in lower-crime areas, and conclude that "municipal neglect contributes to unequal crime rates that are experienced by different neighborhoods".

The Foundation places that here deliberately. Nothing in this comment should be capable of being read as an argument for leaving broken street lamps unrepaired in poor neighborhoods, and the Foundation disclaims that reading in terms. Its position concerns the optical characteristics of

lighting that is installed and working — how bright, what spectrum, what modulation — and not whether municipalities should maintain their equipment. A city that chose a lower luminance and a longer wavelength would still owe every neighborhood the lighting it has specified, maintained to the same standard. The Foundation's objection to unequal exposure, set out at Part VIII, runs the same way: the people least able to avoid a badly-chosen lighting environment are the people who most need the choice to be made carefully.

The one study of this question a health department commissioned

The subsection closes with the study the Foundation regards as the most important document in it, for a reason that has nothing to do with its crime findings. It was commissioned by a health department, it is the only study in this subsection that was, and in its published conclusions it identified the gap this comment exists to address. It did so in 2015.

Perkins C., Steinbach R., Tompson L., Green J., Johnson S., Grundy C., Wilkinson P. and Edwards P., What is the effect of reduced street lighting on crime and road traffic injuries at night? A mixed-methods study, Public Health Research, volume 3, issue 11 (September 2015), pages v to 107, doi:10.3310/phr03110. Described at Appendix C.124. Known in the field, and earlier in this subsection, as the LANTERNS study.

Three facts about its provenance bear on the use the Foundation makes of it. It was funded by the Public Health Research programme of the United Kingdom's National Institute for Health Research, now the National Institute for Health and Care Research, under project number 11/3004/02. Its copyright notice records that the work was produced "under the terms of a commissioning contract issued by the Secretary of State for Health". And the authors declared no competing interests. So far as the Foundation has been able to establish by its own searching, this is the only study of the consequences of a change to the lighting of the public realm ever commissioned by a health ministry of any country.

The scale, which is the largest in this subsection

Every local authority in England and Wales was approached. Of the 174, the project reached 140 and obtained usable data from 62, covering more than thirty thousand kilometers of road on which lighting had been changed. By December 2013 the participating authorities had installed white light on 15,833 kilometers, part-night lighting on 12,101 kilometers, dimming on 10,519 kilometers and permanent switch-off on 946 kilometers.

The collision series ran from 2000 to 2013 and contained 859,935 collisions, of which 161,049 occurred at night. The crime series ran from December 2010 to December 2013 and contained 581,837 burglaries, 475,657 vehicle thefts, 67,470 robberies and 730,280 offenses of violence. Anti-social behavior and criminal damage, 2,882,758 and 486,367 offenses respectively, were excluded from analysis because some forces reported them incompletely.

The design is the one this subsection has been holding others to. It is a panel analysis with fixed effects, so that anything constant in a street or area over time contributes no information and cannot confound the result; night-time collisions are adjusted by the change in daytime collisions on the same roads; and all four interventions were entered in a single model so that they could not confound each other.

Road collisions: four nulls and one adverse regional signal

The figures below are rate ratios for night-time collisions after adjustment for the change in daytime collisions, which the authors describe as their most robust measure.

- Permanent switch-off: 0.97, interval 0.82 to 1.15.
- Part-night lighting: 0.95, interval 0.84 to 1.07.
- Dimming: 1.00, interval 0.91 to 1.10.

- Conversion to white light: 1.01, interval 0.93 to 1.09.

Restricting the analysis to collisions in which someone was killed or seriously injured, which are the collisions most reliably reported, left the estimates unchanged and less precise. Stratifying by area deprivation produced no association in any stratum.

One regional estimate runs against the national picture and the Foundation reports it where a reader will see it. In London, conversion to white light was associated with an increase in night-time collisions, 1.30 with an interval of 1.03 to 1.65, which the authors describe as weak evidence. The national estimate for the same intervention shows nothing. The Foundation does not present the London figure as establishing that white light increases collisions, and notes that in a study reporting estimates for every region of England and Wales across four interventions, one interval excluding no effect is what chance alone would produce. It records the figure because it is the only quantitative signal the Foundation has located anywhere that converting street lighting to white light was followed by more collisions, and because the authors did not dismiss it either.

Crime: what the study found, including the parts against the Foundation

The crime estimates are expressed for an area in which the intervention reached every kilometer of road, which no area approached, so they must be scaled down before they mean anything. The authors supply the arithmetic: dimming at 0.84 for full coverage corresponds to a two percent reduction where a tenth of road length is dimmed, with an interval running from a four percent reduction to no change at all.

- Part-night lighting: 0.96, interval 0.86 to 1.06. No evidence of an association.
- Permanent switch-off: 0.11, interval 0.01 to 2.75. The Foundation reports this figure only to say that it carries no information. An interval spanning a ninety-nine percent reduction and a near-tripling is a statement that 946 kilometers of permanent switch-off were too few to measure anything, and the authors say so.
- Dimming: 0.84, interval 0.70 to 1.02.
- Conversion to white light: 0.89, interval 0.77 to 1.03.

The last two are the findings in this subsection that run most directly against the Foundation's position, and the Foundation states them as the authors stated them rather than as the intervals alone would permit. The authors characterize both as weak evidence for a reduction in crime. They add that the estimates were directionally consistent: across the offense categories examined, every estimate for dimming and every estimate for white light pointed toward less crime. Two specific estimates are reported, each stopping just short of excluding no effect: part-night lighting with robbery at 1.48, interval 0.99 to 2.21, and dimming with violence at 0.78, interval 0.60 to 1.01.

The Foundation does not represent the white light figure as a null. Elsewhere in this comment it has insisted that an interval crossing one means the effect is not established, and that holds here: 0.77 to 1.03 does not establish a reduction. But the point estimate is a reduction, the authors called it weak evidence of one, and a comment that reported the interval while suppressing the characterization would be doing the thing this comment criticizes others for doing.

The finding that makes the crime results hard to use in either direction

The study found strong heterogeneity between police forces. Of the thirty-one forces analyzed separately, there was strong evidence that part-night lighting, dimming and white light were associated with decreases in crime in some forces and strong evidence that the same three interventions were associated with increases in others. The authors read this as showing the importance of context, and offer two candidate mechanisms that would operate in opposite directions: that switching lights off may signal municipal decline and so generate disorder, and that darker streets may make some offenders feel less conspicuous.

The Foundation draws the conclusion that follows for a federal agency. A national average assembled from estimates that are strongly positive in some jurisdictions and strongly negative in others is not a number on which a nationwide standard can be built in either direction. It is a reason to stop asserting that outdoor lighting levels have a determinate effect on crime, which is the assertion this subsection was written to examine.

The distinction that explains the literature, from the report's own account of it

The report's introduction summarizes the systematic review on which the case for lighting as crime prevention principally rests, and that summary contains what the Foundation regards as the single most useful analytical point in this subsection. The review found a reduction in crime in those studies that examined changes across the entire day, daylight hours included. In the four studies that examined night-time crime alone there was, in the report's words, "no evidence of an impact of changes to street lighting on crime". The report adds that a major limitation of the review was the use of inadequate control areas in the underlying studies: only two used multiple controls, and in some the control area adjoined the treated area.

A street light cannot illuminate anything during daylight. A benefit that appears by day as well as by night is therefore not a visibility benefit, whatever else it may be. The central result in the literature relied on by authorities asserting a relationship between lighting and crime is accordingly a result that cannot have been produced by the mechanism they assert.

That is the second time this subsection has reached that conclusion from independent data. The Thames Valley study above found white light associated with a reduction in burglary measured across the whole day, 0.72, and no night-time effect at all, and its authors attributed the result to community cohesion rather than to visibility on exactly this reasoning. Different data, different decades, different authors, the same place arrived at. The Foundation submits that the convergence is the most defensible proposition in this subsection: whatever crime benefit has been detected in association with improved street lighting, it has not been detected in the hours of darkness, and it is therefore not a benefit of the light.

The consequence for this Department is direct. If the benefit does not depend on the light, it cannot be traded against the biological effects of the light. A municipality that wishes to signal investment in a neighborhood has other ways to do it, and none of them requires short-wavelength content at the retina of every resident for every hour of every night.

Three things in the report that cut against the Foundation, stated before the use the Foundation makes of it

First, perceived safety fell where lights were switched off, and it was measured. The report includes a household survey in one Shropshire area, sampling five hundred households in streets with part-night lighting and five hundred in streets without, returning 483 responses. Of residents in part-night streets, 15.6 percent felt very safe walking alone in their neighborhood after dark, against 26.2 percent in the unaffected streets, an odds ratio of 0.52 with an interval of 0.32 to 0.84. That was the only item in the survey on which the two groups differed significantly, and it is a real cost. The Foundation reports it because Part V.G of this comment treats affective response as a health matter and cannot treat it as one only when the sign is convenient.

Second, the authors identify a confound in their own crime results, and the Foundation adopts their statement of it rather than softening it. They could not account for other crime prevention or road safety measures introduced at the same time, such as closed-circuit television, policing operations or improved road markings, and they write that it is likely such confounding accounts for part of the crime associations they observed. That cuts against the reductions attributed to dimming and to white light, and the Foundation says so for that reason.

Third, the authors record a limitation that bears on the collision nulls and not in the Foundation's favor. They had no measure of exposure. If fewer people walked, cycled or drove on streets where the lighting was reduced, a reduction in casualties could reflect fewer people present rather than no

increase in risk, and any increase in hazard to those who remained could have been masked. They state that they could not test this. The Foundation therefore does not claim that reducing lighting is shown to be safe for a pedestrian. It claims that at the scale of a nation, reductions in lighting were not followed by the increase in casualties that had been predicted.

An internal inconsistency the Foundation does not resolve

Two passages in Chapter 3 cannot both be relied on. The analysis by deprivation reports that the stratum-specific estimates "were not materially different from the overall estimates, and each was imprecise", and states expressly that there were insufficient data for switch-off. The discussion of generalizability then reports that the stratified analyses suggest switch-off was associated with an increase in burglary and vehicle crime in more deprived areas and in city and town centers, while part-night lighting was associated with decreases in less deprived areas. The Foundation can see no way to reconcile a finding about switch-off with a statement that the data for switch-off were insufficient, and it declines to use either passage. It records the inconsistency because the second of them, which is the one that would appear in a summary, is the one the report's own results section does not support.

What the Foundation asks the Department to read, which is in the published conclusions

Everything above concerns crime and collisions. The reason the Foundation places this report last is that its authors, having been commissioned by a health department to study the consequences of changing street lighting, wrote into their published conclusions that the question they had been asked was not the question the public was raising. The abstract's conclusions state that the study found little evidence of harmful effects on road collisions or crime, and then continue:

> "However, the public were also concerned about other health outcomes."

And they close with a recommendation:

> "Research is needed also on other public health impacts of light at night."

The qualitative chapter records what those other concerns were. Among the effects members of the public raised were benefits in sleep with less light pollution; and in urban areas where authorities were installing white light rather than switching lights off, the report records that the concerns raised were more likely to relate to light pollution and to the impact on sleep from existing lights. People given the opportunity to comment on a change to the lighting of their own streets raised, unprompted, the biological subject matter of this comment.

The report measured none of it. Its outcomes throughout are recorded crime and recorded road casualties, which Chapter 3 describes as "two important public health outcomes". No chapter measured a visual, physiological or biological endpoint of light exposure. What the public said about sleep was collected as perception, in interviews and in a survey, and the report is explicit that this is what it is.

Why that is a finding and not a shortcoming

The Foundation makes no criticism of these authors. They were commissioned to answer a question about crime and casualties; they answered it with more rigor than anything else in this subsection; and they then told their funder, in the published conclusions, that a different question needed research. That is what a competent research team is supposed to do. The Foundation's point concerns what happened next.

Part V.M has now placed before the Department a county police force that recorded no health implications because it had no means of identifying any; a city council that assigned a monetary value to a crime benefit and none to a biological one; and a national health research program that identified the public health impacts of light at night as a research need and published that finding in 2015. Three bodies, three levels of government, one country. In each the health question was

reached, and in none was it answered, because in none of them was there a body with both the mandate and the competence to answer it.

The Foundation submits that the Department of Health and Human Services is that body in the United States; that paragraph 360ii(a)(2) of the Public Health Service Act directs the Secretary to plan and conduct exactly the research this report named as needed; and that eleven years have passed since a health ministry put the need in print.

One statement in the report the Foundation does not adopt

The report characterizes the evidence that light at night affects health as weak, citing proposed links to circadian disruption and sleep and, in its own word, theoretical links to anxiety, depression and cancer incidence. That was written in 2015 and the Foundation does not adopt it. Parts V.C through V.G of this comment set out the literature as it now stands, including work on melanopic photoreception that postdates this report, and Part V.K treats the three expert assessments. The Foundation relies on this report for what it establishes about the institutional record and about crime and collisions. It does not rely on it as an authority on the state of the health science, and asks the Department not to, because the report does not claim to have reviewed that science and its characterization of it has been overtaken.

VI. PRODUCTS

This Part sets out what is actually in the exposure environment. It asks the same four questions of each class: what the product is, who is exposed to it and under what conditions, which agency if any asserts jurisdiction over it, and whether any federal emission limit applies. Subsection A states the principle on which the classes are ordered and the characteristics by which they differ. Subsection U reserves a summary of the regulatory position by class, and subsection V treats the tariff classification, which is the one place where this Department already describes these products at the border.

A. Product Taxonomy and Exposure Characteristics

The classes in this Part are ordered by the conditions under which people meet the products, and the Foundation states the principle expressly because the ordering is not obvious and is not what a reader might assume.

What the ordering is not

It is not by the number of units deployed. The Foundation has no properly sourced deployment figures for any of these classes and does not state any, which is a limitation it records rather than conceals: the figures in circulation come from trade sources and press material, and Part V.J.4 sets out why the Foundation declines to build on sources of that kind. Appendix C records one volunteer survey of the composition of the night environment in a single country over a single autumn, and there is no American counterpart to it. So the comment cannot say which of these classes accounts for the most exposure, and it does not try.

It is not by technology either. Every class in this Part uses the same emitter. That is the premise of the whole comment and it is why the characteristics at Part III rather than the product categories are the thing the Foundation asks the Department to bound.

What the ordering is

Three groups, and then four classes that cut across them.

First, the classes a person meets involuntarily in the public way and cannot decline: motor vehicle lighting at subsection B, emergency and warning lamps at C, roadway and area lighting at D, signage and dynamic message displays at J, aircraft and obstruction lighting at O, residential exterior

lighting and light trespass at P, rail and marine lighting at Q, traffic control signals at R, and the accent lighting on unattended equipment at S and on mobile devices at T.

Second, the classes a person meets because they have to be in the place: interior lighting in schools, workplaces and healthcare settings at subsection E, and retail and commercial interiors at F, which a person can leave but which Part VII.F records people ceasing to enter.

Third, the classes a person chooses and controls: consumer lamps and household products at subsection G, displays and personal devices at H in their personal use, and lighting on bicycles and personal mobility devices at N, which the user chooses and other road users do not.

And four classes defined by something other than the setting. Subsection I is defined by purpose, being lighting installed to deter rather than to illuminate. Subsection K is defined by the deliberate use of change as the point of the product. Subsection L is defined by a property of the product, which is that it emits radiofrequency energy as well as light. Subsection M is defined by the exposed person rather than by the product, and Part III.F and Part IX.L set out why that is a category this comment needs.

The characteristics by which the classes differ

Part III identifies sixteen characteristics of an emission that require boundaries. Those are properties of the light. This Part turns on a second set, which are properties of the encounter, and the Foundation lists them because they are what makes two products with identical photometric output different in their effect on a person.

Whether the exposure is voluntary. Whether the person can look away, and whether looking away costs them something, as it does for a driver. How long it lasts, and whether it recurs daily by necessity. The distance, and whether the source subtends a small angle against a dark field, which Part V.D identifies as the condition the ordinary metrics do not reach. Whether the installation belongs to the exposed person or to somebody else, which is the distinction Part VIII turns on. Whether the source moves, which Part III.D.9 treats. And how many emitters are in the field of view at once, which Part III.D.8 treats and which Question 15 of the notice raises.

The relationship to this Department's own classification

The Foundation's taxonomy is not the Department's. The Department already classifies these products, by product code, and Appendix F sets out the codes: twenty-three assigned and thirteen the Foundation proposes. The two schemes do not correspond one to one, and the Foundation does not suggest that the Department adopt this Part's ordering. Appendix F maps each class in this Part to the code or codes that reach it, and Part VI.U reserves the statement of regulatory position by class. Where a class in this Part has no code, Appendix F says so, and that is the more useful fact.

B. Motor Vehicle Lighting

This is the product class on which the Foundation has done the most and about which the federal record is longest, and the Foundation states at the outset what distinguishes it from every other class in this Part. It is the only one for which a federal standard exists that sets numerical limits on emission. Federal Motor Vehicle Safety Standard No. 108 governs the photometric performance of vehicle lamps, it is administered by the National Highway Traffic Safety Administration, and Part II.H.5 and Part IV.C describe the Foundation's dealings with that agency at length.

The consequence is that the question this comment puts to the Department is sharper here than elsewhere. In the other classes the Foundation asks what should be done where nothing is done. Here a federal instrument exists, it is enforced, and the agency administering it has twice told the Foundation in writing that the expertise relevant to the health questions resides in this Department. What Part VI.B describes is not a vacuum. It is a division of labor that has never been performed on one side.

The Foundation also states a boundary it has observed throughout this comment and observes here. Part II.H.3 records that the Foundation does not ask any agency to regulate light pollution, that the Environmental Protection Agency has no authority to do so under the law as written, and that the Foundation agrees. Nothing in this subsection asks this Department to regulate skyglow or the appearance of the night sky. Where this subsection uses evidence gathered by researchers whose subject is light pollution, it uses it for what it shows about the quantity of radiation emitted and received, which is the subject of 21 U.S.C. § 360ii, and for nothing else.

1. Headlamps and high-intensity forward lighting

What the products are needs no description. What has not been established anywhere in the federal record, and what this subsection establishes first, is whether their emission is changing.

The trend, measured

The Foundation has found one quantitative study of the question, described at Appendix D.8. It analyzes the photometric data published by the Insurance Institute for Highway Safety for its headlight ratings: 287 car models from 27 manufacturers over the years 2016 to 2025, comprising 3,386 records and 13,544 individually measured lights, weighted by brand sales share. On that sample the luminous intensity of the headlamps of the average car grew over the period by:

18 percent for high beams combined, a compound annual growth rate of 1.9 percent a year;

35 percent for low beams combined, a compound annual growth rate of 3.4 percent a year;

22 percent for the mean of the two, a compound annual growth rate of 2.2 percent a year.

Combining the intensity trend with the growth in the number of vehicles, the author estimates the total emission from vehicle headlamps to have grown at 3.6 to 3.7 percent a year in the United States and the European Union, and at 10.6 percent a year in China.

Why the low beam figure is the one that matters

The low beam grew at nearly twice the rate of the high beam. The low beam is the beam in use in town, the beam that faces oncoming drivers, and the beam that a pedestrian at a crossing receives. The high beam is used on unlit road and is dipped when a vehicle approaches. The quantity that has risen fastest is therefore the quantity to which people are actually exposed, and the author draws the same inference, observing that the rate was larger for the low beams and that this suggests a faster growth of vehicle-induced emission in urban areas.

What this does and does not establish

It is the only measurement of the trend the Foundation has been able to find, and the Foundation states its weaknesses in full. It is a preprint and has not been peer reviewed. Its author describes the results as having been obtained “from a limited sample of cars and using very strong additional simplifications, so they should be taken with a grain of salt”, and offers them “as a first approximation and as a stimulus for further research on this topic”. His own considered statement is narrower than his abstract: that the results are “strongly suggestive of a steady and non-negligible increase of the vehicle headlight emissions during the last ten years”.

It contains no spectral data of any kind. It reports luminous intensity and luminous flux and nothing about wavelength, correlated color temperature or short-wavelength content. No part of this comment cites it in relation to blue light, and the propositions at Part V.B.3 and Part V.F rest on other sources entirely.

And it contains nothing about health. Its subject is light pollution, and its author’s purpose is to assess the contribution of vehicle lighting to skyglow. The Foundation takes from it one fact only, and that fact is about emission: the quantity of optical radiation emitted by the headlamps of an average vehicle rose measurably over the last decade, and rose fastest in the beam aimed at other road users.

Why that fact belongs before this Department

Because paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. A measured increase of 35 percent in a decade, in the emission a person meets head-on from a product class numbering in the hundreds of millions, is a condition of exposure within the ordinary meaning of those words. The Foundation does not ask the Department to find that the increase is harmful. It asks the Department to notice that the increase was measured by a retired astronomer in Galicia from a public American dataset, and that no federal body has asked what it means for the people exposed.

The dataset, which the Foundation asks the Department to notice separately from the study

The underlying data are not the author's. They are published by the Insurance Institute for Highway Safety, a research organization funded by automobile insurers, which has measured and rated the headlamps of new vehicles sold in the United States since 2016 and publishes the results. The measurement capacity for this question therefore already exists, in this country, maintained continuously for a decade, outside both the agency that regulates the lamps and the Department that holds the radiation authority.

That is the clearest instance in this comment of the point Part II.H makes about liaison. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from other agencies, professional organizations and others concerned with electronic product radiation. A decade of photometric measurements of the forward lighting of the American vehicle fleet exists and is public. What has never been done is to ask of it the question this Department is charged with asking.

What the people exposed report, measured at scale

The measurement above is of emission. It says nothing about what that emission does to the person who receives it. In April 2024 ten European motoring organizations placed before the United Nations body in which the international vehicle lighting regulations are developed a study of that second question. The Foundation describes it at length because nothing of comparable scale has been put before any body in the United States — the nearest American counterpart, the evaluation by the American Automobile Association described at Part VI.B.2, rated glare with a panel of five — and because the document says several things about the approval standards themselves that this comment has elsewhere had to establish from first principles.

The document is informal document GRE-90-20, Glare on Road Traffic: European consumer study 2024, Revision 1, dated 26 April 2024, submitted by the expert from the Fédération Internationale de l'Automobile to the ninetieth session of the Working Party on Lighting and Light-Signalling, held at Geneva from 29 April to 3 May 2024, under agenda item 12. It runs to sixty-eight pages, of which the report proper occupies pages 3 to 10 and five attachments the remainder. The same study was presented to that session on 2 May 2024 by Burkhard Boettcher of the Allgemeiner Deutscher Automobil-Club in informal document GRE-90-40. The participating clubs were the Automobile Club du Luxembourg, the Allgemeiner Deutscher Automobil-Club, Avto-moto zveza Slovenije, the Koninklijke Nederlandse Toeristenbond ANWB, the Bosanskohercegovački auto-moto klub, IAM RoadSmart, Norges Automobil-Forbund, the Österreichischer Automobil-, Motorrad- und Touringclub, the Touring Club Royal de Belgique and the Touring Club Schweiz.

The study was conducted in two arms using the same questionnaire. In the first, four clubs joined the German club in commissioning a market research company to survey a structured, supervised and demographically balanced sample of about one thousand drivers in each country. In the second, five clubs invited their own members to complete a six-page questionnaire through club magazines and social media, and about twenty-two thousand members responded. The report describes the difference between the two in its own words: in the representative arm, "not only do those who feel blinded give their opinion, but a structured and supervised survey of a good 1,000 drivers in each

case, taking into account the demographic balance". The fieldwork was conducted up to the end of 2023.

The representative arm interviewed 4,312 people in Germany, Austria, Switzerland and Belgium, with a further 447 in Luxembourg reported separately. On that sample the report states its conclusions for the four countries as follows:

> "71 % find the glare intolerable or annoying";
>
> "32 % almost always or regularly feel dazzled";
>
> "51 % of respondents pinch their eyes shut or even close them briefly";
>
> "58 % have problems perceiving objects in the vicinity of the dazzling light source";
>
> "30 % stated that they continued to see an image of the light source for a limited time after passing it (afterimage), or even felt pain".

The report marks the fourth and fifth of those items with an asterisk and explains the mark: "Indication of physiological glare and restriction of perception/vision". That distinction is the one the Foundation regards as the document's most important contribution, and it is taken up below. Seventy-five percent of the representative sample considered it necessary, in the report's words, "to review and update the regulations on reducing glare from vehicle lighting".

Why the Foundation relies on the representative arm, and what the authors did about the obvious objection

The second arm was self-selected, and a self-selected sample of people invited to say whether a thing bothers them will overstate how much it bothers the population. The authors anticipated the objection and recorded it before reporting their results: "The expectation was that people complain more when offered the opportunity." They then reported what happened: "That is also somewhat observable. The results of this study were unexpectedly in line with those in the ADAC report."

The figures bear that out in direction and in magnitude. Every number in the self-selected arm is higher than its counterpart in the representative arm — eighty percent against seventy-one, fifty against thirty-two, sixty-four against fifty-eight — but none is higher by the margin that would be expected if the self-selected respondents were a different population rather than the same population more sharply motivated to answer. The Foundation nevertheless cites the representative figures throughout, treats the self-selected arm as consistent rather than as independent corroboration, and notes that the report's own executive summary quotes the self-selected figures in its headline statements.

The finding on age, which does not support the Foundation's position

The survey reached a conclusion on age that runs against what Part V.C.5 of this comment argues from optics, and the Foundation states it here rather than leaving it to be found. The report's conclusions say: "The assumption that glare is predominantly a problem for older people due to the ageing of the eye and the associated visual impairment was not confirmed by the survey. On the contrary, the proportion of younger drivers who feel dazzled is significantly higher." Earlier, in its statement of motivation, the report puts it more strongly still: "However, age does not play such a major role; the often-heard argument that older people in particular suffer from glare (and perhaps should stop driving) is completely debunked by the study."

Three things must be said about that, and the first is that the Foundation does not dispute the measurement. What is measured is the frequency with which a respondent reports feeling dazzled. That is not a measurement of susceptibility, and the report does not claim it is; its own executive summary concedes the physiology in the same breath as the finding, recording that "youngsters seem to experience the same discomfort as elderly people, despite elderly people having more physical reasons for this".

The second is that the report supplies the confound without connecting it to the age result. Among its summary findings is this: “Some people feel their freedom is limited because they no longer drive their car in the dark.” A person who has given up driving at night has given up the exposure, and will report less of it. Whether that accounts for the age gradient the survey found is not something the survey tested, and the Foundation does not assert that it does. It states the possibility because the alternative is to let a self-report finding stand as though it were a finding about the eye.

The third is that the report’s own cited authority runs the other way, and the report misstates it. Its statement of motivation tells the reader that “it is known that the recovery of the driver’s eyes after glare can take up to 9 seconds”, attributes the figure to the Royal Society for the Prevention of Accidents, and computes from it that a driver covers seventy-five meters at thirty kilometers an hour, one hundred and twenty-five at fifty, and two hundred and fifty at one hundred. The arithmetic is correct. But the reference list at page 9 discloses what the body text omits, describing the same source as finding that “Between the ages of 15 and 65, the time it takes to recover from glare increases from 1 to 9 seconds.” The nine seconds is a sixty-five-year-old’s recovery time, and the distances computed from it in the body of the report are a sixty-five-year-old’s distances presented as everyone’s. The Foundation records the error rather than relying on either version of the figure, and notes that the underlying gradient, if the characterization is accurate, is an age-related physiological finding sitting unreconciled in the same document as a conclusion that age was not confirmed as a factor.

One demographic result in the representative arm does align with Part V.C.5. Respondents who use a visual aid while driving reported being dazzled more often than those who do not. The Foundation draws no more from that than the report does, which is to say nothing beyond the observation itself. Part V.C.5 rests on the optics of scatter in the aging eye and on the sources cited there, and no part of this comment cites this survey for the proposition that susceptibility rises with age. It is cited for what it measures: that a large majority of drivers of every age report that their vision is impaired by the forward lighting of other vehicles.

The measurement the approval standard does not make

The passage that follows is the reason this document is in the comment at all. Under the heading Possible causes and effects, the report states:

> “The requirements for approval of vehicle lights are set in illuminance values of the light beam and the light distribution. The (human) eye instead ‘measures’ luminance and contrast. Due to the construction of the eye, it copies a sharp picture of the light source in all details onto the retina. The higher the luminance of the light source and the sharper the contrast in the light source, the more side effects occur in the eye.”

Alongside that passage the report prints a diagram of the eye, sourced to Seibersdorf Laboratories, AUVA-Report Nr. 53 Optische Strahlung, with a caption stating the geometric consequence: “The angular extent α characterises the size of the source on the retina. The smaller α, the smaller the image of the source on the retina. As the luminance must be increased for the same light performance on the road with a smaller angle α, it is also higher on the illuminated part of the retina.”

That is the proposition this comment argues at Part V.B.8 and Part V.C.2, stated as settled by a party to the international regulatory process: that a standard written in illuminance at a measurement point does not constrain the quantity that determines what happens at the retina, and that shrinking the emitter while holding road performance constant drives that quantity up.

The report then supplies a measurement of the shrinkage. It prints a photograph of the emitting surface of a modern low beam headlamp photographed against a grid, captioned: “Illustration of the light emission of a modern LED lowbeam headlight with very high luminance: each box measures 5x5 mm. The light emission area perceived by the eye is only around 5 cm^2 in total.” The source given is ADAC e.V. For comparison, the emergency warning lamp measured at Appendix D.4 and discussed at Part VI.C.1 was found to emit from 10.4 square centimeters across three diodes. The

two products are unrelated and serve different purposes, and the Foundation draws from the comparison only the fact they have in common, which is that the emitting area of a high-output vehicle lamp is now measured in single-digit square centimeters.

The clubs draw an inference from that geometry which the Foundation records as their proposal and not as a finding, since they state it in the first person: "The brightness is caused by the smaller dimensions of headlight units. We think there should be a minimal dimension for these lights to stop this." Whatever its merits as vehicle engineering, a minimum emitting area is a performance characteristic of a radiation-emitting product of precisely the kind section 360kk contemplates, and it is a characteristic no American instrument addresses.

The significance of the passage for this comment is that it is the second time the Foundation has been told the same thing by a body that regulates vehicle lighting. Part II.H.5 records the letter of 13 February 2024 in which the Acting Chief Counsel of the National Highway Traffic Safety Administration wrote that "FMVSS No. 108 does not directly regulate what you describe as peak luminance as measured in nits or the spectral power distribution of the headlamp light source". The European approval regime and the American one are differently drafted and differently administered, and this comment does not treat them as interchangeable. What they have in common is the gap, and neither of the bodies that administers them holds a public health mandate.

What the clubs asked the international regulator to do

The report's recommendations open with a conclusion about the adequacy of the approval regime: "The results of the survey indicate that the current approval requirements within the framework of the UN ECE approval procedure are insufficient to protect road users from glare." Seven recommendations follow. The third of them, printed in bold in the original, is the one the Foundation places before the Department:

> "The luminance of light sources must be limited, both at a distance and at close range, in order to reduce glare and exclude the risk of injury to the eye at close range (e.g. in stationary traffic, children crossing in front of standing vehicles, etc.; compliance with and review of German § 30 StVZO Para. 1)."

A sixth recommendation asks for the research that would support such a limit, calling for further studies "to investigate the causes of glare in more detail, to determine limit values for illuminance and luminance and to justify them on the basis of scientific findings on the glare effect in the eye". The presentation of the same study recommends in addition that the Working Party "should recommend WP.29 the establishment of a taskforce on glare (prevention)".

The Foundation states plainly what that recommendation is and is not. It is a recommendation by a consumer organization to a regulator. It binds no one, it was not adopted by the Working Party, and the word must in it is the language of advocacy rather than of law. Its weight lies in who said it and to whom: an organization that represents the national motoring clubs of a hundred and forty-seven countries told the body in which the international vehicle lighting regulations are developed that the luminance of vehicle light sources must be limited in order to exclude a risk of injury to the eye, and no such limit exists in those regulations, in Federal Motor Vehicle Safety Standard No. 108, or anywhere in Part 1040 of this Department's regulations.

The close-range injury question, which is not a glare question

One paragraph of the report leaves the subject of glare altogether, and the Foundation treats it separately for that reason. It appears at the end of Possible causes and effects, immediately before the conclusions:

> "There are indications that light sources with high luminance and a high proportion of blue light at close range can cause damage to the eye. There are still few studies on this, as today's luminance levels have only recently become available thanks to the latest LED technology. Unlike long-wave light, blue light produces chemical reactions on the retina that can lead to damage. However, it must be taken into account that the main beam of light can be viewed

> directly in front of the headlamp, either by passers-by when the vehicle is stationary or during maintenance work on the vehicle. The risk of injury must be safely excluded."

Glare is an effect on visual performance. It is temporary, it is measured in contrast and recovery time, and it is the proper business of a highway safety agency. The paragraph above is about something else: photochemical alteration of retinal tissue by short-wavelength optical radiation. That is the mechanism the blue light hazard weighting function describes, it is the subject of the exposure limits treated at Part V.B.2 and Part V.B.3 and of the instruments catalogued at Appendix D.2, and it is the subject matter of the electronic product radiation control provisions of the Federal Food, Drug, and Cosmetic Act.

The exposure geometry the paragraph describes is also different, and it is the geometry this comment has argued is unaddressed. The persons named are not drivers meeting a beam at a closing speed. They are a pedestrian standing in front of a stationary vehicle and a technician working on one. Both are stationary, both are close, and neither is protected by the aversion and averting behavior on which the continuous-source exposure limits implicitly rely. Part V.C treats that assumption and the conditions under which it fails.

The sentence the Foundation asks the Department to read twice is the second one. "There are still few studies on this, as today's luminance levels have only recently become available thanks to the latest LED technology." That is the structural argument of this entire comment, stated by a motoring organization to an international regulator in 2024: the exposure changed, the research record did not follow it, and the absence of findings is being read as an absence of risk.

The Foundation does not ask the Department to find that vehicle headlamps injure the retina at close range. The report does not establish that, says it does not, and the Foundation will not convert an indication into a finding. What the Foundation asks is narrower and follows from the statute. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. A question of photochemical retinal injury from a mass-market radiation-emitting product, raised in an international regulatory forum in 2024, acknowledged there to rest on few studies, and directed to a body with no health mandate, is a question that paragraph places with this Department. No agency of the United States has asked it.

What this document is, and the weight the Foundation places on it

It is an informal document submitted to a working party by an interested party, and each of those words carries a qualification. An informal document is a submission to a session, not an instrument of the body and not adopted by it. The submitting organization represents motorists, and a motoring organization's interest in less glare from other people's headlamps is a consumer interest that this comment states rather than conceals. The study was not peer reviewed, its questionnaire and respondent-level data are not published with it, and its figures are summary figures reported by its sponsors.

The authors say the first of those things themselves, and say it before reporting anything: "This survey is not a scientific study on the effects of glare on the road. Unfortunately, there is hardly any, and if there is, it is somewhat older." The Foundation records that sentence both as the authors' own characterization of their work and as a further instance of the proposition at Part II.G, that the literature on this exposure is thin and dated.

Three claims in the document the Foundation does not adopt. The first is the assertion that "US research shows that there is a link between glare from lights and road accidents", which names no study in the body and is followed by an argument from plausibility rather than from evidence. The second is a figure appearing only in the reference list, where a secondary source is described as reporting that glare from oncoming high beams accounts for twelve to fifteen percent of all traffic accidents in the United States; the Foundation has not obtained that source, has not verified the figure, and does not rely on it. The third is the statement that light output "has increased tenfold",

which appears in a quoted respondent comment and is an impression rather than a measurement. The measured trend in this subsection is the one at the beginning of it.

The Foundation also records, because candor requires it and because it bears on how the document should be read, that the study is not an attack on the technology. Its executive summary states that "This study is not an indictment of new types of vehicle lighting, such as LED lighting; this is widely used and has many advantages", before concluding that "the current regulations are not adequate" and calling for "an examination as to whether the current UNECE rules regarding vehicle lighting are suitable for the newest generation of beamers and lights and their functionality". That is the Foundation's position as to the American rules, and it has been the Foundation's position throughout this comment.

What survives every one of those qualifications is not the survey. It is the statement about metrology. Whether seventy-one percent or eighty percent of European drivers find glare intolerable is a matter on which a consumer survey can be challenged. Whether an approval standard written in illuminance constrains the luminance of the source is not a matter of opinion, is not affected by who asked the question, and has now been answered the same way by the clubs that submitted this document and by the agency that administers Federal Motor Vehicle Safety Standard No. 108.

The variable the standard does not control

Two things have been established in this subsection so far. The emission of these lamps is rising, and the people who receive it report that it impairs them. There remains the question that stands between the emission and the person, which is where the radiation is pointed. In October 2023 the agency that regulates these lamps published a measurement of how accurately they are pointed on new vehicles, together with a statement of what the federal standard requires on the subject. The statement is the more important of the two.

The report is Voyzey N., Mazzae E. N. and Andrella A., Assessment of Headlamp Aim for New Vehicles, Report No. DOT HS 813 481, published by the National Highway Traffic Safety Administration in October 2023 and performed at that agency's Vehicle Research and Test Center at East Liberty, Ohio. It is described at Appendix C.101. Fifteen vehicles of model years 2022 and 2023 were measured soon after delivery and before any other testing.

What the agency states the federal standard requires

Twice, in identical terms in its executive summary and its introduction, the report states:

> "There are currently no requirements in Federal Motor Vehicle Safety Standard (FMVSS) No. 108, Lamps, reflective devices, and associated equipment (49 CFR § 571.108, 2011), for aiming headlamps on a vehicle."

The guidance the testing was conducted against is a voluntary practice of the Society of Automotive Engineers, and the report disposes of its federal status in a footnote: "SAE J599 is not an incorporated reference standard to FMVSS No. 108." So the only aim criteria in existence in the United States are voluntary, and they are not incorporated into the standard that governs these lamps.

Where the chain breaks, and why it bears on everything this subsection has said

The Foundation sets out the architecture using only statements the agency has made in its own documents, three of which are now before the Department. In the Federal Register notice of 8 December 2022 the agency wrote that "the integral beam photometry requirements are for the lamp, not the light source". In the letter of 13 February 2024 it wrote that the standard "does not contain performance requirements for a light source that is part of an integral beam headlamp, but instead specifies performance requirements for the complete headlamp". In the research report of October 2023 it wrote that there are no requirements for aiming headlamps on a vehicle.

Read together those three statements describe a chain with a break in it. The light source is not regulated; the lamp is. The lamp is certified against photometric values specified at angular positions defined with respect to the lamp itself, which is to say in the lamp's own coordinate frame, on a bench, before it is installed in anything. The lamp is then fitted to a vehicle. Where that vehicle points it is governed by no federal requirement at all. The frame in which compliance is established belongs to the lamp. The frame in which a human being is exposed belongs to the road. Nothing in the standard fixes the relationship between the two.

That is the precise answer to the position the agency took in its letter of 13 February 2024, which Part II.H.5 records: that peak luminance and spectral power distribution are "indirectly regulated through the headlamp performance requirements". Indirect regulation through photometric requirements is regulation in the lamp's coordinates. Whether any of it reaches a person depends on a variable that the same agency, four months before that letter, reported to be outside the standard entirely. The Foundation states the chronology and does not characterize it.

What the measurements showed

Aim was measured by the procedure of SAE J599: the lower beam was shone on a matte screen twenty-five feet from the vehicle and the vertical position of the beam's cutoff was located relative to the height of the headlamp's optical center. Every vehicle was measured with no load and again with a 165-pound load in the driver seat. All fifteen were measured visually and five of them also with an imaging photometer, the two methods agreeing to an average magnitude of 0.12 degrees.

Judged against the voluntary SAE criteria, most lamps passed. Judged against the aim target specified by the vehicle's own manufacturer, fewer did. Of the ten vehicles whose manufacturer specifications could be obtained, and taking the condition with a driver load aboard, nine of ten driver-side lamps and five of ten passenger-side lamps were within the manufacturer's tolerance on visual measurement. On photometric measurement of the smaller subset the passenger-side figure was one of five.

The direction of the error is the part that matters here, and the report tabulates it. Taking the ten vehicles with manufacturer targets and no driver load, six of ten driver-side lamps and six of ten passenger-side lamps were aimed above the manufacturer's target rather than below it. The largest upward deviation recorded was 0.50 degrees. Upward is the direction the report's own rationale associates with glare to oncoming drivers.

What half of one degree is, and the arithmetic is the Foundation's

On the twenty-five-foot test screen, 0.50 degrees is about two and a half inches, which is why an aim error of this size reads as trivial in a laboratory. The exposure does not occur at twenty-five feet. The same angular displacement raises the beam by about 0.44 meters at fifty meters and by about 0.87 meters at one hundred meters. A deviation invisible on the test screen is most of a meter of vertical displacement at the distance at which oncoming drivers, cyclists and pedestrians actually meet the beam.

The Foundation states the limit of that arithmetic as plainly as the arithmetic itself. It does not establish that any particular beam entered any particular person's eyes, which depends on the mounting height of the lamp, the profile of the road and the geometry of the encounter. What it establishes is that the quantity left uncontrolled is not a small one where the exposure happens.

And the report addresses only the static case. A vehicle on a road pitches: under braking, under acceleration, over a crest, across a depression, and with every change of load. Each of those displaces the beam in the same coordinate frame the standard does not reach. The submission described earlier in this subsection makes that its central mechanical claim, stating that "The main problem of glare in traffic is the pitching movements of the vehicles and thus the significantly higher illuminance levels at the eye than those permitted by law in point B50L or zone 3", and naming among the conditions that should be taken into account "uneven road surfaces, bends, crests,

stopping times at junctions". Neither the static aim state nor the dynamic displacement about it is within Federal Motor Vehicle Safety Standard No. 108.

Two further disclosures in the report

The first concerns what can be known. For five of the fifteen vehicles the manufacturer's aim target could not be stated, because, in the report's words, some manufacturers "do not publicly disclose their aim target and tolerance information" and such information is recorded in the report as Confidential Business Information. The aim specification of a radiation-emitting device operated on public roads is, for a third of the sample, a trade secret. The Foundation notes the consequence for any study the Department might undertake under paragraph 360ii(a)(4): a third of the conditions of exposure in this sample could not be established from public information by the agency that regulates the product.

The second concerns what the fleet now is. Of the fifteen vehicles, fourteen were fitted with light-emitting diode headlamps, in projector or reflector optics, and one with a halogen projector. That is not a statistical sample of the fleet and the Foundation does not present it as one. It is a photograph of what a federal laboratory found when it bought fifteen new vehicles for unrelated research in 2022 and 2023.

The capability that exists, and the question nobody has put to it

The report records that "An imaging photometer was acquired during the course of this work", and identifies it. The agency that regulates these lamps now holds, at a federal test facility, an instrument that images and measures the light a headlamp emits. It was used to locate the position of a gradient in a beam pattern. It has not been used, so far as any public record shows, to measure what that beam delivers to the eyes of a person standing or driving in front of it.

That is the liaison point of paragraph 360ii(a)(3) in its plainest form, and it is the second instance of it in this subsection. The first was the decade of headlamp photometry held by the Insurance Institute for Highway Safety. This is the second: the instrument, the facility, the vehicles and the technical staff all exist inside the Department of Transportation. What does not exist there is the mandate to ask what the measured radiation does to the person who receives it. That mandate is here.

What this report does not establish, stated because the Foundation relies on it

It does not measure glare, and the Foundation says so before anything else because the title and subject matter invite the opposite assumption. The word appears twice in twenty-eight pages, in one sentence repeated: "High headlamp aim can result in an abundance of glare for drivers of oncoming and preceding vehicles." That is the stated reason for caring about aim. It is not a finding, and no measurement in the report bears on it. There was no human subject. No illuminance was measured at anyone's eye. No biological endpoint of any kind was assessed. The entire reference list of the report consists of two items, the standard itself and SAE J599, and contains no scientific literature on glare or on vision.

Nor is it a survey of the fleet. Fifteen vehicles were measured, and they were vehicles the laboratory had purchased for other research rather than a sample drawn to represent anything. The deviations recorded are deviations from manufacturers' own aim targets and from a voluntary practice, not from any safety limit, because no safety limit exists. The authors describe the work accurately as "a good initial assessment".

The Foundation therefore cites this report for three propositions and no others: that the federal standard contains no headlamp aim requirement; that when a federal laboratory measured the aim of fifteen new vehicles, the majority deviated upward from the manufacturer's own target; and that the measurement capability for this class of question exists within the Department of Transportation. The first of those is the one that matters, and it is a statement the agency made about its own standard.

What the design target set actually contains

The three movements above describe a rising emission, a population that reports being impaired by it, and a geometry that no federal requirement fixes. The question that remains is what an engineer designing one of these lamps is actually required to achieve. That question has a documentary answer, because designers publish their work.

The Foundation takes as its example Hsieh C.-C., Tsai C.-L., Hung C.-C., Lin H.-H. and Li T.-C., Design of Multi-module LED Headlamp of Vehicle Under Federal Motor Vehicle Safety Standard, Sensors and Materials, volume 35, number 7 (2023), pages 2433 to 2448, described at Appendix C.102. It is a peer-reviewed optical engineering paper by five authors at three Taiwanese institutions, reporting the design, simulation and construction of a light-emitting diode low beam headlamp built expressly to satisfy Federal Motor Vehicle Safety Standard No. 108. It is chosen because it is explicit about its target: the authors state that they used "the low-beam headlamp regulations in FMVSS 108 as the verification standards in this study", and they cite the Electronic Code of Federal Regulations section for Standard No. 108 as their source.

The target set, as the designers reproduce it

The paper reproduces the photometric requirement as a table of eighteen numbered test points. Each row gives an angular position, a required luminous intensity in candelas, and the corresponding illuminance in lux. The positions are expressed in degrees up, down, left and right of the lamp's axis, written in forms such as 10U-90U, 0.6D-1.3R and 1.5D-2R. The measurement is made at a stipulated distance of sixty feet, which the authors give as 18.3 meters, at a test voltage of 12.8 volts plus or minus 20 millivolts, and the illuminance column is derived from the intensity by the inverse square of that distance.

Two things about the structure of that table matter to this comment, and neither is apparent without counting the rows.

The first is the coordinate frame. Every one of the eighteen positions is an angle measured from the lamp. Compliance is therefore established in the lamp's own frame, at a fixed distance, on a bench, at a regulated voltage, before the lamp is fitted to any vehicle. That is the architecture the preceding movement described from the agency's own statements, and here it is visible in the requirement itself.

The second is the asymmetry between floors and ceilings. Of the eighteen test points in the lower beam table, eleven specify only a minimum intensity, five specify only a maximum, and two specify a range. Sorted by direction the pattern is sharper. Of the ten test points at or above the horizontal, five carry a maximum, and those five are the whole of the lower beam constraint on light thrown toward the eyes of other road users. The Foundation confines that statement to the lower beam, because the standard does cap the upper beam: Part VI.B.2 records that the maximum permitted intensity of a United States upper beam is 150,000 candelas, against 430,000 in Europe. Of the eight lower beam test points below the horizontal, six carry a minimum and no maximum at all. Among those six are the two brightest requirements in the table:

- test point 11, at 0.6 degrees down and 1.3 degrees right, requires at least 10,000 candelas, and specifies no upper limit;
- test point 14, at 1.5 degrees down and 2 degrees right, requires at least 15,000 candelas, and specifies no upper limit.

The two ceilings that do exist below the horizontal are at test point 13, which admits a range of 1,800 to 12,000 candelas, and test point 17, which caps intensity at 12,500. Neither applies at the points where the beam is required to be brightest.

That asymmetry closes a loop opened at the beginning of this subsection. The measured growth of low beam intensity over the last decade, thirty-five percent on the sample described above, required no exemption and broke no rule. At the points where the beam is brightest the standard sets a floor

and nothing else. A lamp twice as intense as its predecessor at those points is as compliant as the lamp it replaced. The Foundation has made the same observation about emergency warning lamps at Part VI.C.1, where the federally funded study of those devices found specified minimums and no maxima. The pattern is not confined to one product class.

What the designers optimized, and what they did not

The paper is a complete record of a design effort, and its figures of merit can be listed exhaustively. The authors optimized luminous intensity in candelas at each of the eighteen test points; illuminance in lux; the height and shape of the left and right cutoff lines; luminous flux in lumens, raised from 228.9 to 334.6 by replacing a shade with an asymmetric floorboard; electrical power, reduced to 16 watts against a 55 watt halogen lamp; light utilization efficiency; the suppression of scattered light above the cutoff; the physical dimensions of the assembly; and the rotation angles of the constituent modules. The reported result is that the system "satisfied illuminance regulations" while requiring, in the authors' words, "only 16 W with 70% less energy, while still meeting the regulations in FMVSS 108".

Not one of those quantities is biological. That is not an impression; it is a property of the document that can be checked by anyone in a minute. In sixteen pages the word eye does not appear. Neither does vision, nor visual, nor retina, nor comfort, nor human, nor health. The word luminance does not appear. Neither does wavelength, nor spectral, nor blue, nor color temperature. The word safety appears four times, three of them inside the name of the standard and the fourth inside the title of a cited conference. The word glare appears twice: once in the introduction, describing earlier work by others, and once in a single sentence of the authors' own, reporting that after a condenser was added to recover light that had been scattered above the cutoff, "drivers of approaching vehicles on the opposite lane do not suffer from any glare caused by scattered light from headlamps".

That sentence deserves its own observation, because it is the only place in the paper where a human being appears. The change that produced the benefit was made to recover wasted light and raise efficiency. The absence of glare is reported as a consequence of that change, not as a criterion the design was required to meet. There was no glare specification to meet, and so there is none in the paper.

Why this is not a criticism of the authors

The Foundation states plainly that nothing in the preceding paragraphs is a reproach to these engineers, and it would decline to make one. They set out to design a lamp conforming to the federal standard and they did so, competently and transparently, and published the result where it can be read. A designer who wished to constrain the luminance of the source, or its short-wavelength content, or the irradiance delivered to a retina at close range, would find no number in Standard No. 108 to design to. There is no such requirement to satisfy, no test point at which it is evaluated, and no unit in which it is expressed. The absence in the paper is a faithful reflection of the absence in the standard.

Which is the proposition this comment has been putting to the Department from Part I, arrived at here from the direction of the drawing board. It is also, word for word, what the agency administering the standard told the Foundation on 13 February 2024: that Standard No. 108 "does not directly regulate what you describe as peak luminance as measured in nits or the spectral power distribution of the headlamp light source". Here is an independent design team on another continent working to that standard, and neither quantity appears anywhere in sixteen pages of their work. The agency's description of its own standard is confirmed by the conduct of the people who build to it.

What this paper does not establish

It is one paper by one group describing one design, and the Foundation does not present it as a survey of industry practice. It is a research design simulated in optical software and built as a prototype, not a production headlamp, and its measured peak illuminance of 700 lux at four meters

fell short of the 1,071 lux its simulation predicted, which the authors attribute to assembly tolerance and reflector finish. It reports no biological measurement, no exposure assessment and no human subject, and the Foundation cites it for no proposition about injury. It is cited for what it is: a published, checkable record of what the federal standard asks a headlamp designer to deliver, and of what it does not ask.

Nor does the Foundation present the paper's table as the regulation. The table is the authors' reproduction of requirements they attribute to the Electronic Code of Federal Regulations as accessed in June 2023. The Foundation relies on it as a designer's rendering of the target set and has recorded.108 before this comment is filed.

The condition the test does not include

One further gap belongs in this subsection, and it concerns not what is measured but where. The photometric requirement described above is evaluated at a stipulated distance of 18.3 meters, in a laboratory, at a regulated voltage, through clear air. Fog, rain and falling snow appear nowhere in it. The conditions under which forward lighting is most needed and least effective are not part of the test by which it is certified.

The Foundation has found one experimental study that varies the spectrum of a real headlamp under a scattering medium while holding the quantity of light constant, and it is described at Appendix C.103: Sefer T., Ayaz R., Ajder A. and Nakir I., Performance investigation of different headlights used in vehicles under foggy conditions, Scientific Reports, volume 13, article 4698 (2023). The Foundation states its limitations before its findings, because they are severe.

What the study is, and what it is not

It is a bench experiment, not a road study and not a driving study. Three production headlamps — a halogen lamp measured at 3031 kelvin, a light-emitting diode lamp at 5122 kelvin and a xenon lamp at 5098 kelvin — were directed into a box measuring one meter by eighty centimeters by one meter, painted matte black inside, into which fog was introduced by a theatrical fog machine. Targets were yellow and red cubes of five centimeters. Twelve participants aged 21 to 36 pressed a counter when they saw a cube. The illuminance at the target was equalized across the three lamps to within five lux, so that only the spectrum differed.

The fog was far denser than any road condition. The paper reports transmittance of about twenty percent at thirty seconds, rising to fifty-three or fifty-four percent after fifteen minutes. On the assumption that the optical path was of the order of one meter, which the box dimensions imply but the paper does not state, that corresponds to an extinction coefficient of roughly 1.6 per meter and, by the Koschmieder relation, to a meteorological visibility of about two and a half meters at the start of a run and about six meters at the end. The arithmetic and the assumption are the Foundation's. The paper's own introduction defines fog as reducing visibility below one thousand meters. The conditions tested are therefore two to three orders of magnitude denser than the phenomenon the study is about, and the detection times, which run from six seconds to nearly three minutes for a cube about a meter away, cannot be read as driving performance.

Twelve participants is a very small sample. The paper also reports a difference in detection time between its six female and six male participants of between 1.72 and 3.65 times, and places that figure in its abstract. The Foundation does not rely on that finding and does not reason from it. Within a single condition the detection times of the twelve participants span a factor of more than eight, which is variation of a size that no comparison between groups of six can survive, and the paper offers no analysis capable of separating a group effect from it.

The result, and the mechanism, which is not the one usually assumed

Two quantities were measured, and they disagreed. On transmittance through the fog, the xenon lamp performed best: "the transmittance values under xenon headlights are approximately 2–3% higher than halogen and LED headlights in almost every measurement". On relative target

luminance, the xenon lamp was also highest for both target colors. But on detection by human observers, at equal illuminance, the order reversed: the authors report that "the target detection times of the participants are the shortest at the halogen headlight, the second at the xenon headlight, and the third under the LED lights".

The Foundation draws attention to the direction of that result, because it is the opposite of what a scattering account would predict and the paper is sometimes read as supporting one. The higher color temperature sources did not deliver less light through the fog. The xenon lamp delivered more. The same study's own survey of the literature records a measurement to the same effect, that "shorter wavelengths (blue and green) are 1.5 times less scattered than longer wavelengths (yellow-green, amber/ochre, and red)". Fog droplets are large compared with the wavelength of visible light, and the scattering is correspondingly weak in its dependence on wavelength, which is why fog appears grey rather than blue.

The authors attribute the result instead to an effect in the eye: "it is seen that detection times under halogen headlights are lower than detection times under xenon and LED headlights. This is because of the white wall effect in the eyes of the participants as a result of the white light reflection in a foggy environment." The light scattered back toward the observer forms a luminous veil, and the veil destroys the contrast of the target against its background. More light reaching the eye produced worse seeing.

Why the divergence is the point

That is the proposition this subsection has now met four times from four directions. The approval standard is written in illuminance; the European clubs told the international regulator that the eye responds instead to luminance and contrast. The agency administering Standard No. 108 wrote that it does not directly regulate peak luminance or spectral power distribution. A published design to that standard contains no biological quantity anywhere in it. And here, where both the instrument and the observer were measured in the same experiment, they disagreed: the source that got the most light through the medium was not the source under which people saw best.

The authors state the methodological consequence themselves, and it is the sentence for which the Foundation principally cites this paper:

> "Since transmittance is insufficient alone to evaluate vehicle headlights' performance under fog conditions, the luminance of the target objects should also be considered. However, the luminance camera measures the luminance of fog instead of the target's luminance due to the fog in front of the object in the luminance measurements. Therefore, user-based tests that consider color temperature and luminance parameters should be conducted for a more realistic performance evaluation in foggy conditions."

A photometric measurement made in clear air at 18.3 meters cannot represent that. It is not a defect of the measurement, which does what it was designed to do. It is a limit on what can be inferred from it, and the limit is invisible unless someone measures the person as well as the lamp.

What the authors recommend, and the quantity it names

Their closing recommendation is spectral: "the use of LED light sources with low correlated colour temperatures may give more successful results, as with halogen light sources". The Foundation notes which quantity that is. Correlated color temperature is a crude summary of spectral power distribution, and spectral power distribution is one of the two quantities the agency administering Standard No. 108 told the Foundation in February 2024 that it does not directly regulate. It is also among the quantities the European submission asked the international regulator to address. Three independent sources in this subsection arrive at the same missing number from three different problems: glare, injury at close range, and visibility in fog.

The Foundation draws no conclusion from this study about any particular product. The lamp it tested measured 5122 kelvin, and the Foundation does not assert that the effect observed scales to

the higher color temperatures found in some production headlamps, because the study tested one lamp at one value and provides no basis for extrapolation. What it asks the Department to notice is narrower: that the spectral composition of forward lighting appears to affect what a person can see under conditions the certification test does not include, that this was demonstrated by measuring people rather than instruments, and that no federal body is positioned to pursue it.

The instrument that measures the effect on a person, and where it is kept

Five things have now been established in this subsection: that the emission is rising, that the people exposed report impairment, that the geometry which decides where the emission goes is federally unregulated, that the design target set contains no biological quantity, and that the certification test excludes the conditions in which forward lighting is most needed. One question remains, and it is the practical one. If the Department were directed tomorrow to evaluate what this radiation does to the people who receive it, with what would it do so?

An apparatus for exactly that purpose was built in 2009 at the Schepens Eye Research Institute of Harvard Medical School, and the paper describing it is Fullerton M. and Peli E., Development of a System to Study the Impact of Headlight Glare in a Driving Simulator, in Proceedings of the Fifth International Driving Symposium on Human Factors in Driver Assessment, Training and Vehicle Design, Big Sky, Montana, 22 to 25 June 2009, at pages 412 to 418. It is described at Appendix C.106.

The Foundation states what kind of paper it is before using it. It is a seven-page conference paper reporting the construction of a prototype. It presents no experiment on human subjects, no findings about any population, and no measured effect on anyone. Its only observation about people is anecdotal, that "Drivers testify to being unable to see the area around the car headlamps". It is cited here for what it built and for what its authors say about the state of measurement, not for any result.

What had to be built, and what that reveals about the source

The authors set out to present an oncoming headlamp to a driver in a simulator at the light level such a headlamp would actually deliver to the eye. They computed what that required from published measurements of American and European beam patterns, and found that for the range of approach distances that matter the display would have to reach luminances between roughly 687 and some thousands of candelas per square meter. They then recorded what displays could do: a cathode ray tube reaches 50 to 100 candelas per square meter, a liquid crystal display of that period 200 to 600, and only experimental high dynamic range displays with individually controlled diode backlights reached 10,000. Their conclusion was that "current display technology cannot yet achieve the necessary luminance to create realistic headlight glare directly on the screen".

The Foundation records that for what it says about the source rather than about the display. A vision research laboratory at a medical school, setting out to reproduce an everyday roadway exposure, found that no commercially available screen was bright enough. The exposure had to be synthesized with a separate diode array, combined into the scene through a fifty-fifty beam splitter, positioned in real time to track the simulated oncoming vehicle, and calibrated against the illuminance measured at the driver's head. The simulator was fitted with combined head and eye tracking so that where the driver looked could be recorded. That is the engineering required to put a headlamp in front of a person under conditions anyone can repeat.

The Department already has a night driving glare test, and these authors say what is wrong with it

This is the sentence for which the Foundation principally cites the paper, and it concerns the Department:

> The current 'standard' test that has been used in a number of FDA studies, the 'Night Driving Simulator' of Vision Sciences Research Corp. (VSRC, San Ramon, CA), does not accurately

> simulate glare in terms of the light intensity (headlights are only shown as part of the film capture).
