I am a 32 year old man. I've lost confidence and the will to drive at night due to the blinding headlights of other vehicles. These are people's low-beams that are blinding me, especially the newer trucks that seem to have a headlight stack 1' tall. It's infuriating that nothing has been done about this issue. It also disadvantages the poor who cannot afford newer vehicles with dimming Sideview mirrors or other mitigation technology. This will eventually cause me to have an accident, and I doubt the person who caused the momentary blindness will have the decency to even look back at what they've caused. If a class action lawsuit arises, count me in. The loss of enjoyment of traveling at night is something I feel a good lawyer could successfully litigate, as well as the documented additional eye strain these lights cause. Until then, I will continue to use my middle finger to show these offending drivers what I think of their vehicle choices, and will not be considering any new vehicles that contribute to this problem.

B.3460 February 15, 2024 — Lawndale, CA

whenever I drive at night, I basically can't see from behind and from the opposite lane. It's scary and a danger to all.

B.3461 February 15, 2024 — Lewisham, United Kingdom

I live in the country driving down back roads then meeting a vehicle coming towards you with LED headlamps is blinding, they are so powerful that they don`t see the glear from your headlamp's so they round the corners on full beam, you latterly have to stop because of blindness then you are there for a few minuets to get your eyes refocused. worse when the vehicle has Auto Dip Mode. Something needs to be done!

B.3462 February 15, 2024 — Scranton, PA

I have noticed more vehicles on the highways with blinding head lights. I've found it difficult to drive at night as I've gotten older, but now it's becoming dangerous. It seems like these vehicles all have their high beams on all the time. If I were to drive with my high beams on consistently at night, would that be illegal? So I'm not sure how these new head lights are considered legal, when so many people are being blinded by them! Please banned these horrible blinding halogen/misaligned/led constant high beams and save lives. Please recall and replace these now!

B.3463 February 16, 2024 — Fort Collins, CO

It's scary driving at night anymore. Peoples led lights are blinding. Especially trucks being higher up. How are lights this bright even legal? It's ridiculous and uncalled for. It's like all led lit vehicles have a free pass to use brights, but they're normal. Drivers also intentionally mess with you all the time. There needs to be state laws to dim these lights. Only so many lumens and the right spectrum for safety. Accidents are waiting to happen and are happening all the time from these.

B.3464 February 16, 2024 — Lompoc, CA

White headlights are very problematic for me while driving at night.

B.3465 February 16, 2024 — MIAMI, FL

The current LED headlights cause me to temporarily see white, and flashes, and affects my ability to navigate safely at night. I have altered plans to avoid driving at night solely for this reason.

B.3466 February 16, 2024 — Smyrna, DE

LED headlights are blinding and dangerous fpr other drivers

B.3467 February 16, 2024 — Van Nuys, CA

I can no longer drive at night because of these dangerous LED headlights. Let's get them off the road now!

B.3468 February 17, 2024 — Roswell, United States

There's a simple solution to safely being able to drive at night and deal with bright headlights and street lighting along with the glare they produce. Just wear polarized eyewear while driving or anytime you're out in the evening. I have been doing so for years and have no issues with bright lighting. The polarized eyewear does make a huge difference in dealing with the glare. I use lenses that clip on to my driving glasses. They are available in different shades to use in the evening or daytime; bronze or amber for evening or rainy weather and shades of grey for daytime use. The polarized lenses also sharpen your vision when driving on the highway during rain and fog. Just be smart about it and don't wear too dark of a lens in the evening.

B.3469 February 18, 2024 — Braintree, United Kingdom

Dazzling Headlights are dangerous.

B.3470 February 18, 2024 — Leamington spa, ENG, United Kingdom

I am 73 and have my eyesight checked regularly. But when driving I find many headlights are far too bright. I don't think it is necessary to have such bright lights and I think they are dangerous, as they dazzle you so much it is difficult to see the road ahead.

B.3471 February 18, 2024 — N Bennington, VT

I might hit you head-on if you blind me. I might hit a pedestrian or biker, as I swerve away from your blinding lights to the edge of the road. So your overly bright and high lights are a safety hazard, even to YOU.

B.3472 February 18, 2024 — Washington, WY

These new vehicles and their headlights and the aftermarket headlights are OUT OF CONTROL. It's way too bright, and will cause many accidents. This needs to be changed, and heavy fines.

B.3473 February 19, 2024 — Leicester, NC

Dear god please dont let me die because some one in a giant vehicle is blinding me while I drive the winding mountain roads where I live!

B.3474 February 19, 2024 — Leominster, MA

I do support the ban on LED headlights from vehicle manufacturers and the aftermarket conversion kits also available for almost every make, model and year of vehicle today. I am a truck driver my self and if it's something that I hat the most during my driving time is the led headlights from other vehicles, specially on the pickup trucks. I understand that night visibility when driving is very important and requires extra attention versus day time driving; but how good and safe it is if in order for you to have a more clear visibility from the road ahead your vehicle headlights need to blind other drivers, pedestrians, bikers and everything else that is in your direction no matter if is a vehicle ahead of you or an income traffic vehicle. How many times did some one had a semi truck turn a highbean followed by a led light bar on the highway as an income vehicle or after you past by the semi truck. See, the driver of the semi truck is me, I'm tired to deal with these led's headlights during night time on the open road and to make things even worse a lot of truck drivers are converting the factory headlights with led kits and that become a big problem. Pickup trucks when load on the bed tend to lower the rear end making the nose of the vehicle point higher and that gives a impression to have a highbean on it instead of a lowbean. Let's go back to the old fashion headlights and that's it.

B.3475 February 19, 2024 — Louisville, KY

High intensity headlights are a safety issue that needs to be addressed!!

B.3476 February 19, 2024 — Minneapolis, MN

I drive between Minneapolis and Chicago often and with my smaller car I am often blinded by those in trucks with LEDs. It's quite frustrating and dangerous since it hurts my ability to see the rest of the surroundings

B.3477 February 20, 2024 — Auckland, New Zealand

Because every time I look at oncoming traffic I get flashbanged

B.3478 February 20, 2024 — Glasgow, SCT, United Kingdom

As one of the millions suffering from migraines, the lights not only completely blind me they make me want to vomit. If that happened maybe I'd end up on top of the oncoming headlight abuser.

B.3479 February 20, 2024 — Harwood Heights, IL

cmon bruh fix the lights

B.3480 February 20, 2024 — tallmadge, OH

I drive a small car and I am short, when i'm driving at night I can't see the road when passing LEDs or high beams. It hurts my eyes

B.3481 February 22, 2024 — Fort Lauderdale, FL

The headlights in all new and recent SUV's, trucks and especially the new Cadillac Escalades are absolutely blinding! It seems the majority of all the cars on the road now have these blinding headlights. I can barely drive at night anymore due to the fact I am constantly being blinded by oncoming traffic and these vehicles coming up behind me, and I know it is only a matter of time until I get in an accident. How can the motor vehicle department allow these lights to be legal? They must be banned or people are going to die!!

B.3482 February 22, 2024 — Westminster, MD

I am tired of car manufactures trying to cram as many LED's and other HID headlights that are intense in lumens, in such a way that it poses a real risk for everyone who has to be on the road with them. Especially when you factor in different heights of many of these vehicles, all the way up to big rig trucks, those of us in cars are absolutely getting wrecked by bright lights boring holes in our retinas. Many eye doctors around the United States are seeing higher rates of eye degeneration, due to being exposed to this blinding high intensity lumens that are allowed to be on the road. These headlights are insanely dangerous, and it is not always feasible for one to just "look away" from the headlights. There are people who are driving around with their headlights, led light bar wrapped around the headlights, their fog lights, and off-roading light bars full of LEDs, and other such headlight kits that absolutely blind the heck out of anyone within 50 ft of them on normal roads and highways. Those kind of people should be ticketed for being a road hazard. If you need that many lights, get off the road at night!!

B.3483 February 22, 2024 — Yardley, PA

I'm literally blinded by every light now. Driving at night used to be enjoyable. Now, it just hurts.

B.3484 February 22, 2024 — Yreka, CA

Let's get rid of these blinding headlights

B.3485 February 23, 2024 — Hillsboro, OR

Yes please. I have been in a few near-misses while being blinded by oncoming traffic.

B.3486 February 23, 2024 — Raleigh, NC

It is atrocious that some people think they need excessively bright Headlights, also the lights were never approved or tested.

B.3487 February 23, 2024 — Stratford, ENG, United Kingdom

Tired of having to literally close mid drive to avoid the blinding glare

B.3488 February 23, 2024 — United States

LED headlights are causing problems.

B.3489 February 24, 2024 — Lithia, FL

our great empire of life is threatened by these pieces of dog fecal mater because it stops you from seeing and you crash and die and there is no heaven so death will be permanent

B.3490 February 25, 2024 — Brooklyn, NY

driving at night has become very scary. I drive a sedan but there are way more suvs and high profile trucks on the road now. The newer ones especially have intense and often large headlight arrangements which sit at angle and emit a light that is absolutely harsh and blinding. It is even worse when during winter your outside windows and car mirrors may be a little dirty because it seems to have a prismatic effect. Add this to the hige rise in rude driving practices such as tailgating, lane hopping, speeding, etc and you basically feel like you're driving inside a disco ball with laser beams being aimed at you from every direction! I have had to purchase special night driving glasses which help somewhat but also diminish my ability to see as clearly. I really wish our govt would get off its ass and do something. These newer style headlights really should have met closer scrutiny before they were allowed to become so prevalent!!!

B.3491 February 26, 2024 — Dunlap, TN

Fuck these LED lights and the assholes who blind everyone with them

B.3492 February 26, 2024 — Saint Joseph, MO

This issue started a few years ago it seemed with about ten percent of cars at night. Lately, its about half of cars I encounter. It takes away my view and now distracts me as I have to turn on my fog lights and sometimes brights, just to be able to see my road. When the pavement is wet, it is just plain dangerous from the glare

B.3493 February 27, 2024 — Glen Ellen, CA

Night driving has become very stressful and difficult for me due to the intensity of headlights on new cars

B.3494 February 27, 2024 — Helena, MT

These headlights create unsafe driving conditions for all road users because of their intense glare and brightness. Operators of other vehicles can be blinded, which can lead to accidents with pedestrians, fixed objects, and other vehicles. Banning these headlights would make our highways and streets safer by reducing the potential for conflicts due to reduced visibility of drivers and pedestrians who have to look at these headlights. A national standard for brightness needs to be set and motor vehicles shall not be equipped with headlights above a certain threshold, period.

B.3495 February 27, 2024 — New York, NY

I drive at night and people are bragging about " lighting up people's cabs". They are blinding me.

B.3496 February 27, 2024 — Portland, OR

The blinding headlights are only getting worse. Now there is a whole big bar light across the front of some cars. They are so bright you can't see what's surrounding them. Dangerous.

B.3497 February 27, 2024 — Portland, OR

They blind drivers in oncoming traffic. Especially older drivers who are a large part of the drivers

B.3498 February 28, 2024 — Knoxville, TN

I can no longer drive at night because of the danger.

B.3499 February 28, 2024 — San Francisco, CA

With the increased popularity of SUV's combined with unnecessarily bright headlights the dangers for driving at night for lower chassis vehicles are increasing as well.

B.3500 February 28, 2024 — Snohomish, WA

FMVSS allows headlight beams that a horizontal. Mandating a 1% drop for instance 4 inch every 33 feet would be a good start. Pickup truck should have more drop because lights are mounted higher up by manufacturers design purely for aesthetics rather than safety of others

B.3501 February 28, 2024 — Stratford, CT

85 yrs old with dry eye and can no longer drive at night.

B.3502 February 28, 2024 — Takoma Park, MD

I want to retain the best possible vision health for as long as possible. Reducing incidents of extreme glare exposure, especially during the heightened-attention activity of driving or at-night driving times when you cannot look away or shield your eyes, seems like a sensible step towards that aim. Furthermore, moments of blinding light exposure while driving also threaten the safety of the public, both those in vehicles and pedestrians, and should be designed away via safety regulations.

B.3503 February 29, 2024 — Hamilton, United Kingdom

I find these blinding lights dangerous. Especially when they are fitted in these higher SUV type of vehicles. I literally cannot see where I am going after passing one on a hill or rounding a corner

March 2024

B.3504 March 1, 2024 — Billings, MT

I can’t drive at night anymore. Early evening when auto lights come on is a struggle and causes mild panic. These LED headlights are so bright, my mirrors are rendered useless, I drive through intersections with my hand in front of my face, and I can’t see lines on the road. Not only are the lights painful and debilitating, they’re simply dangerous. If I cannot see someone or something crossing the road because of another oncoming vehicle, there’s a huge problem. Sometimes they are so bright, I can’t even see if it’s safe to pullover. These are worse than traditional brights. I’m not even 40 and I can no longer drive at night. It used to be my favorite time.

B.3505 March 1, 2024 — Corydon, IN

These lights on the way home at night after a long day help me fight sleep, but only because I CAN'T SEE AND FEAR DEATH. These lights should be banned anyone who doesn't change their headlights within 3 months should receive a 5k fine and a driver safety course covering the effects your lights have on drivers.

B.3506 March 1, 2024 — Los Angeles, CA

They are hazardous.

B.3507 March 1, 2024 — Los Angeles, CA

Pedestrians of all ages and movement abilities are absolutely invisible when drivers are blinded by these lights. The danger created in our communities is HIGHLY underestimated.

B.3508 March 1, 2024 — Melrose, MA

These headlights are a hazard to every driver on the road!

B.3509 March 2, 2024 — Caledonia, MI

Is it too much to ask that it not be legal for headlights to be aimed right at my face as a sedan driver?

B.3510 March 2, 2024 — Dallas, TX

Obnoxiously bright headlights are very dangerous.

B.3511 March 3, 2024 — Minneapolis, MN

The blinding headlights need to be band. It is blinding, day and night time.

B.3512 March 3, 2024 — New York, NY

We are moving further away from what is good for us, and must reverse course.

B.3513 March 3, 2024 — United States

I'm tired of being blinded by terribly bright headlights

B.3514 March 3, 2024 — Van buren, ME

Led headlights are so damn bright that sometimes i cant even see the road 5 feet in front of my car, and thats while the oncoming car with the led's is still 1000 feet away, just gets worse as the car gets closer, theres been times i thought i was going off the road. Also led's in the rearview is a big issue.

B.3515 March 3, 2024 — ny, NY

They are dangerous

B.3516 March 4, 2024 — Amherst, MA

Most of my driving is on country roads, often winding and without any streetlamps anywhere. These new headlughts are a disaster for me. I am afraid to drive at night because of them. Suddenly I can't see that the road curves or that there is a deer ahead. I have to slam on my brakes until the other car passes because I'm completely blinded.

B.3517 March 4, 2024 — Bellerose, NY

I drive a sedan and have been "blinded" by the bright lights of oncoming traffic. These lights need to be aimed and focused properly to minimize the danger this poses.

B.3518 March 4, 2024 — Bellingham, MA

"AAA has published numerous studies about headlights and related issues such as glare and did not find a problem" Are they kidding? Are they paid off? I have to focus my vision at the right side of the highway when one of these insanely bright cars is approaching or risk temporary retina burn that makes it nearly impossible to see. And don't get me started about these LED light when the idiot driver has the high beams on...

B.3519 March 4, 2024 — Bradenton, FL

These headlights are dangerous. I almost had many accidents because I was blinded by them.

B.3520 March 4, 2024 — Burlington, MA

It's a type of impaired driving to me. When your blinded and guessing where the road is. It's a safety hazard plain and simple.

B.3521 March 4, 2024 — East Northport, NY

LED lights need to have stricter beam pattern regulations than traditional headlights. They also should not be allowed a certain height off the ground for these behemoth American trucks

B.3522 March 4, 2024 — Greenfield, MA

Today's LED headlights make driving so dangerous for so many drivers. Most of my driving in done locally, so I don't have the advantage of driving on a divided highway, so the oncoming traffic's LED headlights literally blind me. I try to drive less and less during the darker times of the day, but can not avoid this more dangerous time because of my work commitments. The brightness of LED headlights is so dangerous for so many people, I can't believe they're not banned! It's a matter of safety!

B.3523 March 4, 2024 — New York, NY

LED headlights are blinding!

B.3524 March 4, 2024 — Olathe, KS

I am 21 years old and have been driving since I was 16 and am scared one day I won't be able to see the road because of how bright these lights are getting from oncoming traffic. I get blinded at least once each night while driving and have trouble seeing for at least 30 seconds, that is 30 seconds at NIGHT that I cannot see while driving because of unregulated headlights and it's only getting worse.

B.3525 March 4, 2024 — Santee, CA

I'm worried I will get into an accident due to blinding oncoming headlights.

B.3526 March 4, 2024 — Trenton, NJ

Both me and my sister cannot drive at night because of the intensity of newer headlights. Several people in my family have diagnoses of migraines which includes light sensitivity and these new lights make it impossible for us to drive after dark. Please get rid of them, they truly are blinding to other drivers, not sure who thought these were okay to be on the road.

B.3527 March 4, 2024 — Watertown, CT

The LED lights in oncoming cars are so blinding that you actually cannot see the road. I am teaching my son to drive and he says it is getting so bad that he is just hoping he doesn't hit anything until the car passes. These lights are completely dangerous.

B.3528 March 4, 2024 — Woburn, MA

I don't drive late at night much but in winter in Massachusetts night starts by 3:30 pm therefore night headlights are needed. Cars with the new bright lights are blinding. I hate them because I can't see ! There has to be another way to improve night driving!

B.3529 March 4, 2024 — Woodbridge, NJ

Ok, so as I see it, there are a few options here. Either: A) ban these blinding headlights. B) require a warmer temperature light as opposed to the harsh bluish light. C) reinstate headlight aim as part of ALL states′ inspection requirements. D) allow tinting of windshields to reduce the glare. I, personally, have found a pair of lightly tinted, yellow lens, nighttime driving glasses reduces the glare to a comfortable/acceptable level while preserving visibility at night when there are no oncoming headlights. Allowing this type of tint (not a dark grey/smoke) would help those who either cannot find or cannot wear an additional set of eyewear. Any loss of visibility would be much less hazardous than being blinded a what could be a critical moment to avoid a collision. In any case, SOMETHING MUST BE DONE! Thank you.

B.3530 March 4, 2024 — oakridge, NJ

Almost everyday I am confronted by blinding headlights be it in a vehicle coming toward me on the opposite side of the road or behind me.I leave early for work before the sun rises and sometimes I am out in the evening. I drive a compact sedan.These lights are often seen on pick up trucks and large SUVs as it seems the drivers are compensating for something missing in there lives.I just turn my rear view mirror so there lights shine back on them and they immediately back off as they know they are purposely trying to show an aggressive behavior an now don′t like the backlash. Pitiful.

B.3531 March 5, 2024 — Barnstable, MA

Beyond the brighter lights and my own age making it harder, I would like to suggest that too many drivers leave their lights on high beam. It′s partly because the little icon on the instrument panel showing high beams disappears among all the graphics. It should be front and center. And I would like to see the ′automatic′ high beams eliminated. Too many opposing cars blind other drivers, whether from leaving on high beam or automatic high beam that is slow to dim, for example approaching a curve.

B.3532 March 5, 2024 — Douglaston, NY

Driving at night has become very difficult due to headlight glare

B.3533 March 5, 2024 — Lake Zurich, IL

i hate led headlights

B.3534 March 5, 2024 — Palm Coast, FL

I′m amazed at how many oncoming vehicles blind me with their headlights. I flash them believing their highbeams are on only to have them flash me back with highbeams totaling three times the light. This is much more light than necessary for navigating safely when dark. Some parameters need to be enacted on intensity and color of headlights as well as automatic operation of highbeams.

B.3535 March 5, 2024 — Ridgefield, CT

In order to see the road at night I have to put my (usually left) hand up to shield my eyes from the, way too bright, LED lights that all new cars seem to have, which could be dangerous if a car is going to turn in front of me. These lights should be outlawed.

B.3536 March 5, 2024 — Roselle, NJ

I have experienced LED lights shining into my vehicle so bright that it whited out my windshield and left me completely blinded, I had to stop my vehicle for a minute and let the other car go by. This is very dangerous. There is absolutely no reason to have headlights shining into peoples eyes and blinding them.

B.3537 March 5, 2024 — Xenia, OH

There are times I cannot see to my left, my right, in front of me, and or behind. I can not see the dividing lines on the road and had to have faith that I'm moving in the right direction. Even low beam LED lights make it incredibly harder to see. I wouldn't want to do that to someone else so I refuse to purchase led lights myself. Many Americans also deal with having an astigmatism which can make lighting more intense as is the case with me. Only police should have these lights on the road. One day I won't see something coming that I'd wish I would have.

B.3538 March 5, 2024 — Xenia, OH

There are times I cannot see to my left, my right, in front of me, and or behind. I can not see the dividing lines on the road and had to have faith that I'm moving in the right direction. Even low beam LED lights make it incredibly harder to see. I wouldn't want to do that to someone else so I refuse to purchase led lights myself. Many Americans also deal with having an astigmatism which can make lighting more intense as is the case with me. Only police should have these lights on the road. One day I won't see something coming that I'd wish I would have.

B.3539 March 6, 2024 — Australia

I am getting affected by these LED and HID light in my everyday life. Maybe its just a matter of time to have an accident. Goverment should ban these lights before it will get too late.

B.3540 March 6, 2024 — Bay Village, OH

I nearly died last week thanks to LED headlights

B.3541 March 6, 2024 — Cold Spring, MN

I often have to hold my hand up to block my mirror or on coming traffic in order to see the road when headlights are so bright.

B.3542 March 6, 2024 — Detroit, MI

Ban bright lights! It blinding us! Get regular and original lights back on all vehicles and bikes for our sakes!

B.3543 March 6, 2024 — Lehi, UT

Please ban bright headlights. I'm so sick of getting randomly blinded just trying to drive down the street.

B.3544 March 6, 2024 — San Diego, CA

Bright headlights blind other drivers making it more difficult to see pedestrians or other vehicles.

B.3545 March 6, 2024 — Tybee Island, GA

LED lights on vehicles and now being installed everywhere are too bright. These modern LED lights are a hazard to other drivers and are also ruining the nighttime environment when installed on houses and landscaping or as motion sensors. There is no current regulation and people are just blinding others with no penalty or law that regulates the brightness this has to stop.

B.3546 March 6, 2024 — Waltham, MA

Bumper height became law by regulation and the same could be done with headlight height made a standard height so that newer cars headlights are not in eyes of sedan drivers.

B.3547 March 6, 2024 — bronx, NY

It is ridiculous that these lights cause so much trouble and danger. Fix them or get rid of them!!

B.3548 March 7, 2024 — Wallingford, CT

These extremely bright and blinding LED headlights are a danger to other drivers and pedestrians! They must be banned ASAP

B.3549 March 9, 2024 — Pleasanton, CA

LEDs are the most toxic light source there is.

B.3550 March 9, 2024 — Rutledge, TN

I have blue eyes and migraines. My eyes are extra sensitive to bright lights. When I'm trying to drive and have to pass someone or someone gets behind me with the bright led lights I cannot see the lines at all and almost run out of the road every time. I'm so so tired of seeing more and more of these lights on the road. They're so dangerous and unnecessary.

B.3551 March 11, 2024 — Aptos, CA

These headlights are blinding, especially when on large vehicles that sit high on the roadways. They pose a danger to all nighttime drivers, pedestrians in crosswalks, wildlife crossing roadways, and to public safety in general. Please ban them.

B.3552 March 11, 2024 — Dalton, GA

I'm tired of not being able to see. Especially bc I live in a place where everyone has raised cars/trucks so their headlights are beaming the light of God in my eyes directly behind me.

B.3553 March 11, 2024 — Putney, VT

It's becoming very hard to drive at night. I drive a little car, lower to the ground. If an SUV or a Pickup Truck are behind me, I can't use my side mirrors. It feels like the person has their high beams on. Where I live, it's all 4x4 vehicles that are higher off the ground than my vehicle. I understand we all want to be safe, but this is just too much. It's so blinding at night, I have started pulling over on the side of the road to let people behind me pass. And if they're coming towards me in oncoming traffic, forget it. I have to cover my eyes or close them quick because I'm blinded.

B.3554 March 12, 2024 — Forney, TX

If i didnt know my town like the back of my hand driving at night would literally be fcking impossible, AND I have tinted windows

B.3555 March 12, 2024 — Lakewood, WA

It hasn't gotten darker over the past few years... so why am I getting multiple X-rays from headlights on my drive home from work every night? These headlights are so bright I have to look to the fog line and barely open my eyes and even then I'm temporarily blinded.

B.3556 March 13, 2024 — Raleigh, NC

they obstruct others view of the road because of the unnecessary brightness, if you need LED lights for driving, you shouldn't be driving.

B.3557 March 13, 2024 — SAN Diego, CA

I have never had an issue driving at night or with headlight glare up until recently. The latest headlights cause such a blinding glare that it is so difficult to drive against them on a normal open road and almost impossible driving against them on tight winding back roads of rural areas. Recently, while driving up to the San Bernardino mountains, I found myself almost crashing due to the intense HI VIZ lights staring back down at me from traffic coming down the mountain. Some thing needs to change... How many lives will it take?!

B.3558 March 13, 2024 — Salt Spring Island, Canada

Anyone with common sense knows that LEDs cause huge accident increases, especially with elderly drivers. LED is known to cause profound, permanent retinal damage and blindness with over exposures, and all through society these killer lights are diminishing the public's eyesight. This is

your typical indiffernce by corporate/government (same entity) to the well-being of we the people! We absolutely need to ban the headlights, street lights, and LEDs in all public and private facilities in most of North America. And likewise abandon mandates against safe, incandescents and the requiring of only LEDS and CFL - fluoresant - which both emit harmful RF energy, have terible spectral signatures which are bad for health, as well as corrupting electrical systems with dirty electricity, which degrades equipment and human/animal health.

B.3559 March 13, 2024 — lafayette, NJ

Bright white HED headlight are a hazard and car manufactures should be forced to revert to tradition holgens.

B.3560 March 15, 2024 — Honeoye Falls, NY

Blinding headlights are awful!!!

B.3561 March 16, 2024 — Boston, MA

I was blindef

B.3562 March 16, 2024 — Burke, VA

Bright AF headlights hurts my eye and causes headaches

B.3563 March 16, 2024 — Fishkill, NY

It is so dangerous for ne driving at night because of these headlights. They are in front and in back of me blinding me and I cannot see where I am going! It′s just terrible. The new SUVs have at least 6 if not 8 of these as standard. Unacceptable.

B.3564 March 16, 2024 — Richland, WA

I drive a sedan and now avoid driving at evening/night because it is becoming increasingly unsafe due to these LED high beam "regular" headlights. Would you want your family, neighbors, and even teenagers learning to drive be blinded resulting in an accident with major life long debilitating injuries or kill them or someone else just because of headlights? The increasing trends of accidents and fatalities cannot be ignored! At best, these lights are temporary blinding and at worst, they kill.

B.3565 March 16, 2024 — Springfield, MO

LEDS should be banned they blind way too many people and cause a lot of wrecks whether the light is led blue or led white it's insanely painful plus they flash too much and that can cause people to go into seizures and panic attacks and sometimes strokes it's absolutely not okay too have them need to be outlawed in all states

B.3566 March 16, 2024 — United States

Having low vision, I struggle anyway, and there is always a "bewitching hour" I leave events because of difficulty seeing while driving at night. I will NEVER forget the first LED lights my eyes got "hit by". I was totally blind. A higher power took my wheel because I COULD NOT SEE!! Just because a few selfish 'very cool' or just 'idiots' see it as a step up? No one can tell me these have caused no problems on any road at night. All you "cool" dudes? You'll save a life or two if you care. But EGOS run high on the people who install them or buy them on their new car. WE SEE YOU ALREADY! VERY COOL CAR. EXCEPT YOUR HEADLIGHTS MAKE YOU LOOK VERY STUPID.

B.3567 March 17, 2024 — Clovis, CA

I'm so weary of having to hold my hand up in front of my eyes as I drive at night when headlights are so blinding you have to block them out to try to see and be safe. What are we doing by allowing this? It's unsafe for everyone and we can easily do so much better. Please correct this immediately and let's get back to common sense road safety where we can all see again to drive without being blinded.

B.3568 March 17, 2024 — Roselle, NJ

There basically high beams. These blazing headlights are causing accidents. The glare is blinding

B.3569 March 18, 2024 — Asheville, NC

I′m only 23 and have trouble driving at night because of the absurd either bright or improperly aimed headlights. Outdated requirements for headlights, and uninforced existing policy has made it hard

to tell sometimes if the car has highbeams or regular brightness lights on. My vision is starting to become worse at night, and I now have a slight astigmatism, more so in my left than right. I shouldn't have to avoid driving at night or suffering headaches just because the people behind me want their lights to be so bright they can see my future. The cool people in their lifted trucks and tall sun's sure don't help, but improved regulation on headlight would be a start. Require new cars to have automatic pitch changing to their headlights as many cars do in Europe. As with most of what we do, the US is lagging behind the current headlight technology.

B.3570 March 18, 2024 — Brooklyn, NY

These lights literally blind u for a few seconds and are extremely dangerous. These drivers have zero consideration for everyone else on the road.

B.3571 March 18, 2024 — Daytona Beach, FL

These blind me and create more danger for drivers on the road. We've been just fine with regular headlights for decades; lets not ruin it with these LED headlights. If it doesn't stop, soon it'll be impossible to drive at night safely

B.3572 March 19, 2024 — Falmouth, MA

I find myself looking away from oncoming traffic even in the daytime because even a brief direct look at the overly bright headlights momentarily blinds me. Dangerous for everyone including pedestrians.

B.3573 March 19, 2024 — Revere, MA

I drive for a living and work early morning and evening hours. I find these excessively bright lights distracting & dangerous.

B.3574 March 19, 2024 — West Roxbury, MA

I thought I was alone or aging rapidly by being blinded by most new cars. I find Hondas/Acuras and the Cadillac Escalade to be the most aggravating. I work in the automobile business for many years and I get tbe technology. Was happy yo see the reported on WBZ and I eaderly sign my name to help find a solution for the offense of these laser-like headlights.

B.3575 March 19, 2024 — newton, MA

Those lights are blinding.

B.3576 March 20, 2024 — Attleboro, MA

It's getting very difficult to drive at night. New, blinding headlights. Either ban these or make brightness limits when getting vehicle inspecting

B.3577 March 20, 2024 — Dallas, TX

Its getting harder and harder to drive to workn in the mornings nowadays

B.3578 March 20, 2024 — Hartsville, TN

I sincerely departedly I'm concerned about this issue some lights in our area are so bright that literally have to stop in the side of the road until the vehicles pass is extra blinding when you live in the country and you have people with SUVs and with trucks that have turned over to LED lights or even projection lights it can cause complete and temporary blindness one of the thing in the state of Tennessee apparently off-road LED light bars are usable and don't need to be covered when on the state highways I am terribly terribly concerned about the condition is some unscrupulous drivers will use their light bars instead of their headlights apparently there's no log insist I feel it is very dangerous these lights are marketed and said to be off Road lights and I believe they should be treated as such if people are going to try to use them on the highways I feel they should be fine and ticketed this is my comment on this subject

B.3579 March 20, 2024 — Huntsville, AL

These light are so bright that are blinding to oncoming traffic. There have been many times when driving at night that I could not see anything in front of me, forcing me to come to almost a complete

stop, causing more danger to me and other drivers. I guess the main thing is "why do these lights have to be so bright that are putting others in harms way".

B.3580 March 20, 2024 — Indianapolis, IN

I had to stop driving at night . The Led lights are so bright and blind you . I shouldn't have to stop driving at night and getting headaches from the bright blinding led lights

B.3581 March 20, 2024 — Indianapolis, IN

Please ban the lights. Don't drive at night because of those lights can blind me and everyone else. Not Safe!!!

B.3582 March 20, 2024 — Lancaster, MA

This is a huge pet peeve of mine, not just the brightness of regular led bulbs but the inconsiderate drivers who exclusively use their high beams without dimming them to oncoming cars or travel behind other cars with their high beams on. Its rude.

B.3583 March 20, 2024 — Merrimack, NH

These lights make night driving dangerous!

B.3584 March 20, 2024 — Mill Valley, CA

It truly is a huge but frustrating common safety issue. Thankfully, it's fixable!

B.3585 March 20, 2024 — Plano, IL

I need to see too! Which I can not with bright white blue light in my face.

B.3586 March 20, 2024 — Quincy, MA

Good cause and so needed! Intense LED lights from oncoming traffic can be brutal - especially from big SUVs and pickups. OVERKILL! 💡 💡 💡

B.3587 March 20, 2024 — San Diego, CA

Light brightness and color is an issue as is car height. Another issue is that many headlights leave the factory miscalibrated. Ever notice a certain T-make illuminating the 2nd story of the building across the street. Yep. They shine at pretty much the same angle as everybody else's brights.

B.3588 March 20, 2024 — Springfield, NJ

Simple fix...set focusing standards and check at inspection stations...not ONLY emissions.

B.3589 March 20, 2024 — Winthrop, MA

I just learned about this BBH organization when it was featured on the local news (at noontime today). I have been concerned about the hazards of intensely-bright headlights and safety. I've been blinded by oncoming headlights and blinded from behind by agressive tailgate drivers. I'm relieved to know about this effort to facilitate changes. These bright headlights compromise our night-vistion and our ability to drive safely.

B.3590 March 21, 2024 — Bryantville, MA

The roads near me are narrow... when an oncoming car is using blinding lights I can't see the edges of my lane and struggle to not go off the road... I also can't see if there is anyone walking and these lights endanger pedestrians...

B.3591 March 21, 2024 — Chesapeake, VA

Aftermarket LEDs are awful!

B.3592 March 21, 2024 — Fort Collins, CO

I constantly feel blinded at night by these types of lights and believe that driving at night is unsafe when I can barely see the road when bright lights in my side mirrors blind me as well as traffic on the other side of the street or highway. It's definitely a big problem and I'm scared that when I grow older I will have more sight issues due to the increased use of these types of headlights.

B.3593 March 21, 2024 — Medford, MA

We need to be able to see when driving at night! No need for lights blinding us.

B.3594 March 21, 2024 — Milford, NH

Over the last few years I have thought "If someone needs a vehicle with that much light to drive at night they should give up driving!" Their "low beams are brighter than lots of vehicles high beams. A MAXIMUM lumens level needs to be set no matter the source providing the light. Eg incandescent/HID (a welders arc)/ LED. A law disallowing any vehicles to be driven on USA highways with a higher Lumen output. Eg. "OFF ROAD USE ONLY" However we also know how well that works (NOT) with exhaust systems sold as "off road use only"!

B.3595 March 21, 2024 — Providence, RI

I wear glasses and that is bad enough but when someone is coming towards me or especially behind me at night I am blinded. I have almost gone off the road. I live in a place that is very rural and street lights aren't always available. When someone is behind me I have to adjust all my mirrors to keep the light out of my eyes, and that is also dangerous. It's gotten to the point where I don't drive at night anymore because I'm afraid of having an accident. These lights have got to go. I agree they are great for night vision - if they're on your car. There has to be a better way around this. Get rid of those really bright ones!!!!!

B.3596 March 21, 2024 — Simpsonville, SC

My question is why do the manufacturers make LED lights so overly bright to begin with? There must be a way to lower the lumens, but no one in the industry seems to care about that or all the problems they're causing for drivers.

B.3597 March 22, 2024 — Belmont, MA

Too-bright headlights are a danger to everyone and they need to be prohibited.

B.3598 March 22, 2024 — Dover, NH

Bright headlights are blinding and hurt my eyes

B.3599 March 22, 2024 — Lincoln Park, NJ

Those lights are terrible and dangerous for workers who work at night on the road. Also for the average person over 40 who have to drive at night you can't see a darn thing they're terrible. I wish they would go back to the old headlights or come up with something that lowers them when they're coming to a lot of traffic.

B.3600 March 22, 2024 — Manchester, NH

Susan Lavallee

B.3601 March 22, 2024 — Taftsville, VT

I'd sign the a million times if I could!

B.3602 March 22, 2024 — United States

I know. We have to deal with this in Houston, Texas, among other places. This needs to end.

B.3603 March 22, 2024 — United States

I have to deal with this each night with my father.

B.3604 March 23, 2024 — Derry, NH

I have such a hard seeing while driving at nigh

B.3605 March 23, 2024 — FLAGSTAFF, AZ

Blinding LED headlights are a disability issue, as well as an issue for everyone on the road. I suffer from astigmatism, which causes light to hit my eyes at a warped angle and creates huge streaks in my vision. Driving at night has always been a bit challenging because of this. But in the past few years, it's become almost impossible. Recently, I was driving a stretch of I-70 in Colorado and was blinded by extremely bright headlights; I didn't see a curve in the road until it was almost too late. That kind of

vision impairment could have lead to me crashing into a barrier at 70 miles an hour. The fact that everyone knows these headlights are too bright, and yet nothing is done about them, is grossly neglectful and desperately needs to be addressed. We don't have to continue this arms race of ever brighter and more deadly headlights.

B.3606 March 23, 2024 — Minneapolis, MN

It is absolutely ridiculous that headlights have gotten so blinding bright. It is almost impossible to look ahead these days, I find I'm driving more and more while looking at the lane markers on the edge of the road, or off out into space just so I can see something, anything!

B.3607 March 23, 2024 — Pace, FL

I'm tired of driving blinded by oncoming headlights.

B.3608 March 23, 2024 — Westfield, NJ

Halogen projectors were more than sufficient for your average person to drive safely at night. If you truly need obscenely bright headlights to feel safe driving at night, then I'd suggest a visit to your opthalmologist.

B.3609 March 24, 2024 — Beaver, PA

Living in hilly Pennsylvania, it seems that every rise and intersection creates a blinding situation. I have often stopped dead in the road to avoid driving while blinded by incoming traffic.

B.3610 March 25, 2024 — Gilsum, NH

LED headlights are blinding to so many car drivers. Car/truck manufactures are making the front ends of trucks and SUVs much higher, so even their headlights on low-beams are hitting drivers of small cars straight in the eyes, blinding them. I know this from experience. It's dangerous and must be made illegal. I also have a problem with those adaptive headlights in other vehicles. Before they reach my front bumper, those lights go back to bright high beams, thus flashing me straight in the eyes right up close! This is a really horrible experience!

B.3611 March 25, 2024 — Solon, OH

Please pass the legislation or implement regulations to standardize car lights. We need to make roads safer!!! Thank you.

B.3612 March 25, 2024 — Wichita, KS

You guys are CLOWNS! LOL The lights aren't blue (oem at least) it's from the projector.... which ELIMINATES the glare . The light itself is white Boomers

B.3613 March 25, 2024 — Wichita, KS

🤡🤡🤡🤡🤣🤣🤣🤣

B.3614 March 26, 2024 — United States

I'm old enough to know the new headlights are brighter than the old "brights".

B.3615 March 26, 2024 — United States

The blinding headlights are just too dangerous!

B.3616 March 26, 2024 — Wahiawa, HI

These lights have triggered my migraines. I feel so unsafe driving when it's dark because those lights literally blind me. I've had to pull over and wait for the aura to leave. It just reminds me of camera flash and I hate it. Rural areas without a lot of city lights/street lights makes this issue stand out even more. It really feels like I'm going to hand over my keys earlier than I could've anticipated because if I'm having this much trouble in my 30s, I can't imagine how it will be when I'm 60.

B.3617 March 27, 2024 — Las Vegas, NV

I can't f-ing see and almost died tonight. I've had enough.

B.3618 March 27, 2024 — Oak Park, MI

Bicyicleist can not see ANYTHING with snow on-coming car with those lights

B.3619 March 28, 2024 — Paonia, CO

LED lights are dangerous and should not be used on cars. The fact that these were designed as a deterrent to environmental safety is a lie. They have a higher content of mercury than the incandescent lights.

B.3620 March 28, 2024 — Portage, MI

I keep getting blinded by LED headlights almost every time I drive at night and I'm sick and tired of it. I've gotten multiple migraines from this and worry that I'll end up getting into an accident because of how much I'm having to look away from the road/close my eyes.

B.3621 March 28, 2024 — Silver Spring, MD

There is absolutely no need for such high intensity automobile headlights! And they are extremely dangerous to drivers from the opposite direction.

B.3622 March 28, 2024 — York, PA

Don't believe the statistics fit the time frame for the yrs. involved but still really hate those lights. Thorough study of their affect couldn't have been done, at least not properly.

B.3623 March 29, 2024 — Los Angeles, CA

These lights are horrible! They make driving at night a safety hazard and scary. Cars with these lights tailgate and when they eventually pass, I am feel like I am blinded for a good while. Please abolish this monstrosity! This is not doing any one any good

B.3624 March 29, 2024 — Miami, FL

Pay VERY Close attention to pages 11 -&- 21 of this study of pedestrian deaths in the US. Besides the usual factors of the increased saturation of taller SUVs/Pickup Trucks, Distracted driving by Electronic Devices, etc, etc, etc notice how we were doing so well with pedestrian death continually on a decline but, it started to skyrocket since 2010 ? Guess what came into increasing prevalence since 2010 (LED Headlights). Also, on page 21, You'll see Dark hours pedestrian fatalities significantly increase while daylight hours stay relatively flat ? Shouldn't they increase at an even rate ? Aren't LED headlights, LED Streetlights supposed to make everything & everyone safer especially at night ???

B.3625 March 29, 2024 — Miami, FL

https://www.ghsa.org/sites/default/files/2023-06/GHSA%20-%20Pedestrian%20Traffic%20Fatalities%20by%20State%2C%202022%20Preliminary%20Data%20%28January-December%29.pdf

B.3626 March 30, 2024 — Bangor, NIR, United Kingdom

Compare headlights 25 years ago and now - it is not only the LED / projector bulb which is an issue, but the surface area of the reflector which is used to disperse the light. Headlights were around 6" in diameter. Stylists have made headlights smaller and smaller until they are often mere slits in the bodywork. There should be a minimum size for the reflector's surface area as well as a maximum luminance ! This combo avoids any need for more electronic gizmos and would correct a basic design fault ! I sometimes walk home from the pub on well lit streets and often have to shade my eyes from intense (dipped) headlights - always from newer vehicles.

B.3627 March 30, 2024 — Columbus, OH

I can no longer safely or comfortably drive or bike at night. It's not just a highway issue, drivers will idle with their lights on in neighborhood streets, unknowingly making the entire corridor an unrelenting hellscape of white light.

B.3628 March 31, 2024 — Framingham, MA

I drive a lot at night on highways. Not only are the lights themselves annoying but the way people tailgate amplifies oncoming streams of light compounding the problem.

B.3629 March 31, 2024 — Millburn, NJ

The newer bright headlights from oncoming cars are glaring and unsafe. They prevent me from seeing the road in front of me.

B.3630 March 31, 2024 — Northampton, MA

The headlights make it very hard to see anything except the on coming lights. It is dangerous!

B.3631 March 31, 2024 — Pepperell, MA

There are so many different levels of headlight brightness coming towards me that I find it blinding and extremely dangerous. It is especially bad on backroads where there are no other lights to light the area and highways where there could be continuous streams of headlights coming towards me.

B.3632 March 31, 2024 — highland, NY

these headlights are blinding to the point you can't even see the lines or people walking etc. however, that is when people decide to turn them on because i've also noticed another problem is people aren't using their headlines when they should be.

B.3633 March 31, 2024 — nantucket, MA

I'm regularly blinded when driving at night. The new headlights must be adjusted so that everyone is safer.

April 2024

B.3634 April 1, 2024 — Amherst, MA

My car is 2008 and the new lights simply blind me, often when they don't even have brights on! It's made me avoid driving at night as much as possible. But where I live all winter it is dark by 4:30 and I get stuck driving home from medical appointments or grocery shopping and streets are glaring with lines of car lights as people come home from schools or work. HELP! I really worry about the bike riders because these lights add to their dangers. All my friends, many of them younger than me, complain about these new lights. On top of this, if you don't own a big recent SUV yourself, the lights are higher and directly in your face. I wear glasses for driving with glare reduction including for blue light and it's still worse than ever before. We need to stop this nightmare on the roads.

B.3635 April 1, 2024 — Briarcliff Manor, NY

I hate getting blinded by those L.E.D. bright lights!

B.3636 April 1, 2024 — Cambridge, MA

I am one of the over 60 drivers and I find these lights nerve -wracking, especially driving in the dark, which has made me increasingly reluctant to drive at night. I don't see this "upgrade" in lighting as a positive development.

B.3637 April 1, 2024 — Central Falls, RI

The brighter lights make it harder to drive at night

B.3638 April 1, 2024 — Plymouth, MA

I am experiencing this so badly that I avoid driving at night. The problem could also be cataracts, folks. But when you experience both, like I do,-wow!

B.3639 April 1, 2024 — Sedona, AZ

I no longer drive in the dark for this very reason. I absolutely cannot see and it is terrifying. To say this is not happening is outrageous. Something needs to be done. Please.

B.3640 April 1, 2024 — santa cuz, CA

I can't even drive at night anymore. this is ridiculous.

B.3641 April 2, 2024 — Arlington, VA

I have found the lights on emergency and Dept. of Transportation vehicles so bright that they are blinding! These lights make me look away when I should be looking at the road and they even cause

blindness for a few seconds. Also, the headlights on cars are so bright that they are dangerous because you can not see a pedestrian crossing the street because the lights blind you. Even the tail lights have gotten brighter and are painful to my eyes. The bright headlights are even offensive from behind and cause me to move my mirrors to avoid the painful effect they have on my eyes. This is dangerous because I can't see passing cars or see the cars behind me. I have many friends who have complained about these same issues. It is time you take action and stop allowing the use of these LED lights.

B.3642 April 2, 2024 — Cheadle Hulme, ENG, United Kingdom

find it so difficult to drive with these bright lights. far to bright and being a small car owner they shine through the windscreen. dangerous.

B.3643 April 2, 2024 — Plymouth, ENG, United Kingdom

they are dangerous the light are a blur

B.3644 April 2, 2024 — fort stewart, GA

Too bright!!!

B.3645 April 3, 2024 — Chicago, IL

OMG do I need to say more. !!! How our Government allowed this is insane. They want us blind, broke and starving. I am on my Senator all the time. Can't drive even in daytime.

B.3646 April 3, 2024 — Chicago, IL

{"videoUrl":"https://stream.mux.com/eVQiHMXbqnvmICItrzLC4kLMSq005HtYPwLHsnkmeHG8","cloudflareUid":"28fe8a804997bffea31de859be9197ed","muxAssetId":"1fCRWiKAAVFeVARS02NW8pi02t7ogiFtZq00rBZl7YvYhg","muxPlaybackId":"eVQiHMXbqnvmICItrzLC4kLMSq005HtYPwLHsnkmeHG8","muxPlaybackUrl":"https://stream.mux.com/eVQiHMXbqnvmICItrzLC4kLMSq005HtYPwLHsnkmeHG8","muxThumbnailUrl":"https://image.mux.com/eVQiHMXbqnvmICItrzLC4kLMSq005HtYPwLHsnkmeHG8/thumbnail.jpg"}

B.3647 April 3, 2024 — Croydon, United Kingdom

I have astigmatisms in both eyes. I am being blined and now not driving in the dark.

B.3648 April 3, 2024 — Dublin, Ireland

I cannot drive safely at night with current levels of glare and brightness from other drivers' headlights

B.3649 April 3, 2024 — Hackensack, NJ

it is so dangerous

B.3650 April 3, 2024 — Indianapolis, IN

I HATE blinding headlights

B.3651 April 3, 2024 — North Royalton, OH

This should be an obvious no brainer, and yet dept of transportation federally and locally are inept...

B.3652 April 3, 2024 — Stockport, United Kingdom

Blinding LED lights have been an ongoing issue for a number of years now and I am surprised that the government has not raised and tackled the issue sooner. I dread to think how many road deaths of car drivers, motorcyclists and pedestrians can already be attributed to this and how many people have their lives restricted by the issue of not wanting to drive at night. Surely if you can select the degree of whiteness of LED lights in your kitchen then manufacturers can do the same for road vehicles. It also appears that there is currently no direction control on headlights. Older MOT.s always had headlights directed to the left in the UK. Reduce road deaths and get this issue resolved.

B.3653 April 4, 2024 — Addington, ENG, United Kingdom

Whoever came up with the idea LED bulbs this bright for cars is a numpty. I know many poeple who say they cuffer or just dont drive at night becasue of this.

B.3654 April 4, 2024 — Chicago, IL

We should get together and sue the government if a death or injury occurs. Take pics asap if you have an accident and of the car with dam lights!!!! The people using them are aholes and don't give a dam!!!

B.3655 April 4, 2024 — Claremont, NH

Get rid of the blinding headlights!!!!!!!!!

B.3656 April 4, 2024 — Claremont, NH

Do you tolerate bright light being shined in your eyes at night? I no longer drive at night because of it. I hope you can see because I can't ! That's right, this is America and you don't care.

B.3657 April 4, 2024 — Houston, TX

LED lights are extremely blinding to the eyes. They should be out right banned for safety reason. Lights also shouldn't be too blue as it hurts the eyes. They should be yellow or soft white.

B.3658 April 4, 2024 — Willesden, ENG, United Kingdom

These LED lights are unregulated and too bright - especially hazardous on SUVs as they are directly in the sight line of drivers in ordinary cars. They are a dangerous hazard and should be regulated so they are less powerful and a warmer colour (2700 - 300 Kelvin would be an acceptable colour temperature) We had no problem seeing the rd with filament lights - so the "safety aspect" of brighter lights being safer - quoted by the manufacturers is irrelevant and unnecessary. All LEDs need proper regulation - but car headlight must be a priority as they are a health and safety issue.

B.3659 April 5, 2024 — Brunswick, GA

I can't even drive at night any more, this has been taken away from me because of other people's LED, high-beam headlights. It is really unacceptable that I am blinded by other people's headlights to the point that it's a safety issue because I can no longer see the road.

B.3660 April 6, 2024 — Warminster, United States

I couldn't be any happier to join in this to get rid of these blinding lights. Especially on trucks and SUVs

B.3661 April 7, 2024 — Knoxville, TN

As a truck driver who often drives at night these headlights are blinding and dangerous.

B.3662 April 7, 2024 — Scarborough, Canada

This is a serious problem

B.3663 April 7, 2024 — Silver Spring, MD

These lights are clearly a hazard to oncoming traffic. How can they even be legal?

B.3664 April 8, 2024 — Glendale, AZ

Going on a roadtrip and its impossible to see anything behind me with those lights!

B.3665 April 8, 2024 — Saint Louis, MO

I'm constantly blinded by these lights in the city. It feels like it's causing me flash blindness which is definitely a safety concern.

B.3666 April 9, 2024 — Albuquerque, NM

The new LED headlights are brighter than the old bulbs were on highbeam, and are DANGEROUS to oncoming traffic as they blind other drivers.

B.3667 April 9, 2024 — Columbus, OH

Car LED lights have a major affect my light blue colored eyes both during day and night time. Besides temporarily blinding me, I also noticed it affects my eye retinas as I also temporarily see black spots more often after getting blinded LED lights as I get older.

B.3668 April 9, 2024 — Spokane, WA

I suffer from epilepsy and in doing some research found this petition. While bright headlights itself does not effect me so much, the use of LED lighting literally everywhere does! It is discriminating against the 3 million people of us within the US who also suffer from this. I can not go in to a store more than 5 to 10 minutes before I have issues, I can not drive under LED street lamps or look at any lights any where that have changed to LED. Places I never had issues going to until just the last year or two I can not be at more than a few minutes. While I understand the rush to "go green", you are not thinking this through for the people who literally can not be around this lighting because it is dangerous! It causes life threatening seizures! And now you can not even buy "normal" light bulbs any more for your home so what do you want us to do that can not handle the LED's? Light our homes with candlelight? Just like the push for EV cars - there needs to be some thought behind things. I am in architecture and design so I am well aware of good design and this is very very bad design!!! The politicians in charge need to stop bickering amoungst themselves and actually LISTEN to the people they claim to represent. ALL THE PEOPLE! Including those of us who can not be around this new lighting!

B.3669 April 9, 2024 — St. Peter, MN

LED lights are garbage and bad for living bodies

B.3670 April 9, 2024 — St. Peter, MN

I'm not good with words but LED lights need to be done

B.3671 April 10, 2024 — Cheadle, United Kingdom

Sometimes you are blinded whilst driving in dark and raining conditions.

B.3672 April 11, 2024 — Hewlett, NY

It's almost impossible to drive at night anymore. As an older adult, my eyes don't recover quickly enough. Makes driving hazardous

B.3673 April 12, 2024 — Pittsburgh, PA

I work in the optical business. These headlights cause disabling glare. In particular if a patient has cataract not removed yet. Terrible idea.

B.3674 April 12, 2024 — Rialto, CA

I've been blinded by vehicles of newer years multiple times it's a very dangerous thing I am afraid of crashing

B.3675 April 13, 2024 — Chicago, IL

We can spray them black or put tape or break

B.3676 April 13, 2024 — Chicago, IL

Under Biden everything stupid now. That's how

B.3677 April 13, 2024 — Holden, MA

The lights are a safety hazard

B.3678 April 13, 2024 — Pittsburgh, PA

I am a victim of these destructive lights, I complained to my eye doctor and they said "unfortunately you have the glare lends, it's the car lights which a lot of people have trouble with" so Fck them lights

B.3679 April 14, 2024 — Bozeman, MT

These blinding bright lights are making being able to drive a hassle because the amount of times I have nearly gotten hit from not being able to see is insane

B.3680 April 14, 2024 — Portland, OR

The people behind this crime against humanity, are killing people intentionally, flat out causing wrecks and blindness. That is the truth, and they should be banned permanently as well as the new led street lights. They are terrible and shame on the people that have imposed upon us.

B.3681 April 15, 2024 — City of Saint Peters, MO

With my astigmatism, I don't feel safe driving any time past sundown.

B.3682 April 16, 2024 — Bishopville, MD

On Nov. 3, 2022 at 9:14 p.m. an approaching vehicle had LED headlights on high beam which blinded my vision and ended up in a ditch. Which the approaching vehicle did not stop kept on driving. My vehicle was totaled and I suffered a very bad concussion. The LED headlights should be banned. My accident could have been a lot worse.

B.3683 April 16, 2024 — Dickinson, ND

These lights make it unsafe to drive. My husband has a horrible time seeing with these led headlights passing by but I have it much worse because of the halos around lights that I get after having lasik. This is a COMMON side effect with lasik. How many accidents need to happen from these horrible lights before common sense prevails.

B.3684 April 16, 2024 — Indianapolis, IN

I value my eyesight and safety. Ultra bright headlights are damaging to the eye and dangerous as they blind you from seeing potential danger.

B.3685 April 16, 2024 — Tenafly, NJ

As a migraine sufferer, these headlights trigger migraines and create dangerous driving conditions for me.

B.3686 April 21, 2024 — Allentown, PA

I have been hurt multiple times by these bright lights and they are unnecessary

B.3687 April 21, 2024 — Cadillac, MI

As someone who has journeyed through the evolving landscape of our nation's roadways, I stand before you at the age of 38, having witnessed a significant transformation in automotive lighting. The advent of LED headlights has brought about a dichotomy of experience: a beacon of progress for those behind the wheel of such equipped vehicles, and yet, a blinding hazard for those ahead. I am privileged to navigate the night sparingly, but let us turn our thoughts to the countless Americans for whom darkness is a daily passage. They traverse vast distances, night after night, to sustain their livelihoods and support their families. It is a journey made perilous by the blinding glare of oncoming traffic. With the passage of time, the challenge only intensifies. The stark, piercing lights that line our roads do not discriminate by age, but the resilience of our eyes does. The danger of being blinded by these lights is not just a discomfort—it is a looming threat to our safety. Consider the plight of my wife, who finds the night unnavigable, plagued by headaches induced by the relentless strain of modern headlights. Her vision, like that of many others, cannot adapt with the swiftness of youth. The glare is not merely an annoyance; it is a barrier that obscures her path and endangers her journey. This is not an isolated struggle. It is a shared burden, a collective risk that we must address. It takes but a fleeting second for an accident to occur—a second where lives can be irrevocably altered. We stand at a crossroads where technology and safety must converge. We must advocate for regulations that protect all travelers, ensuring that innovation illuminates our path forward without casting a shadow upon others. Let us strive for a future where every American can drive under the starlit sky with clarity and peace of mind. Thank you.

B.3688 April 22, 2024 — Fort Worth, TX

The State used to take responsibility for checking headlights annually with vehicle inspections. What happened? Most mornings my family experiences temporary blinding from just a handful of selfish TX drivers. This happens in school zones and is infuriating. We don't feel safe driving blind around children! Get em out!

B.3689 April 24, 2024 — Madison, OH

Yes please. Some people don't have them on or off when necessary, certain times of the day here in Ohio, but sometimes law has not gone far enough to protect our health and life.

B.3690 April 25, 2024 — Newmanstown, PA

I get a headache when under LED, Halagon and florescent

B.3691 April 25, 2024 — Roseburg, OR

I can't see when someone with bright headlights on.

B.3692 April 26, 2024 — Kearney, NE

Daytime driving is now negatively impacted with bright LED headlights distrupting depth of field vision and creating blind spots.

May 2024

B.3693 May 1, 2024 — Culver City, CA

Do not want any more emails about this. Please remove my name.

B.3694 May 1, 2024 — Dillsburg, PA

My heart went out to the elderly patients in a nursing home recent Iy as the hallways were insanely bright.

B.3695 May 1, 2024 — Macedon, NY

Tired of being blinded on the road. It is not safe given that after exposed I cannot see a thing.

B.3696 May 1, 2024 — Melbourne, Australia

I drive city to country regional one night a week and don't need extra aggrevation on my eyes on a 80 minute trip. Besides night should be calmer. I don't want night to be like day or I can't sleep at home. It disrupts our circadian rhythms. The world seriously needs *less stress* right now.

B.3697 May 2, 2024 — Adelaide, Australia

After 13 years as a delivery driver I am now blinded almost every night by maniacs in huge utes/4wds/suvs with giant bullbars and massive extra high-beam LED spotlights used completely inconsiderately, sometimes intentionally, causing eye pain, blindness and nausea. We've had 124 years of automobiles and never deemed any of it necessary except in the past 5 years. This is entirely mental illness (narcissism/psychopathy).

B.3698 May 2, 2024 — Chicago, IL

I'm 49 and can't drive at night in a major city, this is insanity. It's too bright! Unfair to keep people off the road like this and it's killing people

B.3699 May 2, 2024 — Glendale, CA

I can't see well at night anyway but being blinded does not help

B.3700 May 2, 2024 — Rochester, NY

Everyone including decision makers who drive at night is well aware of this hazard particularly in wet weather. It's time for leaders to step up, take accountability and act accordingly.

B.3701 May 2, 2024 — Toms River, NJ

This is so dangerous to the on coming driver, completely blinding them, especially the trucks with 4-6 lights coming towards a car. Think about other people for once.

B.3702 May 3, 2024 — Mechanicsville, VA

Please! Stop blinding me so that I don’t have a car accident that could lead to the loss of life!

B.3703 May 3, 2024 — Tacoma, WA

Screw LED headlights! And screw poorly done HID and LED retrofits! There are people who would still be alive today if these things weren't on the road!

B.3704 May 4, 2024 — Doylestown, PA

These new headlights must be removed they are a huge pain and companies must be forced to get rid of them and replace the ones they sold for free.

B.3705 May 5, 2024 — Ashland, PA

It's scary to guess where the road is because of another driver's LED headlights, and it's even more scary for the people that are not driving a truck, SUV, or van. It's time we make evening driving safer for everyone.

B.3706 May 5, 2024 — Fairport, NY

So glad someone is doing this. My last night trip was awful because of those lights Thanks for doing this

B.3707 May 7, 2024 — Australia

I hate driving at night now every second car blinds you i think these people must be scared of the dark.....

B.3708 May 7, 2024 — Reno, NV

This petition matches the goals of my Nevada Civil Action Project, and as someone with astigmatism, I would greatly appreciate a reduction in the brightness of LED headlights.

B.3709 May 10, 2024 — Denver area, CO

LEDs lights and to me, especially used on cars, are a real hazard; my city will now no longer use anything other in its streetlamps than LEDs in showing the world what a "green" and sustainable place it is. Ban or at very least, regulate this type of light to where we are not continually in danger of harm.

B.3710 May 10, 2024 — Golden Valley, MN

LED lights are blinding.

B.3711 May 11, 2024 — Evansville, IN

I can not see when these cars headlight are coming towards me.

B.3712 May 11, 2024 — Halifax, Canada

It's dangerous to drive with blinding lights in your eyes at night. Get rid of them

B.3713 May 11, 2024 — Philadelphia, United States

Thanks for the highly useful information. I will now quickly adopt more incandescents in my home environment.

B.3714 May 12, 2024 — Ely, United Kingdom

Very dangerous

B.3715 May 12, 2024 — Portland, OR

Finally!! led lights are fine in some cars, mostly German, but new Toyota, Hondas, Subaru and Mazda have so much glare, that it's frustrating to drive at night. Worst offenders are trucks or higher cars!! This is both a law enforcement and lack of policies governing light intensity problem. Most people don't realize if their headlights are misaligned and are causing glare to the opposite traffic. And manufacturers have started putting LEDs in reflector headlight assemblies which makes the issue of glare even worse. We need policies that limit the intensity of glare. Matrix LEDs are too expensive but do a great job at not blinding the opposite traffic.

B.3716 May 14, 2024 — Portland, OR

This LED headlight epidemic and the resulting difficulty and stress of simply being outside has impacted my life so greatly, I feel like I'm now a handicapped person--just for having a slight astigmatism. I'm trying everything I can to adapt: I wear sunglasses all the time now, I bought blue-light filtering glasses, I tilted my side mirrors down, I'm going to tint my windows, including my windshield. This is such a glaringly (pun) obvious oversight and negligence by the NHTSA. Nothing else--not divorce, not a terrorist attack, not politics, not drugs--has affected my day-to-day quality of life like this has. It sounds pathetic, but I can't stop obsessing and feeling heartbroken for just being reminded of the mass ignorance and selfishness in this country every time I leave the house. All of these people purposefully chose to make the worst part of life EVEN WORSE. It may have been the

last straw on the camel's back, but I seriously need therapy now because I just don't know to cope and be "normal." My life is literally worse because of this. Is this not the most eligible scenario for a class action lawsuit, like ever?

B.3717 May 14, 2024 — St. Augustine, FL

I think are far too dangerous.

B.3718 May 14, 2024 — sagada, Philippines

I hate LED

B.3719 May 15, 2024 — Glasgow, SCT, United Kingdom

These lights are so bright, they're dangerous.....accidents waiting to happen.

B.3720 May 15, 2024 — Kansas City, MO

They are blinding!

B.3721 May 15, 2024 — Westfield, IN

I have bad night vision and try to avoid driving at night. I'm heavily dependent on lighting and road markings. I was in an area where the lights were off and the markings weren't well maintained. A truck was across from me and it was tall enough to shine its extremely bright headlights into the cabin of my car and into my face. The light lingered in my eyes for a while afterwards and a car was behind me trying to turn left. I could not see and almost hit the median. I looked up why the lights lingered for so long and it's because the lights are bright enough to burn the cells in your eyes responsible for night vision.

B.3722 May 16, 2024 — Livermore, CA

Blinding headlights, especially when drivers leave them on the high or brightest setting causes accidents and make driving at night harder.

B.3723 May 17, 2024 — Philadelphia, PA

These hyper bright LED headlights are DANGEROUS!!! Even in daylight traffic my retinas are burned by them as they approach me, and they are especially especially blinding at night!!! They should be illegal and taken off the market!!

B.3724 May 22, 2024 — Campbell, CA

I've lost count of the number of near accidents because of blinding LED headlights.

B.3725 May 22, 2024 — Secaucus, NJ

Every other car on the road it seems has had insanely bright lights that make it impossible to see where you're going without hurting your eyes. It's dangerous and it has been an issue that seems to just be getting worse for at least a year now. I've noticed this in various states across the US.

B.3726 May 23, 2024 — Candler, United States

I had a TBI in 2011 and have been hypersensitive to direct high-contrast ever since. While I have had some improvement in my condition over time, this timeframe also coincides with the brightening of headlights on the roads at night. I can not safely drive at night or in the rain due to the threat of high-intensity LED headlights. This impacts my employability. I have changed jobs several times since my injury, and finally sold my house & moved in right next to where I work. Even walking at night is hazardous for me, as I can experience dizziness, blurred vision and even "blinding out," where all I see is white light. This also often leads to migraines, which cause me to miss work and suffer greatly. I would appreciate any and all efforts to regulate headlights to a level that is safe for other drivers.

B.3727 May 24, 2024 — Katonah, NY

The light pollution that is occurring on U.S. highways is the beginning of the newest environmental disaster for wildlife, especially migrating birds

B.3728 May 26, 2024 — Brooklyn, NY

Intense LED headlights are irritating and the glare is dangerous.

B.3729 May 26, 2024 — Quechee, VT

If you can't see with regular headlights, you shouldn't be on the road at night anyway. Your compensating lights blind everyone else, including those whose vision is perfect. Road hazard.

B.3730 May 27, 2024 — Phoenix, AZ

I have been blinded by those super bright lights.

B.3731 May 29, 2024 — Parrish, FL

Bright blinding headlight glare gives me a near death experience at least once per week! It must be tamed!

B.3732 May 31, 2024 — Chicago, IL

I put reflective material in my rear window. It works great and sends the light back to that ignorant driver. They could do something but don't. I shine my LED light out my window also when there's an *** toward me.

B.3733 May 31, 2024 — Chicago, IL

We will all get macular degeneration. They have an evil agenda with this. Under Biden's admin.

B.3734 May 31, 2024 — Chicago, IL

Our evil admin. has a plan that's why nothing's being done. It's not America anymore.

B.3735 May 31, 2024 — Fountain Hills, AZ

STOP those damn blinding headlights! Consider where these lights are from just like the mercury lights! Our enemy wants us blind! They are illegal and TOO BRIGHT!

B.3736 May 31, 2024 — Jacksonville, FL

Ban the production and sale.

June 2024

B.3737 June 3, 2024 — Pflugerville, TX

I am in my mid-to-late 20s and I have recently noticed that driving at night has become significantly more difficult due to the prevalence of extremely bright LED lights on vehicles. We need to fix this now!

B.3738 June 4, 2024 — Lombard, IL

I can't see when driving on the road. I'm 20 I'm supposed to have good eyesight and for the most part I do, but I can't drive when I'm being blinded by the light of god on all sides. I've started driving at night with sunglasses because I genuinely can't see. And what's worse is that I see better with the sunglasses on that without them because the LEDs light up the entire road. The best part is that even with sunglasses on tho, they're still blinding at times. Isn't it illegal to have something on your car that impares another driver? Well the LEDs are imparing my ability to see so I don't get why they aren't illegal. I even tried talking to a cop about why they never pull people over for their brights and LEDs and I was told they aren't "high enough priority". Funny how someone driving 5-10 miles over the speed limit is higher priority than not being able to see the road at all. Either I have to wear sunglasses or put my hand in front of my face to not be blinded but then the problem is if my hand is in front of my face I can't see the road at all. These LED's aren't safe and there's no way for me to avoid them. Sure they make it easier to drive at night for YOU. But what about ME? What about every other person on the road that's not in the same car as you? What about those of us with shorter cars? Are we just supposed to suffer? I don't feel safe driving at night. And it's even worse on cop cars too. Especially when you get pulled over and all of their lights are blinding not only the person who's pulled over but every other person on the road but now it's white, red, and blue lights blinding you while they blink on and off. And I'm wondering if cops aren't as affected by the LED's since their windows are tinted so people can't look in. Doesn't it work both ways? If people can't look in I'd assume it means it blocks out a lot of the light from LEDs. Something has to change there's no way this is safe for people. The people who love them are the people in tall cars with blinding LEDs since no other car is tall enough for it to bother them. I just want to be able to see the road when I'm

driving. Isn't that the whole thing we were taught in school? Don't drive if you can't see? I can't just stop in the middle of the road but I might if people keep doing this. I shouldn't have to choose between not seeing the road or just barely seeing the road.

B.3739 June 5, 2024 — Chicago, IL

Please stop allowing people to drive with these blinding headlights. I can not see well when they are coming toward me and feel as though I could crash. They are just too dangerous.

B.3740 June 6, 2024 — houston, TX

bright LED lights are a hazard to other drivers. Be safe

B.3741 June 7, 2024 — Manchester, MO

It is wildly dangerous. I'm a ride-share driver, and working at night has become genuinely frightening. If they were pointed down even a few degrees, it would make a world of difference.

B.3742 June 7, 2024 — Toronto, Canada

Vehicles should annully be checked for dip

B.3743 June 8, 2024 — Brooklyn, NY

These headlights need to be regulated as to acceptable total brightness to avoid the blinding glare. It needs to be handled as soon as possible to prevent further accidents.

B.3744 June 8, 2024 — Niceville, FL

Those lights blind me.

B.3745 June 8, 2024 — Round Rock, TX

This is very frustraiting

B.3746 June 8, 2024 — Salem, NJ

The lights are blinding! This needs to stop

B.3747 June 8, 2024 — Santee, CA

Driving at night is unbearable with blinding headlights.

B.3748 June 8, 2024 — Somerset, MA

I agree it is very dangerous for pedestrians and also have experienced the pain in my eyes from them.

B.3749 June 9, 2024 — Bellevue, WA

I've never had an issue seeing the road in my 1990 Toyota, but since led lights became normal I can barely drive at night. My friends with astigmatism are even worse off, many no longer able to drive at night at all. End this disgusting hazard once and for all.

B.3750 June 12, 2024 — Beverly Hills, CA

I just want to drive at night without having to swerve to avoid being blinded

B.3751 June 12, 2024 — Beverly Hills, CA

I just want to be able to see

B.3752 June 12, 2024 — Kirkland, WA

I never had migraines before the recent onslaught of super-bright LED lights in all the new vehicles. I don't remember anyone claiming that existing cars' headlights weren't bright enough but all of a sudden in the last few years, I can't drive after dusk without being blinded. It's horrible being subjected to massive light-induced migraines on a daily basis just to get home from work. It has cost me so much in my quality of life. It needs to end now.

B.3753 June 13, 2024 — Ahmednagar, India

I almost had accident due to this white light people use it as upper which blinds the car ahead and front of them

B.3754 June 13, 2024 — Cedar Rapids, IA

LED headlights trigger my migraines and make it extremely difficult for me to drive at night, and I'm a YOUNG ADULT. I can only imagine how it's impacting older people. You don't need a 5,000 lumen industrial-grade spotlight to drive your awful SUV at night.

B.3755 June 13, 2024 — Parsippany-Troy Hills, United States

It causes accidents.

B.3756 June 13, 2024 — Tallahassee, FL

The brights on a car with halogen bulbs are a special light that must be activated by a lever. If your headlights are the same as standard brights, it is too dangerous.

B.3757 June 14, 2024 — Winston-Salem, NC

What changed? It used to be that running brighter high beam headlights within 500' of an oncoming vehicle was illegal because it blinded the opposing driver. Now manufacturers are allowed to install even brighter "low beam" lights that cannot be dimmed, blinding oncoming drivers when cresting a hill or when the vehicle is loaded in the rear or is pulling a trailer. This is dangerous and should be brought back under sensible control. Please regulate the brightness of low beam headlights.

B.3758 June 15, 2024 — Newtown, United States

Used to love driving at night, my eyes are so sensitive I can barely do it anymore.

B.3759 June 15, 2024 — silver spring, MD

i get migraines whenever i drive at night now

B.3760 June 16, 2024 — Ashland, OR

Super bright Led headlights are harmful to the eyes and super dangerous. I have to wear yellow glasses at night so I can still see without being constantly blinded. This shouldn't be allowedto happen. This is outright dangerous and needs to be banned immediately

B.3761 June 20, 2024 — Indianapolis, IN

I absolutely hate driving at night now it's like everyone is driving with their brights on. I can't see and they blind me and I am only 38 years old. I have 20/20 vision. There is nothing wrong with my eyes and there is everything wrong with these LED bright lights. They need band and they need band immediately

B.3762 June 20, 2024 — Springdale, AR

I've almost crashed a few times already with how bright some trucks have their headlights. I drive a sedan so I'm constantly blinded by these cars and trucks that have even brighter headlights than I do. I've came across a few already where they light up my whole entire car just by being behind me at a red light. It's becoming a bigger issue as time passes and something needs to be done about it.

B.3763 June 30, 2024 — East Point, GA

I absolutely HATE these lights. I drive a regular car, not a truck or suv. I hate them most when people are driving with them on in the middle of a bright sunshine day!! Why!! I can't even go out at night anymore, as most people are now driving with the bright beams regardless of on coming traffic. Please Make It Stop!!!!@

July 2024

B.3764 July 1, 2024 — Austin, TX

This causes a dangers to approaching traffic.

B.3765 July 1, 2024 — Fort Worth, TX

I literally cannot see at night.

B.3766 July 9, 2024 — Greenville, SC

This is so important!

B.3767 July 11, 2024 — Huntley, IL

I mean. Has there ever been a time where a single human being has said, “I love those LED headlights in new cars!!! They help me see so much better now that more people have them!” ?????? Your honor, I rest my case. — also, I want to note that does f150s/f250s are like the second or third most purchased car in the entire United States — so the most blinding incident when it comes to stupid LED headlights (a truck that is raised up & apparently has enough headlights that it can double as a stadium light for football fields…) — this is an incident that happens regularly, and Al too often. The only thing worse than an LED headlight would be two strobe lights. Legit one step above strobes. Ban them.

B.3768 July 13, 2024 — New Orleans, LA

I use yellow lense safety glasses for night driving. They work well .The yellow lenses knock out the glare from on coming traffic .

B.3769 July 16, 2024 — Severna Park, MD

Go back to YELLOW LIGHTS these bright white LED and the ones abused by idiots thinking it will blind others should be outlawed. LED were adopted to be used as a communication device later. Halogen could not be used for that purpose.

B.3770 July 21, 2024 — Navarre, FL

They’re truly insufferable, it makes me fearful to drive on roads without street lights as is most common in the USA. I fear i won’t be able to see someone or something in the road or miss a curve if I’m on an unfamiliar road, they’re as bright as regular high beams but that’s just their normal setting! There needs to be heavy regulations on how bright they can be or an outright ban and return to the yellow that used to be standard, the LEDs make the roads more dangerous and are only safer for those that have them but even then I’m sure they’re unable to see as well when they come upon another vehicle with them.

B.3771 July 22, 2024 — Cambridge, United Kingdom

Iwmacer

B.3772 July 25, 2024 — Sebastian, United States

Michael Ciufo

B.3773 July 30, 2024 — Auburn, WA

This is a real problem, and needs addressing. Lights are brighter than they were in the past, and drivers don't think of others.

B.3774 July 31, 2024 — Rocklin, CA

Yes this is f*cking rediculous. I also sent an email to the national highway traffic and safety administration. By the way, never "chip in" on this website, it's a scam. 100% of the money goes to change.org. None of it goes to the cause you want to support.

B.3775 July 31, 2024 — Sacramento, CA

I have a bad case of astigmatism and these lights at night maje it so dangerous for many while driving at night.

August 2024

B.3776 August 1, 2024 — Searsmont, ME

I'm sick of halfway veering off the road

B.3777 August 2, 2024 — Port Charlotte, FL

These unregulated led and ultra bright headlights are a major distraction and safety issue.

B.3778 August 4, 2024 — Amherst, MA

Turn your high beams off when passing oncoming cars too!

B.3779 August 4, 2024 — Conway, AR

Driving at night is too dangerous because of LED lights. I want the road to be safer for my family.

B.3780 August 5, 2024 — Mesa, AZ

I can't drive at night with out being temporarily blinded by a giant SUV's bright headlights

B.3781 August 6, 2024 — Norwich, CT

The new headlights are very blinding.

B.3782 August 8, 2024 — Albemarle, NC

I already have bad eyesight as is and even with me wearing glasses at night I still get flash banged and I absolutely cannot see anything for a solid 5 seconds and have to slow way down so I don't wreck into anything. This morning, we're in the middle of a hurricane and I'm on my way to work and it's still pitch black. This truck has the most god awful obnoxious amount of headlights and awfully bright along with that. I was horribly blinded and couldn't see anything but god himself and all his glory on the front of the truck and almost ran off the road. Keep in mind with this hurricane and it raining like it is, it's already hard to see so I'm already on the verge of having a meltdown driving to work because the roads are flooding and there's sticks and whatnot in the road, so to be flashbanged by some a**hole who likes to see the hair on a raccoons a** at night, I definitely cried after that.

B.3783 August 9, 2024 — Saugus, MA

These headlights are a major safety hazard! Oncoming blind you so that you are forced to slow down to an almost complete stop. When they drive behind you, they shine in you rear and side mirrors making it virtually impossible to safely change lanes. I literally have to angle my mirrors completely away from my vehicle because I cannot see. They need to he out lawed.

B.3784 August 14, 2024 — Fairchance, PA

I drive a small car and I have come across issues where i am completely blinded due to a truck behind me blaring their led "low lights" straight into my back shield lighting up the whole car, piercing into all three mirrors, reflecting perfectly into my iris. the only solution to this free laser eye surgery is to flip my rear view mirror and completely turn my outer mirrors so that they are completely useless. well in my case, it's more useful to not see what's on my sides in exchange for the ability to keep my eyes open.

B.3785 August 14, 2024 — Peoria, AZ

I almost dread having to drive at night now, it's ridiculous that I can't drive without being constantly blinded by these LED lights, it's outta control. I'm so glad to see I'm not the only one who thinks this has got to stop!

B.3786 August 18, 2024 — Knoxville, TN

I have an '85 Camaro & it's INSANE too drive at night with ALL the STUPID, ARROGANT self-centered IDIOTS who BLIND me from behind with these INSANE, after-market egotistical HID/Xenon lights that SHOULD BE BANNED!!!!! Enough is enough NHTSA!

B.3787 August 20, 2024 — Niceville, FL

I have astigmatism. It makes light sources look like a lens flare in a movie. The brighter the light compared to the ambient light, the bigger the flare. The LED headlights are so bright that they can occupy my entire field of vision, especially at night. This leaves me unable to see signs, lines, and other cars on the road. It is wildly unsafe. I am one of thousands of drivers in the US with astigmatism. I cannot emphasize how dangerous these lights are to other drivers.

B.3788 August 21, 2024 — Abbeville, LA

I, along with many others, are about to lose our ability to drive at night because of these outrageously bright lights.

B.3789 August 22, 2024 — Australia

Health is affected by bright light.

B.3790 August 23, 2024 — staten island, NY

I have started to drive less and less at night because I can't stand being blinded in my mirrors while driving. It's unsafe, and it can be very distracting. I also have sensitive eyes, so those strong bright lights hurt sometimes as well.

B.3791 August 26, 2024 — Victorville, CA

These lights are very blinding they have blinded my eyes to where I only see blackness and makes it very dangerous to drive with these on your face on your eyes

B.3792 August 31, 2024 — Gulf Breeze, FL

These led headlights are dangerous and I've almost crashed already multiple times. They should be banned completely in the name of public safety.

September 2024

B.3793 September 4, 2024 — laurel, MS

I'm signing because these kinds headlights or what caused the wreck that my mother-in-law died from and my sister-in-law is in bad shape

B.3794 September 5, 2024 — Middleburg, FL

Headlights have become so bright they are blinding even in the day time. In Florida!

B.3795 September 5, 2024 — Philadelphia, PA

It hurts my eyes so much and i dont understand why people put them on their cars. Its not cool at all.

B.3796 September 6, 2024 — Louisville, KY

I'm blinded and can't see anything going to cause me to have an accident. They're getting worse every day.

B.3797 September 9, 2024 — Dayton, United States

I flash my flash light at them so they can see how it feels

B.3798 September 9, 2024 — San Francisco, CA

I struggle with driving at night for long distances because the reflection of these bright lights in my mirrors + with glasses triggers migraines for me. Almost as annoying as the amount of times my husband complains about the bright lights to me. ;)

B.3799 September 10, 2024 — Henrico, VA

I am 23 years old and can barely drive at night due to LED headlights. I am forced to make reckless driving decisions because I cannot see behind or beside me, let alone in my rearview mirror. There is no need for any vehicle to have headlights that are automatically that bright; that is why 'brights' exist. Save it for back roads when there is no ambient lighting and no other drivers.

B.3800 September 10, 2024 — Old Forge, PA

I hit a deer because the person coming my way had bright led's and i couldn't see! The deer had jumped out into the road but it was last second when i finally saw it!! Had significant damage to my car and anxiety for over a year when driving at night!!!!

B.3801 September 10, 2024 — Wixom, MI

What a ridiculous world we live in where this has gotten so completely out of hand. What a great way to show you literally care about nobody but your yourself. The manufacturers need to be sued for the countless deaths I'm sure they've directly caused due to these lights.

B.3802 September 11, 2024 — Saucier, MS

Imagine driving on the winding roads of one of America's national parks before sunlight. Now imagine blinding headlights speeding around a curve. How is it fair that only some individuals get to use public roads after dark?

B.3803 September 12, 2024 — Dallas, TX

Astigmatism, these lights make it impossible to leave work or go anywhere in the cool afternoon/night.

B.3804 September 12, 2024 — Encino, CA

In the last few years I've noticed all the headlights are too bright. I can't look directly at anything and I'm always afraid I'm going to hit a pedestrian at night because the lights are so blinding you can't see anything in the road. I can't see behind me at night and all the trucks with daytime running lights blind me in the daytime. This is really too out of hand and it seems like auto makers are really trying to kill people by causing blindness or seizures or accidents. We need dimmer headlights, not brighter.

B.3805 September 12, 2024 — Fredericton, Canada

This flickering causes me so much pain both in daytime and night. I think it′s absurd to have this amount of light, or this amount of flicker in an auto′s forward facing lights. I am terrified that there is an animal or (heaven forbid) a person beyond the beam of light while I try to navigate the roads at night.

B.3806 September 12, 2024 — Oskaloosa, IA

I have a family member who has epilepsy and I have conversion disorder. Nobody should have to lose their independence because we can′t look out for our vulnerable members of our society.

B.3807 September 12, 2024 — Queens, NY

Driving at night has become incredibly dangerous with these ridiculously blinding headlights.

B.3808 September 13, 2024 — Anchorage, AK

Mathew S

B.3809 September 13, 2024 — Ashland, OR

These lights are unnecessary and causing more trouble than they are worth. And who is benefitting from this push? And who are the pushers? Suspicious and corrupt.

B.3810 September 13, 2024 — Fremont, CA

The road feels less safe and makes for tiring driving

B.3811 September 13, 2024 — Mesa, AZ

I have been blinded by lights in the city and on highways from people behind me. It's made it dangerous to drive at night because their lights are So Strong!

B.3812 September 13, 2024 — Wellesley, MA

I have astigmatism and I am nearly blinded by the ultra-bright lights on the road, to the point where I have been forced to pull over at times. This so extremely unsafe.

B.3813 September 13, 2024 — san antonio, TX

The height of newer truck fronts, and their headlights, have become blinding / dangerous for standard size vehicle drivers …

B.3814 September 14, 2024 — Aguilar, CO

crashed my bike once because I was blinded by bright headlights 👍🏽 people die because of this.

B.3815 September 14, 2024 — Tucson, AZ

I used to love driving at night because there fewer cars on the road, all I had to do was watch out for wildlife crossing the road…. But now I have to wear sunglasses at night and constantly adjust my mirrors, raise my hand to block the light reflecting on my rear view mirrors. What's the point of these mirrors anyway if we can't even see ? That's the problem with these LED lights WE CAN'T SEE because of them. And they're completely unnecessary.

B.3816 September 15, 2024 — Albany, NY

Enough is enough. Laws should have been put in place before this became the nightmare it has become. These headlights are not only a safety hazard but a health hazard as well. Quality of life has diminished in towns and cities across the U.S due to these ridiculous headlights, the prevalence of chopped illegal mufflers and super bikes. Banning these headlights would be a step in the right direction. After that how about the police start enforcing the noise laws already on the books to hand out tickets en masse to stop the increasing prevalence of illegal loud chopped mufflers on import cars and motorcycles, as well as super bikes? Do something now! The people have had enough!

B.3817 September 16, 2024 — Conroe, TX

Blue light activates two receptors in the eye (of three total). It activates them in an area where they are both highly sensitive. Blue light appears to humans to be brighter than it is because of this. LED lights usually emit light in nearly a single wavelength because it is cheapest to produce single-wavelength LEDs. Not only do I believe that LEDs are exceeding legal limits for other headlight emitters, but I also believe that they have almost no consideration built into the law for the fact that single-wavelength blue-light LEDs appear MUCH brighter (to humans) than their luminosity would suggest because the blue light is so easily detected by the human eye whereas there are large swathes of the light spectrum emitted by other lights that are harder for the human eye to detect, but which are still measured in luminosity tests. Using something like OKLab to test PERCEIVED luminosity of previous headlamp emitters which were legal and not widely considered too bright ... then scaling that to any proposed (or existing) light emitters would make for a great start to reducing glare which is blinding the HUMAN eyes on the road. We need NHTSA to make changes.

B.3818 September 17, 2024 — Kalispell, MT

I am tired of not even wanting to drive at night. I am ready to put a mirror on my bumper!

B.3819 September 18, 2024 — United States

https://www.tpr.org/news/2024-05-16/pennsylvania-woman-may-be-the-first-in-u-s-to-be-tested-on-ties-between-non-epileptic-seizures-and-led-exposure

B.3820 September 18, 2024 — Weare, NH

Please put limits on how bright car lights "appear". Also require that cars have a default setting of low beams and it requires manual change for high beams.

B.3821 September 19, 2024 — TN, United States

I cannot see a foot infront of me when a truck with LEDs drives twords me. It's 2024, I don't want to hit something I can see.

B.3822 September 20, 2024 — Clayton, NY

Not only are DRLs blinding other drivers , they are also very distracting when someone is driving close behind you or tailgating you with those lights. These lights are completely unnecessary in daylight and they are also contributing to climate change, by cars using more fuel to constantly power these lights and the lights releasing extra heat into the environment, especially on hot, sunny days and with billions of cars on the roads.

B.3823 September 20, 2024 — Las Vegas, NV

My vision for the past month now has been terribly disrupted by these led lights. They're visible from miles away and not for a good reason. I'm tired and irritated that these exist. Specially in a bright, super lit city. It's actually disgustingz

B.3824 September 20, 2024 — South Orange, NJ

Duh

B.3825 September 23, 2024 — Hamburg, NY

I find them blinding!

B.3826 September 24, 2024 — Berkeley, CA

blinding headlights are a life-threatening hazard causing serious accidents

B.3827 September 24, 2024 — Chicago, IL

Those explosively bright lights on a dark road temporarily disable one's vision, and require a period of re-accommodation once they pass. It's simply an unsafe situation. This is where government needs to step in and act on behalf of the populace.

B.3828 September 24, 2024 — Derby, IA

I have noticed that a lot of LED lights for any use are damaging our eye's one of the first things affected is depth perception then focus and then can't read anything for nothing. I also think fog lights should be banned along with most LEDs. And if people would dimm there dash lights they could see better to because they glare on the windshield blocking view. Then ban any light on buildings shining directly towards roadways. And motion detection light that comes on when car goes by

B.3829 September 24, 2024 — North Providence, RI

I have to avoid driving at night because of how unbearable modern headlights are, Also those lights make it harder to see turn signals and license plates.

B.3830 September 24, 2024 — Watsonville, CA

This is long overdue!! LED headlights are without a doubt BLINDING to oncoming drivers! I know as so many do, enough near death experiences!

B.3831 September 25, 2024 — Escondido, CA

I feel my brain physically hurt from the constant blinding flood lights of oncoming cars. Even the cars behind me, their lights bling me from the rear view. I'm 23 years old and I feel scared for the future. It's so painful and dangerous to have to deal with this.

B.3832 September 25, 2024 — Santa Cruz, CA

I'm being blinded every time I drive! They burn a hole in my head.

B.3833 September 25, 2024 — Strasburg, VA

Those lights are blinding!

B.3834 September 26, 2024 — Berkeley, CA

So many headlights I find quite blinding. They are truly hazardous and could cause an accident!

B.3835 September 27, 2024 — Leawood, KS

It feels like a matter of when, rather than if anyone will get in an accident due to being blinded by insanely bright LED headlights. I am losing count of the number of times I will be driving at night and then, from hundreds of feet away, I can already see blindingly bright headlights coming my way. That is bad enough, but people will even have their brights going with these, making it feel like you are driving while staring in the sun. This whole thing is selfish and stupid. Please ban these.

B.3836 September 27, 2024 — Montgomeryville, PA

I suffer from migraines, light sensitivity and my daughter has astigmatism. There have been many times where we were almost in a car accident due to excessively bright headlights passing us or behind us.

B.3837 September 27, 2024 — Salt Spring Island, CA

I have been blinded by the bright headlights so much that I have had to come to a complete stop... not good at night perhaps. They should not be allowed. Our safety is more important than one person seeing way too clearly.

B.3838 September 29, 2024 — Gulf Breeze, FL

I've personally almost crashed multiple times and have had a collision with a boat sticking out in the road, you can't see nothing when those cars are coming at you with those led headlights. Another failure in the name of public safety.

B.3839 September 29, 2024 — Winston Salem, NC

This really needs to be addressed.

B.3840 September 30, 2024 — weaverville, CA

I've almost been killed driving at night on my mountain roads. Try to avoid night driving altogether now because of this but sometimes it's unavoidable. Whomever thought this was a good idea should be shot!

October 2024

B.3841 October 1, 2024 — Murrysville, PA

Connie

B.3842 October 2, 2024 — Winston-Salem, NC

I already have vision issues I don’t need unnecessary bright lights impeding my vision when driving

B.3843 October 4, 2024 — Ooltewah, TN

They’re AWFUL

B.3844 October 5, 2024 — Falls Creek, PA

If People Need THAT HORRIBLY BRIGHT Of A Headlight To See To Drive. Then They Shouldn't Be Driving AT ALL...

B.3845 October 5, 2024 — Leander, TX

I’ve had so many near horrible accidents due to how bright they are. it’s ridiculous that they were able to even be allowed in the first place.

B.3846 October 6, 2024 — San Diego, CA

Something has to be done! With so many experiencing issues and difficulties with nighttime driving due to glare of headlights, how can this problem be ignored. It’s unsafe but necessary to drive during nighttime. It looks like everyone is driving around with high beans on. Older model headlights are safer. How could the powers that be in California not want to make the roads safer for all.

B.3847 October 9, 2024 — Herriman, UT

I'm a young adult with decent vision and am starting to have a hard time driving at night because so other people's lights are so bright they blind me. I can't feel confident making left turns when LED headlights are in front of me because I can't see if other traffic is coming or if there are pedestrians in the crosswalk.

B.3848 October 10, 2024 — Portland, OR

Since money is the biggest motivator in the USA: Think of all the lost money, and hit to the economy from every person who avoids driving at night now due to being blinded. These lights need to go. Regulate them. Ticket them, and generate even more money as you fix this.

B.3849 October 11, 2024 — Evansville, IN

I'm tired of being blinded by blue light LED headlamps and outside lighting.

B.3850 October 11, 2024 — Shreveport, LA

Mechelle D Thompson

B.3851 October 13, 2024 — Nashville, TN

Other drivers on the road that have these super bright headlights make it nearly impossible for me to drive at night without the use of sunglasses. I have been pulled over multiple times because of it and given written warnings. The manufacturers of these super bright headlights need to stop and politicians need to start banning them in their states. Without sunglasses I literally cannot see the road to drive. I have nearly wrecked several times driving home from work over the last couple of weeks, because I couldn’t see the road.

B.3852 October 13, 2024 — Phoenix, AZ

I drive 1500-2000 mi./wk for Lyft in the PHX metro area ("The Valley") and I am astonished by how many times I am blinded by LEDs in cars behind me/in mirrors & from head on traffic. It is literally like everyone is driving w their hi-beams on, but they're not. Last time I checked, before these f***ing LED headlight bulbs became a thing, if you had your brights on and approached a police cruiser from the front... if said police vehicle flashes you to turn your brights off and you don't, you would be pulled over and ticketed! So why are these a**holes who use these nuisances for bulbs in their vehicles headlamps not being pulled over and ticketed now?? It's the most egregious safety hazard I have ever encountered in the road in 37 years of driving. These things are DANGEROUS AF!!!!!!!!!! Ban them already, FFS!!!!!!!!!!!

B.3853 October 14, 2024 — Kansas City, MO

the headlights are way out of control and endangering me and my family while we're on the road at night. I'm generally not a huge fan of lots of regulations for stuff in transportation or any other industry, but this is a big problem.

B.3854 October 15, 2024 — City of Saint Peters, MO

I ride motorcycles and have almost gone off the road at night due to the insanely bright LED headlights from oncoming large new trucks and SUVs. Sometimes when cars are tailgating me their lights are so bright I can no longer even tell if mine are on? Driving at night sucks now. I'm just grateful I was a youth during the halogen days when you didn't go blind driving at night. Deeply sorry for all the lives lost and folks hurt from our government's inability to address this issue in a timely manner.

B.3855 October 16, 2024 — Corning, United States

Every day when I take my children to school I have to ride with my visor down because of these lights. And it still doesn't help. My car sits low and I'm short so the bigger vehicles shine directly into my windows, rear view mirror and causes a major glare. In the short 10 mins it takes to get them to school I have eye pain and a headache from the brightness. I can't see at night so I don't drive. I've bought transition lenses for my glasses which do nothing. These lights are a safety risk and need to be banned or dimmed way down.

B.3856 October 18, 2024 — Boulder, CO

These lights are absolutely horrible, we need to get rid of all the bright LED lights!! Bike lights, head lamps, car, truck, motorcycle, semi.....all of them! We do not need these lights so bright!!

B.3857 October 18, 2024 — Rockmart, GA

I believe LED headlights are dangerous. No matter how low they are "aimed", if the road grade or curvature is on a slope the lower-positioned driver will still get blinded. The situation becomes extremely perilous on any two lane undivided highway or country road.

B.3858 October 18, 2024 — pascagoula, MS

These LED Headlights are blinding us out here on the road trying to safely get to where we are going!!! Ban and outlaw LED headlights NOW!!!

B.3859 October 20, 2024 — Cleveland, OH

I have been pulled over more than once for going too far RIGHT in right hand lane. Why? I was blinded by led headlights. I can no longer drive after dark which means I do less shopping (not a 'day person', and refuse to change) and has severely effected my social life. Really feel they (government) are trying to blind us. Yet another reason not to trust them.

B.3860 October 20, 2024 — Jonesboro, GA

Ban these lights! It's ridiculous.

B.3861 October 21, 2024 — Harrisburg, PA

Have seen cases in clinic, primarily deer-strikes, where a driver couldn't see the deer because of oncoming headlight glare. Please do the absolute smallest thing for us and better regulate automotive headlights.

B.3862 October 21, 2024 — Woodridge, IL

I have a dimming rearview mirror and it's a testament that lights are too bright when that's not even enough anymore to keep lights from blinding me from behind. Not to mention, changing lanes becomes dangerous when some jerk is hitting you with his high beam LEDs. I've also noticed that not long after being hit with a blast of light to the eyes, a migraine often sets in. Enough is enough. We know that we can't trust consumers to act responsibly. There is no reason auto manufacturers should even give them the option to endanger others like this.

B.3863 October 22, 2024 — Bolingbrook, IL

SAFETY!!

B.3864 October 22, 2024 — Concord, MA

These LED headlights are a hazard for oncoming drivers

B.3865 October 22, 2024 — Lewiston, ME

LED headlights seriously need to be banned. If we can't legally use our high beams, then how are these okay instead? My high beams are dimmer than most LEDs! Driving at night is truly a nightmare for me, especially with my astigmatism. These lights are unnecessary, no one needs to be able to see 40 miles ahead, for goodness sake. Ban these. They're terrible and unsafe.

B.3866 October 22, 2024 — Paoli, PA

I have chronic and severe migraines that make me photophobic almost all of the time. This makes night time driving very painful and difficult.

B.3867 October 23, 2024 — Mechanicsburg, PA

These LED lights are dangerous!!! The lights are so bright and always in the on coming traffic eyes!! You would think these lights would at least be pointed down at the road instead of up at the eyes??? I've lost sight of the road multiple times when vehicles with LED lights coming towards me. Something needs to be done about these lights!!!!

B.3868 October 23, 2024 — Minneapolis, MN

Been driving me crazy(lol) that a lot of people don't understand how dangerous these are, and even end up getting upset at the drivers who's vision becomes affected. Still dealing with a blind spot from the amount on the roads where I live.

B.3869 October 24, 2024 — Macon, GA

It's truly a problem

B.3870 October 24, 2024 — Salem, MA

Blinding headlights are a totally unnecessary problem which can be fixed with this simple legislation

B.3871 October 24, 2024 — Toronto, Canada

I'm blinded daily by headlights that are too bright and probably not pointed in the correct direction - it makes my commute to work in the morning very difficult and much less safe than it could be

B.3872 October 25, 2024 — New Albany, IN

I myself struggle to see on the roads with people with LED headlights that are on during the day and brights are almost always on at night!! today (October 25th 2024) for example, multiple and I mean multiple cars with their brights on during the DAY for christ sake and at night just to have them on do headlights really need to be this bright?? NO they do not. I'm blinded every day and unable to see properly because of these headlights they are unethical for main road use!!! Many people crash due to these lights blocking their view of the road. LED LIGHTS DO NOT NEED TO BE ON CARS!

B.3873 October 27, 2024 — Melbourne, Australia

I believe that this causes accidents especially in remote areas going around bends it's literally blinding and I believe has taken lives already we need to make sure this is passed immediate In 2012 led's were still classified as lasers ffs!

B.3874 October 28, 2024 — Los Angeles, CA

Things have gotten so far out of hand with these bright headlights. These car manufacturers care more about installing spy software in your car than issuing a nation wide recall and replacing these blinding headlights with softer lights. Even after all of the accidents and deaths no one in power who can make a difference seems to care. Only in America!

B.3875 October 28, 2024 — Paris, KY

You can't see anything and you can't even hardly see the moon and stars

B.3876 October 28, 2024 — Titusville, NJ

These are increasing even though I'm pretty sure they used to be illegal. Scientific research has been supporting the use of red-based lights at night, to the effect of blue-filtering lenses being sold widely. There is no logic behind bright blue lights at nighttime other than being able to see everything on the road-- however, this fails to consider the other drivers approaching who are then unable to see past these lights. It is actually a road hazard, and can disrupt our sleep and for some people potentially even at least temporarily damage their retinas.

B.3877 October 29, 2024 — Nalgonda, India

https://education.nationalgeographic.org/resource/light-pollution/ National geographic channel on light pollution. Its bigger that we think it is. Its about day and night light pollution as LED DRLs during day are adding to increased hot temperatures.

B.3878 October 31, 2024 — Rome, GA

People shouldn't be blinded while traveling 60mph+, the fact this hasn't been dealt with sooner is a failure to keep the public safe.

B.3879 October 31, 2024 — San Francisco, CA

Impossible to see oncoming cars with those headlights that were typically pointing down and to the right with older cars. Intersections and people following blinds drivers in mirrors as well.

B.3880 October 31, 2024 — Sugar Land, TX

Everyone's life is precious and worth saving

November 2024

B.3881 November 1, 2024 — Aurora, IL

I drive in the dark alot. I've noticed that even some of the "auto" dimmers appear to switch to a low beam but don't do it until the car light beams are past the on coming car. Also these headlights seem to be aimed down at the road which is great but when that car comes over a hill or the crest of an intersection or over a bump in the road the lights shine right into oncoming traffic. I don't think these smart headlights would work in those cases. So even with the smart aim type system there will still be major problems. These lights also are so bright that even when there is a large median between lanes they blind on coming traffic even like a tollway with 30 feet of separation. Also the auto system won't work when a car is on the inside of a curve those lights shine right into oncoming traffic on the outside of the curve. They must be dimmable not just aimed.

B.3882 November 1, 2024 — Rensselaer, IN

The new LED headlights cause temporary blindness . Or you have to take your eyes off the road and look away . Many cars are driving with Led on bright . They leave them on auto dim but still blind you to point it seeing green dots in your line of sight after the car passes by. You also have individual putting led lights in headling housings not made for LED lights and those are probably the worse for causing head on traffic to be blinded. I have seen many vehicles just stop in the middle of the because they cannot see with on coming traffic with LED lights . It's dangerous, unnecessary and most of those older vehicle have illegal lights that are only for off road purposes.

B.3883 November 2, 2024 — Grand Rapids, MI

I have been struggling with this for some time and thought I was the only one who had an issue. I try to compensate for the blinding LED by looking to the side of the at the right should line, but that

rarely helps and I am left blind for a few seconds after the opposing car passes me. The effect is even worse in rainy conditions when the headlights reflect off the road. Another issue, equally as bad is when a car with bright Leads comes up behind you and you are blinded in your side mirror. I have to hold my hand up to block that light, move my mirror, or shift in my car, all the while hoping that an opposing vehicle doesn't come at the same time! I hope this gets addressed soon because I am getting to the point of not wanting to drive at night!

B.3884 November 2, 2024 — Louise, TX

Excessively bright headlights in rural America make driving at night unsafe. Temporary blindness from the bright light couples with lack of street lights, reflectors to signal curves in the road and wildlife poses entirely too many safety risks.

B.3885 November 2, 2024 — New York, NY

Please ban those evil and rude Teslas installing high beams as low beams! Ban Teslas, save lives!

B.3886 November 4, 2024 — Oxford, United Kingdom

I'm sick of getting BLINDED.

B.3887 November 4, 2024 — Paris, KY

There are two reasons why I need those headlights to be banned. First of all I get migraines and I cannot look at those lights without getting one. Secondly, I have to avert my eyes to the right side of the road because I cannot see the road when they are coming at me, I almost ran off the road in a terrible place that would not have ended well. I am begging the makers of those headlights to stop making them and I pray that the ones that are out there are banded. Also, I just remembered an incident where one was behind me and it was so blinding. I could not focus on the road in front of me. They are just dangerous.

B.3888 November 4, 2024 — Providence, RI

They're dangerous. They've literally blinded me from seeing the road at night several times.

B.3889 November 4, 2024 — San Diego, CA

LED headlights are a danger to the public. Proper angles mean nothing unless roads are completely flat, which they aren't.

B.3890 November 4, 2024 — Somerville, MA

I can't see at night - if you're in a sedan and an SUV comes up behind you, they are at the level of your rear window and seemingly blind you. I have astigmatism and it makes it so much harder to see at night

B.3891 November 4, 2024 — Stoneham, MA

How is this shit legal? As someone with astigmatism, I don't need Uncle Fester tail gating me in his yee haw ass monster with cornea destroyer 9000's.

B.3892 November 5, 2024 — Orange, MA

If doctor, nurses, paramedics and emts can't use LED in their pen light because it destroys eye, who thought it was a good idea to put them in cars. Someone didn't do research.

B.3893 November 6, 2024 — Coral Gables, FL

It is extremely dangerous for everyone!!!!!

B.3894 November 6, 2024 — Irvine, CA

Driving in Irvine necessarily means contending with sunspots or using sunglasses at night. It is a dangerous endeavor as oncoming headlights and overly bright tail lights obstruct the view by not just washing out the view of the road but also by causing blind spots to occur by burning the retinas. Driving is a necessity since Irvine is a hyper car-centric city but driving becomes more and more dangerous as lights get brighter and brighter. The most memorable car was a new yellow mini due to being able to cause me sunspots in broad daylight. I had that union jack burned into my vision and missed the green light. Honestly glad I didn't miss a red.

B.3895 November 6, 2024 — Montague, CA

Yep. Good Ole saftey features…. not. When the lights are so bright they overshadow your own lights , it′s too bright.

B.3896 November 7, 2024 — Akron, OH

If you drive a sedan, you know what it′s like to be blinded by some big@$$ truck tailing you. It′s made all the worse by people who keep their high beams on all the time. I′d personally prefer NOT to die because of someone else′s stupidity or laziness, thanks.

B.3897 November 7, 2024 — Cary, NC

Yes, LED headlights can damage the retina: https://www.eduardobessermd.com/blog/are-led-lights-safe#:~:text=It%20revealed%20that%20long%2Dterm,fatigue%2C%20and%20risks%20of%20accidents.

B.3898 November 7, 2024 — Dallas, TX

I feel as though we could use them as the bright but not as the main lights. These lights blind people to where your almost going off the road.

B.3899 November 7, 2024 — Parlin, NJ

Thank goodness for this petition. I am blinded at night by these extremely bright headlights. It is painful and there is no way to avoid seeing them. I have had to pull over even on a highway because they are so bright you cannot see. This needs to be fixed. Go back to the old type of headlights or put adapting LED headlights on SUV′s and cars.

B.3900 November 7, 2024 — Stow, OH

The new headlights and police lights make it so I can’t see at night. It’s dangerous.

B.3901 November 7, 2024 — United States

headlights are too damn bright

B.3902 November 8, 2024 — Ashford, ENG, United Kingdom

To bright

B.3903 November 8, 2024 — Burlington, VT

I don’t feel safe driving at night because these lights are so blinding. When a car with these lights is passing by I have to look completely down at the road so I can see where the lines are (can barely see the lines and can’t see them at all when it’s raining). If something were to be stationary in my lane of travel I have no doubt I’d hit it due to being blinded by these lights. They are so incredibly unnecessary…

B.3904 November 8, 2024 — St. Louis, MO

I am always getting blinded by these new overbriggr new dangled headlights. It is downright dangerous.

B.3905 November 10, 2024 — Avon, OH

Night driving is awful lately

B.3906 November 10, 2024 — Coatesville, PA

Night driving is so challenging for me and many others due to the extremely bright headlights of other cars on the road.

B.3907 November 10, 2024 — Humacao, Puerto Rico

Estoy de acuerdo

B.3908 November 10, 2024 — KS, United States

They are painfully bright.

B.3909 November 10, 2024 — Mount Desert, ME

Headlights are too bright and it’s a legitimate safety concern

B.3910 November 10, 2024 — New York, NY

My eyes are getting bad due to LED lights. I get so angry on the road due to this and we need to take a stand. Let's go back to good old fashion yellow lights. LEDs are hurting us not helping us. More accidents and for the health of our eyes please take them away.

B.3911 November 10, 2024 — Philadelphia, PA

It cause driver to look sight and can cause an accident

B.3912 November 10, 2024 — Richmond, VA

This blue light is driving people insane.

B.3913 November 10, 2024 — Salem, MA

These lights have affected me from seeing properly on the road. I've seen accidents occur due to these blindly lights! This is a public safety concern! We need change.

B.3914 November 10, 2024 — United States

Scott Kane

B.3915 November 10, 2024 — jupiter, FL

While we're at it let's also ban the idiots that don't know they're supposed to turn their brights off as soon as another car is visible

B.3916 November 11, 2024 — Edgewood, NM

It's even worse when you have astigmatism.

B.3917 November 11, 2024 — Inwood, Canada

Those bluish white headlamps give me an insta headache. No need for them to be that bright! The yellowish ones did fine for decades!

B.3918 November 11, 2024 — Knoxville, TN

I drive 3 hours between cities after dark regularly. I cannot look in my mirrors at all without blinding myself in the night. I have to lean forward as far as possible to avoid the intense glare in my peripheral vision, allowing myself to see the road at the expense of seeing my speedometer. I make frequent lane changes, without the use of my mirrors, to allow the brightest headlights to pass me on the road, in an attempt to be able to look in my mirrors again. It's at the point where I would need to choose between sunglasses and having no mirrors to drive comfortably. Certainly, with the way things are now, there is no such thing as safely driving at night anymore, unless you are the only person on the road in both directions.

B.3919 November 11, 2024 — Lyndhurst, NJ

The lights are too damn bright! Especially in rainy weather and they reflect. Driving is the most dangerous thing we all regularly engage in. Let's make it a bit safer for everyone.

B.3920 November 11, 2024 — Sarasota, FL

apart from being an aesthetic crime, bright white LEDs in our vehicles and street lights are dangerous because they blind drivers, make it very hard to accurately judge the distance of cars behind us (unlike old incandescent headlights which gently contour the vehicle) and have negative effects on our circadian rhythms, hormones and overall health. Driving at night was generally a pleasant and soothing experience but it is now a harsh, tense and, most importantly, dangerous endeavor.

B.3921 November 11, 2024 — Warrensburg, MO

These blinding lights make it dangerous to drive at night.

B.3922 November 12, 2024 — Bowling Green, KY

I often have to turn my mirrors down and away if a car with LEDs is following behind my car and hold my hand up to shield my eyes when a car with oncoming LED lights is heading towards me in order to ensure I can drive and see!

B.3923 November 12, 2024 — Woodstock, MD

I am a driver and this affects me directly as well as other drivers

B.3924 November 13, 2024 — Cincinnati, OH

It's absolute bullshit that others need to see the fuckin moon when they drive pisses me the fuck off

B.3925 November 13, 2024 — Hood River, OR

The LED's seriously need to be reevaluated, or maybe they were designed to be blinding and increase accidents...hmmm

B.3926 November 13, 2024 — Portland, OR

The headlights on cars are to blinding way way to bright they need to be banned there is no need to have that bright of a headlight the old ones were good enough

B.3927 November 13, 2024 — Rincon, GA

i gotta drive at night to get to work and its a struggle with all the bumps near me in the roads

B.3928 November 14, 2024 — Chaska, MN

I can see just fine at night but when an oncoming car or another directly behind me has those blinding lights I struggle to even stay on the road. I am a healthy 21 year old with no sight issues but have a hard time with those overly bright headlights. I can only imagine how others with astigmatisms or light sensitivity may feel.

B.3929 November 14, 2024 — Midlothian, VA

I've almost had several accidents due to being blinded by excessively bright headlights. The most recent one being an oncoming Is vehicle blinded me to the point I couldn't see the stopped vehicle with dim taillights. Had I spotted him 1 second later, I may very well not be here to type this message. I wonder how many lives these is unnecessarily bright headlights have already claimed.

B.3930 November 15, 2024 — Elgin, TX

I'm so sick of being blinded by 2/3 of the cars on the road. It's ridiculous.

B.3931 November 15, 2024 — Leander, United States

I have issues with lights at night producing starburst. The new LED headlights absolutely blind me and are a safety hazard to others.

B.3932 November 15, 2024 — Montclair, NJ

It's difficult to see while driving with these LEDs!

B.3933 November 16, 2024 — Provo, UT

I have very sensitive blue eyes and driving at night these days sometimes feels like a gamble with my life. People driving through a well-lit city street or on a lit highway DO NOT NEED multiple LED headlights!!! And if you're driving through a darker area, do the courteous thing and turn off your brights when there is opposing traffic! We have to get after the car companies who are designing and installing a feature that makes driving more dangerous for others on the road. Come on.

B.3934 November 17, 2024 — Cameron, MO

I am for the ban, but above & beyond that, people need to pay attention to what they are purchasing. As long as these companies get your money they could careless about your safety. Do the research and buy from companies that do not have years of recalls, etc... Once they have your money you are no more to them but a dummy. What people buy determines what they keep making. Please test drive and inspect any vehicle before buying even if that means taking it on a rough road because an irritated noise can become a dominoes effect. Not all vehicles are assembled the way people assume they are.

B.3935 November 17, 2024 — Fairland, IN

They are a danger to everyone on the roadways

B.3936 November 17, 2024 — Seattle, WA

these suck!

B.3937 November 17, 2024 — Westlake, OH

I have several medical conditions that make me sensitive to light, namely LED light. It blinds me, makes me nauseous, get headaches, disoriented, dizzy, and the increasing difficulty to attain softer lighting is ridiculous! I can't even find lighting for my own home as easily as I used to. I am disabled and poor so finding the older kind of bulbs is increasingly difficult for me. My neighbors porch light is blinding! Christmas lights are now also blinding, and to drivers thats too distracting/disorienting ! Headlights are blinding and that's sooooo dangerous for drivers! Why on earth is that something they think is ok??? I don't know what they manipulated in the "research" that they claim says LEDs are better, but they do not nearly long enough, you have to buy them more and more often. I believe their "efficiency" just means they work poorly, so you have to go buy more, shameful. I am sick of getting sick because of these stupid lights. A trip to the Dr's is soooo dreaded because I know that I will be sick the whole day, I don't need more of these lights to bombard me everywhere else too! I get as much as I can delivered to me because one of the reasons I can't go into stores is the lighting. I am begging here, begging them to stop with the E LEDs!!

B.3938 November 18, 2024 — Arlington, MA

LEDs are technology gone too far. We are losing connection with the natural world and drowning ourselves with blinding blue light. Help bring darkness back.

B.3939 November 18, 2024 — Chicago, IL

I'm too young to not want to drive at night anymore!! Headlights are blinding!

B.3940 November 18, 2024 — Miners Rest, Australia

Glaring lights increase driver difficulty in perceiving distance and speed of oncoming vehicles. This is especially dangerous for drivers entering a carriage way when head lights are used in the daytime. This is particularly dangerous with motorbikes which have the headlights hard wired on by law and other drivers who choose to leave their head lights on during the day causing a lethal problem even without the added glare of the new LED headlights.

B.3941 November 18, 2024 — Portland, OR

I can't see!!!!

B.3942 November 18, 2024 — oakland, NJ

Blue wavelengths are known to be experienced by the human eye as "glare," which literally hurts. That's why the Serengeti sunglasses company used orange in their lenses. Orange is the opposite of blue. Cutting the blue wavelengths allows a person to SEE comfortably without pain in their eyes. "Daylight" headlights allows a driver to see the road well, BUT when those same headlights are aimed toward other drivers, THEY ARE BLINDED BY GLARE. This results in more accidents, not less. I support a full ban on daylight headlights for the safety of all drivers.

B.3943 November 19, 2024 — Euless, TX

The LED headlights that are being made are too bright. Driving down a country road, I have to stop every time I see those blinding headlights coming from far away, because I know by the time they get closer, I won't be able to see the road. I'm afraid I'll end up in a ditch if I keep driving.

B.3944 November 19, 2024 — Fernandina Beach, FL

These LED lights are nauseating and dangerous. The instance of wrong way collisions is as high as ever, and the intense glares from LEDs create a deer in the headlights situation for anybody who doesn't have them. I can't imagine anyone would properly be able to avoid danger with these lights headed straight at them, they are completely blinding.

B.3945 November 19, 2024 — Kalispell, MT

I'm a healthy 24 year old with no sight issues but I do have green eyes that are somewhat sensitive to light. When a car with halogen lights is coming towards me I have no issues but when the vehicle has

led lights it's unbearable. There's no point to them. We've used halogen lights forever and they have worked.

B.3946 November 19, 2024 — Lincoln, NE

Literally why not?!?! It's safer for everyone.

B.3947 November 19, 2024 — Lynnwood, WA

I try to avoid driving at night. Every time a newer vehicle is driving toward me I am unable to see the road in front of me, and am still somewhat impaired after they have passed. When they are behind me, I have to flip my rear view and readjust my side mirror so the lights are out of my eyes. As you might imagine, that makes it very difficult to drive safely. There needs to be a cap on the lumins allowed for lights on cars.

B.3948 November 19, 2024 — Tampa, FL

Yes im in favor of banning bright headlights , i have 20/20 vision and it hurts my eyes at night .

B.3949 November 20, 2024 — Highlands Ranch, CO

It's insane and irresponsible to think that these bright lights are okay with any auto makers. Newer cars with these LED's seem as they have their brights on all the time.

B.3950 November 20, 2024 — Long Beach, NY

How do car companies like GM (the Escalade especially) and Acura get away with these blinding headlamps?

B.3951 November 20, 2024 — New York, NY

I don’t feel safe driving after dark anymore because I can’t see.

B.3952 November 21, 2024 — Pasadena, CA

Blinding lights are dangerous!

B.3953 November 21, 2024 — Winchester, VA

It is difficult to see the road at night in a lot of oncoming traffic with the newer bright blue- white headlights which all seem to be aimed too high. My eyes don't have a chance to adjust, and I get eye fatigue and headache from the glare.

B.3954 November 21, 2024 — crysal river, FL

I drive 1 hour to work every morning and the amount of lights that are blinding me in my mirrors behind me and oncoming traffic is insane. Something needs to be done there is no need for lights to be that dam bright

B.3955 November 22, 2024 — Bronx, NY

These LED lights on these automobiles are blinding. I honestly could say that I'm not in control of the car that I'm driving due to the blindness from these lights.

B.3956 November 23, 2024 — Chestnut Hill, MA

I was just rear ended by another car while pregnant. The oncoming headlights were so bright they prevented the driver from seeing my brake lights. Now I worry about my unborn child and my husband sustained a brain injury from this. There is no explanation for the increase in dangerous accidents at such a level other than these absolutely excessive and violating use of bright headlights.

B.3957 November 23, 2024 — Deptford, NJ

the headlights are awful, you can’t see, you get angry, and they mess up you’re circadian rhythm

B.3958 November 23, 2024 — Massillon, OH

i’m tired of having migraines from driving and not being able to see

B.3959 November 23, 2024 — Orlando, FL

There is a huge negligence in safety with studying the effects of headlights. There needs to be more regulations on how powerful car headlamps are. There is no point in being "mindful" on safety

devices in your car to protect you in a crash when headlamps are becoming more of a hazard causing more crashes. I've personally had to start wearing different type of sunglasses at nighttime while driving due to getting massive night blindness with super bright headlights beaming into my pupils and the older I get the more of a struggle this becomes. This really shouldn't be a issue.

B.3960 November 23, 2024 — San Bruno, CA

With the clouding of my own headlight lenses with older halogen lights, it's already a bit difficult to see, but when I get hit by the oncoming LEDs, it creates a momentary blindness, and it is getting quite scary every time this happens. On top of it, if my windshield should be slightly filmy on the inside, I basically end up with a pure white "screen" in front of me instead of a view of the road. I literally hate driving at night nowadays.

B.3961 November 23, 2024 — San Francisco, CA

I sign because there is no reason for us to be subjected to "dazzling" while driving , while enjoying (?) time at home, while out and about recreating, etc. Enough is enough. We must no let up on regulatory agencies. I wish there were a class action lawsuit in place. Nothing will change until we find a way to put our symbolic knee on the (symbolic) neck of automobile manufacturers and lighting manufacturers. This is the same as my having to breath second-hand smoke or subjecting me to chemical hazes be it in theatres (for lighting effects) or pesticides used on crops. STOP THE MADNESS

B.3962 November 23, 2024 — Summerville, SC

These blinding headlights are killers!

B.3963 November 24, 2024 — Fairlawn, VA

I have astigmatism and try to avoid driving at night. But I had to on this particular night. I was hit with the most blinding white headlights that I was blind and it caused me to run off the road. Luckily I was not hurt. LED headlights are dangerous to people who have vision issues and should be banned.

B.3964 November 24, 2024 — Mississauga, Canada

I've had a seizure from these damaging lights!!

B.3965 November 24, 2024 — Seattle, WA

These lights are dangerous and harmful to vision

B.3966 November 24, 2024 — Zimmerman, MN

{"videoUrl":"https://stream.mux.com/hPHREDMQm27gdcF6zlMJeokOtIbpLVAkRDHwBu8pck00","cloudflareUid":"c60fd03bc12b6b27c96d9eacd5be6194","muxAssetId":"NJ96plcveVGwHbKtS6YTMZM1dcppbMQaSjRkGqUrlEc","muxPlaybackId":"hPHREDMQm27gdcF6zlMJeokOtIbpLVAkRDHwBu8pck00","muxPlaybackUrl":"https://stream.mux.com/hPHREDMQm27gdcF6zlMJeokOtIbpLVAkRDHwBu8pck00","muxThumbnailUrl":"https://image.mux.com/hPHREDMQm27gdcF6zlMJeokOtIbpLVAkRDHwBu8pck00/thumbnail.jpg"}

B.3967 November 25, 2024 — Auburn, CA

When thrse light shine in my view, I cant see well it inpairs my viewing abilities . Please ban them.

B.3968 November 25, 2024 — Danielsville, GA

I'm blinded by these lights and am becoming afraid to drive at night.

B.3969 November 25, 2024 — Hanover Park, IL

To state the obvious, it's really frustrating to flash your headlights at an oncoming vehicle when you think they have their blinding brights on but it turns out that's the way their headlights always look. It's really not the driver's fault so we need to do something at the manufacturing level.

B.3970 November 25, 2024 — Macon, GA

I'M TIRED OF BEING BLINDED AT NIGHT! I DON'T EVEN LIKE TO GO OUT!🤨

B.3971 November 25, 2024 — PA, United States

So far, three times since DST started, I have almost gone off the road by being blinded to disorientation to my own position on the road. Offenders are typically ″monster″ trucks with jacked wheels and with nuclear bright headlights and light bars that are at eye level, even to SUVs. I have to come to a complete stop so I can close my eyes as not to crash. Nobody is doing anything about this.

B.3972 November 25, 2024 — South Milwaukee, WI

It's dangerous and annoying

B.3973 November 26, 2024 — Buffalo, NY

These stupid modern lights have made driving more dangerous, not safer. Oncoming glare has caused me great difficulty in noticing other obstacles in the road and even pedestrians. If I were a new driver today instead of having my 17 years of experience I have no doubt I probably would have struck someone by now.

B.3974 November 26, 2024 — Walnut, CA

Our community has a problem with individuals who use high beams on top off already blinding LED lights!

B.3975 November 27, 2024 — Glen Head, NY

I 100% agree with this petition but there is a very significant point that needs to be made. This problem is not an issue of LEDs, its an issue of lighting design and lack of regulation. There needs to be regulation about the overall CHARACTERISTICS of light emitted from headlights. The issue isnt specific to LEDs The way we perceive light is the result of a COMBINATION of factors: Intensity (illuminence, ″brightness″), Light Wavelength / Color temperature (ex: 1700K is a ″warm amber″ color, 4000K is ″cool″ white, 8000K is cold white). Light sources need to be adapted to fit their intended applications. Headlights should not produce blinding bright white lights, there should be guidelines and enforcement of the rules to keep everyone on the road safe.

B.3976 November 27, 2024 — Portland, OR

I drive for a living and it has become increasingly dangerous to be out on the road at night when I can′t see it because of all the newer vehicles with excessively bright headlights. Not only are these headlights creating a safety hazard, but a health hazard due to the increased eye strain on nighttime drivers. I get headaches after being subjected to hours of bright lights in my face when I′m driving for work. Sometimes, the headaches are so bad that I have to take the rest of the night off. Headlights used to be around 1000 lumens, but now the standard headlights go up to 4000 lumens and some aftermarket headlights are much brighter than that. The automotive industry should be held accountable for creating dangerous road conditions and the sale of excessively bright headlights should be banned because they make driving less safe for everyone on the road.

B.3977 November 28, 2024 — Knoxville, TN

I really don′t know how this isn′t in the hundreds of thousands.

B.3978 November 29, 2024 — Dallas, TX

These things are literally the worst and I hate driving with them.

B.3979 November 29, 2024 — Luton, ENG, United Kingdom

They are a hazard on the roads!

B.3980 November 29, 2024 — Republic, WA

It′s hard and dangerous to drive when I am being blinded by insanely bright headlights.

B.3981 November 29, 2024 — Solvang, CA

The lights are just too bright and the wrong color for our eyes and our local wildlife. Sometimes on long roads and an approaching vehicle has these bright blue halogen lights (not on high beam) I have to pull off the road and wait. Even at a quarter mile the bright light is damaging to my sensitive eyes (which I use for work) I also work through the night. I failed to mention I work only outside and these lights are brutal on your vision and are very dangerous. I live out in the country with no street lights,

buildings, it's very dark outside. This is not the city full of more light pollution. The bright lights need to be banned or have a light filter installed over the light bulb itself.

B.3982 November 29, 2024 — WA, United States

The lights are too bright! We need more yellow/orange/red tinted lights so we don't lose our night vision. It's ESPECIALLY DANGEROUS for people that live in more rural mountainous areas that have animals like deer, elk, moose, among other animals that like to hangout in the road.

December 2024

B.3983 December 2, 2024 — Lebanon, MO

Can't see anything when driving at night been ran off the road and everything

B.3984 December 2, 2024 — Lebanon, MO

Nobody needs lights that bright. They're blinding for the rest of us and I literally see spots after they pass

B.3985 December 2, 2024 — Thames Ditton, ENG, United Kingdom

I am totally frustrated driving at night and being constantly blinded by cars having lights that looks like full headlights, accident waiting to happen! It should be illegal like in Canada and Denmark

B.3986 December 3, 2024 — Oakland, CA

It's a PROBLEM!

B.3987 December 3, 2024 — Sunnyvale, CA

Headlights pitched on a upward curving road are making it impossible to see what actually matters: the road. Please do something to introduce additional technology already adopted by some OEMs in the EU which help to prevent this problem

B.3988 December 3, 2024 — Tomball, TX

With such bright lights around, the human eye cannot contract/expand the way it needs to against these oppressive lights. It is a danger to myself and those on the road with me, not only including other drivers, but pedestrians as well.

B.3989 December 3, 2024 — Troy, TX

I've narrowly avoided getting into accidents caused by these headlights. They are so blinding, so unsafe, and make driving in front of someone with these lights borderline impossible. There are already so many hazards associated with driving - artificial blindness shouldn't be one of them.

B.3990 December 4, 2024 — Missouri City, TX

I see it everyday. It takes away nearly all visibility at night. It's like when you turn the lights on and off and your eyes have to adjust, so you can't see anything. This one day I was going down a road and this truck's lights were so bright I couldn't make out anything of it - not the shape, color, make, or license plate. So I thought in that moment, if I end up running over someone because I can't see literally anything, the only way I could find out who has those blinding lights is if I ask the neighborhood who was driving down that certain road at that exact time. Otherwise that truck was completely unidentifiable and I would be at fault for hitting someone when I couldn't even see anything because of those blinding headlights.

B.3991 December 4, 2024 — Richmond, VA

These lights blind me from the front and the back. It takes me 5 to 10 seconds for my vision to get the brightness to get better but doesn't go fully away and so far I have been lucky not to crash but I have come close!!! I only missed the car because I turned sharp enough to miss it not because I saw it because my eyes were still blinded by the headlights. I also adjust my rear view mirror and my side mirror so the lights from behind don't blind me to bad so I'm pretty much driving blind and can't use my safety equipment to keep me and everyone else safe!!! Anyone that denies these lights are dangerous and should be banned obviously don't care about life and safety and just want money. I hope these lights get bannned asap and they become illegal

B.3992 December 4, 2024 — United States

Headlights shouldn't be too bright because they can blind people, hurt them, and even kill them.

B.3993 December 4, 2024 — san antonio, TX

Getting dark means get home fast. This keeps a segment of society not being able to drive anywhere after dark, it keeps us at home isolated. Not Fair.

B.3994 December 5, 2024 — Middletown, CT

I WANT TO SEE AT NIGHT AND NOT FEEL LIKE MY LIFE IS IN DANGER EVERY SECOND I AM BEHIND THE WHEEL

B.3995 December 5, 2024 — Presque Isle, ME

Living with astigmatism is tough, but it is outright unbearable with other cars' retina searing capabilities. I'd love to see something done about it.

B.3996 December 5, 2024 — forestville, CA

The situation is out of control

B.3997 December 6, 2024 — Alhambra, United States

Can't see at night, man. Ain't right. Oncoming traffic with white LED lights are like flashbangs.

B.3998 December 6, 2024 — Austin, TX

Headlights have gotten too bright and make safe driving impossible.

B.3999 December 6, 2024 — Bay City, MI

My eyes hurt, and I like being able to see the road I and others drive on.

B.4000 December 6, 2024 — Berkeley, CA

Lights are to damn bright

B.4001 December 6, 2024 — Des Lacs, ND

I am so sick of being blinded by every vehicle newer than 2018. Unless you drive a giant SUV or Pickup taller than everyone else's vehicles (in turn becoming the one who blinds others), you will be blinded by every single oncoming vehicle. And don't tell me headlights adjustments are the problem, I live in one of the flattest cities in one of the flattest states. Small bumps in the roads or bridges negate those projector cutoffs. People's "dim" lights will blind you just as bad because of them.

B.4002 December 6, 2024 — Destrehan,, LA

Nearly ran off the road last night because it was like I was trying to look through the sun. Had to stop travel completely to see the curve in the road and not continue straight. Lack of manufacturer ethical responsibility and no local enforcement of the law are leading to extremely unsafe conditions at night. There needs to be accountability.

B.4003 December 6, 2024 — Eau Claire, WI

I'd say "there outta be a law," but I feel like this really falls under the already existing legislation on high beam vs low beam headlights. It's already illegal to drive exclusively with high beams exactly BECAUSE it creates a hazard to other drivers. But somehow an LED headlight, which on average is anywhere between 3-10 times brighter than a standard halogen light is legal (low beam halogen bulbs typically run around 700 Lumens while LED low beams typically run anywhere between 2,000 - 10,000 Lumens)?!? C'mon, man!

B.4004 December 6, 2024 — Hanford, CA

I frequently take several-hour drives with my daughter to Disneyland from the Fresno area, and driving when it's dark has become borderline dangerous because of the intensity of the brightness of modern headlights and the lack of enforcement on aiming angle and power. I literally have to put my hand in front of my face, as if I was staring at the Sun, in order to be able to see any vestige of the road in front of me. This is dangerous and completely unneeded. Action needs to be taken to get this serious problem under control and avoid any more injuries and/or deaths to innocent citizens.

B.4005 December 6, 2024 — Long Beach, CA

Because these lights are too bright!!!!!

B.4006 December 6, 2024 — Minneapolis, MN

I don't like to be blinded while driving

B.4007 December 6, 2024 — Mooresville, NC

I'm sick of being fucking blinded when I'm driving at night. That's it. That's the only reason. It's annoying and it can cause accidents.

B.4008 December 6, 2024 — Onaway, MI

The lighting is dangerous and with winter here and long nights it makes driving to and from work very perilous.

B.4009 December 6, 2024 — Ponchatoula, LA

Melissa Thomas

B.4010 December 6, 2024 — Randolph, MA

i have light sensitivity yet we live in a car brain dead society were i can't even drive because people have their high beams on 24/7

B.4011 December 6, 2024 — Saint Louis, MO

They hurt my eyes when driving at at night now and makes it much harder to drive in the rain.

B.4012 December 6, 2024 — San Jose, CA

I can no longer drive at night and I'm only 53!

B.4013 December 6, 2024 — Santa Cruz, CA

Driving home the other night on a rural two lane highway I almost caused accidents several times because I couldn't see as a result of the blinding headlights coming at me from the other direction. It's getting to the point that I don't want to drive at night because I'm afraid I'll cause an accident from being blinded for a few seconds. I've never heard an issue with headlights blinding me until maybe the last five years. We need changes made or there will be fatalities as a result of someone being blinded by these things. Sometimes the white line isn't on the right hand side of the road so you're basically guessing where to steer.

B.4014 December 6, 2024 — St Louis, MO

These lights suck!

B.4015 December 6, 2024 — Tacoma, WA

I'm signing because I have to drive at night for work, with children (foster care kids), and I've lost count of how many times I've been forced to come to a COMPLETE AND TOTAL STOP in the middle of the road, because even putting my hand up to shield the glare, I am completely and totally blinded. This is UNACCEPTABLE! And it's terrifying. Utterly and completely terrifying.

B.4016 December 6, 2024 — Tucson, AZ

it's so bad I have started wearing sunglasses to drive at night time

B.4017 December 6, 2024 — Vancouver, Canada

Even after double cataract surgery and secondary cataract laser procedure on the lens capsule in both eyes the excessively bright, glaring headlights of vehicles on the road is a safety concern to me...even as a pedestrian in the city (they blind me to what is underfoot) and certainly when I am at the wheel of a vehicle or on a bicycle. It is socially irresponsible for car makers to turn headlights into virtual weapons on the road. Safety for drivers is NOT enhanced by harming others. This has to change.

B.4018 December 7, 2024 — Calgary, Canada

i want to be able to see at night

B.4019 December 7, 2024 — Cheney, WA

One of the best ideas I've heard of in a very long time. Please get RID of these ridiculously bright lights, they're everywhere and on everything, not just the cars. I passed a lighted billboard recently and felt as though I was going to have a seizure. I tell my kids not to look at the lights, afraid that their vision will suffer. Time to tone it down! Thank you.

B.4020 December 7, 2024 — Chicago, IL

The crop of headlamps appearing in the last five years or so are outrageously bright and seem to be indistinguishable from what used to be “high beams”. I find I need to take my eyes off the road and follow the right lane stripe to control the vehicle. Very dangerous. Also trucks and SUV placement is at eye level for normal cars and they don’t need to be.

B.4021 December 7, 2024 — Chicago, IL

The glare is painful from oncoming cars when night driving. But headlights also don’t provide enough light when night driving on remote roads.

B.4022 December 7, 2024 — Hayward, CA

Vehicle LED lights is not the solution for not replacing and repairing street lights. Head on glare of the LED vehicle headlights is blinding and dangerous especially in areas with limited street lights. For seconds, you can not people existing vehicles, bicycle ride, pedestrian unexpectedly crossing and vehicles. The industry is suggesting to purchase yellow tinted glasses or were shades at night instead of fixing the public safety issue.

B.4023 December 7, 2024 — Houston, TX

I feel if you can’t see without a 40000 lumen light bulb you shouldn’t be driving at all, this issue really effects us car drivers, as your raised or non raised trucks headlights are level to every single mirror in the car, when you’re behind us at a red light, we’re being blinded from every angle, not to mention the people who are waiting at the opposite side of the intersection is also just far enough away where their headlights are also eye level, it makes it hard to see the road which is EXTREMELY dangerous

B.4024 December 7, 2024 — Kansas City, MO

The level of agitation I'm struggling to regulate now has caused me tears time and time again. I have two major things that make me especially vulnerable when driving: astigmatism, and autism, the former being a condition that effects probably 4 of every 10 people on earth. So the amount of people that can't stop the glare is a vast portion of drivers on the road. Being okay w blinding even one car by chance, is NEGLIGENCE and at this point it's offensive driving.

B.4025 December 7, 2024 — Memphis, TN

I almost crashed being unable to see the road because a SUV was behind me with those blaring lights. Those lights should be banned they are dangerous.

B.4026 December 7, 2024 — Oak Creek, WI

I have experienced night time glare from LED headlights so extreme it blinded me, leaving me dangerously unable to distinguish my own lane position. This is extremely dangerous, especially on a two-lane road in the dark of night.

B.4027 December 7, 2024 — San Mateo, CA

Please also address the issue of blindingly bright LED brake lights. These are causing temporary blindness for other drivers. The current situation with LED headlights and brake lights makes it too dangerous to drive after sunset.

B.4028 December 7, 2024 — Springfield, MO

After a TBI 9 years ago, I have extremely painful trouble with flashing bright lights, such as the LED emergency vehicles lights. It's like being shot in the head to passa wreck, and migraines are frequent. Now these headlights - pure torture. I have literally stopped the car in the middle of a road until someone passed, and even stopped in the middle of a curve. I'm temporarily blinded to blackness, I stand terrible pain, and cannot see to operate a car safely even for seconds. I'm constantly moving mirrors and avoiding direct visual from behind, and it is impacting my life to even try to navigate

after dark. No one needs this intensity to see better, while blinding the other driver. For me, it's impact plus pain and suffering. Their lights cause my reaction, which could cause me to wreck or impact another person driving. This is dangerous. Please change to outlaw for the sake of everyone impacted!

B.4029 December 7, 2024 — miami, FL

There was no reason to change it. It's impossible to even see beyond my windshield and most of the time it feels like I'm leaving it up to chance getting from one point to another. Horrible.

B.4030 December 8, 2024 — Freehold, NJ

I literally can't see the road while I'm being eye-blasted by LED headlights. Them being blue makes it even worse. It's a huge safety concern when my only option is to pray that there's nothing in the road after being temporarily blinded by these lights.

B.4031 December 8, 2024 — Richmond, IN

I find the blinding glare from these headlights to be not only annoying but painful and blinding enough that I can lose my ability to see the lane lines to maintain my vehicle in the correct lane. In cases where there are no lane lines, as on dark nights on narrow country roads the glare from these headlights is particularly dangerous. I find myself having to slow my vehicle to nearly a stop to avoid crossing the center line or driving off the side of the road.

B.4032 December 9, 2024 — Seattle, WA

I got in a really bad wreck cuz someone in a Benz was driving behind and blind spotted me . I couldn't see with those very bright lights straight looking into my eyes and blinding me

B.4033 December 9, 2024 — Spartanburg, SC

I can no longer drive at night due to the blinding of the headlights

B.4034 December 10, 2024 — Lancaster, CA

i'm sick of being blinded on the road. if you need LEDs to drive, you shouldn't be driving at night period.

B.4035 December 10, 2024 — clovis, CA

I can barely drive at night anymore, the glare of oncoming headlights is so intense! Please help !!

B.4036 December 11, 2024 — Alton, ENG, United Kingdom

I can no longer drive at night as the glare blinds me and I don't feel safe.

B.4037 December 11, 2024 — Apollo, PA

The turn to LED replacements everywhere is beyond horrible. HPS lamps being replaced with extremely bright white LED has disasterously affected local ecosystems along with the circadian rhythms of people. LED headlights absolutely destroy your night vision capablilities and very often completely wash out your sight to where you cannot see on the road. Its insane how often i have to literally stop in the middle of the road so that i can genuinely take a second to figure out where im going rather than just be able to look and see. Instead i have someones headlights completely taking away my vision.

B.4038 December 11, 2024 — Chicopee, MA

I have been saying this forever, these LED headlights need to be banned. I'm at the point where I am not comfortable driving at night period. Not because of my abilities but because these are mind numbingly blinding. I feel like either a deer in the headlights or a moth to the flame when these are oncoming, it's one or the other no happy medium. This makes me feel unsafe! We aren't supposed to legally use our high beams, but these are these okay? Driving at night is truly a nightmare for me, it's awful I've always loved driving at night. These lights are out of control and unnecessary. Whether they are head on or behind, it is unfair. I have to constantly adjust my mirrors when these are behind. These lights are ridiculous. They truly are blinding, they cause pain and are absolutely 1000% unsafe. Then add in rain and forget it, especially since I too have astigmatism. Vehicles with these lights are

basically weapons and are responsible for accidents that will, not if, happen plain & simple. Get these off the road. Ban these. They're unsafe.

B.4039 December 11, 2024 — Indianapolis, IN

Modern headlights are needlessly bright, to a point which 1. Provides no added benefit for the driver, and 2. Makes driving at night significantly more dangerous for the rest of us by REDUCING visibility due to their overwhelming brightness. A road full of blinded drivers is not a safe road. There needs to be a legal limit for these things.

B.4040 December 11, 2024 — San Antonio, TX

I CANT SEE AND ITS DANGEROUS - OKLAHOMA

B.4041 December 11, 2024 — Springfield, MO

There needs to be regulation on how bright headlights can be from manufacturer and after market alike.... it causes headaches, temporary blindness, and is incredibly dangerous to everyone around them. i am sick of running across these entitled assholes who think that driving behind the full force of the sun so only they can see is ok. i cant even legally tint my windows to diffuse the lights so i can see.. why should they be able to blind everyone on the road? ticket the drivers every time they drive with blinding light and the manufacturers should get a ticket every time one of their cars is stopped with blinding lights too.

B.4042 December 11, 2024 — brooklyn, NY

Its extremly dangerous to the point im afraid to drive

B.4043 December 12, 2024 — Pluckemin, NJ

Driving home on back roads can feel horrifying when I round a corner and get blinded by these high intensity lights. Their inclusion in cars was a mistake in design.

B.4044 December 13, 2024 — Murrysville, PA

Blinding drivers on the road is unsafe and unnecessary. And painful! Add your voice.

B.4045 December 14, 2024 — Alexandria, VA

These lights are causing lots of health issues in people including seizures, migraines, etc.. they should be banned

B.4046 December 14, 2024 — Asheville, NC

All LED lights (including the ones that illuminate the screens we're using right now) are antithetical to visual and mental health & wellbeing, but when used in headlights-- and at such an intense level-- they are absolutely deadly. It's beyond criminal that these products are available for purchase. Take ALL LED lights off the market, and bring back warm, inviting incandescent lighting!

B.4047 December 14, 2024 — Bangor, ME

This needs to cease, I remember a time when KC lights needed a cover because they were illegal to drive with. Now the LED lights are 10x brighter than a KC light ever were. Under the guise of OEM being legal. OEM needs to be regulated.

B.4048 December 14, 2024 — Easton, PA

I'm sitting here after driving an hour with a pounding headache in the dark and my brightness on my phone turned all the way down and still too bright. I'm in so much pain but this needs to be done. I almost drove off the road tonight because I couldn't see any of the road and have had this massive throbbing headache from all of the intense blinding lights behind and in front of me all night. And especially considering everyone in my state likes to drive behind you with not just their blinding headlights but also their blinding highbeams. First off Homie if you're the blind that you need both when your low beams are already brighter than the goddamn sun, you shouldn't be driving, second if you're behind someone you don't need your highbeams and third if you're coming towards someone it's bad enough that your low beams are blinding, but if your highbeams are on too, I'm assuming you want them to crash. There's literally no reason for it. If you can't drive at night without them then here's a quick solution, don't drive at night. How many fatal accidents gotta happen for the people in

charge to give a fuck? Good to know that our lives and well beings are regarded as this unimportant that no one's outlawed these yet.

B.4049 December 15, 2024 — Downers Grove, IL

I have almost had accidents because of these lights. What's worse is when it rains it doubles the problem because they also reflect on the wet road.

B.4050 December 15, 2024 — Harrogate, ENG, United Kingdom

Im finding driving in lanes at night dangerous driving because of blinding head lights

B.4051 December 15, 2024 — Lagrange, OH

I hate being blinded.

B.4052 December 15, 2024 — Long Beach, CA

This is dangerous for all of us

B.4053 December 15, 2024 — Mount Vernon, NY

Laura Carrera

B.4054 December 15, 2024 — Peterborough, ENG, United Kingdom

They,distract and lose my full attention. On the road in front of me, when in darkness you need more attention driving . I would estimate that it,possibly only 25%,with the blue,light beams.

B.4055 December 15, 2024 — Plattsburgh, NY

I can't see the road at night

B.4056 December 15, 2024 — San Francisco, CA

I have a astigmatism and this blinds me at their lowest. They provide little to no extra benefit for sight on roadways. While blinding others. You obviously didn't do properly research on headlights when you came out with this product. If you did you'd understand why we have yellow tinted lights instead of white lights. Instead your neglecting actions have now led to multiple acticdents and possibly liability to death due to your choice of headlight design that would probably lead to the biggest recall of vehicles. I hope that California stops being the place where we think good things come from this state has caused nothing but problems for this country.

B.4057 December 15, 2024 — Spokane, WA

I'm a petite driver. While driving at night I'm constantly blinded by the headlights of other vehicles. I will tell you only halogen headlights blind me like LED headlights do. I've resorted to wearing sunglasses at night. My eyes take longer to recover from a flash of LED light then they do from a flash of incandescent light.

B.4058 December 15, 2024 — Staplefield, ENG, United Kingdom

I am struggling to see on the commute home in the dark, due to being dazzled by these lights.

B.4059 December 16, 2024 — Bellingham, WA

I am in my twenties, have perfect vision, and I'm not normally sensitive to light. However, I notice more than ever that driving at night feels especially stressful now because so many cars have horribly bright LED lights. The blue tint actually hurts my eyes. The main freeway I drive on doesn't have a lot of overhead light either, so the lights from oncoming traffic are even more blinding. Most of the time it seems like drivers have their brights on, but it's just the LED. Regardless of whether these new lights are considered more energy efficient, I actually find this to be a really dangerous development for anyone who drives a car, AND counterintuitive to safe driving conditions. Please get these lights banned and find another solution!

B.4060 December 16, 2024 — Cincinnati, OH

It is blinding to those with astigmatism.

B.4061 December 16, 2024 — Miami, FL

I cannot SEE when the headlights from the LED lights come towards my direction - I FEAR AN ACCIDENT since I cannot see what's in FRONT OF ME due to blindness of LED lights - PLEASE MAKE OUR ROADS SAFER ... remove them!

B.4062 December 16, 2024 — Seattle, WA

OUCH. MY EYEBALLS.

B.4063 December 16, 2024 — Suffolk, VA

I'm 57 years old and cannot drive at night because of blinding headlights. My adult children (only in their 20s) are having trouble seeing as well. This MUST change.

B.4064 December 17, 2024 — Westerly, RI

Everytime someone with LED headlights comes up behind me I have to slow down and move out of their way. It's the same with people who have their high beams on behind me. I simply have to slow down nearly to a stop because I can't see. I know this is unsafe for me to do especially on highways that I travel often on like I-95 considering it's a high speed limit but what else am I supposed to do when I can't see. It's illegal to drive within a certain distance of vehicles with high beams, yet drivers who have LED headlights suffer no consequences even when it has the same effect. It's a risk to many people's safety and causes anger and frustration across the masses of drivers.

B.4065 December 18, 2024 — Bel Air, MD

I'm ready to sue the Department of Transportation for allowing those highly deadly LED lights to be used on motor vehicles. I escaped death within seconds after being completely blinded by these dangerous lights to be used. I'm getting peolple to file a class action suit against the DOT. I want to know who has been affected, had an accident, has a friend or family member hurt or killed in an accident because they were so blinded they couldn't even see the road. Im sick and tired of some big truck pull up behind me with those dangerous lights blinding me so bad that I have run off of the road. How fair is that. The DOT needs to be completely taken down for such a gross and negligent violation against the rights of drivers to have safety rules in place. Whoever approved these headlights should be put into prison for killing people. It's BS and I'm starting a class action suit for anyone who has been affected, hurt or killed because of them. WTF is going on here. The DOT is going down for this and I don't care what I have to do, I want them charged criminally for the distasterous and deadly have a class action suit

B.4066 December 18, 2024 — Essex, MA

I think bright headlights are dangerous.

B.4067 December 18, 2024 — Garland, TX

I suffer from chronic migraines and not only can overly bright lights trigger a migraine, they cause me physical pain when I am already in a compromised state. I cannot drive after taking my migraine medication, so I frequently have to suffer through driving in the dark with a migraine and being blinded by headlights so that I can get home and take my medication.

B.4068 December 18, 2024 — Newark, CA

Fuck bright headlights. It's impossible to drive safely with those in your eyes

B.4069 December 18, 2024 — Tucson, AZ

There is absolutely no reason someone would need such bright lights. Seeing as I can see just fine with my old school headlights and I have pretty bad eyesight.

B.4070 December 18, 2024 — seattle, WA

I live in L A and spend a lot of time on the road. Many of the newer cars have lights that are extremely blinding. It makes driving uncomfortable, tiring and dangerous. I wish there would be regulations about light height, intensity, amount of lights on a car to limit the strain on the eye and driving experience. Thank you.

B.4071 December 19, 2024 — AL, United States

LED headlights are a public nuisance in causing temporary blinding glares that prevent other drivers from seeing their surroundings properly and safely to avoid needless accidents or fatal harm to themselves and others. LEDs are unsafe for the driving community overall.

B.4072 December 19, 2024 — Akron, OH

Automotive lighting needs to be examined and regulated. If lighting is distracting, annoying or impairing than it′s a problem

B.4073 December 19, 2024 — Albany, NY

I'm 56 and have glaucoma in both eyes. It's being treated, but in recent years it's gotten worse. With the bright LED headlights of oncoming cars (4 times brighter than the halogen headlights that vehicles USED TO have), I've become very uncomfortable driving after dark, especially in the rain or someplace I'm unfamiliar with. These too-bright LED headlights are disorienting. I've resorted to organizing my life so that I never need to drive at night, but sometimes it's unavoidable. And I shouldn't HAVE TO stop driving at night; the headlights shouldn't be this bright!

B.4074 December 19, 2024 — Caledonia, MI

All the bright LED headlights makes it very unpleasant and unsafe to drive at night!!!

B.4075 December 19, 2024 — Carrollton, OH

When you have leds in headlights, turn signals and dont have respect for others you are blinding as you drive...if you need lights that bright, you don′t need to be behind the wheel

B.4076 December 19, 2024 — Chicago, IL

I agree with that women said those led are so bright you can even see the road.they are to bright!

B.4077 December 19, 2024 — Cleveland, OH

Constant blinding by headlights, usually on overly huge trucks and suvs

B.4078 December 19, 2024 — Cleveland, OH

LED lights are way too blinding at night and early mornings when dark.

B.4079 December 19, 2024 — Glouster, OH

They literally blind me on the road and I must adjust my rearview and side mirrors on LED cars behind me, haven't you?

B.4080 December 19, 2024 — Heath, OH

People with mild cataracts, like me, have problems with LED car headlights lights causing very bright sparkly halos around the headlights at night. This makes oncoming vehicles at night a big problem. The sparkly halos are blinding people and very unsafe. I avoid driving at night now. This has been a well documented problem for several years. Note: I am a retired Quality Assurance Manager from the largest lighting company in the world. I have a lot of experience with LED lighting. This LED problem has existed for a long time.

B.4081 December 19, 2024 — Macedonia, OH

Leds Make it hard to see the markings on the road so i find myself slowing down when a car or especially a a pickup truck with led lights is approaching. its hard to tell when they have there high beams on and then there′s aftermarket lights that you can install yourself these are even worse. This is a no brainer make the manufactures fix the problem and save some lives!

B.4082 December 19, 2024 — Minerva, OH

The LED lights on pick up trucks literally blind you! There has got to be a safer way for headlights than LED. We survived for how many years without them? Seriously people!

B.4083 December 19, 2024 — Mount Perry, OH

I have to stop right in the road because I am so I blinded by LED headlights that I can′t see the road

B.4084 December 19, 2024 — Sandusky, OH

I also have vision and neurological issues. Driving at night is tough enough without blinding headlights. Please stop the LED lights!

B.4085 December 19, 2024 — Seabrook, TX

My husband suffers from seizures, and these LED headlights have caused him numerous seizures while just being a passenger.

B.4086 December 19, 2024 — Shiloh, OH

I have astigmatism

B.4087 December 19, 2024 — Springfield, MA

Lives are being endangered by the extreme brightness of cars' headlights & they're not the high beams. The automotive industry needs to address & correct this huge problem!

B.4088 December 19, 2024 — Trophy Club, TX

As someone who struggles with astigmatism, alongside multiple family members of driving age who also have astigmatism, LED headlights are not only blatantly inconsiderate of other drivers on the road, they're blinding to the point of disabling road visibility, headachingly painful to drive against, and proven to be dangerous. It is selfish and criminally negligent for vehicles to continue harboring these reckless weapons when a safer alternative is and has been available. Each life of every driver and every passenger is immeasurably valuable; Ensuring roadway safety is of imminent and paramount importance. I sign in agreement to politely demand that Congress, the Department of Transportation, NHTSA , and the FDA take this matter seriously and properly regulate LEDs as spatially non-homogeneous, directed energy radiation. BAN LED HEADLIGHTS in vehicles driven in shared spaces and public roadways.

B.4089 December 19, 2024 — United States

https://www.cleveland19.com/2024/12/18/local-woman-joins-push-ban-led-headlights/

B.4090 December 19, 2024 — Waynesville, OH

These lights give me a headache and I'm unable to drive at night now because of how blinding these lights are, it take up to 30 seconds before I can actually see to drive again.

B.4091 December 20, 2024 — Beltsville, MD

This is a matter of extreme public safety. Driving at night is already dangerous because of low visibility. We have minimize this with headlights. However we are now being blinded by these headlights. Particularly, the led lights on newer models. I have to avert my eyes from the road inorder to not become disoriented from the unnecessarily bright lights of oncoming cars.

B.4092 December 20, 2024 — Chicago, IL

Its dangerous

B.4093 December 20, 2024 — Columbus, OH

LED headlights are very blinding and distracting. I have to look at the white line on the side of the road while driving to work in the dark morning hours. When they have thier brights on its 10x worse.

B.4094 December 20, 2024 — Dayton, OH

When driving on dark roads that do not have street lights you want to be able to what is ahead in front of you. To be blinded by the bright LEDs from incoming traffic is absolutely dangerous, you are either trying to avoid being blinded or are blinded both of which takes your eyes off the road which can potentially cause accidents. Whoever originally thought of utilizing LED headlights clearly did not think of the repercussions on the road and to drivers

B.4095 December 20, 2024 — KIRTLAND, OH

Please include verbiage that includes restrictions on and accountability for headlight alignment and angle of emission. Headlights should be prohibited from egregiously crossing over the center line. Oncoming traffic headlights have no business being in my face when I am on the other side of the

road. Blinding other drivers makes our roads dangerous and makes night driving impossible for. Headlights used to align to the shoulder. It should remain like this. Thank you for this petition.

B.4096 December 20, 2024 — London, United Kingdom

THESE LIGHTS ARE BLINDING

B.4097 December 20, 2024 — OH, United States

There’s no good reason for these LED headlights, they’re blinding most drivers and that’s a danger to all lived

B.4098 December 20, 2024 — Struthers, OH

Those lights may "shine brighter and further allowing you to see further." However they for people even with 20/20 vision they are blinding. Just as bad as staring directly into the sun!

B.4099 December 20, 2024 — Willoughby, OH

LED lights are far too bright for use in vehicles. There's no good argument for them, they are beyond unnecessary and extremely unsafe!

B.4100 December 21, 2024 — Akron, OH

This is dangerous.

B.4101 December 21, 2024 — Edgewood, KY

It makes driving at night a burden. Why should I need to consider spending money on tinting my windows to avoid the bright lights?

B.4102 December 21, 2024 — Greensboro, NC

We need to be taking more steps to making US roads less of a deathtrap like so many European countries have.

B.4103 December 21, 2024 — Harwood Heights, IL

These lights are so dangerous my husband and I are older and drive a smaller car and I worry that we will get into a accident

B.4104 December 22, 2024 — Aurora, IL

My wife can’t see

B.4105 December 22, 2024 — Greenwood, IN

I have Astigmatism which when paired with the crazy bright LED headlights, means I can’t drive at night and I’m 30. It’s not safe as the lights are so blinding I cannot even see my lane. Please do something.

B.4106 December 22, 2024 — Portland, OR

Driving at night has become increasingly dangerous every year due to these new cars coming with extremely bright LED headlights. I've nearly been in many accidents from going around bends only to be blinded by an oncoming car. I live in a state where it rains 9 months out of the year, which only makes the glare worse. And not only is it awful seeing it from the front windshield, but these lifted trucks who's headlights shine directly through my back window and reflect off my rear view mirror make it difficult to concentrate on what's in front of me. They need to be banned ASAP.

B.4107 December 22, 2024 — South Yorkshire, ENG, United Kingdom

These headlights are downright dangerous

B.4108 December 23, 2024 — Blackwood, NJ

I think this is a concern for people's health, the lights really cause a lot of stress, and it makes people really angry that we have people driving 1 you act like that can't see to have really high lights is disgusting it's nasty. There were many times I wanted to get out my car and take a bat to light and solve the issue my way. The radiation isn't good and hurts the human eyes. I think instead of tints, having really high lights on when driving should be band and illegal and jail time should be served, on any car and government car. Like I said it's blinding.

B.4109 December 23, 2024 — Buffalo, NY

The widespread use of LED lights, particularly the extreme brightness of white LEDs, has become a significant concern for both humans and wildlife. These lights are often unnecessarily bright, disruptive, and harmful to health and the environment. Their negative effects must be addressed with greater consideration for all forms of life. For humans, the brightness of LED lights can be overwhelming. Personally, I find it difficult to drive at night with these lights glaring into my eyes. They cause headaches, discomfort, and an overall sense of unease. It's unfair to subject people to such harsh lighting in everyday situations, whether they're walking down the street or driving a car. This issue is even more pronounced for wildlife. Insects, trees, and other organisms are all negatively impacted by these lights, which disrupt natural cycles and habitats. The argument that LED lights are "cheap" isn't enough to justify their widespread use. History has shown us that prioritizing cost over quality can have dire consequences. For example, asbestos was once considered a miracle material, but its long-term health hazards forced us to abandon it. LED lights may be cheaper to operate, but they're already causing harm. Over time, they could lead to widespread eye problems, increased reliance on corrective lenses and technology, and more waste in landfills due to the need for constant upgrades and replacements. We need to prioritize quality lighting solutions that respect both human and wildlife needs. Higher-quality lighting may cost more to operate, but the benefits far outweigh the drawbacks. No one should fear having their neighborhood streetlights replaced with bright, glaring LEDs that trespass into their homes, disrupt their peace, and destroy their right to private enjoyment of their property. For example, a covered front porch should remain a usable, enjoyable space—not rendered useless by light pollution from harsh streetlights. Streetlights in residential areas should not exceed 2,200 Kelvin. Lighting above this threshold is too harsh, creating a sterile, unnatural environment that clashes with the character of our homes and neighborhoods. These LEDs aren't even traditional lightbulbs—they're engineered products that don't provide the same warmth or quality. They don't "rewind" any damage done to the environment and are not a panacea for climate change. Instead of focusing on overly bright, harmful lighting, we should consider planting trees to offset carbon footprints, preserving existing wildlife, and ensuring solar farms are placed on rooftops rather than on valuable natural land. In conclusion, while LED lighting is marketed as a cost-effective solution, it comes with significant hidden costs. The health, environmental, and aesthetic impacts are too great to ignore. We must advocate for lighting solutions that are both environmentally sustainable and respectful of human and wildlife needs. Quality lighting isn't just a luxury—it's a necessity for the well-being of our communities and the planet.

B.4110 December 23, 2024 — Cleveland, OH

I have vertigo as well from LED light sensitivity. It is definitely a hazard for those who still are capable of driving at night but with limited driving distance due to the LED headlights.

B.4111 December 23, 2024 — Ontario, CA

When I am faced with someone with these headlights, it blinds me for about 20 seconds. I've almost been in countless car accidents as a result.

B.4112 December 24, 2024 — Lake Havasu City, AZ

As our population ages, eyesight is a concern. These horrible bright lights are blinding and older eyes don't react as quickly as they once did. There is no reason for them.

B.4113 December 24, 2024 — Seattle, WA

It is too dangerous to have to turn my head to the right when there is oncoming traffic. Or when I'm walking my dog and I lose much of my vision because an oncoming car is 2 blocks away. Or driving a short distance in my neighborhood and being blinded from cars in my side view mirror. Or even sitting in my living room, cars 3 blocks away lighting up my interior. It affects life off the roads too, stress and eye health - huge safety concern.

B.4114 December 24, 2024 — Tucson, AZ

Nothing has diminished my quality of life in the modern world like the new headlights. It's hard to drive a mile to the grocery store without nearly running over a pedestrian due to headlight induced blindness. The headaches after a long night drive can last hours, and my last cross country trip was

increased by days because I had to stop driving at sundown. Driving at night was a pleasure in the 90′s and early 00′s. I

B.4115 December 25, 2024 — Auburn, NY

I strongly feel that these blinding headlights are an issue and especially as someone who already doesn’t have the best vision, it has decreased my vision more than before even with blue light blocking glasses.

B.4116 December 25, 2024 — Ludington, MI

I CANT FUCKING SEE!!!’

B.4117 December 25, 2024 — Minneapolis, MN

Regulation and enforcement on the issue of overly bright headlights is long overdue. This should be common sense.

B.4118 December 25, 2024 — Valley Mills, TX

When high beams are on, they blind me and make it hard to see the road. I drive an older car without bright lights, so it makes the situation even more difficult.

B.4119 December 26, 2024 — Bridgewater, MA

Or or or, and hear me out, require headlights be mounted at a lower height on the vehicle. No more headlights above 3ft on new vehicles

B.4120 December 26, 2024 — Calgary, Canada

Cars can be dangerous weapons of death, and we need to hold manufacturers accountable for creating safety risks for everyone on the road/bike lane/sidewalk.

B.4121 December 26, 2024 — Canandaigua, NY

I’m on the verge of needing to change my work hours so I don’t drive at night. I have a 30 minute drive home and many nights I arrive home with a headache from squinting to avoid the lights of oncoming traffic. I’m also pulling over if anyone is driving behind me at a distance that causes their headlight to him the rear and side mirrors at the same time.

B.4122 December 26, 2024 — Cedar Grove, NJ

There are far too many times where I′m blinded driving in the middle of the night. I like to take mountain roads where there′s no one there and I have my high beams on. However, I turn them off immediately when a car passes and they typically do the same. There are too many times where I was blinded and I thought that they had their high beams on. I flashed them with my own and boy, was I wrong when they actually did put their own high beams on. I would have to come to a physical stop because I couldn′t see and I didn′t want to drive off the road. It′s disgusting. I can′t drive in peace in the middle of the night without getting blinded or have an excruciating headache. My normal lights are yellow. My high beams are LED. That′s what it should be. It shouldn′t be regular lights are LED and high beams being an even more blinding LED. Ban bright headlights. There′s no need for a constant LED light in my face whenever I′m driving.

B.4123 December 26, 2024 — Chesapeake, VA

Please stop destroying my eyes. I may literally die and kill all of my passengers by accident one day if this continues. I don′t want that but, like all creatures with eyes, I can′t see when blinded.

B.4124 December 26, 2024 — Goshen, KY

If I get blinded by 1 more lifted pavement princess I will cause a head on collision

B.4125 December 26, 2024 — Highland, IL

The risk to the public, particularly families with small children, caused by these absurdly bright lights is outrageous. One′s life and one′s safety on our public roadways should and do outweigh the preferences of those who out of malice or to overcompensate for other…issues blind drivers on the roads.

B.4126 December 26, 2024 — Milton, FL

Every night, me and my wife come across these blinding LED headlights, pointed right at eye level for smaller cars, making it impossible to see anything until they pass, leaving us with ghost vision, a terrible headache, and immense eye pain. These headlights are brighter than our brights. They are completely unnecessary, and more importantly, dangerous. Especially in a state with elderly drivers, blinding people can cause serious traffic accidents and already has. This needs to change, before it gets even more out of hand.

B.4127 December 26, 2024 — North Hollywood, CA

Why do you need lights that damn bright? Especially in the city! Having astigmatism makes the situation a whole lot worse. Stop blinding drivers!!!!

B.4128 December 26, 2024 — Provo, UT

Time to ban LED headlights and automatic high beams. The lights are excessively bright and blinding. And the auto bright feature doesn't work, staying on far too long. Enough is enough. It doesn't have to be hard. Just ban the LEDS altogether.

B.4129 December 26, 2024 — San Antonio, TX

I get blinded by excessively bright headlights practically every time I drive after dark. Thankfully it has yet to cause me to miss a curve, vehicle or pedestrian in front of me. But it is only a matter of time before something terrible happens.

B.4130 December 26, 2024 — Seattle, WA

Regulate these led lights

B.4131 December 26, 2024 — Tallahassee, United States

I'm so tired to being blinded by these new ridiculously bright headlights. They are dangerous and need to be better regulated. Please do something to fix this issue.

B.4132 December 27, 2024 — Burley, ID

Every time I get blasted with these intense led headlights, my optic nerve sends a shot of intense pain through my brain, down my spine and back again. It's become such a problem in my area (because almost everyone has them) that I'm almost ready to quit driving at night altogether. There are people I need to drive for, but this problem just gets worse. Something needs to be done!

B.4133 December 27, 2024 — Burnaby, BC, Canada

It's a GLOBAL issue actually...

B.4134 December 27, 2024 — Deer Isle (family property), ME

Three minutes of blinding, center-of-vision afterimages in drivers is INSANE! Prohibit these headlight! Now!

B.4135 December 27, 2024 — Eagle River, AK

LED Headlights are dangerous! Ive had to pull over before because my eyes hurt and I couldn't see, it is a safety concern.

B.4136 December 27, 2024 — Milwaukee, WI

Such a danger to drive with what seems to be a total lack of headlight brightness regulation. Some are blinding even in daylight. The ones that strobe are terrible. I'm afraid to drive at night for fear of being blinded not only by oncoming traffic, but also by reflections of them in the rear view mirror. Some are as bright as a car with their "brights" on. Something seriously needs to be done!

B.4137 December 27, 2024 — New Orleans, LA

I want to be able to drive safely again at night. I am night blinded every time I try to drive after dusk because of these overbright lights.

B.4138 December 27, 2024 — Santa Cruz, CA

LED lights are bad for our eyes, great place to start would be with our cars' headlights.

B.4139 December 27, 2024 — South Glastonbury, United States

Who the fuck is in support of blinding other drivers. No shit we need to ban LEDs

B.4140 December 28, 2024 — Cincinnati, OH

I've started night driving a lot more for work. Ever since my eyesight has been dwindling and I'm unable to see things like I could just a few months ago. I mostly blame it on LED lights because they are so bright they hurt my eyes and I have no choice but to endure them so I don't get in an accident.

B.4141 December 28, 2024 — Cudahy, WI

These new headlights are dangerous. How could they be allowed? Accident waiting to happen.

B.4142 December 28, 2024 — Detroit, MI

It hurts my eyes come on guy

B.4143 December 28, 2024 — Ferguson, MO

Super Blbright LED lights should not be used for regular headlights on a car. People shouldn't have to get tinted windows or have to put on sunglasses just in case another driver has irritating LED headlamps. Every time these vehicles approach from behind to pass your vehicle, you have to adjust your sitting position or shift your side/rear view mirror so you don't get blinded. It's even worse for vehicles driving from the opposite lane as you have no choice but to shield your eyes and slow down/stop in the middle of the road to avoid driving while blinded.

B.4144 December 28, 2024 — Fruitland Park, FL

I have had multiple instances where I have almost run off the road due to blinding incorrectly aimed led headlights from oncoming vehicles. I have had to stop multiple times and wait for the vehicles to pass so I could see the road again.

B.4145 December 28, 2024 — Gaithersburg, MD

Avoidable, dangerous, careless headlights without options.

B.4146 December 28, 2024 — Garden, MI

These lights are so bright as to be obviously unsafe, I recall reading a report some time ago that LED lights do not improve visibility of the road ahead for the drivers of these vehicles, I can't remember who did the study but it makes sense as the light is focused rather than dispersed.

B.4147 December 28, 2024 — Irvine, CA

These headlights make it dangerous for other drivers. These newer bright headlights are getting way to bright

B.4148 December 28, 2024 — Murphysboro, IL

While I'd love to have personal freedom, I've been avoiding getting my license for 4 years. I'm 19 now, but my eyesight is just too poor to drive on the same road as LED headlights. I can never even tell the difference when someone switches from high beams to low beams or vice versa because they're just that bright. Having hereditary migraines certainly hasn't helped me. Almost everyone I talk to agrees that they're too bright for the road.

B.4149 December 28, 2024 — North Olmsted, OH

The sun can be too bright at times and I can wear sunglasses, but with some of these factory LED headlamps, I am almost blinded at night and forced to look at the right side of the road to maintain my position in my lane. It can be very disorienting.

B.4150 December 28, 2024 — Sacramento, CA

i keep my hi-beams on all the time now. they are still not as blinding as those f#%*ing led lights

B.4151 December 28, 2024 — San Carlos, CA

I'm nearly unable to drive at nights, due to the blinding effects of the bright LED headlights.

B.4152 December 28, 2024 — Sandy, UT

Anytime i am driving at night and someone has the LEDS im blinded for a certain amount of time because theyre so bright, people are selfish about it. as long as they can see its fine right? but nobody else matters right? i hate LED headlights, they are extremely dangerous, and selfish. do better

B.4153 December 28, 2024 — Sapulpa, OK

I am tired of other people's selfishness and inconsideration blinding headlights being allowed on our streets and highways. This is a safety issue that needs regulations, enforcement, and fines.

B.4154 December 28, 2024 — Seattle, WA

I started driving again after about 4 years. I got a job and then daylight savings hit and I was driving home in the dark. I was astounded at how hard it was to drive while being faced with such bright headlights. The headlights have definitely gotten brighter in the time I wasn't driving. I've tried everything to help, like blue light filtering glasses, but its still so hard to see and I don't feel like I'm able to drive as safely at night. This and the size of vehicles needs to be regulated. People are dying because cars in the US are becoming bigger and brighter.

B.4155 December 30, 2024 — Aurora, CO

I am just learning how to drive and had to do night driving as to get my hours in and I have been blinded by these dangerous bright lights!! I also have astigmatism which does not help at all!! my eyes are already poor due to this and I am not trying to go blind or crash for my first time driving!!

B.4156 December 30, 2024 — Aurora, CO

{"videoUrl":"https://stream.mux.com/ZI26ELUaASg2Fqj9q019RbWQiRqBGxJgfo004j4i5kr3w","cloudflareUid":"d282dd45ceb19d4a943b6d016d3f38a7","muxAssetId":"DrOL02NKhTT35QSO4scwA58roEm01LcbTYDDk6yjBh01pI","muxPlaybackId":"ZI26ELUaASg2Fqj9q019RbWQiRqBGxJgfo004j4i5kr3w","muxPlaybackUrl":"https://stream.mux.com/ZI26ELUaASg2Fqj9q019RbWQiRqBGxJgfo004j4i5kr3w","muxThumbnailUrl":"https://image.mux.com/ZI26ELUaASg2Fqj9q019RbWQiRqBGxJgfo004j4i5kr3w/thumbnail.jpg"}

B.4157 December 30, 2024 — East Sparta, OH

I no longer drive at night because this issue is so bad. Insane that this is acceptable.

B.4158 December 30, 2024 — Goodlettsville, TN

Dark Sky Advocate in Tennessee. We have too many overbright headlights on raised pickups that blind everyone on the road. The NTSB should also allow safer lights that can point down when needed.

B.4159 December 30, 2024 — Milan, PA

I have total more vehicles than I care to count because I couldn't see what's in front of me because the other vehicle coming at me had extremely bright lights. I've almost been hit by multiple 18 wheelers and more due to blinding headlights. I'll be happy to see them banned.

B.4160 December 30, 2024 — San Francisco, CA

Technology has outpaced regulations to keep us all safe on the road.

B.4161 December 30, 2024 — cambridge, MA

LED's have significantly changed my life. I can no longer drive, walk outside at nighttime, go food shopping, etc. I also end up with intense migraines and anxiety. In addition, they change the circadian cycle, animals need to be able to rest at night, too. Not to mention all of the car accidents!

B.4162 December 31, 2024 — Southampton, ENG, United Kingdom

I support the control of LED headlights

Comments left in 2025

January 2025

B.4163 January 1, 2025 — Boulder, CO

I'm amazed that these lights are still legal. Frequently, they are worse than traditional high beams. There are instances when I can not see lines on the road or a turn of the road.

B.4164 January 1, 2025 — Burlington, NC

These headlights are actually brighter when the car or truck is on a rise. Then they do appear to be “high beams”. I’m always flashing my lights at these blinders because it appears they are using their high beams! This has been going on for years. Something must be done, please!

B.4165 January 1, 2025 — Canby, OR

Because I have astigmatism and there are times when I feel that I can't see. That I need to be wearing sunglasses

B.4166 January 1, 2025 — Central Point, OR

I have migraines and these super bright headlights are like an ice pick in both eyes. I suffer for several days after having to drive at night, particularly in the rain.

B.4167 January 1, 2025 — Franklin Lakes, NJ

I am blinded when I drive at night in dark winding roads :(

B.4168 January 1, 2025 — Glen Head, NY

I am 62 and drive a small car. These new headlights aim right into my face. I have been able to mitigate them substantially with special yellow tinted night driving glasses but getting rid of these headlights altogether would be far better.

B.4169 January 1, 2025 — Grants pass, OR

Since the new led headlights, I’ve had to stop driving at night. They are beyond blinding, terrified I’ll get into an accident because of on coming traffic as well as someone behind me with the blaring light. Shouldn’t be legal.

B.4170 January 1, 2025 — Longmont, CO

I live in a more rural area, with lots of trucks. These new headlights almost blind me at night. I too have astigmatism and between the new LED headlights, and now vehicles with one long headlight across the front,, it just blinds you, even on low beams. These need to be outlawed, before more people are hurt or killed.

B.4171 January 1, 2025 — McMinnville, OR

As an individual that has this issue the newer vehicles? The newer headlights are literally blinding me to the point I have to get brighter headlights just to be able to see over theirs. This is a battle where nobody will win. This needs to be regulated.

B.4172 January 1, 2025 — Meriden, CT

So many cars seem to have their high beams on... at least that's what I originally thought, but seeing the difference between the softer lights and brighter ones led me to believe that more and more cars have LED lights which are just too bright. I always think people have high beams on which is so aggravating but it's just LEDs. These things are not safe.

B.4173 January 1, 2025 — Newville, PA

Because of these lights I've almost been in several accidents. Everytime I start to see the bright lights it just makes me what to stop right in my tracks.

B.4174 January 1, 2025 — North Bergen, NJ

There will be more pedestrian struck by blinding drivers

B.4175 January 1, 2025 — Pontiac, IL

I hate those lights. .

B.4176 January 1, 2025 — Seymour, IN

These headlights blind me with astigmatism that I have

B.4177 January 1, 2025 — Trenton, NJ

I'm constantly blinded by these headlights

B.4178 January 1, 2025 — Woods Cross, UT

These lights are blinding. I also wonder if there is something in the Disabilities Act that would make these illegal since it makes it impossible to see when these lights shine at me while I'm driving. I have astigmatism in one eye. What about those with eye disabilities who are licensed drivers? These overly bright lights will take their freedom to drive where they want or need to go at night. Personally I despise these lights, even though they are on our vehicles.

B.4179 January 1, 2025 — cincinnati, OH

I drive!

B.4180 January 1, 2025 — fort walton beach, FL

I can't see when cars are coming towards me

B.4181 January 2, 2025 — AR, United States

I have perfect vision and no astigmatism and it is still seriously hard to drive when you are blinded by someone with stupidly bright lights. It's not right. There has to be some kind of regulation so that other drivers are safe !

B.4182 January 2, 2025 — Bedford, IN

The LED headlights do need to be outlawed. I absolutely agree it's light shining the brightest of flashlight in a person's eyes. I have experienced this so many times I've lost count. I actually have to put my fog lights on. And keep looking down at the road lines till that vehicle goes by. To be perfectly honest. I don't drive at night anymore. Because I am afraid of having a wreck.

B.4183 January 2, 2025 — Cooperstown, NY

Because I can't drive at night anymore

B.4184 January 2, 2025 — Grass Valley, CA

I have astigmatism, so these super bright LED headlights are much worse for me. They're blinding. According to the American Academy of Ophthalmology, approximately 33% of Americans suffer from astigmatism. That should be enough right there to ban these.

B.4185 January 2, 2025 — Hohenwald, TN

I don't understand why they aren't illegal. Could see well enough with the yellow lights, these white LED just blind everyone and make the roads dangerous.

B.4186 January 2, 2025 — Indianapolis, IN

Definitely BLINDING! It's hard to drive straight on winding roads and when I slow down to a crawl cars get mad. That's extra wear and tear on my brakes and many other things on my vehicle as well as unsafe. From squinting and being on edge it adds extra wrinkles causing premature aging

B.4187 January 2, 2025 — Lake Stevens, WA

Headlights so bright that they temporarily blind incoming traffic are an obvious and avoidable hazard. They need to be regulated!

B.4188 January 2, 2025 — Meredosia, IL

These lights blind me as I drive a hr home every night. I wear glasses and have astigmatism these headlights are out of hand. Especially on full size pick ups.

B.4189 January 2, 2025 — Omaha, NE

I have astigmatism and because of that, bright lights from these new headlights causes more of an issue than that of the older incandescent headlights.

B.4190 January 2, 2025 — Palos Hills, IL

I have astigmatism and these lights blind me at night.

B.4191 January 2, 2025 — Parrish, FL

I drive 2-lane rural roads at night and cars with blinding lights have me navigating the road (at 50-60 mph) by focusing on the edge of the pavement where it meets the shoulder__if there was anything in the lane in front of me, I'd run right into it! These overly bright lights are a definite hazard, particulary to anyone in sedan-like vehicle, and not a jacked up truck with headlights that are 4- feet above the ground. Thank you NHTSA, for dropping the ball and not doing your job!

B.4192 January 2, 2025 — Philadelphia, PA

https://www.youtube.com/watch?v=nFalI-hT2Uk

B.4193 January 2, 2025 — Spokane, WA

As a young mom it's terrifying driving at night due to the high volume of cars with LED lights. As someone who already suffers from astigmatisms and is borderline legally blind in one eye, it's hard to feel safe driving in the dark. They tell you to look at the right side of the road when facing bright headlights but these are so bright that it glares over the entire windshield basically making it so I hope and pray I don't get in a crash. Let alone the amount of pedestrians that are barely seen crossing roads with oncoming LEDs frying your corneas, you can't see them crossing until they're just out of direct LED headlights. There's no amount of corrective lenses or sunglasses that can combat the blinding lights.

B.4194 January 2, 2025 — Staten Island, NY

This is an accident waiting to happen. People are already driving into police cars and ambulances with bright led lights. We'll be driving into other cars next.

B.4195 January 2, 2025 — Suffolk, United States

These lights are blinding and could cause someone blinded by them a bad wreck

B.4196 January 2, 2025 — United States

https://www.dailydot.com/news/led-headlights-astigmatism/

B.4197 January 2, 2025 — United States

Extremely dangerous especially when you have cataracts in addition. Please get with times and do something about this. Almost 50% of the population has an astigmatism.

B.4198 January 2, 2025 — Utica, PA

The brightness in all the led lights today are in my opinion more dangerous than what used to be. From personal vehicles to emergency vehicles. Blinding always.

B.4199 January 2, 2025 — Westfield, United States

Those lights are dangerous to everyone on thee road

B.4200 January 2, 2025 — austin, TX

The LED headlights on cars are way too bright. I avoid driving at night now, because those lights literally blind me to what's in front of me. It just isn't safe. Please ban these lights.

B.4201 January 2, 2025 — burbank, CA

The auto makers don't really realize that those LED lights even on the trucks that leave them on the high beams. That could give migraine headaches, it also has us trying to avoid them, but we can run off the road. The pick up truck owners don't care what they're doing to oncoming traffic or they following behind somebody. I have to adjust my mirrors because of the lights are so bright. I want to

continue driving at night time, but not at the expense of the LED lights that are doing to me and other drivers

B.4202 January 3, 2025 — Angleton, TX

I live in a rural town 30 mins south of Houston. Our road quality isn't the best and paired w these led headlights it is impossible to drive safely anywhere. They will run you off the road after they blind you w their lights. Please, help bc praying and driving isn't doing it.

B.4203 January 3, 2025 — Atlanta, GA

On the health side of things.... These new white/blue LEDs are very fatiguing to the eyes. Blue light could potentially damage retinal cells and it can also disrupt your circadian rhythm. This damaging blue light has been found in the LEDs. The bad thing is that we are forced to be exposed to this light everyday. LEDs on cars is a horrible idea it causes more damage than it does good, from potentially damaging driver's eyes from prolonged and repeated exposure, to completely blinding and potentially causing an accident. You don't need to see so much in front of you when you are usually not alone on the road... They should make car light bulbs that have both the yellow light and the bright white light. Being able to toggle between the two would have been the better way to implement LEDs into cars. It still would not have been ideal, because there are people who would use the white light for everything, but it would at least have given an option that's not available now. "How are those lights not illegal!" I've said to myself many times after being completely blinded by LED headlights. I'm sure everyone loves playing guess where the road is when you get blinded on a curve. I get that it's better to be able to see more of the road, but isn't blinding everyone else worse? I have had to resort to lowering my side view mirrors (luckily I drive on a 1 way road to and from work) so I don't get blinded from the cars behind me. I flip the tab on my rear view mirror so I'm not blinded by cars behind me. For the incoming traffic I use a shaded pull down visor that's supposed to be for the sun, but now has the function of keeping me from getting blinded. That seems like a bad idea, but it's the only way I comfortably see the road.

B.4204 January 3, 2025 — Atlanta, GA

I CANT FUCKING SEE AT NIGHT IM DAMN TIRED OF IT

B.4205 January 3, 2025 — Attleboro, MA

I feel they blind me at night and I have to pull over until my eyes are better, I have astigmatism

B.4206 January 3, 2025 — Brockton, MA

Driving at nights has become so difficult i dint want to do it anymore. The led lights makes my eyes feel like they are burning. You're literally blind and can't see nothing infront of you.

B.4207 January 3, 2025 — Cheyenne, WY

I'm a mechanic, auto manufacturers need to step down the brightness of LED headlights, they are becoming dangerous and they should know better.

B.4208 January 3, 2025 — Cincinnati, OH

I don't like looking at them.

B.4209 January 3, 2025 — Cullman, AL

How are these safe when the only person who can see is behind the wheel. Everybody else is blinded, but that one person is more important than everyone else?

B.4210 January 3, 2025 — Des Moines, IA

I also have astigmatism

B.4211 January 3, 2025 — Fort Dodge, IA

I HATE THESE LIGHTS

B.4212 January 3, 2025 — Greensburg, IN

This needs to be investigated but higher command. Im su its not just about astigmatism . No one can see with thise lights.

B.4213 January 3, 2025 — Haymarket, VA

I drive where other vehicles are. Can these things be made to auto dim when other light is around? I drive slower when I can't see forward, hopefully the car behind me will eventually pass. Blinded in front? You know the road is under what is blinding you. I avoid dark driving.

B.4214 January 3, 2025 — Houston, TX

I thought I was the only one with this issue. It seems to be way more than me. I have astigmatism also and it is blinding. So much so I be scared that I'm going to hit something or someone. Please ban the use of these lights unless necessary.

B.4215 January 3, 2025 — Jackman, ME

Basically avoid driving at night now because of these lights. Hell even during the day, some of these lights are still very noticeable from a good distance. Doesn't help that some vehicles are so tall the headlights are face level as well so even with low beams they can xray your brain.

B.4216 January 3, 2025 — Johnstown, PA

New headlights are too bright, blinding to other drivers making driving at night unsafe for everyone on the road.

B.4217 January 3, 2025 — Knoxville, TN

I'm an early riser. Have been for the past 20 years and almost every single morning I have to take a two lane road to get to work with these awful blinding headlights coming towards me. I have to wear night glasses to block out the sight of these led and ridiculously bright lights every now and then. Incandescent bulbs in my opinion are much safer and have been approved multiple times by different automakers and the DOT.

B.4218 January 3, 2025 — Lake Oswego, OR

At 24 years old, my eyesight has never felt worse than it has driving on the road at night now. I am constantly blinded, having to turn my mirrors outward, and flip my rear mirrors, essentially giving me 0 visibility. Cars should not be allowed to have headlights this bright and be unregulated. Someone needs to be held accountable. I genuinely fear for my life driving on the road with intense rain and weather conditions.

B.4219 January 3, 2025 — Louisville, KY

LED headlights, especially on pickups and other high vehicles, are blinding. This is especially true when they are cresting a hill.

B.4220 January 3, 2025 — Phil Campbell, AL

I shouldn't be scared to drive at night at age 36. These lights are ridiculous and behind times compared to the rest of the world. The research and statistics should be enough for a change already.

B.4221 January 3, 2025 — Prescott, AZ

LED headlights, physically make me instantly angry. I use blue light glasses at night to try to make the brightness of the LED lights not so aggravating. I feel these type of headlights need to be banned. They are so blinding.

B.4222 January 3, 2025 — Providence, UT

Many, if not most, drivers are experiencing night blindness solely due to the extremely high intensity of vehicle lights currently in use on our roads & highways. Personally I an appalled that basic roadway safety is so easily & frequently violated. These lights must be eliminated.

B.4223 January 3, 2025 — Silver Spring, MD

You don't need to have an eye problem to know those headlights are blinding. They should be banned.

B.4224 January 3, 2025 — Tucson, AZ

I thought it was me!! Thank you for doing this. I drive to work at 6am and I fight this everyday. My rear view mirror is permanently in the up position.

B.4225 January 3, 2025 — United States

https://www.dallasobserver.com/news/texas-law-allows-for-intensely-bright-headlights-21411057

B.4226 January 3, 2025 — Wolfforth, TX

I can't even drive at night anymore due to several close calls on the road due to blinding headlights. I drive a Beetle so if someone comes up behind me, it's pretty much over. Add in my astigmatism and blue eyes, and it's a recipe for a serious crash. Something needs to be done about this.

B.4227 January 4, 2025 — Forest Lake, MN

Those headlights are dangerous for oncoming traffic they are completely blinding! You know it's bad when you actually have to close your eyes as they come towards you and it's becoming more and more dangerous driving at night. In my honest opinion I feel there will be more and more accidents happening because of these headlights and that's a shame because nobody should get into a car accident and possibly lose their lives over headlights being too bright

B.4228 January 4, 2025 — Hugo, MN

These lights are blinding

B.4229 January 4, 2025 — Medford, NY

These headlights are blinding, there's no need for them. They are absolutely dangerous.

B.4230 January 4, 2025 — Nashville, TN

This issue has been a struggle for not just me but also my family ever since LEDs became popular. My mom has astigmatism and wears glasses. Whenever LEDs became the new normal my mom always had to pull over in fear of hitting the oncoming vehicle. LEDs when too bright can effect even those who have 20/20 vision. My dad also has had issues driving at night with bright LEDs And he does not wear glasses. I have even had to pull over or stop because I had to adjust my eyes back to my normal peripheral vision. Before I even got my license to drive I've been saying something needs to happen with these blinding lights theres no reason for them to be that bright. They should only have to be complyaint to traffic laws. Not far beyond that.

B.4231 January 4, 2025 — Palm Coast, FL

I think everyone can agree that LED headlights can be blinding and being blinded while driving can cause accidents!

B.4232 January 4, 2025 — Seattle, WA

Astigmatism is making it really un safe with these lights. i see some people using their high beams to counter. fix this.

B.4233 January 4, 2025 — Spartanburg, SC

I am blinded by these headlights.

B.4234 January 5, 2025 — Asheville, NC

seeing at night with blinding lights in front and behind me is impossible now

B.4235 January 5, 2025 — Bellaire, TX

These lights pose a real danger

B.4236 January 5, 2025 — Redmond, WA

Glare is a problem and these new "brighter" lights are the cause.

B.4237 January 5, 2025 — San Diego, CA

I'm tired of bright cars constantly damaging my eyes to the point that it hurts.

B.4238 January 5, 2025 — Snohomish, WA

My primary concern for the safety of myself and my family is driving at night, especially in the rain we experience in Washington. During the winter the sun sets at 4:30 and I find myself driving to work and back home in the dark on rainy streets. Oncoming traffic and vehicles behind me will temporarily blind me and I find myself looking down and to the right to focus on the white lines in the road just so

I can make it home. I'm absolutely terrified that I will get in an accident and god forbid cause harm to myself or others. Halogen bulbs are perfectly acceptable. The harsh blue light of LEDs is completely unnecessary, and many aftermarket bulbs exceed NHTSA standards. Something needs to be done to make our roads safe to drive at night.

B.4239 January 5, 2025 — United States

https://supercarblondie.com/driver-with-astigmatism-blinding-led-headlights/

B.4240 January 5, 2025 — York, SC

I'm not tryna die 🙏

B.4241 January 6, 2025 — Annandale, VA

LED lights are extremely dangerous when used as headlights and can cause many sensitivities in people when used to light offices and homes.

B.4242 January 6, 2025 — Columbia, SC

I'm sure other people have said this but I'm scared to drive at night because if I'm on a two lane road and someone has these bright lights coming at me there's about 10-15 seconds where I literally can't see anything. Not figuratively, literally. It's terrifying. If they're behind me, they light up my entire car and I can't check my rear view mirror or side mirrors at all.

B.4243 January 6, 2025 — Lisle, IL

These exceptionally bright LED headlights make it dangerous for oncoming traffic. Especially when applied to truck headlight use. Please regulate

B.4244 January 6, 2025 — London, Canada

I wear glasses and they blind me which is so so dangerous

B.4245 January 6, 2025 — Los Angeles, CA

LED lights are too bright and create a problem for drivers. I have noticed brighter lights on the road and it is becoming harder to actually see the road with all the glare from other LED headlights.

B.4246 January 6, 2025 — Memphis, TN

Some of the cars headlights are so bright, that you would think they had high beams on. It's just the regular head light. This is so dangerous especially at night when you are being blinded from behind AND in front. Not only that but people nowadays are so selfish they will ride on the back of you with high beams on to make you get out of the way, but somebody like me goes super slow, if im Inconvenienced so are you! Some of these people have the audacity to turn on high beams like they are in the middle of nowhere surrounded by darkness blinding you now from ahead and dont have common curtesy to shut them off until they pass you. I am 24 years old. I have been driving the roads since I was 16 and this was not a bad issue, especially with high beams. Now we have a high beam probably AND those cars headlights that are naturally high beam. Who idea was it to change how bright headlights are? Why is there not being a test to see how bright the lights look from the opposite direction and from behind another car.

B.4247 January 6, 2025 — Oakmont, PA

Blinding headlights can cause accidents

B.4248 January 6, 2025 — Ypsilanti, MI

I don't consider myself to be especially light sensitive, but driving at night has become increasingly difficult for me in the last few years. I love that LED lights conserve energy, but, like each one in my home, they need a dimmer. We limit lumens in our homes, based on activity, and they should be limited on our roads in an enforceable way. Without regulation, it will continue to be a race to the brightest. If your neighbor drives with super bright regular headlights, you feel the need to increase the brightness of the ones on your car, just so you can see. This needs to be put to a stop. Drivers also need to be aware that although their cars have "automatic brights," they often don't pick up those who need to see the most: pedestrians, cyclists, motorcyclists and road workers. Also, having the

brightest lights on the market won't save your precious vehicle from a bounding deer. It only blinds the oncoming car that is also going just as fast as you.

B.4249 January 7, 2025 — BON SECOUR, AL

These things are a hazard and have nearly caused me to wreck on multiple occasions by rendering me unable to see.

B.4250 January 7, 2025 — Citrus Springs, FL

I would love to just give up my car I hate driving mainly because of other drivers it used to enjoyable now I only drive when I have to I try to do everything in one trip to avoid as much driving as possible the lights are by far the most stressful because the roads are flowing with people animals trash it's so stressful to drive trying to avoid hitting someone or something temporary blindness has caused me to hit things in the roads heart rate going through the roof people are dying out there who's next how many died while writing this please do this one thing to help save lives with people walking down the streets it's only a matter of time who can live with that kind of guilt the stress alone can cause heart attacks killing others please listen to all these pleas it's real

B.4251 January 7, 2025 — Cleveland, TN

I had no intention of being limited to daytime driving because of laws being broken regarding the limits of headlights brightness limits. Is there anywhere I can sign up on a class action suit

B.4252 January 7, 2025 — Kirkland, WA

Unnecessarily bright lights and tall cars are sold as a safety feature, but they are only safe for those in that car. They are much more dangerous for everyone else!

B.4253 January 8, 2025 — Dalton, GA

I too have astigmatism & LED lights make it nearly impossible to see the road. It was already hard enough but these new LED lights make me not even drive at night anymore unless need be.

B.4254 January 8, 2025 — Deshler, OH

I'm a driver with two different lenses in my glasses, since my left eye is more farsighted and my right more nearsighted. I also have an astigmatism which makes lights expand into vertical, bright lines. When these LED headlights come into view, not only do I see dual reflections from my glasses, but they cover the ENTIRE road with light because of my astigmatism. I compared this with regular red-hue light and the effect is easily looked around otherwise. How come I have intense glares covering my entire view ONLY when LED headlights are on the road? I have to ride the white line, barely on the road sometimes, just to make sure I'm not getting too close since I can't see their car at night OR the middle yellow line because of the astigmatism. How long do I have to tread on the edge of bridges and old roads before I crash because of these things?

B.4255 January 8, 2025 — Leitchfield, KY

Tired of being blinded and having to stop in the road way because unable to see. And these lights go up to several cars ahead. We don't need these on regular vehicles they are the same as spotlights.

B.4256 January 8, 2025 — Los Angeles, CA

Driving is already a danger as it is. But I've increasingly noticed the harsh bright lights on my drives. The blaring lights are a distraction and often times I've had to resort to flipping my rearview mirror to be able to see on the road.

B.4257 January 8, 2025 — Madison, WI

I've been driving quite often at night due to work and personal matter. I wear glasses and have never had issues with seeing at night besides one instance - when other people have excessively bright LED headlights which blind me completely. If someone is behind me, my side mirrors and rearview mirrors become totally unusable when (a) they are driving a car which sits higher than mine and (b) when they have those bright LED headlights which flash their lights directly into my mirrors. If someone is in front of me, their headlights are bright enough at this point where they can be on the other side of the road and totally blind me. It feels unsafe and at this point, I fear for my safety and others when having to drive through more rural, mountainous, or forestry areas.

B.4258 January 8, 2025 — Pittsburgh, PA

I have to cover my eyes due to the intensity of these headlights which is obviously NOT IDEAL when you are driving!

B.4259 January 8, 2025 — Portland, OR

The glare from most of these true-white LED headlights is so bad, that they look more like an array of laser-pointers to my eyes, and I only have a slight astigmatism. The featured photo basically showcases the experience, but not totally. That doesn't just happen with the windshield and/or camera lens. There's that much glare on the windshield and then just as much in my eye. I seriously can hardly drive anymore because I can't see. Way beyond that, I'm stressed out on a daily basis because of the presence of these things everywhere, constantly glaring in my eyes even when they're just in my periphery, even when I'm at the dog park. The worst offenders around Portland are the Trimet buses (annoyingly), then some Teslas, Subarus and Mazda SUVs in particular, but then most other late-model vehicles. Then lots of people are putting absolutely bonkers bright aftermarket LEDs from Amazon in their older cars with projector housings or reflectors. So some truly are laser-like and others are glaring in all directions. Others are putting bright white LEDs on the backs of their vehicles and aren't getting pulled over. Huge LED light bars are all the rave. It's depressing and maddening. Life is effing hard right now. I'm losing my mind over this.

B.4260 January 8, 2025 — Redmond, WA

Driving has become seriously dangerous at nighttime. I shouldn’t have to worry about driving blind two different ways.

B.4261 January 8, 2025 — Redmond, WA

Tesla models specifically seem to be adjusted to blind oncoming traffic instead of illuminating their lane. Tesla needs to change the "factory" setting to not blind oncoming traffic.

B.4262 January 8, 2025 — Roberts, WI

Please do something about this. I literally have to stop in the middle of the road to let oncoming vehicles go past me because I can’t see the road. This is extremely dangerous.

B.4263 January 8, 2025 — Seattle, WA

I am tired of being blind for most of my drive home.

B.4264 January 8, 2025 — Smithtown, NY

I can't see the road with a car or suv, truck that has these LED headlights. I get temporarily blinded. Why were these headlights ever allowed in vehicles on public roads? Who/whom personally approved them, should have their Surety Bonds pulled and be held personally liable and accountable with their personal wealth confiscated.

B.4265 January 8, 2025 — Smithtown, NY

It's time to sue all that approved these LED headlights for public roads. Sue them personally for all their wealth and file claims against all their Surety Bonds. They need to be held accountable and liable PERSONALLY and not the corporate construct of any State or Corp.

B.4266 January 8, 2025 — Tampa, FL

I have to wear sunglasses at night just so I'm not blinded by these headlights, cops can't tell if it's new headlights or high beam's so they can't do anything about it either

B.4267 January 9, 2025 — Goleta, CA

The more and more these new cars are made with LED lights, the harder it becomes to drive at night. Especially on roads that are barely lit, it’s very hazardous.

B.4268 January 9, 2025 — Hyattsville, MD

I drive every day and have experienced the blinding glare of a vehicle with LED lights during various times of the day. But it's truly amplified at night. There have been a number of times when driving, that another car with LED lights either entering or exiting the lane I was in, headlights hit my mirrors unexpectedly and gave a me dose of blinding, white light that made my heart speedup some beats.

Because in that those few seconds, I could see nothing and held tighter to the wheel to keep it steady until I could adjust the way I was sitting or my mirrors, so the light was no longer blinding me. Please help regulate their intensity

B.4269 January 9, 2025 — Sammamish, WA

Desperately needed

B.4270 January 9, 2025 — San Jose, CA

The new white and bright head lights have become a problem for night driving. Especially combined with people moving over to suvs and cross overs that have higher head light placement. On top of that the modern cars are coming with automatic high beams which I think people are just leaving ON, causing added issue. I drive a regular sedan, it's very noticeable for me and i have to adjust by focusing my eyes else where while trying to stay in lane using peripheral vision. Sometimes the headlight from oncoming suv/truck is so bright, especially on undivided two way road, that I can't see the road properly and I have to slow down significantly and prepare to brake if needed. I don't understand why such bright white led head lights are needed. My car has yellow lights that are angled to project just enough and I can comfortably see the road. I am not sure what to do at this point other than constantly adjust during night driving and wear sunglasses at times. Or spend a ton of money to get a higher riding vehicle to mitigate some of this, but I worry that this will add another vehicle into the traffic creating same issue for others.

B.4271 January 9, 2025 — Summerville, SC

I can’t see when there coming at me

B.4272 January 9, 2025 — Vista, CA

there's been multiple times when driving at night where i'm blinded by the bright headlights. i have astigmatism and it gets worse with the on comming headlights and those that shine from the rear view mirror making it difficult to see the road without causing a crash. i had to put on my hazards from time to time to pull over cuz i couldn't see. in the early 2000's there weren't blinding lights and flickering bright lights outside on the streets. i think they should be banned and those who can't drive without the power of jesus shouldn't be driving at all.

B.4273 January 10, 2025 — Katy, TX

Driving in big cities has become 10x worse because of the blinding brightness of new headlights. Makes it impossible to even see the road because of the glare.

B.4274 January 10, 2025 — Los Angeles, CA

It takes my eyes so long to lose that "camera flash" effect - even after a car passes me by, I'm still blinded for another minute or so afterwards. I never needed sunglasses to drive at night before!

B.4275 January 10, 2025 — Mountain Home, ID

I almost hit a car and pedestrian due to not being able to see because of the LED headlights. They need to move back to halogens so I'm not almost killing people every time I drive at night

B.4276 January 10, 2025 — Norman, OK

I am tired of being scared to drive at night due to the too bright headlights, they cause migraines and make it very heard for me to see the road while I’m driving. Often causing blind spots in my vision momentarily. It is a safety hazard and it negatively affects my life and wellbeing.

B.4277 January 10, 2025 — Savage, MN

These bright headlights are insane, and they force you to look away from the road down on your dashboard or in the ditch which causes accidents. As far as I’m concerned, there should be lawsuits against the manufacturers using these bright lights.

B.4278 January 10, 2025 — Seattle, WA

I am signing this petition because usually people with those lights are dangerous to begin with. Road rangers!

B.4279 January 10, 2025 — Vancouver, WA

Bright LED headlights are so dangerous. I am nearly blind trying to drive around town. And its not just a few cars here and there, it is the majority of the cars on the road. I live in the Pacific Northwest where it rains much of time which makes it even worse with glare everywhere. Couple that with poor road maintenance in the town I live in. You can hardly see the road stripes at night in good conditions. It has gotten the point where I am unable to drive after sunset/night or risk wrecking or hitting a pedestrian. This is huge infringement on my freedom and it is not right!

B.4280 January 10, 2025 — Yardley, PA

It's a serious problem not only for headlights but for many other light sources

B.4281 January 11, 2025 — Austin, TX

I can't drive at night anymore because of the blinding LED lights. Same goes for the streetlights in my town that they switched from a nice warm yellow glow to blinding white. Now I hear these LED lights could be harmful to humans and animals.

B.4282 January 11, 2025 — Bloomfield Hills, MI

I am a new driver and drove in the snow last night before the roads were taken care of, and not only could I not see the lines on the road, but I couldn't really see anything because of how blinding the other cars headlights were

B.4283 January 11, 2025 — Cedar Rapids, IA

Needs to change

B.4284 January 11, 2025 — Denver, United States

It's too dangerous

B.4285 January 11, 2025 — San Luis Obispo, CA

I can't believe I found this site. I try not to complain about anything but this has been a big issue for a long time. One of the main issues, which is funny but not funny, is people with these new cars they don't know how to work their light system. They've got their fog lights on they're high beams on they're low beams on and anything else that's on they don't know how to adjust it to just daytime lights. I have a friend that has a car that's maybe 10 years old the car was like brand new he didn't know how to work the lights. Now, you've got these cars that have the stripe across the front so these people are driving with both beams on, fog lights and this white stripe across the top! Not only is it blinding, especially when they're coming up behind you, it's distracting. These people know that they're high beams are on I mean they can see the back of your skull when they're behind you. It's ridiculous, it's unsafe on so many levels. I do not have an issue with bright lights per se, however driving down the freeway or especially in town, a car comes around the corner and the blind you, I mean you can't see in front of you it is so blinding. It is like someone shinjng a flashlight in your face, even at a distance. Yes,.you could kind of look away to the right side of the road but my focus is on the road hello. SOMETHING'S GOT TO BE DONE!!! People that are driving with all these beams on like they don't know how to work the cars it's too much light. Also, that white stripe is ridiculous it's distracting and unsafe. How do they not know this, many of us can figure it out but who are the people that are making this "okay"??? I mean what's the point? I have got so much to say, but I'll stop for now. I'm pissed...again it is the driver's fault too. People need to know how their car operates correctly and driving around at night with every light on that you could imagine coming at you or behind you is unsafe to the umpteenth level!!!

B.4286 January 11, 2025 — avondale, AZ

i have an astigmatism that makes these lights even brighter. i feel like i need sunglasses at night it's so bad.

B.4287 January 12, 2025 — Tivoli, NY

oncoming car headlights have become unacceptably bright, making it hard for me and my wife to drive at night.

B.4288 January 13, 2025 — Idaho Falls, ID

It's really terrible when I flash my lights at an oncoming car to tell them to turn their high beams off and then they flash me back telling me that their high beams aren't even on! Please, low beams do not need to be this blindingly bright!

B.4289 January 13, 2025 — Manchester, ENG, United Kingdom

Is a real danger to on coming traffic.

B.4290 January 13, 2025 — Miami, FL

My vision is not the best especially at night. Almost every car on the road has bright white led headlights that point directly at my mirrors, causing my vision to become more compromised than what it already is. I have been in many near accidents due to this issue.

B.4291 January 13, 2025 — Middleton, MA

i already have astigmatism these lights make driving at night so unsafe. we've all been saying this since they started coming out and nothing has been done. no regulations on the brightness of lights will end lives. i personally have to drive to work at 4:00 am on a very curvy road and if i wasn't so familiar with it, id be swerving into the other lane because of another car. its happened to me before but i just try to tell myself "just keep the wheel in the same direction and slow down" to avoid CRASHING BECAUSE OF HEADLIGHTS. my headlights give me incredible visibility and they don't blind anyone. let's go 2006 toyota sienna

B.4292 January 13, 2025 — Middleton, MA

i personally have to drive to work when it's still pitch black in the mornings on a very curvy road. even though i've driven this road for years and know every twist and curve, when a car passes me with those lights, on multiple occasions i have swerved into the other lane or cut way too close to the margin. these lights can kill people coming around even the simplest corners. its so aggravating that we've all been saying these lights are dangerous since they started appearing and nobody has done anything. we need regulations for road safety! plus, they're so unnecessary. my 2006 toyota sienna got replacement lights about a year ago and i can see extremely well without making it so others can't.

B.4293 January 13, 2025 — Salem, OR

It's becoming an issue at night or these bright headlights should be becoming a hazard for me to drive correctly and safely. I fear that when I drive and I see them, but I'm not gonna be able to see an object or the road curvature and I'm going to crash my vehicle these things need to be dimmed and not as bright for the safety of everyone around them.

B.4294 January 13, 2025 — South Hiendley, ENG, United Kingdom

Because it's dangerous . They blind oncoming traffic . And with the LED street lights being so dim it will lead to more deaths . You cannot see pedestrians dressed in black at all . And then a car passes with LED lights on . No contest impossible to see them till it's too late

B.4295 January 14, 2025 — Garrettsville, OH

I have a double astigmatism. I literally have to stop my car when these lights are coming towards me. There is no reason they have to be that bright. Very dangerous.

B.4296 January 14, 2025 — Mount Juliet, TN

I turned 16, the legal age to drive in my state, a year and 3 months ago and I'm too terrified to drive on my own because of these bright lights.

B.4297 January 15, 2025 — Alburnett, IA

It has become extremely dangerous to drive nowadays. As an almost 18 year old driving a small car, I get blinded daily on the road. Most underaged kids are driving small cars, and guess who are driving the big cars with these headlights in question? EXPERIENCED DRIVERS!!! This is a growing and dangerous problem. It needs to be fixed.

B.4298 January 15, 2025 — Calgary, Canada

These lights are dangerous

B.4299 January 15, 2025 — Richlands, NC

Driving at night is so dangerous because of the new led headlights. People will get killed if they are not banned.

B.4300 January 15, 2025 — SEQUIM, WA 98382, WA

I can't see at night when raining and the lights reflect off the ground! It also looks like they have their brights on all the time! Should be illegal and LEDs are bad for your eyes! Common sense!

B.4301 January 15, 2025 — Woodstock, Canada

Its really annoying when you drive in the night and that people hurts the eyes with that lights,

B.4302 January 16, 2025 — Bellevue, WA

The blue/purple headlights blind me in the evenings and at night. Very, VERY dangerous. I am also a walker and if any vehicle with these headlights is coming it blinds the other drivers and creates a hazard for walkers.

B.4303 January 16, 2025 — Grafton, MA

Astigmatism makes this an even bigger issue when on the road at night. Get our voices heard.

B.4304 January 16, 2025 — Portland, OR

They definitely take your ability to to see anything what gets me is people are using them incorrectly by adjusting them wrong using brights and driving lights so 6 bright LEDs 2 LEDs are to much

B.4305 January 16, 2025 — San Diego, CA

I drive at night for work and it's at the point that my eyes sometimes have blind spots caused by the constant LED lights beaming directly into them. I fear if I continue, I'll go blind one day. These conditions are not safe.

B.4306 January 16, 2025 — San Francisco, CA

The newer headlights are blinding. On rural two lane roads vehicles even miles away with their brights on look like an airplane getting ready to land in your passenger seat. Has no one in government driven in the last few years? I even drive a truck (sitting higher up) and Teslas or Subarus will still blind me. I frequently use my hat to block my field of vision and stare at the white line when oncoming traffic is close (but not all that close!), which puts a ridiculous amount of trust in oncoming traffic to not come into my lane or do something stupid. Something has to give. I'm not a fan of over regulation but this needs regulation AND enforcement now.

B.4307 January 16, 2025 — Spokane, WA

I drive at night in NH and the LED head lamps make driving dangerous. They are so painful on the eyes that I have to look at the painted white line along the median to avoid looking at the LED headlights. These need to be banned. To anyone with eyes, they are obviously damaging and dangerous.

B.4308 January 16, 2025 — Straughn, United States

I used to like driving at night. Now between the LED headlights, people failing to turn down their high beams in addition to the already-to-bright LED lights and then the use of LED spotlights and security lights on some residences, businesses and public areas often pointed in a direction that causes a driver to be unable to see the road or traffic...this is one of the most dangerous things facing me and other drivers right now. I can no longer feel safe driving at night so am forced to stay home or have someone else drive me. I should not have to compromise my driving freedom because of an unregulated and not thoroughly researched light source that poses a risk to myself and others. On several occasions I have almost drove off the road or been in an accident because of these ultra-bright LED lights. If someone or something were to be in the road while these lights are shining at me, I would never see it and possibly hurt someone else because I cannot see past the painfully bright headlights. It is an utter disregard for general human safety and health and I'm ashamed of the FDA, auto makers, auto LED light manufacturers and our politicians for not taking action on this yet.

B.4309 January 17, 2025 — Murfreesboro, TN

I live in an area that doesn't have many street lights. I hate driving at night because of the LED headlights. Whomever thought this was a great idea did not think it through. It looks like bright lights are on and it is a blinding light. It should be illegal to have headlights that bright on a vehicle. They need to either restructure where they are located inside the vehicle or find a way to dim the lights.

B.4310 January 19, 2025 — Fairfield, CT

The LED headlights on cars are blinding especially at night. The flashing LED lights on police vehicles make it impossible to see the road. I try not to drive at night anymore. These lights need to be banned.

B.4311 January 19, 2025 — Houma, LA

I've noticed an increase in very bright LED headlights. They're painful to the eye, create much more nuisance glare than traditional halogens, and they force me to look away from the roadway toward to shoulder. These bright lights are distracting, and they create a safety issue. They should be better regulated or banned to create safer roadways.

B.4312 January 19, 2025 — Kalispell, MT

I live in rural Montana. There are alot of rolling hills which is absolutely the worst when LED lights come at you. On top of that there is very little to none road lighting. I bitterly have to almost come to a stop some times do to being Blinded. My Brites are less bright then most LED regular lights. That is not right at all! I came from Salt Lake City. There is street lighting every where. You never need to use your brites. Plus you don't notice the LED in a big city as much. Your eyes are already adjusted. I propose if we have to have LED lights. They be installed as only brights. And low lights can go back to soft lights. Thank you

B.4313 January 19, 2025 — La Fontaine, IN

somebody time travel back and destroy all of them;) report back #orcawacacaca

B.4314 January 19, 2025 — Williamsport, PA

Headlight brightness has more than tripled over the past 30 years and here in PA they use line paints that wash off and have no reflectivity after only a year of being applied.

B.4315 January 19, 2025 — santa rosa, CA

LED headlights installed on vehicles driving on the roads have consistently made driving dangerous and difficult for me. The possible damage and loss of life from an accident and the long term damage to eyes from repeated exposure to these unnecessarily bright headlights should be stopped immediately.

B.4316 January 20, 2025 — Brockton, MA

These headlights make my windshield become something that obstructs my view of the road almost entirely. The only thing that remains visible as the offending vehicle passes is those glaring headlights. If someone cut infringement of me in a car, a bicyclist, a pedestrian.. I would have zero warning until those lights pass me not allowing much reaction time depending on distance.

B.4317 January 20, 2025 — Ontario, CA

Blinding on coming headlights make it hard for people to see and can easily be fixed and save life's...My kids father was killed in a car accident When they were babies...

B.4318 January 20, 2025 — Stoughton, MA

Simple, because the blinding lights never should have been allowed in the first place

B.4319 January 20, 2025 — Winchester, NH

i hate them

B.4320 January 20, 2025 — chicago, IL

Blinding headlights have motivated me to avoid night driving and use other modes of transportation like walking and biking. I will continue to plan my life around this issue as long as it is prevalent and increasing in our car society.

B.4321 January 21, 2025 — Brunswick, ME

I drive, I fucking love driving it is everything to me. But I swear to god these LED headlights are going to make me go off the road and crash and DIE. I SWEAR TO GOD. If I ever am in a accident because of these god forsaken sent from hell headlights. The blame is on the other person. And I will fight until I get all my money. And then, in c***** und******'s words. I will dig my key into the side, of their pretty little souped up four wheel drive, carve my name into their leather seats. Watch your back LED headlight car drivers. My name on this petition is COMING FO YO ASS.

B.4322 January 21, 2025 — Franklin, NH

I thought my difficulty driving at night meant that I needed to have cataract surgery. But then I realized that I don't have difficulty with regular headlights coming at me, it's only the LED headlights. On country roads I often have to pull off the road until an oncoming car passes because I'm literally blinded by LED lights. In heavy traffic at night I aim both side mirrors down to avoid LED lights from behind. This isn't safe---it makes it harder to be aware of traffic around me. I try to avoid driving at night, which reduces my freedom to take longer trips if I can't get home before dark. I find it incredible that the government has not banned these dangerous LED headlights. Why should I have to have risky eye surgery when the problem isn't really my eyes, it's LED headlights? Why am I deprived of the freedom to travel where and when I want to?

B.4323 January 21, 2025 — Lafayette Hill, PA

They are dangerous.

B.4324 January 21, 2025 — Macomb, MI

As a lifetime eyeglass wearer with little-if-any depth perception (due to crossed eyes at birth that were surgically overcorrected as an infant), all driving carries added risk compared to "baseline" vision (however you might define that...). Driving at night is the worst, especially trying to pull out of a neighborhood onto a high-speed (50+ MPH) multi-lane road, since I can barely discriminate which lane a vehicle occupies with only headlights visible. Headlights over a certain strength are truly painful to look at, especially refocused by my glasses, day or night. Yet nighttime is worse when I need to visually track those lights in many driving situations. If your headlights mean that I cannot effectively "see" to drive, then clearly overall community/social safety has not been increased; it is decreasing, and I fear for my life and that of my family when they're in the vehicle. (Whine time... Brand pet peeve #1: JEEPs. #2: All other SUVs (including the Jeeps) and full-size pickup trucks since I'm often driving a low-to-the-ground Ford Focus sedan and getting 100% oncoming headlight brightness right at my eye level. I wish all those other drivers knew how that feels!)

B.4325 January 22, 2025 — Chicago, IL

I really hope this can make a real impact. I hear about this problem and experience it everyday!

B.4326 January 22, 2025 — Collierville, TN

I think we are all saying the same thing, and there is not much more to add. I just hope that if this critical ban comes to fruition that all the loopholes are adequately addressed and it is quickly implemented.

B.4327 January 22, 2025 — New York, NY

Even as a pedestrian those lights are annoying and dangerous. If one is walking outside on dark winter evenings, sudden bright lights in one's eyes obscure everything else and make a pedestrian more likely to trip or slip and fall or walk into obstacles or get hit by drivers or bike riders who are also blinded by the lights.

B.4328 January 22, 2025 — Vermillion, SD

I have the right to not be scared of driving at night

B.4329 January 22, 2025 — Wylie, TX

I literally cannot see the road in front of me at night and even wearing sunglasses doesn't help my vision of the road when these bright headlights are in my eyes. I'm genuinely worried that I might get into a crash someday because of someone's headlights blinding me.

B.4330 January 23, 2025 — Belleville, NJ

I can't drive qt night anymore and fear getting into an accident

B.4331 January 23, 2025 — Belmont, NC

I can't see at night and they trigger migraines

B.4332 January 23, 2025 — Dublin, CA

Bright and improperly mounted/designed headlights are dangerous. People dont need spotlights to see at night, it's ridiculous. Please help make driving at night safer

B.4333 January 23, 2025 — Reno, NV

I am 33 years old and no longer want to drive at night because I am scared of both cars behind me and in front of me causing me an accident all because I couldn't see properly from their headlights. I also suffer from migraines and bright lights are a trigger for my brain to give me an ocular aura. Ocular auras make you see things in your vision that are not there and leave you with a massive headache and fatigue. Please ban these headlights that are too bright! There is no need for them!

B.4334 January 23, 2025 — United States

https://www.michigandaily.com/opinion/columns/blinded-by-the-car-headlights/

B.4335 January 23, 2025 — Val-David, Canada

Les lumières del sur les véhicules sont tout simplement une abomination pour les conducteurs et les règlementations ne tiennent pas compte de la perception humaine de ces lumières.

B.4336 January 24, 2025 — Atascadero, CA

the new bright LED lights cause intense pain behi my eyes and to my brain, as well as an after image resulting in distraction and temporary blind spots for myself. I know avoid driving at night time as much as possible for this reason. Even during the day time, some lights are still too bright to also cause this as well. I request that this issue be heard and looked into by the now thousands affected by this and hopefully addressed! Thank you for taking time into looking into this matter!

B.4337 January 24, 2025 — Riverhead, NY

In my town of the cops don't enforce the headlight laws, so it's basically impossible to drive at night anymore, you just cannot see the road at all when these people are behind you or coming the other way.

B.4338 January 24, 2025 — Templeton, CA

It's so dangerous!

B.4339 January 25, 2025 — Anaheim, CA

I SPECIFICALLY AVOID DRIVING AT NIGHT DUE TO THE BLINDING HEADLIGHTS. ITS TOO DANGEROUS

B.4340 January 25, 2025 — Cedar Park, TX

As someone who drives early morning. These lights are horrible and impede driving .

B.4341 January 25, 2025 — Gainesville, GA

These lights are going to cause serious accidents. It is very disorienting, it has caused me to swerve because I was unable to see the road and blinded even after vehicle passed me. I have witnessed the car in front of me swerve and go down into a ditch. My daughter is about to get her license, she won't be able to drive night right away due to being a new driver and our state laws for new drivers. I'm thankful for this and pray something is done about this issue before she has to deal with this. In the areas we live in, it's popular to have jacked up truck with the brightest whitest headlights as well as a

bar of lights across the roof, lighting up the wheels and undercarriage. It is a hazard when this is coming at you head on, it's is just as hazardous and blinding when you are in a small sedan this comes up behind you either on the expressway going 80mph or so and the truck is hot on your bumper. This happened to me and actually happens several times a week. The lights on this truck were so bright I couldn't judge the other lane in my mirror to get over, I flipped my rear view mirror to try to divert the light so I could and it helped none. I felt like the truck was pushing me and I was doing 80 in a 70 as it was going down hill on the expressway, trying to judge if I could get over and checking my mirrors I had to hit my brakes trying to see my own lane this apparently angered the driver who proceeded to ride my bumper, when I finally could judge enough to get over I got off at next exit and truck changed lanes with me, got off exit and followed me. He pulled beside me and had the nerve to ask what my problem was and I said his headlights he told me he had no control over his headlights that this is how truck came. Frankly I don't care if the manufacturer did it or the individual took it upon himself to modify. It needs to be illegal either way. New cars yes have extremely bright lights and that is a manufacturer issue that must be dealt with. Problem is those in charge are oblivious to how the general public live and the things they deal with unless their chauffeur drive happens to complain or their pockets get lined enough to change their point of view. Then you have those that see things on tiktok and there ya go everybody's gonna run out and get bright white lights plastered all over their vehicle so they will be liked. I simply don't want my children or anyone else harmed and you'd think our government would attempt to protect it's citizens. Maybe if we make a tiktok video about it we could get some action.

B.4342 January 25, 2025 — Van Nuys, CA

The light are blinding and unsafe to other drivers

B.4343 January 26, 2025 — Cedar City, UT

I drive around lots of mountains, and falling off of the cliff is so much more likely because these lights blind me.

B.4344 January 27, 2025 — Asheville, NC

I CANT SEE WHEN DRIVING AT NIGHT

B.4345 January 27, 2025 — Easton, MD

I've been in two bad accidents that I was not at fault for, and because of that, I much prefer driving at night when all of the irresponsible 16-19 year olds + elderly people aren't on the road. Due to the increase in LED headlights, I'm not able to enjoy this privilege anymore.

B.4346 January 28, 2025 — Fort Walton beach, FL

I used to be able to see at night but now with these new bright blue lights on cars I feel like I’m staring into a 1500 lumen flashlight. It looks like people are driving with their high beams on (even though they aren’t) I can’t see the road when these new cars are driving head on towards me not to mention my eyes hurt after driving, I’m sick of it please change the laws to prevent this s from having to suffer permanent eye damage or vision loss

B.4347 January 28, 2025 — Nalgonda, India

Hello everyone, I have also reported about Light pollution to UN body and yet to hear from them. People when they talk about pollution must now consider light pollution as well. I shall keep you all posted on any updates I receive regarding this.

B.4348 January 28, 2025 — Overland Park, KS

The modern lights are too bright. There used to be a federal regulation. It seems that has gone to the wayside

B.4349 January 28, 2025 — Stockport, ENG, United Kingdom

The Precautionary Principle dictates that LED lighting may pose health risks and absent more detailed studies to disprove potential harms, they should be banned.

B.4350 January 29, 2025 — Allentown, PA

Because of these led headlights I'm starting to lose vision in my left eye. Along with suffering from major chronic migraines as well.

B.4351 January 29, 2025 — Berwyn, United States

Everyday I drive up and back through chicago and at least once a day I get hit with these blinding lights. Usually bigger SUV's or jeeps but they are horribly blinding. I don't see why these types of headlights are legal here when they are illegals everywhere else. Talkin about LED headlights btw

B.4352 January 29, 2025 — Chester Springs, PA

I am blinded by these lights. I think the light trucks are the biggest offenders as their drivers seem to be more aggressive, such that when they are tailgating me, I am blinded in my rearview mirror, despite the self dimming feature!

B.4353 January 29, 2025 — Chico, CA

Every night this is an issue for me. Normally I can see while driving at night even with traditional headlights, but the excessive blue-ish LEDs immediately blind my night-adjusted eyes

B.4354 January 29, 2025 — Kiev, Ukraine

I don't want to get into an accident because I was blinded by oncoming traffic or rear view mirror.

B.4355 January 29, 2025 — Oklahoma City, OK

When driving at night, newer headlights frequently make it harder to see and drive, on more than one occasion I've come close to fatal accidents as a direct result of lost visibility, because the individual behind me has headlights that were brighter than they had any reasoning to be. This problem needs to be fixed.

B.4356 January 29, 2025 — Post Falls, ID

The amount of times I've lost sight of the actual road in front of me because of bright headlights can be counted on more than two hands. That is a terrifying realization. Many times it's during ALREADY dangerous weather, like snow or heavy rain. These bright headlights will catch on the rain/snow and become even BRIGHTER, obscuring the lines on the road more than they already are by the weather.

B.4357 January 29, 2025 — Sacramento, CA

More visibility on the road is always more desirable. However, when ones own personal visibility becomes the detriment and cause for danger for everyone around that person, it's no longer advantageous, but instead creates a terrifying experience for anyone on the road. We will continue to see a rise in damage and hostility among our peers until this issue is resolved. Bright headlights do more harm than good. People think it's a great idea, until their choices cause the harm or death of someone important. Who's death or injury will it take to correct this issue? Or do we as a people not care about our fellow human anymore?

B.4358 January 29, 2025 — West Des Moines, IA

It takes the fun out of night drives when I can't see what's ahead of me

B.4359 January 29, 2025 — peoria, IL

Blindingly bright headlights endanger everyone on the road. It only makes sense to have a legal limit to how bright headlights can be.

B.4360 January 30, 2025 — Blythewood, NC

This is important for safety.

B.4361 January 30, 2025 — Grandview, MO

It's stupid that we have rules against using your phone and drunk driving but not overly-bright headlights and billboards.

B.4362 January 30, 2025 — Kingsport, TN

Powerful headlights are the bane of my existence. As someone with an astigmatism, these headlights would make me ACTUALLY UNABLE TO SEE THE ROAD. People behind me in their lifted trucks, blinding the heck out of me with these lights would make me crash.

B.4363 January 30, 2025 — Klamath Falls, OR

I'm blind

B.4364 January 30, 2025 — Midlothian, VA

The second the sun dips a centimeter everyone's brights come on and introduce my retinas to the gates of heaven in an instant. No one needs to fucking see the microscopic structure of the road, the level of brightness is completely unnecessary. Either we get rid of brights or we turn our cars into fucking disco balls with superglue and mini mirrors

B.4365 January 30, 2025 — Oklahoma City, OK

I didn't ask for glasses. I didn't ask for my appointments to be after the sun went down when I was driving as a teenager. I can't see. "Be an adult!" "If you can't see, then dont drive at night." Hello??? It's 5:30 the sun is down and all I see is another giant white dodge ram flashing their brights from behind me and across the lane. I shouldn't be able to drive at night because I can't see? I can with my corrected vision. If this is how it is going to be, then ban the lights or I get to park in disability, because being visually impared is disability, and driving with a disibility. this needs to be fixed.

B.4366 January 30, 2025 — Philadelphia, PA

It's ridiculous

B.4367 January 30, 2025 — Shingle Springs, CA

I like being able to see while driving at night.

B.4368 January 30, 2025 — Woodward, IA

I would like to be able to keep my vision when I pass by a car at night.

B.4369 January 31, 2025 — Rochester, NY

I have astigmatism and LED lights make seeing so much worse at night. My eyesight becomes blurry.

February 2025

B.4370 February 1, 2025 — Essex Junction, VT

I get awful migraines from the blinding headlights

B.4371 February 1, 2025 — Hannibal, MO

The safety issues caused by oem led headlights from the factory has caused many accidents for surrounding vehicles. With the increase of manufacturers going led, ignoring the negative attributes of led and only focusing on the positives is no longer acceptable. Government regulation needs to be implemented and upheld to meet certain safety criteria to remedy the unregulated and unsafe actions auto manufacturers have blindly accepted as normal.

B.4372 February 1, 2025 — Llandysul, WLS, United Kingdom

I'm very conscious of being blinded on the road whilst driving.

B.4373 February 1, 2025 — New Haven, VT

I fear for my safety

B.4374 February 1, 2025 — Sacramento, CA

I can't see!

B.4375 February 1, 2025 — Stowe, VT

I work delivery at night. Bright lights are near death experiences for me. I can't see!

B.4376 February 1, 2025 — United States

https://www.centraloregondaily.com/news/consumer/the-led-headlight-debate-safer-or-too-bright-europe-has-a-smarter-option/article_4de7c9f6-e010-11ef-b471-87d2461b22f5.html

B.4377 February 2, 2025 — Sherwood Park, Canada

These headlights are dangerous!!

B.4378 February 2, 2025 — Tooele, UT

The headlights in the past weren't as blinding as they are now. With how blinding bright they are now I'm nervous to drive at night. There are times I feel like I could get into an accident, and when it's raining or snowing my vision is blurred and I can barely see the lines on the road. I hope this can be changed, for the safety of all.

B.4379 February 3, 2025 — Chapel Hill, NC

Bright headlights are plain dangerous! There was a reason why we kept them soft initially. Nowadays, there is very little difference between headlights and bright lights and it is becoming increasingly cumbersome. I feel less safe, especially when it rains as the reflection on the wet roads increases the blinding effects. I often find myself lifting my hand up to block headlights from coming directly into my eyes and I know this cannot be safer than keeping both of my hands on the wheel. Regulation and implementation is a must to save lives or simply to improve the quality of a night drive.

B.4380 February 3, 2025 — Julian, NC

They are blinding to other drivers!

B.4381 February 3, 2025 — Salt Spring Island BC, Canada

These LED headlights are literally blinding at night on narrow single lane roads. Dangerous and ridiculous.

B.4382 February 3, 2025 — Salt Spring Island, Canada

these LED lights pose a significant hazard to oncoming drivers.

B.4383 February 3, 2025 — Waterloo, Canada

I'm signing because high beams and overly bright headlights can be hazardous and we need government support to enforce car manufacturers to solve the problem they created.

B.4384 February 4, 2025 — NY, United States

I have very light-sensitive eyes (photophobia) due to light eye color, astigmatism, and chronic migraines. Night driving is already a more dangerous circumstance due to more limited visibility, and has become increasingly stressful with the introduction of LED lights, which are hazardously bright. Even when I use my rear view mirror's night mode, this is problematic because (a) this feature is not available for my side-view mirrors and (b) this doesn't protect me from the headlights of cars driving toward me on the other side of the road, and (c) I still also get a painful, blinding bolt of light in the eye whenever I look back to check my blind spot. I know that I am not alone in this concern, and I hope you will make changes to improve this very fixable public health concern by banning LED lights in headlights.

B.4385 February 4, 2025 — Sidney, Canada

These lights are blinding and make it impossible to see

B.4386 February 5, 2025 — Bay Shore, NY

These LED headlamps are blinding even in early morning light and dusk lighting conditions

B.4387 February 5, 2025 — Bend, OR

This is a dangerous hazard.

B.4388 February 6, 2025 — Bethesda, MD

I can’t stand driving at night feeling like I might go blind or crash because someone decides they need to have their high beams on.

B.4389 February 6, 2025 — Jacksonville Beach, FL

I'm tired of being blinded while driving at night! This is too dangerous and something needs to be done about it.

B.4390 February 6, 2025 — O'Fallon, MO

As someone who’s been personally victimized by these bright led headlights, they gotta go. I understand needing to be able to see cars at night or in low visibility but not at the risk of running other drivers off the road due to these blinding lights.

B.4391 February 6, 2025 — Plano, TX

Excessively bright headlights that aren't required to be adjusted angled down on kit lifted heavy duty vehicles in the hands of the common people is a rampant issue that desperately needs fixing. This kills people. It leaves people disabled. It ruins families. It's a burden on the infrastructure and ruins the flow of traffic daily. Do better.

B.4392 February 6, 2025 — Saltspring Island, Canada

I'm blinded by them!

B.4393 February 7, 2025 — Ames, IA

I bought a new Ford Maverick and discovered it had those bright headlights I have been complaining about for years. I asked dealer if they could swap out and they said it would cost me a fortune! How dumb!

B.4394 February 7, 2025 — Boulder, CO

Blinding headlights are a growing safety hazard, and I have experienced several issues because of them. One of the most dangerous problems I face is when a vehicle with overly bright headlights comes up behind me at night. The intense glare creates a sharp shadow in front of my car, making the road appear much darker, as if my headlights are off. At times, the effect is so extreme that I cannot see my own headlights illuminating the ground, making it difficult to see obstacles, road markings, or anything ahead of me. The glare in my mirrors is also unbearable, to the point where I have permanently adjusted my rearview mirror to help dim the brightness. And this is only one of the many challenges I have encountered, from temporarily being blinded by oncoming traffic to dealing with reduced visibility in critical situations. It is an issue that needs to be addressed to keep the roads safer for everyone.

B.4395 February 7, 2025 — Columbia, MO

While both sedans and pickup trucks/SUVs have blinding headlights, pickup trucks/SUVs headlights are also higher, so that they shine directly into the windshields of sedans and other lower vehicles (not to mention the eyes of pedestrians). The number of larger and higher vehicles on the road means that they are bigger to the problem of blinded drivers on the road. It would be helpful if manufacturers of these larger vehicles began designing headlights on these vehicles to be at the same height as those on sedans and smaller vehicles.

B.4396 February 7, 2025 — Denver, United States

Yes it's convenient for the people driving the cars, but this is really becoming a danger especially on mountain passes like here in Colorado.

B.4397 February 7, 2025 — Loveland, CO

Not only are the headlights annoying and blinding, recently I have noticed these LARGE pickup truck owners illuminating the underside of their trucks. WHO THE TRUCK approved that? That is 1000% worse!

B.4398 February 7, 2025 — Lynnwood, WA

I'm in my fifties and finally ended up quitting my job as a driver because due to astigmatism the right white or LED headlights make it so that I'm completely blind at times when driving in at night. To the point where especially if they come up behind me I have to actually pull over until they pass. When they're coming at me I have to slow way down I could be on the freeway or on the highway and it's just so bright that not only am I not seeing correctly but literally blind for a moment. And if I'm on a long drive I'll get a migraine headache out of this world. I believe they to be a safety hazard a health hazard and are causing a lot of traffic fatalities today.

B.4399 February 7, 2025 — New York, NY

Those LED headlights should be banned, period!

B.4400 February 7, 2025 — Omaha, NE

blinding headlights are dangerous

B.4401 February 7, 2025 — Woburn, MA

Headlights are getting out of control, especially on trucks that are the eye line of those driving in smaller vehicles.

B.4402 February 8, 2025 — Arcata, CA

New headlights are too bright and dangerous for other drivers

B.4403 February 8, 2025 — Beacon, NY

LED lights have been used without any thought to the effects they have. They are now everywhere since they're so cheap. Driving at night not only subjects you to extremely bright lights from cars but also from lots & lots of buildings. We need light trespass laws. Driving (and walking) at night has become very stressful. It is a health hazard.

B.4404 February 8, 2025 — Bronx, NY

I genuinely cannot see the road sometimes and I have an astigmatism in my eyes, which makes it ten times harder to see with these new lights, the old lights never had any issues

B.4405 February 8, 2025 — Cambuslang, SCT, United Kingdom

Road safety

B.4406 February 8, 2025 — Columbus, United States

These are worse than the 'brights' of old that people were required by law to switch off when other drivers approached. When these new LED's come at me, I flash my brights at them or just click them on until the car passes to let them know how I feel.

B.4407 February 8, 2025 — Cumming, GA

This is a frequent issue for me! It is so dangerous.

B.4408 February 8, 2025 — Erie, United States

The blinding headlights are so dangerous. The brightness is so bad it makes it hard to drive on the road and to see any pedestrians.

B.4409 February 8, 2025 — Fort Worth, TX

I try not to drive at night at all due to the harsh and blinding lights I encounter with oncoming traffic and even worse, drivers behind me with their bright lights. It's the newer, too bright LED's that are the problem.

B.4410 February 8, 2025 — Freehold, NJ

I used to have LED headlights on my car, but at some point I realized how blindingly bright they are, and had them removed. (I didn't want my headlights to be the cause of an accident.) Unfortunately, my regular headlights are so dull in comparison to all the other cars around me that I'm at a disadvantage. It seems there's no way to balance others' safety with my own when it comes to headlights.

B.4411 February 8, 2025 — Nashville, TN

These blinding headlights at night are completely unsafe. These agencies have to do something immediately! I can not see to drive when the cars coming at me have blinding headlights! After these cars and trucks pass me I feel like my eyes are burning and I can't see anything. And that's just one car or truck I have to pass hundreds at night to drive somewhere. Do something about it!! How can this be legal for other vehicles to completely blind me with ultra bright led headlights?? Most time I can't even see the road and feel like this will cause a head on collision because I can blinded by the headlights! Fix this now!

B.4412 February 8, 2025 — Newnan, GA

I avoid driving at night if I can. Whenever possible I drive a path divided by a median. I've had to come to a near dead stop many times as I could not see due to the headlights of an oncoming car.

B.4413 February 8, 2025 — Roseville, CA

I struggle with night driving because of blinding hesdlights

B.4414 February 8, 2025 — Saratoga Springs, UT

I almost died tonight on a snowy road, with a big pickup blinding me from behind. I couldn't see a thing! This happens far too often.

B.4415 February 9, 2025 — Bloomfield Hills, MI

I cant even drive when the sun goes down

B.4416 February 9, 2025 — Dallas, TX

With lumen maximums set, enforcement is incredibly necessary. Law enforcement should be equipped with lumen meters, as damage to the citizens' eyesight and ability to be safe on the road will result in nothing positive towards the politicians' workforce and supporters.

B.4417 February 9, 2025 — Fallon, NV

The lights are too damn bright!

B.4418 February 9, 2025 — Golden, CO

Making headlights brighter to supposedly increase safety for the driver of a given car translates into decreased safety for every other driver on the road. Ironically, that same "safer" driver is less safe overall because they are equally exposed to their fellow "safer" drivers whose cars have overly bright lights!

B.4419 February 9, 2025 — IL, United States

LED lights blinds Lives

B.4420 February 9, 2025 — Nalgonda, India

Even led lighting started to impact sport matches. https://www.msn.com/en-in/sports/cricket/it-has-more-glare-and-sometimes-former-pakistan-captain-blames-pcb-over-led-light-issue-after-rachin-ravindra-gets-injured/ar-AA1yG7oL

B.4421 February 9, 2025 — Tampa, FL

Headlights are so bright now I'm wearing sunglasses at night!

B.4422 February 10, 2025 — Augusta, GA

These newer LED lights are absolutely horrible, not only for my astigmatism, but in general the blinding effect of these lights AFTER they have passed you or moved over last so long. I have to drive rural backroads all of the time when going home from college, and I have to slow down almost to the point where I have to completely stop so I can try to focus and see the road, otherwise I would for sure run off the side. This is not only a concern of being able to see, but it is extremely dangerous to slow down on a very dark road at night when there are other cats behind you. The same way you get pulled over for going too fast over the speed limit, you get pulled over for going too slow because that's dangerous as well. Having to go from 55+ mph on a two lane road to around 30 mph very suddenly is not safe at all. These LED lights consume my entire windshield and leave me partially blinded

afterwards. Not only are these lights dangerous on rural roads, they're just a dangerous on city roads. Driving behind someone with your brights on is illegal... so why aren't these LED headlights regulated? I digress

B.4423 February 10, 2025 — Pinetop-Lakeside, AZ

I can't see at night! These new headlights are ridiculously bright. You can't even see the car behind you because their lights are so bright blinding you! There needs to be regulation on how bright headlights can be!

B.4424 February 10, 2025 — SARATOGA SPRINGS, NY

It ain't just the brightness -- it's the fact that the whiter or blue-er the light the less you can see in the shadow areas of your view AND the more blinding the light is compared to yellow light.

B.4425 February 10, 2025 — San Antonio, TX

A vehicle was stopped on the wrong side of the road, facing me with bright headlights, on a rainy night. The dark and damp conditions made it hard to see, but their bright lights were so blinding, I couldnt see that there was a pedestrian on the road in the path I would've taken to get around the stopped vehicle. It was an all around dangerous situation

B.4426 February 10, 2025 — Whittier, CA

I have astigmatism & I literally CANNOT see with these new lights. We need regulations on these lights ASAP!!

B.4427 February 11, 2025 — Plainsboro, NJ, NJ

No one should have to crouch in the driver's seat so that they avoid the glare of the headlights behind them, which I find myself doing all the time while driving at night. Also makes it quite difficult to look both ways while at a stop sign without getting visually distracted. It's bad enough there are so many overly bright LED flood lights on people's homes and other buildings, but these new headlights are especially a concern.

B.4428 February 11, 2025 — Rocky Mount, NC

LED headlights have gotten so bad that I have to almost come to a complete stops because I simply cannot see a single thing in front of me. It’s already bad enough driving at night having astigmatism, but having headlights so bright it strains your eyes, glares on your windshield so you can’t see out of it, gives you headaches, etc. No low bean headlights should be blinding people.

B.4429 February 12, 2025 — Madison, WI

In the state I live in it's legal to flash your brights at drivers who have them on. More often than not the driver will then engage their brights which are not too much brighter than their normal headlights. My vision is regularly negatively impacted by headlights that are too bright. I understand there's a mode on newer cars that allows them to drive with brights on. The sensor in their car is supposed to switch to normal lights when a certain amount of light is detected. Apparently my own headlights are not enough to engage this feature so I'm stuck in a bad situation. Regular headlights need to be dimmer. If someones headlights are bright enough to compare other drivers then the headlights are just too bright.

B.4430 February 12, 2025 — Riverside, CA

i’m sick of jerks on the road putting me and other drivers around me in dangerous driving conditions all because they want to have a slightly clearer view of the road

B.4431 February 12, 2025 — Washington, DC

These lights make it dangerous and obnoxious to drive at night and early morning; they pull your attention away from where it should be - on the road

B.4432 February 13, 2025 — Conroe, TX

These bright headlights should be banned because it's EXTREMELY dangerous. I have binocular vision dysfunction, bright lights hurt my eyes and make my vision distorted. I have to slow down and

let them pass me, so that I feel safe enough to drive. It's terrifying driving at night on freeways with those lights.

B.4433 February 13, 2025 — Greenbrae, CA

I have astigmatism and significant photosensitivity. I have had to bring my life to almost a complete standstill because of how difficult and dangerous LED headlights have made the road. I live in a rural area and get flash banged around every corner and over every hill, day and night. I have had people around here maliciously turn their lights on at me both while driving and as a pedestrian because they think it's funny (I've seen them laughing as a pedestrian). I have a headache after every drive and my visual snow syndrome gets worse the more I'm exposed. The cops do nothing and are now ADDING aftermarket ultra bright LEDs to their vehicles. I just want to exist safely and comfortably.

B.4434 February 13, 2025 — Hinesburg, VT

I try not to drive at night because of the brightness of the head lights. I have friends who will not drive in the dark at all.

B.4435 February 15, 2025 — Casper, WY

More than once, I have had to shut my eyes in the presence of those infernal things, an event fraught with danger.

B.4436 February 16, 2025 — Indianapolis, IN

I no longer feel safe driving at night because I'm constantly being blinded by these headlights. They make the road way more dangerous for everyone.

B.4437 February 18, 2025 — Meridian, ID

Many others and myself have feared for our safety when blinded by bright head lights. there's not always reflectors to help and only newer cars have night mode for their rear view mirror, these were what I was told I should do when I get blinded and obviously they don't always work. not only do the head lights blind you while they are driving towards you but also after when your vision has to adjust to such an extreme change in brightness, which may leave blind spots for minutes.

B.4438 February 21, 2025 — Philadelphia, PA

LED headlights are blinding

B.4439 February 22, 2025 — Collingwood, Canada

Oncoming cars with these lights look like they have their high beams on. When I see one coming I try to mark where the road is in front of me so I can continue driving when I am finally blinded when these cars get closer. Need regulation on this, it is such a pointless hazard.

B.4440 February 22, 2025 — Fredericksburg, VA

I drive back and forth from the colonial Beach and Fredericksburg area so I can go to work and it sucks having to drive that far and I have to pull over and wait for some car to go past so I can drive safely

B.4441 February 22, 2025 — Kinggeorge, VA

We as people do like newer and brighter things but it's ridiculous that my safety as a driver is at risk because of bright lights I can't drive down my road coming home and someone comes by with high beem leds not knowing or seeing what's in front of me because of it

B.4442 February 22, 2025 — Summerville, SC

I am an Uber Driver, and I mainly drive at night, quite often from dusk until dawn. I enjoy this schedule, and moreover this job, above all other schedules and jobs I've worked in the past. However, the only issue I have with driving at night are the blinding headlights that greet me maliciously on the roadways- and worse, negligent drivers who have their even brighter highbeams on. I have nearly wrecked numerous times, however other drivers may not be so lucky and fortunate. The soft, yellowish lights from the late 1990s and early 2000s were perfect- one could see perfectly on the road with them, without needing to flip one's own highbeams on, and could see whenever someone else's yellow headlights came across them. We need soft light back, and we need it now.

B.4443 February 25, 2025 — boslsob, Canada

I'm signing because the politicians will not do anything, the automobile manufactures will do nothing, and the police are powerless. This is frustrating to see the road safety governance fail us and let this "cash cow" grow. High beam them at the last second, it's the only power you have.

B.4444 February 26, 2025 — Frisco, TX

On top of the obvious, proven, health and safety concerns that the switch to LED lights by car manufacturers has caused, I personally also can't stand the negative psychological effects white lights have compared to warmer lights.

B.4445 February 27, 2025 — Japan

https://chng.it/t46S4fBVXG

B.4446 February 27, 2025 — Saint Charles, IL

As someone who drives a "normal" car, driving in America SUCKS. What used to be a comforting sea of yellowish-white lights is now composed of collapsing suns from Tellurides and other unreasonably large vehicles. Since I've got incandescent headlights, I just drive with high beams on all the time since no one cares about other folks' retinas anymore.

B.4447 February 27, 2025 — Salem, MA

The combination of increasingly bright headlights, vehicles getting taller, and the adoption of a "cold" hue of light is literally lethal, and is directly costing Americans their lives. Laws need to be put in place to mandate the brightness, angle, and hue of headlights to prevent drivers from being blinded. There have been many occasions where I haven't been able to see a pedestrian crossing the street until the last few seconds due to a truck or SUV with unnecessarily bright headlights in the oncoming lane, and this story is becoming more common as the years go on. It's also been proven that "cold" or "hard" lights (like the ones you see in modern cars) are far more blinding than "soft" or "warm" lights (like you see in older cars), even at the same level of lumens, which is adding to the problem. The only way to solve this problem will be to put a limit on how bright headlights can be, mandate using a warmer hue for the color of the light, and ensure that these lights are pointed at the right angle. And as much as I'm sure a lot of people don't want to hear this, the only way to enforce these laws is with yearly inspections in EVERY state. As a car enthusiast, I typically hate having the government tell me what I can and can't do with my car, but the reality is that the safety of our fellow humans needs to take precedent.

B.4448 February 27, 2025 — Taylorsville, UT

LED headlights are blinding and dangerous.

B.4449 February 27, 2025 — Washington, DC

I started driving in 2022, three years ago. I have no eye issues medically. Since 2023 after my first year driving I can no longer drive at night due to not being able to see the road after LED light exposure from oncoming vehicles and the vehicles driving behind me. My eyes are filled with spots and color dots for about 30 seconds after LED beams hit my eyes. I am not old, I'm 21 and cannot see while driving!

B.4450 February 28, 2025 — London, Canada

these lights are dangerous and make night driving(past 4pm in the winter here) dangerous for even people with mild stigmatism

March 2025

B.4451 March 2, 2025 — Mitchell, NE

Headlights are getting too dangerous.

B.4452 March 2, 2025 — Mount Prospect, United States

Blinding headlights are very real safety concern. I often must slow down when an oncoming vehicle is so blinding I cannot safely see the road.

B.4453 March 2, 2025 — Pittsburgh, PA

I work as an optician & I hear every day about these headlights. Unfortunately, there is no real solution with eyewear to do so. The only product I can suggest because I use it myself is a yellow custom made clip for my glasses. It is called a Chemistrie Clip available nationwide. The color yellow cancels the blue light to a light green. It would be even better if polarized, but alas it is not. Though it is better than nothing at all. This glare is oftentimes disabling which makes for a dangerous situation. One of our patients is a police officer and he agrees. I really hope a petition like this can get some results and relief.

B.4454 March 3, 2025 — Carmel, IN

Because of my job and generally the things I do on a day-to-day basis, I often find myself driving at night. The amount of times in one drive I have to shift my mirrors or lift my hands up to block oncoming lights is insane. I am on the younger side and haven't been driving for as long, but I've still been at genuine risk of crashing at least two times because oncoming cars completely blinded me, making it so I can't see anything. When driving through backroads, I feel genuine dread everytime I approach a hill because if the road doesn't do anything other then stay straight and clear and there is an LED headlight car coming my way, there's no way I'm gonna see it. I genuinely hate LED lights, and I encounter them so much its insane.

B.4455 March 4, 2025 — Avon, MN

I wish could hold up a giant mirror in front of every LED-equipped vehicle. Then you would see what we see. By the way, your ability to "see better" with excessively bright lights comes at the expense of everyone else seeing worse! In the last few years, I have had to severely limit how much I can drive—both during the day as well as at night. That's because all LED headlights now stab us in the eyes regardless of the surrounding conditions. Even when wearing multiple layers of variously colored sunglasses, the LED lights are aggressively eye-piercing. Thus, I can manage to drive during the day, but it adds needlessly to the stress on my body. Stressed drivers are not safe drivers. It's far worse at night. Because I need to darken the LED headlights by wearing sunglasses, this makes everything that isn't bright or reflective virtually invisible. Obviously, this is not safe, but this is the position you have put me in by allowing the proliferation of blinding headlights. Thus, I am calling on transportation safety officials to actually regulate the industry! The current rules are far too lax, allowing manufacturers to "cheat" the lumen restriction by gaming the detection method. We are being experimented upon by any and every manufacturer's "bright" idea who have no regard for health and safety. DO NOT TREAD ON ME!

B.4456 March 5, 2025 — Greenwood, IN

These LED headlights have given me black spots in my eyes while driving and make me not able to see while I am driving. They are pointless and need to be banned

B.4457 March 5, 2025 — Sterling, VA

Yeah, tired of these. Major strain on the eyes at night, heck I can't even take walks out on our little neighborhood trails they blind me there too! As well as I can't tell you how many times I've worried someone was blinking their lights at me to alert so ething to me only to later realize ITS THE BRIGHT LIGHTS FLICKERING WHEN THEY HIT BUMPS IN THE ROAD!

B.4458 March 6, 2025 — Arlington, TX

Every day I have issues with LED headlamps. They're too bright and very blue. Long story short, worst cases I've experienced are momentary blindness with eye pain/headaches. It's very scary because I wonder if it'll be the time I miss something in the road and get into a serious accident because someone had the brightest headlamps on the road. The most recent experience was the scariest. The truck was lifted with aftermarket off road LED lamps along with the factory LED headlamps. I literally could not see anything else around me but him. I had to slow down and wait for him to get around me because I was afraid I would hit someone or vice versa.

B.4459 March 6, 2025 — Eugene, OR

As a delivery driver who drive mostly at night, I've notice that headlights have gotten unbearably bright. Many times a night I have to shield my eyes with my hands to avoid being blinded by other drivers. Some of them leave spots in my vision and make seeing in the dark impossible after they

pass. Lights that obscure your view of the road ahead are a major hazard to drivers and pedestrians! The projectors headlights in the Rav4s and Subaru Outbacks are the worst offenders by far. They are blinding even from a mile away! The worst is when the oncoming driver crests a hill, and all of sudden you are engulfed in dazzling white light with no view of the road ahead. I can't imagine what older drivers must be going through. The local authorities need to step in stopping people from installing them aftermarket, and the NHTSA needs to overhaul its testing of these lights. Its a shame that this has been allowed to go on for so long.

B.4460 March 6, 2025 — Taft, TN

I drive with my sun visor down and hold my left half up to block the areas it doesn't cover. At night I don't go above 40mph because I can only see about 40 feet of road in front of me. I've almost crashed twice now. Some day ill end up driving through a red light not realizing it's there. But at least that lifted truck will be able to see the accident from 5 miles away.

B.4461 March 7, 2025 — Mount Pleasant, MI

I know of a young driver who lost her life due to bright headlights of a pickup truck. These need to be regulated now.

B.4462 March 8, 2025 — Savannah, GA

These LEDs on new cars and after markets are over the top bright. They cause oncoming traffic to become momentarily bling which is taking eyes off of the road. It’s illegal to text and drive due to taking our focus off the road. So, why are vehicle lights that are causing people to lose sight of traffic and the road allowed?

B.4463 March 9, 2025 — Manchester, NH

There have been so many instances where I have been blinded by these lights and struggle to just see the road. They absolutely need to be illegal but they would rather ban pev for saving gas and money smh.

B.4464 March 9, 2025 — Summit Hill, PA

I have astigmatism, and have almost crashed TWICE because of LED headlights, they are not only a nuisance but they are dangerous, not only to you as a driver but a health concern to your eyes, it only takes 1,000 lumens of light shone at the eyes to cause temporary blindness, LED headlights are usually 3,000 lumens, if headlights are leaving black spots in someones eyes, shouldnt we reevaluate the safety of them???

B.4465 March 10, 2025 — Beaverton, OR

As a firefighter I can tell you that extremely bright headlights can alter a driver's vision which can lead to them drifting into an oncoming lane of traffic causing a fatality accident. There is no need for these extremely bright lights and when a vehicle switches on they're bright lights it gets Evan worse. These lights have blinded me in my personal vehicle as well as in an emergency vehicle while responding to an emergency. These lights need to be federally banned in automobiles.

B.4466 March 10, 2025 — Berlin, CT

These white LED headlights need to be banned from all road vehicles You drive around and can't see anything when these cars are coming at you head on or from behind. It's extremely dangerous to drivers. I know I've been blinded multiple times each week just dropping my child off at school.

B.4467 March 10, 2025 — Hendersonville, NC

I commute 75 miles one way for work. It is dark when I leave home, and often dark on the return trip. I suffer from migraines and ocular migraines. Both are often triggered by bright lights. I understand needing to see the road, but the LED headlights are ridiculous. LED lights literally blind you for a moment and that's never safe when driving.

B.4468 March 11, 2025 — Burlington, Canada

LED are a road hazard

B.4469 March 11, 2025 — Portland, OR

Please get rid of these! It's unsafe! I go blind each time!!

B.4470 March 13, 2025 — Atlanta, GA

I had an accident cause by the blinding lights of an incoming vehicle. My car went up in the air when I hit the median, flew a couple feet and once it landed, two tires blew up. I spoke with my adjuster and she said this is becoming way too common now. Unfortunately, I can't even claim it as UM and now I'm facing higher rates in my premium after this claim.

B.4471 March 13, 2025 — Atlanta, GA

{"videoUrl":"https://stream.mux.com/4qTgWnjON18SBrhJ00puId57OV6So3rWV02cWmQWOkMT8","cloudflareUid":"2d3858e55a51258eb284f853a13c0200","muxAssetId":"ZOsqF5OaQW2ttlwJRi8kC8Xot9mJbfSfJ00z01f3O59EA","muxPlaybackId":"4qTgWnjON18SBrhJ00puId57OV6So3rWV02cWmQWOkMT8","muxPlaybackUrl":"https://stream.mux.com/4qTgWnjON18SBrhJ00puId57OV6So3rWV02cWmQWOkMT8","muxThumbnailUrl":"https://image.mux.com/4qTgWnjON18SBrhJ00puId57OV6So3rWV02cWmQWOkMT8/thumbnail.jpg"}

B.4472 March 17, 2025 — Vancouver, Canada

I can't drive

B.4473 March 18, 2025 — Boston, MA

LED bulbs are greatly cost-effective but the bulbs used for headlights need to be regulated. LEDs vary significantly depending on the wavelengths they emit. I have not tested any headlights from newer cars, but I would guess based on the pain I feel in my eyes that they are predominantly emitting blue light, which is very harmful for our eyes. There should be a limit on how much radiometric power is being emitted by headlights and high beams vs regular lights should not be a slight angle adjustment. Being slightly down hill from new cars is a very dangerous position to be in these days.

B.4474 March 18, 2025 — Chicago, IL

GET RID OF THESE DAMN BRIGHT HEADLIGHTS NOW!!!! IM SICK OF IT

B.4475 March 21, 2025 — Stuart, FL

it is terrifying being blinded by peoples headlights while driving. I drive 2 hours to get to school and there have been multiple times where I've feared getting into a car accident because other people's regular headlights are so bright that I can't even see the road.

B.4476 March 25, 2025 — Ironton, MO

{"videoUrl":"https://stream.mux.com/Yh8x3WjVHPSj2FdBCT3afY5aURWFvOLCcZW4HkB6S7s","cloudflareUid":"30ed0a8675655548ab500542ed69fbc2","muxAssetId":"fx00ybMRVZM3JmlMfXPeSbRbVPYeu3IOfuXlTB8P8y8U","muxPlaybackId":"Yh8x3WjVHPSj2FdBCT3afY5aURWFvOLCcZW4HkB6S7s","muxPlaybackUrl":"https://stream.mux.com/Yh8x3WjVHPSj2FdBCT3afY5aURWFvOLCcZW4HkB6S7s","muxThumbnailUrl":"https://image.mux.com/Yh8x3WjVHPSj2FdBCT3afY5aURWFvOLCcZW4HkB6S7s/thumbnail.jpg"}

B.4477 March 30, 2025 — Export, PA

it's not safe!!!

B.4478 March 30, 2025 — Pasadena, CA

I drive an older car that sits lower to the ground and with the prevelance of more SUVs and trucks which sit higher off the ground I find that any time I drive at night I am utterly blinded by these headlights as they are shining directly at eye level. This is more than just an annoyance and is a matter of equity and safety for anyone who uses the road. While these headlights may make it easier to see for those who drive newer and more expensive vehicles it actually makes it more unsafe for those of us who do not. I believe it is a failure of our government to not be regulating these in terms of safety to other users of the road and I implore government officials to take into account the safety of all road users

B.4479 March 30, 2025 — Somerville, MA

I thought I was going crazy but instead it is true, others are experiencing the same issues I have at night due to the brightness of headlights. Please someone do something, it has gotten too dangerous

April 2025

B.4480 April 1, 2025 — Fort Myers, FL

I get frequent migraines and these lights are a trigger. I have to move my mirrors everytime a vehicle is behind me, blinding me with these lights. It's a safety hazard because my mirrors are all out of place and I can't keep adjusting them back and forth while driving. PLEASE GET RID OF THEM!!

B.4481 April 1, 2025 — San Francisco, CA

Headlines have become so bright these days that I am having to drive one-handed during night time. My left hand covers my eyes from glare in the rear view mirror and from oncoming traffic. Worse yet, I drive a Prius and headlights from tall vehicles literally illuminate my cabin. Legislators please act. To my fellow drivers with bright lights: I want to see the road and be safe too.

B.4482 April 3, 2025 — Mount Airy, MD

I live in an area with a lot of sharp turns, hills, and ditches. It’s extremely easy to run off the road even without being blinded by LEDs. At night, and especially when it rains, LED lights make it nearly impossible to see the yellow and white, because EVERYTHING turns white. If you went back a few years and used LEDs on the road, people would tell you to turn your brights off. These lights have made it is unnecessarily dangerous to drive at night, and I’ve nearly run off the road multiple times after being flashbanged

B.4483 April 5, 2025 — Belleville, IL

Blinding LED and blue headlamps are DANGEROUS.

B.4484 April 5, 2025 — Brooklyn, NY

Overly bright lights at night are a dangerous issue that must be addressed. Sometimes I can see my own car’s shadow in front of me, even though my own lights are on, because the lights behind me are so bright.

B.4485 April 5, 2025 — Broomfield, CO

The incredibly disorienting bright white glare from LED lights on large snowflakes at night on a dark snowy road is most certainly dangerous. Who researched the level of LED safety in the snow??? This is an absolute must.

B.4486 April 5, 2025 — Chicago, IL

{"videoUrl":"https://stream.mux.com/wxU1XgPVoJpb9ZCHyCNrx2LBnA11rkyoVr00oc2QnHnQ","cloudflareUid":"005742ac6909f14920e3f0e26ff8d426","muxAssetId":"ngwqzY300SyZkBYYigEm4cvnd3fdYhvkjwJCZDH01OD9A","muxPlaybackId":"wxU1XgPVoJpb9ZCHyCNrx2LBnA11rkyoVr00oc2QnHnQ","muxPlaybackUrl":"https://stream.mux.com/wxU1XgPVoJpb9ZCHyCNrx2LBnA11rkyoVr00oc2QnHnQ","muxThumbnailUrl":"https://image.mux.com/wxU1XgPVoJpb9ZCHyCNrx2LBnA11rkyoVr00oc2QnHnQ/thumbnail.jpg"}

B.4487 April 5, 2025 — Milwaukie, OR

The worst offenders are cheap aftermarket replacement headlights and light bars. Existing rules on forward facing lights need to be enforced, and limits need to be clarified to address new technology. Nobody wants to see endlessly increasing regulation, but headlight brightness has become an arms race that puts pedestrians and other drivers at risk in order to turn the night into daylight.

B.4488 April 5, 2025 — Phoenix, AZ

If they are really concerned with our safety they'd get rid of those blinding lights. I've even seen them a bright yellow!! Enough.

B.4489 April 6, 2025 — Los Angeles, United States

The new headlights make it so unnerving to drive at night, especially for those of us with astigmatism. Like who in the heck was the "genius" that thought making head lights brighter was going to help things? Its obvious to me that no one consulted and sort of optomestrist, opthomologist or any sort of vision professional. we need to go back to the old school headlights now!

B.4490 April 6, 2025 — United States

https://www.vox.com/explain-it-to-me/407147/bright-car-headlights-leds

B.4491 April 8, 2025 — Calgary, Canada

I find that the new brightness of headlights feels blinding and irritating. How is that helpful and qualify as higher safety standards? It may help the driver but what about the other drivers that are squinting or having to look away because their eyes are blinded. In my opinion, a driver who is blinded is being handicapped by the light intensity and should anything happen as a result, perhaps a lawyer should be consulted.

B.4492 April 8, 2025 — Calhoun, GA

It appears that pickup. Trucks and SUVs that are installing larger tires and lift kits are doing so without verifying that their headlights are aimed correctly. This lack of consideration for on coming drivers is blinding drivers. It should be mandatory that when a vehicle has modifications from their stock configuration that a headlight aim be checked by an authorized third party.

B.4493 April 8, 2025 — Cincinnati, OH

Sometimes, when a vehicle has bright headlights, approaching from behind, I need to pull over & let the vehicle pass. Additionally, I have my rear window tinted.

B.4494 April 8, 2025 — Cumberland, MD

I can't drive on high-speed roads at night anymore....too dangerous, especially with enormous SUVs and pickups beaming light into my brain from above my smaller car. The reflected light in my rear-view mirror is so blinding I have to avert the mirror to drive at all! The light is AGGRESSIVE and DANGEROUS

B.4495 April 8, 2025 — Denver, CO

Other drivers and pedestrians are blinded by too bright headlights. To save lives, NHTSA needs to address this dangerous situation immediately.

B.4496 April 8, 2025 — Herndon, VA

I have experienced the torture of the headlights being so bright and couldn't drive for a day. My eyes needed to rest after being on the road for a week straight with breaks in between. When I saw this article it all made sense. I pray that this gets to the floor and change happens. It's not making traveling better. It's making it worse. Drivers can't see if it's safe to get in the next lane because of these blinding lights. It's really bad especially on highway 95 on the east corridor line.

B.4497 April 8, 2025 — Highland TWP, MI

Please limit the car lights & save our eyes

B.4498 April 8, 2025 — Madison, WI

We need safety regulations! Monster SUV and trucks seem to be the worst offenders.

B.4499 April 8, 2025 — Parry Sound, Canada

The bright lights are dangerous and it's not acceptable.

B.4500 April 8, 2025 — Phoenix, AZ

Unmentioned issue: The problem is exacerbated for those suffering from cataracts!!

B.4501 April 8, 2025 — Winnipeg, Canada

I get blinded by car drivers all the time. Often it seems they have their high beams on, but whe I flash them to remind them to turn their high beams off, they flash back with even brighter lights. Night vision is completely destroyed

B.4502 April 8, 2025 — Woodruff, SC

I can no longer drive at night because of the intensity of headlights. Please begin regulation of headlight strength to a lower level!

B.4503 April 9, 2025 — Calgary, Canada

This LED headlights madness needs to stop and become properly regulated. They′re a road hazard, no doubt about it. They′re damaging our driving, our eyes and safety of everyone involved. Now the old cars Install the LEDs and then it′s even worse. We used to be able to see if the car coming your way is moving slightly towards you and might hit you, so that you can avoid, but now it′s just you can′t even look at the corner of the car to get a sense of its direction. You just look away and pray all goes well.

B.4504 April 9, 2025 — Calgary, Canada

This LED headlights madness needs to stop and become properly regulated. They′re a road hazard, no doubt about it. They′re damaging our driving, our eyes and safety of everyone involved. Now the old cars Install the LEDs and then it′s even worse. We used to be able to see if the car coming your way is moving slightly towards you and might hit you, so that you can avoid, but now it′s just you can′t even look at the corner of the car to get a sense of its direction. You just look away and pray all goes well.

B.4505 April 9, 2025 — Chapel Hill, NC, NC

I used to be able to drive at night and not worry about it too much. The worst that could happen was some other driver leaving their brights on. These days any long trip in the dark is a recipe for migraines and it′s entirely due to the intensity and location of modern vehicle lights. I think LEDs are a great technology, but like anything else, they have to be used in a reasonable way.

B.4506 April 9, 2025 — Flemington, NJ

I thought my eyes had suddenly aged. Turns out, there has been an increase in LED headlights that coincided with an increase in my nighttime driving. The headlights are awful

B.4507 April 9, 2025 — Phila, PA

Like so many others, I too thought I was only one being blinded by car headlights in the recent years! It’s literally become painful to drive at night, from experiencing headaches to losing vision on the road, I am completely on board to banning blinding headlights!

B.4508 April 9, 2025 — Richmond, KY

It is very hard to drive now days because of the intense brightness of head light and all most to the point of being blinded and driving 70 and not knowing where you are on the road until a car passes, and praying nothing is in front of you and your still on the road until your sight comes back to you. My mirrors are not where the should be for traffic behind me for the same reason. Instead of blinding lights, inhance to paint or marker on the roads. Rain is the worst when the lines are not visible and glaring headlights are beaming. A person driving a car has no hope.

B.4509 April 9, 2025 — Scottsburg, IN

Has anyone ever thought about the seniors with cataracts and the effect these headlights hv on glare. It’s very blinding and look how many senior citizens we have. There are no lines to guide you on side streets and frontal impact wrecks are the most deadly!

B.4510 April 9, 2025 — Scottsburg, IN

Does the insurance institute and NHTSA take into account seniors driving on the roads who have cataracts? And how many seniors drive? Frontal impact crashes happen because it’s hard to stay on your side of the road when passing car when night blindness from LEDs compound the problem.

Do a study on frontal impact wrecks on side streets with no lines and seniors driving. We all aren't young anymore

B.4511 April 10, 2025 — Chicago, IL

I was hit by a driver who stated that she was blinded by bright LED headlights. Luckily I survived but this issue is life and death

B.4512 April 10, 2025 — Doylestown, PA

I drive every night from doylestown pa to Philadelphia, and i have to suffer this problem every night. Very rude and dangerous.

B.4513 April 10, 2025 — Michigan City, IN

I work nights and driving to and from work is becoming more of a challenge due to these lights! Plus it does not help when inconsiderate people do not turn off their bright lights, which are their LED bright lights. Worse invention ever for vehicles in my opinion, need to get rid of them.

B.4514 April 10, 2025 — North Vancouver, BC, Canada

BC needs regulations on maximum intensity of headlight power intensity, as the Motor Vehicle Act Regulations formerly provided. Currently Section 4.06, 1b and 5 address ″striking the eye of an oncoming driver″ with no mention of actual candle-power of low-beam & prohibited high-beam. Exact maximum intensity power maximums are badly needed currently. Thank you

B.4515 April 11, 2025 — Greenwood lake, NY

{″videoUrl″:″https://stream.mux.com/601WKHDP1gW9JW4N7NdCsYt49UlEvRzbMitfpSZYdyWE″,″cloudflareUid″:″16d1cf102da02c80f377a9d03c3915da″,″muxAssetId″:″ITyhY800qJGzdXT00hs38VMcX01Gwas9Trbdq431f1Tlro″,″muxPlaybackId″:″601WKHDP1gW9JW4N7NdCsYt49UlEvRzbMitfpSZYdyWE″,″muxPlaybackUrl″:″https://stream.mux.com/601WKHDP1gW9JW4N7NdCsYt49UlEvRzbMitfpSZYdyWE″,″muxThumbnailUrl″:″https://image.mux.com/601WKHDP1gW9JW4N7NdCsYt49UlEvRzbMitfpSZYdyWE/thumbnail.jpg″}

B.4516 April 11, 2025 — York, PA

Cannot stand when one of these SUVs with insanely bright lights is behind me. Was happy to see this petition to immediately sign. They light up the inside of my car like high beams! I often try to turn my side mirror far enough hoping it's beaming the light back into their own freakin eyeball- not to cause a wreck of course- but they've gotta see for themselves how bright their dumb headlights are! Someone's gotta make legislation limiting the bulbs!!!

B.4517 April 12, 2025 — Amarillo, TX

My husband and I both have issues with the LED headlights. I had someone behind me that has them and it took up my entire side mirror. They hurt my eyes. If somebody is blinking because of the brightness then. that means they′re not able to watch the road properly. It′s dangerous. There are times that I will see someone crossing the street, but then another vehicle with bright lights will come up and I can′t see them anymore. Can you imagine having to deal with that when there′s too close to tell that there′s someone there?

B.4518 April 12, 2025 — Fallon, NV

The headlights are ridiculous and dangerous to oncoming drivers. I drive for a living. Something needs to change. What good does it do to help one driver see better while blinding another. It looks like everyone is driving with there high beams on now. DANGEROUS!

B.4519 April 12, 2025 — Solon, OH

These new headlights are not at all safe, they blind oncoming traffic and can cause accidents. Please do not continue to install in any cars and recall all the existing ones !!

B.4520 April 13, 2025 — Montague, CA

These led lights are abviously way too bright. It shows how only one person cares about himself and not others. They are blinding even on low beam. Ill have to slow down to 30mph depending on location to let the go by. It is not safe!

B.4521 April 13, 2025 — Salt Spring Island, Canada

I find the new headlights dangerously blinding. In a rural area it's not only oncoming, it's also being blazingly lit from behind making it impossible to see out of the windshield.

B.4522 April 13, 2025 — San Diego, CA

I have to have my sun glasses on to oncoming traffic

B.4523 April 15, 2025 — Grand Rapids, MI

An AARP article maintained there is no difference in the brightness of vehicle headlights. Causes me to be skeptical of their automobile reviews. Or, maybe they aren't testing in real-world conditions. See John Draneas article in Feb 25 Sports Car Market.

B.4524 April 16, 2025 — Colorado Sptings, CO

Driving at night has become increasingly painful for my eyes and dangerous because i have to avert my eyes from the road to avoid the glare. This should have never been allowed.

B.4525 April 16, 2025 — Murrieta, CA

I drive everyday for school and work. I get off late at night usually and most of the times I have to take side roads. I always have to adjust my eyes to see in the dark which is easy and not usually a problem, until some car crosses my path with the sun for headlights. This is when I have to turn to look at the side of the rode which can be dangerous and very unsafe, however this is still better than getting blinded for a few seconds. I have also noticed the positioning of the lights is at the perfect angle and gets both side mirrors and my rearview mirror so I really am getting blinded from all directions.

B.4526 April 19, 2025 — Mt pleasant, MI

I am now on migraine medicine everyday because of these headlights and porchlights, which only helps slightly. They are literally killing me.

B.4527 April 22, 2025 — Beaverton, OR

I can't count the number of times I have been terrified for my life and for the lives of those around me because a pair of excessively bright headlights has rendered me essentially blind, especially for small things like lane markers - or worse, pedestrians. Sometimes the lights are in front of me, sometimes behind me shining at my side mirrors. I try to slow down as much as possible until I can see again, but lights can strike very suddenly, and there are many situations when one can't slam on the brakes without danger. (The middle of intersections, a fast-moving highway with cars tailgating you, and many more!) Adding to that, I get migraines from excessively bright lights. (Note that older or yellower headlights do not cause this issue!) This both means that I want to look away to protect myself (but I still need to see!) and means that in the event of a migraine there are still more reasons it makes driving dangerous. Auras obscure my vision, my thoughts become cloudy, and my reaction time slows. (In that case, of course I try to stop driving until it passes, but again, one can't do that instantly.) So far, I haven't gotten in any accidents, but there sure have been close calls, all due entirely to overly bright lights! I can't think of anything else which has put me in so much danger.

B.4528 April 24, 2025 — Arlington, MA

Lumens, Beam Angle, Beam spread, Headlight mounting height -- none of these seem to be regulated or uniform! I drive a small car, not a high SUV or truck, and the oncoming car headlight beam often shines directly in my eyes making the overly bright lights even worse! It is as if drivers are using their high-beams (and maybe they are!) I now try to avoid driving at night or use my spouse's higher-clearance car, a slight improvement, but still -- for a fatal split second -- wouldn't be able to see a pedestrian in a crosswalk directly in front of me! It is terrifying!

B.4529 April 24, 2025 — Manahawkin, NJ

Some of the issues presented are quite valuable and need much support. I am sorry not to be able to donate due to every time I put a credit card into any Computer it has been immediately hacked and I have had a really bad time contesting the phony charges which prevent the legitimate charges to be paid.

B.4530 April 25, 2025 — Sheffield Lake, OH

As more and more sources of blue light become our everyday I have noticed my eyes deteriorating faster. I was recently diagnosed with an astigmatism in both eyes. These headlights make the difficulty of driving at night almost impossible. I am terrified to drive anywhere unfamiliar once it gets dark now as these LED lights are sometime so blinding I can't even see past the car, let alone my windshield. My head aches and they even make me nauseous. I have said for years that they are out of control, but now it seems they are worse than ever. After reading the extensive history of trying to fight this and how illegal it has been the whole tine infuriates me. I rarely do things like this, but people are dying from this and I have had enough.

B.4531 April 27, 2025 — Fayetteville, AR

Most nights when I'm driving home it's impossible to see the road, so I need to line up my car with the oncoming traffic's movement. This needs to change or people like me (with poor vision) will eventually be unable to even do this indirect half-solution.

B.4532 April 27, 2025 — Salt Lake City, UT

I'm a healthy 28 year old with 20/20 vision and I am now too scared to drive at night most of the time due to the new LED headlights. I have had so many near misses driving in rural places with no overhead streetlights where the LED lights on oncoming cars are completely blinding. Sometimes the lights trigger a cluster headache or migraine for me and I have to pull over. I am a Masters of Public Health student and I thoroughly believe these headlights not only pose serious safety risks as they increase the likelihood of car accidents, but they also cause long term eye damage. We need to get rid of them!

May 2025

B.4533 May 3, 2025 — Orem, UT

I have almost been in multiple accidents due to the glare of LED headlights, particularly when the vehicle is modded or lifted and the angle of the headlights is not adjusted. Bright headlights should be taken more seriously - they're more than a nuisance, they're a full-on hazard.

B.4534 May 9, 2025 — Cambridge, MA

Blinding LED headlights not only damage my precious (to me) eyesight, they double my chances of hitting on-coming cars, parked cars, pedestrians, and animals. If driving is a a right, so should be the right to protect my own eyes and my right to feel safe , when driving. I'm more concerned about accidents from LEDeadlights than I am about alcohol, drugs, or sleep-deprivation.

B.4545 May 25, 2025 — Boston, MA
These lights cause excruciating pain to people with photosensitivity.

B.4546 May 30, 2025 — Columbus, OH
The headlight aiming regulations need to change in the U.S. it's absolutely ridiculous

June 2025

B.4547 June 10, 2025 — Shohola, PA
The aftermarket headlight bulbs many people install are sometimes 2-3x brighter than factory, with no consideration for headlight re-alignment. These people just have absolutely zero consideration for others on the road. I can feel these types of headlights cut through my eyes to the core of the back of my head, and my eyes REALLY HURT when this happens. It is blinding and my vision is deteriorating because of these aftermarket headlights. Anyone can see the difference between factory and aftermarket, and the aftermarket headlights are ridiculously way too bright. I literally feel like I'm going to have permanent eye damage - I complain to the eye doctor every visit.

B.4548 June 14, 2025 — Bonney lake, WA
I am blinded every day for several seconds each time by these headlights. Even if you make an effort to look away, passing and turning cars WILL blind you. All we need are yellowing and dimming stickers on these headlights. It can't be so hard to make an effort.

B.4549 June 14, 2025 — Groton, CT
LED headlights are genuinely dangerous and so unnecessary they're constantly blinding me and my friends on the road, it's so annoying, GET THEM OUTTA HERE

B.4550 June 17, 2025 — Geelong, Australia
AUSTRALIA HAS HAD ENOUGH!!!!

B.4551 June 18, 2025 — New Market, AL
This has become a matter of life and death around here. I will vote for candidates that promises to introduce and support legislation regulating this increasing hazard!

B.4552 June 18, 2025 — Pawtucket, RI
I drive at night and most of the time it's scary because the bright lights are very blinding, the manufactures should be held to a higher safety standard for the safety of everyone on the road. This is what state, and government should be taking into account (saving lives)

B.4553 June 18, 2025 — Southbridge, MA

Half the time I believe drivers have their high beams on when in fact they′re just in a new car with low beams ! Its just blinding when they DO have high beams running on a new vehicle ….YOU CANT EVEN SEE THE ROAD !!

B.4554 June 18, 2025 — United States

https://www.wpri.com/target-12/yes-car-headlights-keep-getting-brighter-heres-why/

B.4555 June 19, 2025 — Austin, TX

Dangerous and painful. Require LED headlight bulbs to match the color temperature and intensity of halogen bulbs.

B.4556 June 19, 2025 — Belchertown, MA

I can’t drive at night anymore because of the blinding headlights of oncoming vehicles. The main road to our home is narrow, windy and hilly. When an approaching car with those super bright headlights appears when I am driving up a hill or as I come around a corner, I am blinded and have to stop because I can’t see where the road is going. Also, once while I was standing near a road in the daytime, a small motorized vehicle with those bright lights came toward me, after which I had a blind spot in the middle of my eyes all the rest of the day. They should be illegal!

B.4557 June 19, 2025 — Greenville, SC

Very dangerous having cars with very bright headlights.

B.4558 June 19, 2025 — Keller, TX

I have migraines that are trigger by bright lights which includes all headlights but the worst are the newer vehicles. It’s too much! Why do they have to be blinding?

B.4559 June 19, 2025 — Palmdale, CA

I drive alot and now it is very hard for me to drive at night because the headlights on other cars are so bright that you are temporarily blinded. That is not safe when you are driving and the spots it leaves in my eyes makes me blinded for even longer. Ive actually just closed my eyes before while driving until the car passed because I couldn′t see. I also sometimes put my sunglasses on to block the bright lights. Something needs to be done about this.

B.4560 June 20, 2025 — Bolingbrook, IL

And these times with blinding headlights I have to drive home with my sunglasses on

B.4561 June 20, 2025 — Lakewood, CA

This is something I’ve noticed more and more over the past few years, and it’s become a serious safety issue. Overly bright headlights aren’t just an annoyance—they’re contributing to real consequences: increased accidents, road rage incidents, and even fatalities. And the worst part? Much of it is preventable. It’s time for common-sense regulation. Manufacturers should face stricter limits on how bright headlights can be, especially with today’s high-intensity LEDs and HIDs. We also need to implement mandatory headlight inspections, similar to smog checks, to ensure proper alignment and compliance—especially for aftermarket or modified lighting systems. Fix-it tickets should be issued for vehicles running illegal or misaligned headlights, and there should be clear enforcement guidelines in place. Beyond that, encouraging the adoption of adaptive headlight technology could make a huge difference—automatically adjusting beams to reduce glare for other drivers. This is a public safety issue, not a style choice. A few smart policies could reduce accidents, improve visibility, and make night driving safer for everyone.

B.4562 June 21, 2025 — Newark, NJ

I am a school bus driver in NJ. I′ve driven over 2,000,000 since I got my license. I drove the 9-11 Commission(with another driver) when they were here in NJ. I worked as a limo driver for 3 years after 9-11 when I came back to Jersey. I′m also a car ″fanatic!″ Especially German cars. Been working, fixing, racing cars since I was avteen. So here′s the deal: These L.E.D. headlights are STUPID and DANGEROUS! If you need headlights THAT BRIGHT then you must be blind and SHOULDN′T BE DRIVING AT NIGHT! And NHTSA should′ve shut down this stupidity when it first

started!! Ford F150. Teslas. Prius. Some Hyundais. It's RIDICULOUS! I worked in DC 16 years. I know how stuff "doesn't" get done. NHTSA should ORDER ALL car manufacturers to STOP using L.E.D. headlights! On top of that, some of these headlights are $2/3000 to replace. That is preposterous! Go back to halogen bulbs for ALL cars. And if you can't see well at night, STAY HOME! This is a SERIOUS problem! Get on it and fix it TODAY!

July 2025

B.4563 July 11, 2025 — Culver City, CA

Pathetic that the greatest nation in the world is collectively blinded by unnecessarily bright LED headlights

B.4564 July 12, 2025 — Mechanicsville, MD

Please make legislation / laws to reduce the intensity of these BLINDING headlights. If you can't see at night without blinding others, you don't need to drive at night. I don't need the POWER OF THE SUN behind me blinding me because of manufacturers putting these unnecessary blinding lights.

B.4565 July 12, 2025 — WAYNETOWN, IN

I'm not gonna make it fancy, but I've hit a multiple things on the road, weather it be a pothole/animal/or even branches all due to people high beaming me or having needlessly bright led headlights

B.4566 July 17, 2025 — Twentynine Palms, CA

I've started using my police unit's spotlights to counter these idiot drivers.

B.4567 July 18, 2025 — Littleton, CO

I've had a couple of concussions and have an extremely hard time with the bright lights, especially the blue emergency lights. The intensity of these headlights and the emergency lights is blinding and excessive. After the cars with the bright headlights have passed, I still cannot see for a couple seconds, and I live in an area where there is a lot of wildlife. I don't want to hit a deer or an elk because the car that has just passed me has blinded my own field of vision. Let's focus on the dangers that these too bright of lights are causing for others.

B.4568 July 20, 2025 — Midlothian, VA

I noticed how challenged, foggy, distracted my eyes are at night every time I am out at night that I limit night driving as much as I can. Not realizing that it is these new LEDs on cars and everywhere else that are the new norm. If this is affecting my eyes at my age 49, how are they affecting our young folks? Will they be blinded by the LED lights the longer they are out on the market? Where are the guardrails for things like this!! It's wrong and evil what has been brought into our lives to improve our lives only to come at a physical cost that is in my opinion not worth it!! Bring back the incandescent lights NOW for the wellbeing of all of humanity!!

B.4569 July 21, 2025 — Long Beach, CA

For drivers who like the increased visibility from LED headlights, how about a switch (like the dimmer switch on regular headlights) so that you can use them when no one else is around? Because oncoming LED headlights blind me for a couple of minutes, making them extremely unsafe! Especially in rural area where roads are dark.

B.4570 July 23, 2025 — kissimmee, FL

The new headlights are blinding and hurt my eyes. They make it extremely unsafe to drive at night, not to mention the concern for eye damage. I have heard similar complaints from many others. It is absurd that such a product is allowed in the market.

B.4571 July 26, 2025 — Crittenden, KY

I just want to get home and bed from work with no issues. I did by a glare night glasses, but those make me more sleepy sometimes depending on how tired I am. There are times I slow down just because there's extremely bright headlights coming.

B.4572 July 28, 2025 — Bon Air, VA

{"videoUrl":"https://stream.mux.com/02ulUuziwxyjr3pNAKq54AF45Z02tAlpqiNeLERFtAX8I","cloudflareUid":"b4d3730f3e312d48d716f85b2f8720eb","muxAssetId":"c79SF00xEX6Im00pg4h1bvLgXe1VqkbIpsKDrmGU00V2As","muxPlaybackId":"02ulUuziwxyjr3pNAKq54AF45Z02tAlpqiNeLERFtAX8I","muxPlaybackUrl":"https://stream.mux.com/02ulUuziwxyjr3pNAKq54AF45Z02tAlpqiNeLERFtAX8I","muxThumbnailUrl":"https://image.mux.com/02ulUuziwxyjr3pNAKq54AF45Z02tAlpqiNeLERFtAX8I/thumbnail.jpg"}

B.4573 July 30, 2025 — San Antonio, TX

Tired of being blinded at night while driving. This is a dangerous situation that need to be addressed by lawmakers.

August 2025

B.4574 August 1, 2025 — lake forest, CA

I want to know who the geniuses are that build SUV's and trucks and puts the headlights right at eye level for anyone inside of a car. I want to know how anyone can think insanely bright white and blue LED and HID headlights (soon to be laser now as well), light so bright you will still be seeing them sixty seconds after passing one due to after image, how can anyone believe this isn't an issue? This is an extremely important issue and one that demands some sort of reigns and regulations/standards be put into place. If someone can be pulled over by the police for window tint why can't some sort of limit be established that can be enforced by police?

B.4575 August 3, 2025 — williamsburg, VA

Please ban those crazy bright headlights

B.4576 August 4, 2025 — Los Angeles, CA

I get headaches so bad I have to stop working. But who will pay the bills?

B.4577 August 13, 2025 — Wilmington, DE

I have sensitive eyes and I experience physical pain when driving at night and another car has LEDs or 30% brighter bulbs. It doesn't help that all these cars are so much taller now, so the beams are directly pointed at my face half the time.

B.4578 August 14, 2025 — Boise, United States

Nothing really caps off a long, tiring day quite like being blinded three separate times on your drive home from work. You want to rest? Let's put you through the gauntlet, see if you live to see your bed! If you can see at all! My younger sibling, who just got their driving permit, mentioned being scared because they couldn't see anything, and began going off the road trying to avoid a truck driving at them. If my younger sibling dies or gets injured over these stupid lights, I will make sure hell reaches the people who make and drive these god forsaken cars.

B.4579 August 15, 2025 — Atlanta, GA

{"videoUrl":"https://stream.mux.com/GNjzGaQGnqbNl00P6pA01KVfzj8uC1Uo2bilrN5CnGu00M","cloudflareUid":"2a4b6ddc35d0cb43cd5bd5eeb79c606c","muxAssetId":"cb4TI8MRfMYoUZw3fmxgfPM00vyL8hDPOd2oRhvq4wds","muxPlaybackId":"GNjzGaQGnqbNl00P6pA01KVfzj8uC1Uo2bilrN5CnGu00M","muxPlaybackUrl":"https://stream.mux.com/GNjzGaQGnqbNl00P6pA01KVfzj8uC1Uo2bilrN5CnGu00M","muxThumbnailUrl":"https://image.mux.com/GNjzGaQGnqbNl00P6pA01KVfzj8uC1Uo2bilrN5CnGu00M/thumbnail.jpg"}

B.4580 August 16, 2025 — Phoenix, AZ

Blue-white LED lights are used by law enforcement officers to temporarily blind suspects for capture, while the "Dazzler" devices also harm the retinal DNA of the eyes, just like these crazy headlights. I must drive at night while wearing my sun shades in order to save my eyesight from those harmful blue-white LED lights, while also removing the massive glare-storm caused by those lights. I am very

tired of being blinded by 40 percent of the vehicles on the road today and it is only becoming worse each year.

B.4581 August 16, 2025 — Phoenix, AZ

Blue-white LED lights are used by law enforcement officers to temporarily blind suspects for capture, while the "Dazzler" devices also harm the retinal DNA of the eyes, just like these crazy headlights. I must drive at night while wearing my sun shades in order to save my eyesight from those harmful blue-white LED lights, while also removing the massive glare-storm caused by those lights. I am very tired of being blinded by 40 percent of the vehicles on the road today and it is only becoming worse each year.

B.4582 August 22, 2025 — Lake Village, IN

None of the aftermarket LEDs people install in OEM incandescent housings are legal. Its a modern trend of lawlessness on the roads. We've had vehicle lighting regulations in regard to brightness, color, and placement on all motor vehicles for 58 years. I see people with red, pink, blue, yellow headlights, people pulling their amber bulbs out of their clear cab light housings and installing clear bulbs, replacing amber running lamps with red lamps, fishtank style rectangle light bars on bumbers. Either modern police do not know the law or they're just not enforcing it. Its also common sense that if tiny blue dots have been illegal for 50 years then so is all the other added nonsense.

B.4583 August 27, 2025 — Victoria, Canada

There is absolutely no reason these headlights are not properly aimed to direct the light to the road where it’s useful and not our faces where it’s not.

B.4584 August 28, 2025 — Bogalusa, LA

LEDs should be illegal! Period! I believe only emergency vehicles and motorcycles should be allowed to have them while also being regulated themselves

September 2025

B.4585 September 1, 2025 — Oklahoma City, OK

I used to work for Doordash in the evenings following my day job, but I've had to quit due to the blinding bright headlights that have taken over the road in recent years. Not only do I get headaches but I literally CAN NOT see the road when taking a left turn with a vehicle behind me that has these LED lights. I've been doing delivery service jobs for over 5 years but it's gotten to the point where I don't feel safe anymore. Many of these lights are stronger than warm high beams. It used to be illegal to pass others with your brights on, and now it's the norm?

B.4586 September 3, 2025 — Saint Augustine, FL

I am terrified to drive at night now when this was never an issue before. I feel like I am temporarily blinded from these headlights and it is extremely scary and causes me a great deal of anxiety, especially with my kids in the car. Please, please ban these headlights. I am begging you. They are so incredibly dangerous.

B.4587 September 7, 2025 — Gulfport, MS

It should not be a fight just to drive home after work at night. The fact that people are literally riding around with THE SUN in front of them is absolutely ridiculous

B.4588 September 7, 2025 — Maple Valley, WA

My boyfriend was heading home from dropping me off tonight. He said he was making a right turn and almost hit a lifted truck with blinding leds. His car is small and old, I understand how its blinding it is. Its just categorically unsafe. Outlaw blue toned LED headlights. So many safe alternatives. I would never forgive myself if he crashed on the way home from dropping me off.

B.4589 September 12, 2025 — Magnolia, TX

Being blinded by oncoming lights when driving at night happens all the time. Those lights are not on high beam either. I've been driving over 50 years and the low beams today are brighter than the old incandescent high beams. We need enforceable regulations that target manufacturers and

aftermarket sellers with penalties or product banning and fines if they are sold. We have to put safety first. I am exhausted by government and corporations that don't put public safety first.

B.4590 September 16, 2025 — Dallas, TX

These headlights blind me and I fear getting into an accident, especially with trucks!!

B.4591 September 16, 2025 — Pittsburgh, PA

It's not legal to combat blinding lights that cause migraines. If we can't tint our windshields, the headlights need made for the people with the most sensitivity to light shining in their eyes. To me this is more dangerous than a police officer not being able to see into a car. Lives are at risk driving 65 MPH with blinding headlights coming at them. I you need to do better for the people. I almost wrecked before from being blinding before daylight. Now I have to wear dark sunglasses when its not even sunny out.

B.4592 September 19, 2025 — Humble, United States

I don't know whose stupid idea it was to used these blinding headlights! At least give the option to go back to soft! No wait! They but be banned no option period! I am tired of having to slow down and put my hand up in front of me to shield just to try to drive safely while passing a car with these lights someone else is going to get killed!! Oh wait I guess this is part of the depopulation agenda!!!

B.4593 September 20, 2025 — Hockessin, DE

Please! Please! Please! Please! Please! Please! Please! Please! Please! Please! Please! Please!

B.4594 September 20, 2025 — Richmond, CA

I thought this was my own problem, because I have glaucoma. I'd no idea others were jeopardized also. I've given up driving at night altogether.

B.4595 September 21, 2025 — Carrollton, GA

I can barely see at night on a highway and I have better than average vision. can't imagine what it's like for people with astigmatism or something.

B.4596 September 21, 2025 — Los Angeles, CA

As a pedestrian with light colored eyes, I avoid going out at night due to the blinding glare of cars driving in my direction. I could not drive at night if I wanted to due to blinding LED headlights.

B.4597 September 27, 2025 — Berkeley, CA

I don’t know wtf the engineers making these cars are up to, but they need to knock it off. Not only is it more dangerous, but I suffer from light sensitivity. After a night drive I’m in pain from these stupid effing ultra bright white head lights for like an hour. And when someone pulls up behind me at a light, especially in an SUV or truck the light from my side mirror blinds me. It’s dangerous, stupid and annoying. A law needs to be made about this or it will just keep getting worse.

B.4598 September 27, 2025 — Stone Mountain, GA

Im a delivery driver in the atlanta metro area and I come home with migranes almost every single night due to modern cars bright LED lights particularly the countless drivers that drive with their highbeams on as if the normal headlights werent enough as is. I have no issues with halogen bulbs, the yellow light does not irritate my eyes, but the LEDs have become extremely problematic. Furthermore on dark dimly lit streets when cars like this come whizzing around a corner out of nowhere it poses a huge safety risk because I become temporarily blinded by the LEDs and it becomes incredibly difficult to see the road in front of me. The issues only getting worse and somrthing needs to be done!!!

B.4599 September 28, 2025 — El Dorado Hills, CA

Led Headlights must Go! It’s Dangerous for Everyone on the road! There were 4 huge trucks driving behind me and other drivers and nobody could see around us and caused an accident! When you have led’s coming at you and behind you there’s no to look to avoid them! Save lives BAD LED HEADLIGHTS!

B.4600 September 29, 2025 — Rogers, AR

“Every morning I drive to work at 5:30 am. There’s no chance for the sun to be out and I drive by at least 4-5 drivers with their led hi-beams on. There’s this bridge I have to go across and every time there’s someone there to blind me and I almost run off the bridge at least once a week.

October 2025

B.4601 October 4, 2025 — Greenwich, CT

I am 73 years old, and my eyes are already growing sensitive to bright lights and glare. The new white lights are a hazard, as they further compromise my vision unnecessarily. These lights, coupled with a noticeable increase in the number of drivers in my hometown using their bright lights without dimming when approaching another car, creates an untenable driving situation.

B.4602 October 4, 2025 — Medford, MA

Warm light is less blinding.. LEDs are cold light. If you are a photographer you’d know. New tech is not always good tech.

B.4603 October 8, 2025 — Matawan, NJ

I thought this was a me issue, I clearly see it is not. I’ve had to come to complete stops on the road several times because of cars coming towards me with extremely bright lights, the cars in the rear view are no better. I’m always wondering do they know their lights are blinding, I can’t possibly be the only one. I am not.

B.4604 October 10, 2025 — Roswell, GA

Just had to come to a complete stop making a left turn because the dam truck made the inside of my car disappear. I used to be a trucker and even a normal cars led lights would blind us

B.4605 October 10, 2025 — United States

If I die in a car accident because some insecure shithead decided that only they should be allowed to see while driving, my ghost is haunting all of you with LEDs

B.4606 October 12, 2025 — Roswell, GA

I cannot believe how dangerous it is to drive at night nowadays. Why the hell has Congress not acted on this? Doesn't anyone on here know a Senator or member of the House who can draft a bill? Please, whoever is reading this, do everything you can! I try never to drive at night because of the idiots who manufacture/use blinding headlights. Thank you.

B.4607 October 13, 2025 — Taunton, MA

I drive an SUV so the issue has nothing to do with being in a sedan/being lower to the ground -- these new lights are just awful, period!

B.4608 October 14, 2025 — East Providence, RI

I hate the super bright headlights, it's like getting flash banged while trying to drive at night. I always think think it's idiots driving with their highbeams on, but it's just their headlights. It's absolutely terrible!! Nobody needs lights that bright. Half the reason you have the headlights is so other people can see you coming, but that's no good if you're blinding them. Ban those things!!

B.4609 October 16, 2025 — Milwaukee, WI

{"videoUrl":"https://stream.mux.com/f7IYDEFtbSMlBOZgVkmsuCdiy6lx86AxsyOkJO4uBvI","cloudflareUid":"dbcd7f12d9d8c96984d4aaed1954df36","muxAssetId":"2AfpNdFH016v015XMjj5ZbhDAT026AAqQN02vqybgeJBIzQ","muxPlaybackId":"f7IYDEFtbSMlBOZgVkmsuCdiy6lx86AxsyOkJO4uBvI","muxPlaybackUrl":"https://stream.mux.com/f7IYDEFtbSMlBOZgVkmsuCdiy6lx86AxsyOkJO4uBvI","muxThumbnailUrl":"https://image.mux.com/f7IYDEFtbSMlBOZgVkmsuCdiy6lx86AxsyOkJO4uBvI/thumbnail.jpg"}

B.4610 October 17, 2025 — Steelville, United States

My wife and I travelled 22 miles this morning while I took her to the Elementary School where she teaches. The driver behind me was in a large Ford pick up truck. He had six headlights on it, and they were incredibly bright white LED lights. I was blinded so badly I could not see correctly to determine where the cars were that were meeting me. This is a serious problem, whethere you are blinded in your rear view mirror, or from the cars meeting you, or both. I finally just had to pull off and let him go by, before we had a serious accident.

B.4611 October 19, 2025 — Kingsville, Canada

I am would like to request clarification regarding the responsibilities related to the regulation and enforcement of vehicle lighting compliance requirements. Specifically, I seek to understand who holds the primary responsibility for ensuring adherence to applicable vehicle regulations: • The car dealer (upon sale of the vehicle), • The car / truck owner (after purchase), or • Legal enforcement authorities like the licensing body A clear understanding of this responsibility is important for both compliance and accountability. I highly dought that the owners of pickups that raise the height levels to look cool, don't follow the head light re-aimed or turned to proper safety requirements for on coming traffic. That would also include the added off road lighting to other SUVs or laser sharp lighting of luxury sedans. Government provides guidance or reference for new vehicles that is relevant legislation or policy outlining this matter yes. But who enforces them the police ? Who tests for compliance license renewal agency ? Thank you in advance for your assistance. I look forward to your response.

B.4612 October 20, 2025 — Kent, WA

In my area many drivers without factory "blinding headlights" are now using high beams at all times. Many more have "upgraded" to blinding lights. Like others I am often completely blinded while driving. I have counted up to 6 seconds on the freeway. 6 seconds at 60mph= 528 feet. 528 feet = 1/10 of a mile. That's 1.5 football fields.

B.4613 October 20, 2025 — Louisville, KY

These lights literally make it to where I no longer am able to drive at night.

B.4614 October 20, 2025 — Louisville, KY

I can't drive at night now due to these LED lights. They are in ALL new vehicles and people are also putting them in older vehicles. They need to be illegal to sell for vehicles and manufacturers should be fined heavily for putting them in new vehicles. Please listen to us!!!!!!!!!!

B.4615 October 21, 2025 — Calumet, MI

The blinding lights need a level of control as the owners of these vehicles leave the high beams on always.

B.4616 October 21, 2025 — Detroit, MI

Led lights are starting to be the only type of light bulbs on shelves. They give me head aches, vertigo, and eye strain. I have to work under them for 50 plus hours a week, and then turn around get blinded my them in traffic. The law enforcement is worried about phones as a distraction when they need to BAN LED LIGHTING! They are causing more harm than good!

B.4617 October 21, 2025 — New York, NY

I have had to stop driving at night, which is a huge problem because that's when im on my way home from work. On more than one occasion, I was totally blinded by the headlights of on coming traffic and the traffic behind me. I get very nervous when night time catches me out driving. Whoever thought such bright lights were a good idea must have a chauffeur.

B.4618 October 21, 2025 — United States

https://landline.media/blinded-by-the-light-are-newer-headlights-putting-drivers-at-risk/

B.4619 October 22, 2025 — Avondale, AZ

I just absolutely hate these incompetent people on the road driving with their brights on I remember people used to be pulled over, over this but now it's completely normalized, I'm from Arizona and you

can only imagine the combination of idiotic drivers and narcissistic bright users is only gonna make the road much for dangerous for Arizonans.

B.4620 October 23, 2025 — Edmonton, Canada

Blinded by oncoming and traffic from behind via reflection. It hurts my eyes, I have to try to not look at oncoming traffic which is dangerous in itself and it blinds you for a second which is also very dangerous. Bring back the soft lighting we had before or regulate how leds are installed. And no led installations in halogen bulb headlight housing.

B.4621 October 23, 2025 — Las Cruces, NM

I drive a fuel truck, and I find it absolutely ridiculous that i am sitting a good 8 or 9 feet up and am getting blinded more than a half a mile out. The closer you get the worse it is.

B.4622 October 24, 2025 — Lexington, SC

The standard for testing the safe limits of brightness of headlights unfortunately no longer applies, because the headlights of the past were of a different (warmer) part of the light spectrum, and the new headlights are much cooler, which means they require much more lumens to be detected by the old testing equipment. It's causing problems not just in the aging population, but I know at least 5 friends that are under the age of 50 that complain of how difficult it now is to drive at night, and that as a result, they are avoiding being on the road after dark.

B.4623 October 24, 2025 — San Diego, CA

I care about this issue because of personal experience with these lights while driving, and also because the LEDs in general have negative effects including on the retina of the eyes.

B.4624 October 25, 2025 — Hubertus, WI

Automatic high beams also need to be outlawed. They dont work properly and the driver must be held responsable for the use of high beams, there are laws to enforce about proper use of them.

B.4625 October 25, 2025 — Laguna Beach, CA

This is one issue we all can agree upon. LED headlights have become a driving hazard at night and on rainy days. Many times I have to put my hand up to block blinding headlights while driving, slow down and wait till I can see again. I try not to drive at night, but on overcast or rainy days it can be just as bad. We need to bring back soft, warm headlights

B.4626 October 26, 2025 — West Bloomfield, MI

Driving at night has become increasingly dangerous because of the new cars that come with LED headlights. Anytime a car with them is coming at me I have to look off the road into the bushes or close my eyes completely. Not to mention driving in hilly areas makes the problem so much worse. I thought to my self maybe im just getting older but then i see a car or truck with halogen (old style) lights and i can see the road infront of me just fine and dont even have to squint. I feel this also puts pedestrians at cross walks in danger because say i have to turn left at a intersection and the cars to my left have LED lights while im turning i can barly see the road im turning onto let alone if there was someone trying to cross the road. Its absolutely astonishing that LED lights where ever allowed in the first place as a standard option on cars. Cant tell you how many times that a oncoming car is a foot or two over the line into my lane but i cant see untill they are literally passing me. Add auto high beams and cornering lights to cars with LED headlights and its just a joke how bad they actually work at turning off in time. Oh and not mention all my mirrors are completely unusable at night because they have to be aimed all the way down due to cars behind me with LED headlights.

B.4627 October 27, 2025 — Fox lake, IL

Unregulated aftermarket LED headlights and new vehicles with LED headlights make driving at night more danger than need be. Sure the driver can see more but what are you hoping to see? When passing these vehicles I am blinded temporarily and it scares me. How is this legal?!

B.4628 October 27, 2025 — Palm springs, FL

Headlights are so bright in new cars that in the last 3 years, I have never been in a car at night without getting a headache from all of the lights shining in my eyes. My friends have said someone needs to

invent sunglasses that only work on headlights because driving at night is unreasonable. My breaking point was someone driving behind me on 295 had headlights so blinding all 3 of my mirrors were white-ed out and I literally could not see in my blind spots. I am not exaggerating or being dramatic, both of my side mirrors and rear view mirror were just pure light reflecting back. This driver stayed stayed behind me for several songs and I cried from the pain of lights beaming into my eyes & fear of not seeing drivers around me, before I had to blindly move into the right lane (the highway ahead was empty so it was not busy) and hoped that no one was there as I physically could not take the lights going into my eyes anymore. The highway was indeed empty so everyone was safe. This experience was not the first I have had like it, and so I have sworn off driving at night hindering my own social life because I would rather not be on the road then subject to lights so bright that I am not the safest driver I can be. I am begging our government to help us & revisit the regulations around headlights.

B.4629 October 28, 2025 — Blue Springs, MO

preach cuh

B.4630 October 31, 2025 — Cleveland, OH

Too damn bright! Like helloooo McFly!! ....(D.o.t.) What are you? A bunch of slackers?

November 2025

B.4631 November 4, 2025 — Lancaster, NY

Having astigmatism and having to drive at night with LED headlights blinding me from the front and behind makes it nearly impossible to drive at night

B.4632 November 4, 2025 — Lexington Park, MD

As someone who often commutes in rural areas at night due to shift work, I have found LED lights to be my biggest enemy on the road. They make me uncomfortable when driving, and I much prefer the incandescent bulbs of older cars to the new, honestly just as effective, if not less than effective LEDs of newer cars.

B.4633 November 5, 2025 — Asheville, NC

The led headlights are very blinding. Sometimes I can't even see the road in front of me when a car with led's is coming toward me. It's hard to believe congress has not done something before now for the safety of drivers like they do with everything else.

B.4634 November 5, 2025 — Potosi, WI

The fact that I AM constantly caused PHYSICAL EYE PAIN multiple times a day because morons allow or install LED headlights on vehicles is just mind blowing. How have we regressed so far that manufacturers and buyers have ZERO EMPATHY for other drivers. Not to mention the eye problems people will have in the future from all this super bright LED (blue) light everywhere we go. THIS IS ONE OF THE DUMBEST THINGS HUMANS HAVE DONE. STOP LED HEADLIGHT PRODUCTION NOW.

B.4635 November 6, 2025 — Honea Path, SC

I'm so passionate about this I feel like I'd vote for anyone who would ban the bright headlights. It's so dangerous, especially if you have an astigmatism.

B.4636 November 6, 2025 — Nehalem, OR

Thanks for voicing this! I thought it was just me! I even try to communicate to drivers by switching on and off my brights, but no response.

B.4637 November 7, 2025 — panama city, FL

These lights are a serious problem for people with epilepsy,seizure disorders and migraines. Emergency LEDS are also a serious problem

B.4638 November 8, 2025 — Marquette, MI

You don’t need to have astigmatism to be blinded by these new headlights. We need there to be regulation on how bright lights on a car are allowed to be. It’s a safety issue and we all know it.

B.4639 November 9, 2025 — Decatur, AL

I don't often drive at night, but I'm starting to actively avoid doing so when possible as the LED headlights have become so bright that I can't see the edge of the road anymore. it's insane to think that blinding other people with what's effectively a pocket sun is any safer than having lights too dim to see at all. I have seen people get into head on collisions and have almost ran off the road myself from being blinded. Something needs to be done

B.4640 November 11, 2025 — Hurricane, WV

I CANT FUCKING SEE AT NIGHT!!! THE LIGHTS ARE TOO BRIGHT

B.4641 November 13, 2025 — Montague, MI

Being flashed all of the time with these ultra bright LED lights causes me genuine anger towards the people driving the cars. It hurts and most of the time I have to move my visor down to block seeing the cars in front of me. It doesn’t help when unnecessarily large trucks have these lights as well since they more easily blind shorter cars. Lights on cars need to be more regulated - they’re getting ridiculous.

B.4642 November 13, 2025 — Thornton, CO

Driving at night is difficult already, these brighter headlights and after market headlights make it more difficult. Often I am blinded, cannot see and see spots after. These brighter lights are causing more safety issues and harm. We need to adopt the auto adjust headlights that Europe has but its gone on so long that I fear it will be hard to undo. I.even see people using fog lights, off road lights, colored lights and aftermarket light bars. Noone cares about fellow drivers anymore and driving has become more dangerous than ever. When are automakers going to change this ? Its unfortunate that negative statistics, including death, may be the only way to get thier attention. Its almost worse than texting while driving...

B.4643 November 14, 2025 — Jackson, CA

I don't understand why it's ok to allow bright headlights. It's a public safety concern that needs to be addressed. Driving home in the winter is getting more and more dangerous with the Leds glaring off of the rain. I'm afraid.

B.4644 November 14, 2025 — Las Vegas, NV

Night driving has become more and more difficult because of the bright headlights. I usually drive in the middle lane on major streets, to be further away from oncoming vehicles. I now use yellow sunglasses at night, which makes the brightness more bearable. When driving in my neighborhood, where the road is narrow, it's very bad. I often have to pull to the side of the road because I am so blinded by the oncoming, brighter headlights, that I can't see the road. Then, I need to wait a bit for my vision to adjust back to normal. Excessive headlight brightness has also caused occasional eye strain and headaches. This is very frustrating and debilitating. If he's with me, I sometimes need to have my husband take over the driving. This is particularly bad with the bright blue lights. I never had a problem with the way headlights used to be. Seems like the car designers never heard of - "If it ain't broke, don't fix it!" Let's go back to what worked before, please!

B.4645 November 14, 2025 — Millington, TN

The ever increasing headlight glare that we have to put up with while driving at night is simply outrageous! This is a glaring safety issue that our government simply appears to ignore.

B.4646 November 14, 2025 — Windsor, CT

The new blinding led lights are hazardous. I was so severely blinded by them that I almost drove off a small country road from these lights on an oncoming car. Is our government going to wait until people die to ban these hazardous headlights? They must also be removed from cars that already have them installed!

B.4647 November 15, 2025 — Newton, MA

I am 29 years old. I have 20/20 vision and have never had any trouble seeing in low light. I've always enjoyed driving at night. Yet, in recent years, it has become increasingly harrowing due to the unbelievable brightness of most headlights. At times, I don't feel safe on the road at night. I'm really fed up. This is urgent; lives are at stake.

B.4648 November 15, 2025 — Round Lake, United States

I agree with those voicing deep concern over too-bright headlights, police lights, etc. and find them to be an increasing widespread hazard. A ban would be welcome.

B.4649 November 16, 2025 — Adrian, MO

I am always driving at night on rural two lane blacktops when my shift ends at midnight. I am an older lady and work full time as a guard. It is very hard to see when cars and trucks pass by on this dark road and these newer type headlights are extremely blinding. This is painful for my eyes and I have to nearly come to a stop and look away toward the ditch when these vehicles pass by, and then it becomes hard to adjust my eyes back to the darkness. Additionally, when cars come up behind me at night with bright headlights I have to speed up to try and put more distance between my car and the approaching vehicle. This makes my drive more dangerous because there are a lot of deer and animals that tend to cross the road at night. But I have to drive this way because the bright lights are reflecting in my mirror and blinding me. I don't feel safe in trying to avoid close proximity with these bright headlights. On my drive home I also travel on US interstate 49 in order to get to the next town on my route. During my drive time on this 4 lane highway it is becoming more common that the drivers in the oncoming lanes are flashing their bright lights appearing that they are blinded or confused by the lights of oncoming traffic and can't distinguish if drivers are using their high beams or low beams. This behavior in turn blinds me more as I meet these passing cars. This driving home 5 nights week from work takes a toll me and strains my eyes considerably and puts my safety at risk. I would like to see the headlight standards changed to prevent these hazards and more testing done to include eye safety standards and more information on the measured effects of the electromagnetic field with these new brighter LED headlamps and their use and effects on the environment. Additionally, my vision is bothered considerably by the blue street lamps that are very blinding and distracting. I tend to see more of these in various places. All of these type of bright blue based LED lights are not pleasant and cause side effects such as stress headaches and an increase in accidents. I think the visually impaired and many older drivers are especially handicapped by these lights and are prevented from doing normal daily activities. This problem needs to be examined and more regulation in place that is mindful of consumer safety on the road.

B.4650 November 16, 2025 — Austin, TX

I drive professionally driving students long distances. I have repeatedly flashed my bright lights at drivers thinking they had there bright lights on, when in fact they would show me they didn't. They just have LED headlights which are blinding.

B.4651 November 16, 2025 — Casa Grande, AZ

Driving at night has become difficult and dangerous due to the blinding effect of very bright led lights of on coming vehicles.

B.4652 November 16, 2025 — Cleveland, OH

The bright LED lights on cars is blinding and is a SAFTY hazard making it difficult to see the road when they are coming at you.

B.4653 November 16, 2025 — Dayton, OR

I purposely avoid driving at night because of more intense headlights on so many cars now.

B.4654 November 16, 2025 — Grimes, IA

These headlights are blinding - makes it SOOO dangerous & difficult to drive at night.

B.4655 November 16, 2025 — Houston, TX

Drive at nite and the lites hurt my eyes

B.4656 November 16, 2025 — Indianola, IA

The headlights are used to transfer energy from car to car like direct energy weapons . Have pictures to showing light transfer.

B.4657 November 16, 2025 — Los Angeles, CA

I care about this issue deeply because I've noticed from personal experience that the effects of this light really causes a lot more anxiety, nausea, and headaches more than I ever have felt before, and really not understanding why or where it was coming from. This information definitely confirms what I Have been suspicious of for many many years thank you for this, and I will spread the word.

B.4658 November 16, 2025 — Louisville, KY

I am no longer able to drive at night due to the glaring lights hitting me in the eyes . They have literally blinded me numerous times hitting me right in the eyes, whether driving behind me or head on. Accidents at night are a frequent event in the area in which I live. Not everyone has the option not to drive at night as they must get to work or other required events. Please support the decision to require lessening the brightness of these headlights before more people are killed or seriously injured! Betty Louisville, Kentucky

B.4659 November 16, 2025 — Miami, FL

I'm sixty four and after cataract surgery LED headlights are way too bright and bothersome to safely drive at night…

B.4660 November 16, 2025 — Ocean City, NJ

I am 79 now and even though my eyesight is good I am finding it very difficult since the advent of these ultra bright headlights

B.4661 November 16, 2025 — Ocean City, NJ

I am 79 years of age now and even though my eyesight is still good I am finding it more and more difficult to drive at night with the advent of these ultra bright headlights on the new cars…I have given up highway driving at night as these lights completely blind me which makes it difficult to visit my grandchildren who live almost 2 hours away as I have to plan to NEVER leave for home when I know I will have to travel in the dark. Also, these headlights are so blinding in my rear view mirror that I must flip it up and also aim my side mirrors away which is very dangerous. I have taken to turning my drivers side mirror far enough out that I hope it reflects back into the eyes of the driver who is passing me on my left thus an

B.4662 November 16, 2025 — Saint Charles, MO

{"videoUrl":"https://stream.mux.com/pQtSyiJPx9AyXf3jvyRq2TuXOzlFGet6zeUj9fOB2HU","cloudflareUid":"245690545a3fd14fd98e2cbbc6cb21d7","muxAssetId":"cM028jCG02DlpRO15CWzTTjc7RcP2hX01ihR01zPde5H1WM","muxPlaybackId":"pQtSyiJPx9AyXf3jvyRq2TuXOzlFGet6zeUj9fOB2HU","muxPlaybackUrl":"https://stream.mux.com/pQtSyiJPx9AyXf3jvyRq2TuXOzlFGet6zeUj9fOB2HU","muxThumbnailUrl":"https://image.mux.com/pQtSyiJPx9AyXf3jvyRq2TuXOzlFGet6zeUj9fOB2HU/thumbnail.jpg"}

B.4663 November 16, 2025 — San Antonio, TX

Not only do LED headlights endanger drivers on the road but LED lights contributing to light pollution have had a catastrophic detrimental effect on our natural world as well as on the future well being of human society by denying our children the ability to be inspired by the awesome and mystifying nature of the heavens by limiting the ability to see such natural wonders in all their splendor to the privileged and the remote places away from cities where few of our future generations have a chance to see such God given miracles of our universe.

B.4664 November 16, 2025 — San Bernardino, CA

The bank is sending me a new debit card. I will make a donation when my card arrives. I hate LED lighting! It makes me sick.

B.4665 November 16, 2025 — San Deigo, CA

LED are blinding when driving at night. Please stop producing them in cars and street lights.

B.4666 November 16, 2025 — Santa Rosa, CA

Aiming sealed beam headlights used to be a required part of mandatory vehicle inspections in California. Can't the newer headlights be properly aimed toward the right?

B.4667 November 16, 2025 — Sebastian, FL

I care because I drive. The problem is not only the brightness, but the color temperature. I have noticed that the brightness of the normal headlights on some cars is the same as the brightness of the high beams. I have heard/read that some countries have self-dimming headlights and that this might be a solution for us here in the USA. That is a non-solution; furthermore, in my experience, the automated headlight controls are not that accurate.

B.4668 November 16, 2025 — Stone Mountain, GA

Blue light resembles strobes all is annoyance to true vision - all about money

B.4669 November 16, 2025 — Tucson, AZ

I drove home at night last week, I thought my eyes were actually failing me, I lost vision with the oncoming traffic and the horrific lights that literally blinded me, I could barely see the huge street signs at main intersections, I thank God for one thing, it isn't just me , these headlights, especially in trucks , should really become a traffic hazard, horrible, horrible injurious injustice placed on the American people who had no say

B.4670 November 16, 2025 — Tucson, AZ

I've been driving all sorts of vehicles since the mid 1970s, both as a civilian and in the military. The headlight situation we have on today's roads kills people. A modern society should have the sense to make the situation less deadly, make the lights less blinding.

B.4671 November 16, 2025 — West Islip, NY

I drive at night. Just last night in my own suburban neighborhood I had to pull over, stop the car and avert my eyes to my lap- until a car drove past . The car was 2 blocks away. I waited 15 - 30 seconds before I could resume driving on my street. Ive NEVER seen such blinding light emitted from a car headlight... something wrong is happening !

B.4672 November 16, 2025 — shrewsbury, MA

This is actually one area where regulation is severely needed. As a sedan owner with non LED lights it’s a real issue. Completely blinded every time I have to drive at night. And the trucks that are higher up and the newer SUVs with a whole line of lights on their grill... it’s maddening.

B.4673 November 17, 2025 — Herriman, UT

There have been multiple instances where I've nearly been in an accident because I've been blinded by someone's aggressively bright headlights. In rainy conditions its 10 times worse.

B.4674 November 17, 2025 — Santa Cruz, CA

My eyes have gotten significantly worse since the 'bright blue lights' have been installed. Automakers must comply for our health and safety! No blinding bright blue lights...

B.4675 November 17, 2025 — Spokane, WA

LED lights were the worst invention for headlights. They just blind you.

B.4676 November 17, 2025 — Spokane, WA

My wife asked the city to put a shield over the city street light so our home was not illuminated with LED, this really helped. Driving at night is terrible, often I need to hold my hand up to block the oncoming LED vehicle headlights, these LED lights are a violation of my human rights and change is needed. I nearly purchased LED’s for my vehicle so I could see better but I can’t add to the problem so good conventional headlights will remain on our vehicles as we cannot create discomfort for others

on the roads. We changed our indoor lights to incandescent and enjoy the warmth and sunlight like quality.

B.4677 November 17, 2025 — san fernando, CA

the lights are absolutely blinding and i no longer feel safe driving at night. the older yellow lights are no a problem.

B.4678 November 18, 2025 — Fairfax, CA

Blinding headlights are a menace! And they are dangerous. If most drivers took the time to lower them for an oncoming car (which they rarely do), it would be different. On dark rural roads I sometimes have to actually stop so I don't drive off the road. Not only that, if there is an oncoming car and one behind you shining in your side view mirror, it's a nightmare.

B.4679 November 18, 2025 — Pasadena, CA

I used to think I was having a problem with my eyes until I found out from my brother that these were new headlights being manufactured for the new cars. With so many drivers tailgating and pulling right up to your bumper, the bright lights shining off my rear view and side view mirrors are painful and blinding. It's beyond comprehension how this headlights were approved to install on cars. If a car is coming towards me, I have to look off to the side to avoid being blinded but then that sacrifices safety on the road. Damn if you do, damn if you don't. So glad for this petition.

B.4680 November 18, 2025 — des moines, IA

I find myself hating my drive to work in the morning. More and more super bright headlights blinding me every day. Not all LED setups are bad, some are tolerable. The problem I run into the most is the hillbillies in their lifted trucks with aftermarket LED headlights and fog lights. Newer Chevy and Ford trucks are also horrendously bright - especially if a lift kit has been installed. It's damned frustrating and I'm tired of seeing spots.

B.4681 November 19, 2025 — Berkeley, CA

No matter how well oncoming drivers can see with their super bright blue light LEDs, I don't think they are safer if their lights are blinding me.

B.4682 November 19, 2025 — Las Vegas, United States

It is ridiculous these new BLINDING headlights even pass inspection. I am a Senior and my kids and Grandkids complain too. So it is a hazzard for all ages!!

B.4683 November 19, 2025 — Santa Rosa, CA

I just had to have my eyes operated on last week to remove cataracts. I understand there is a growing rate of cataract surgeries as well as those who now have macular degeneration because of LED lights. My eyes have become increasingly light sensitive now because of LED lights. I have a very hard time driving at night. I have heard of truck drivers who try to drive with yellow tinted glasses to protect against the LED oncoming traffic lights, but the glasses make they drowsy. So they can't use them. Something must be done to stop such bright lights before more accidents happen and more eye surgeries are necessary.

B.4684 November 19, 2025 — St. Petersburg, FL

An industry has grown without any regulation. I witness that people buy cheaper lights to use to save money, that are totally inadequate for the task. People are using light bars which are flood lights NOT approved beams for traffic use. This needs to be regulated, we NEED YOU to make this safe please.

B.4685 November 20, 2025 — Honeoye Falls, NY

I shouldn't be having problems driving at night, but these newer led headlights are genuinely hard to tell if the high beams are even on or its just their low lights. LED headlights are way too bright and allowing people to attach light bars makes it even worse.

B.4686 November 20, 2025 — Sacramento, CA

During late fall and winter months, it's very difficult for me to drive anywhere, even nearby grocery stores.

B.4687 November 20, 2025 — St Augustin, FL

{"videoUrl":"https://stream.mux.com/Nf9u6WR5CAhqOmoWKUSL02cG00JaUawxGdzlTmdGvYgg8","cloudflareUid":"c1e44408b91564cb9f295c09efc5e5ea","muxAssetId":"9Fd021yTN502UkOFezktGMDqYqh9KG002J743X7btgpRBQ","muxPlaybackId":"Nf9u6WR5CAhqOmoWKUSL02cG00JaUawxGdzlTmdGvYgg8","muxPlaybackUrl":"https://stream.mux.com/Nf9u6WR5CAhqOmoWKUSL02cG00JaUawxGdzlTmdGvYgg8","muxThumbnailUrl":"https://image.mux.com/Nf9u6WR5CAhqOmoWKUSL02cG00JaUawxGdzlTmdGvYgg8/thumbnail.jpg"}

B.4688 November 20, 2025 — Syracuse, NY

If nothing else, not allowing blinding bright low-beam headlights would be a help.

B.4689 November 20, 2025 — Vancouver, Canada

New car's headlights are dangerously bright. Headlights are supposed to make driving at night safer not more hazardous

B.4690 November 21, 2025 — Columbia, SC

When I drive during the day or night, I have to leave the anti-glare switch on my mirror down because so many vehicles have painfully, distractingly bright lights. Many of my associates have mentioned their migraines are also exacerbated by these bright white LED lights at night. Others have mentioned to me "I realized that.. LEDs are why I hate driving at night now. I don't feel safe."

B.4691 November 21, 2025 — Stephens city, VA

I get really bad headaches and sometimes migraines when I drive at night. Lights are so bad that I often get spots in my vision because of how bright they've gotten. Please regulate these overly bright lights

B.4692 November 21, 2025 — Youngstown, OH

They keep getting brighter and brighter. There needs to be a limit. Otherwise we'll soon have headlights that start forest fires and cause permanent retina burns. If someone needs that much light, put the lights under the car, facing the ground, rather than pointing at eye level.

B.4693 November 22, 2025 — United States

I absolutely HATE bright headlights. I have blue eyes, and people with blue eyes are known to be sensitive to bright lights. It makes me beyond angry, especially when I'm being tailgated by an idiot in a huge truck and all I can see in my rear view is the grill of their truck and the blinding headlights.

B.4694 November 23, 2025 — Sanford, FL

Please ban blinding headlights and blinding street lights. So many times I have encountered drivers blinded by blidning headlights weaving on the road. I have had to pull over because of blinding headlights destroying night vision. Blidning street lights make it very difficult to see at night because they cause pupils to constrict and then right after passing them it is hard to see. Please ban these kinds of lights and make driving safe again.

B.4695 November 24, 2025 — Arroyo Grande, CA

Its dangerous, how are these not illegal?

B.4696 November 24, 2025 — Minnesota, MN

I work 6 to 11 at my job (5 Below staff member.) Coming home at night and being utterly blinded on the drive home is becoming a daily occurrence. And it needs to end. I don't feel safe on these roads.

B.4697 November 24, 2025 — Sacramento, CA

I'm a truck driver, I drive line haul night I've been complaining about this specific issue for the last seems like the last 6 or 7 years it's been escalating, seems like the new factory vehicles coming out every year were the main culprits eventually after market high performance automotive headlamp manufacturers of different brand names jumped on the band wagon flooding the shelves at all the auto part stores, online, etc. It's flat out rediculous now by the time I get off work in the morning my retina's are on fire. Those factory and after market projector headlamps should also be banned, is

going to give someone an epileptic attack the way the light changes colors and floats up and down. I notice not only the new headlamp bulbs out of control bright, but some people are now driving around with after market off road light bars mounted on their grills, I can't see a thing not even the fog line. Let's bring the bright headlamps back down to basics that's safe for everyone and keep it enforced so it stays that way, that also means no more off road light bars unless they are covered up..

B.4698 November 25, 2025 — Abingdon, VA

It is increasingly unsafe to drive at night. Super-bright LED headlights make it almost impossible to see the road in front of me, which means that it's impossible to see if there are any obstacles (animals or pedestrians) in the road. LED headlights should be banned, and the automotive industry must take accountability for the danger into which they have put everyone on the road.

B.4699 November 27, 2025 — Henrico, VA

I am fully capable of driving with having a seizure disorder, doc verified everything before allowing me to drive. I absolutely cannot drive past sunset. Ever. Even when I'm in the passenger seat I have to wear sunglasses. Let me repeat I HAVE TO WEAR SUNGLASSES AT NIGHT BECAUSE OF THESE LIGHTS. My granny and grandpa can't drive at night. My fiancé who has no ailments gets migraines after driving at night. It's awful. People have been killed, car accidents in intersections, not being able to tell how far a car is, literally just being blinded by light every time I leave the house. I'm not sure about you but if you have seizures, these lights are extremely dangerous. They have caused seizures before when I was not medicated. Please take this seriously the children with epilepsy at younger ages are more likely to die from a seizure so please for the love of God and our country, make some changes for your people. I really miss going out at night and being able to drive to pick up a $2 sonic drink, go to the ocean to hear the waves. Drive when I need to let off steam. Travel out of town to see family. All of this is no longer a possibility. It may not seem like much to some but our freedoms have been stripped from our lives. Please take this seriously- sincerely SICK OF THIS

B.4700 November 28, 2025 — East Patchogue, NY

I drive a regular car and the suvs and other higher vehicles actually blind me on the highway in both directions but are especially dangerous when they are directly behind me. ! So unsafe and hurtful. Even other regular cars going in the opposite direction on highways and streets with the Bright white lights are harmful and hurtful. So relieved someone is alleviating this dangerous problem.

B.4701 November 30, 2025 — Arlington, MA

LED lights kill.

December 2025

B.4702 December 3, 2025 — Monroe, MI

MY EYES -that one sponebob fish

B.4703 December 3, 2025 — SC, United States

These LED headlights are a constant nuisance! Something needs to be done! I get blinded from my side mirrors as well as on-coming traffic forcing me to adjust my side mirrors to the point that my mirrors become useless. The fact that these lights have not been taken care of yet after being available for so long is insane.

B.4704 December 4, 2025 — AZ, United States

LED auto headlights make driving at night dangerous and need to be banned. I've been complaining about this for years, and it seems each year it gets worse with more new cars on the road. Thank you!

B.4705 December 4, 2025 — Chapel Hill, NC

I'm a runner and walker in addition to being a driver and I'm blinded by LED headlights which most approaching drivers do not dim.

B.4706 December 4, 2025 — Stamford, CT

I have to wear sunglasses at night when I drive because modern headlights are blindingly bright. It is dangerous and intrusive. I don't even know how this happened I thought there were regulations about this sort of thing.

B.4707 December 5, 2025 — Calgary, Canada

Bright Headlights are blinding and very dangerous! No one needs these ! They are unsafe and cause accidents!

B.4708 December 7, 2025 — Concord, NC

{"videoUrl":"https://stream.mux.com/dOZIzA98muBe6UZC00NZa00z074v369EZLzjS01EVVbUTw","cloudflareUid":"598651b4e52d0af65ad1e83f2042b54c","muxAssetId":"zZn84LZ2lEgKUtoJb702ht32C28Lpse2VzhSY6FbgczM","muxPlaybackId":"dOZIzA98muBe6UZC00NZa00z074v369EZLzjS01EVVbUTw","muxPlaybackUrl":"https://stream.mux.com/dOZIzA98muBe6UZC00NZa00z074v369EZLzjS01EVVbUTw","muxThumbnailUrl":"https://image.mux.com/dOZIzA98muBe6UZC00NZa00z074v369EZLzjS01EVVbUTw/thumbnail.jpg"}

B.4709 December 8, 2025 — Hendersonville, NC

For example, tonight, for a few seconds, I Couldn't See The Road At All!!!!

B.4710 December 8, 2025 — Portland, OR

you can never see anything . always squinting to be able to see and on top of it everyone who has leds always keeps there high beams on just because they feel like it.

B.4711 December 9, 2025 — Cincinnati, OH

They are too dang bright

B.4712 December 9, 2025 — Fairbanks, AK

I live in Alaska where darkness is a thing that lasts for months and driving at night is not optional. I have been blinded countless times by overly bright headlights and "Moose Lights". There have been times that I have been forced to pull over and stop because the light that I passed was so bright that it literally blinded me and it took quite a few seconds for my vision to return enough to drive. In addition, I had spots in my vision directly after these incidents that have not gone away. Each time equals more damage and I am tired of being assaulted by lights that should not be allowed on motor vehicles.

B.4713 December 9, 2025 — Kenai, AK

I work night shifts. I have a diagnosed astigmatism and driving to work every night literally blinds me. I'm afraid to drive and the blinding headlights don't make anything better. I just want to drive safe again without the fear of crashing..

B.4714 December 9, 2025 — Marlboro, NJ

Not sure why there needs to be a petition. This issue is clearly one-sided. Standardized the darn bulb!

B.4715 December 9, 2025 — North Tonawanda, NY

Regs need to be changed, manufacturers are blatantly gaming the system to have much brighter headlights than they are supposed to, and brighter than most people can handle. It has made driving at night less safe.

B.4716 December 10, 2025 — Austin, TX

I can't see at night

B.4717 December 10, 2025 — Chatham, MA

just tired of being blinded while driving at night. It's not bad enough that the headlights are piercing but most also augment the pain by driving with the super white LED fog lights. I had to come to a dead stop recently in the road after turning the corner onto my own road as I could not see any of the sharp curve in the road ahead as a vehicle approached the intersection from the opposite direction.

B.4718 December 10, 2025 — Coal Township, PA

THESE NEW LITES ARE REALLY A BLINDING HAZARD. THEY ALSO DO NOT LIGHT THE ROADWAY THE SAME AS THE OLD HEADLIGHTS. THEY ARE REALLY A STEP BACKWARD UNLESS YOU ARE IN THE VEHICLE REPAIRE BUSNESS. THANK YOU!!!!!!!!!!!!!!!!

B.4719 December 11, 2025 — Newburgh, NY

I'm a healthy adult male without eye issues; and over the last year or two I have been blinded and dazzled nearly every time I drive at night. New model cars have low beams that are indistinguishable from bright lights on a car less than five years old. This is literally a public safety hazard.

B.4720 December 11, 2025 — Scappoose, OR

Bright headlights are impeding on my ability to travel freely. Something must be done.

B.4721 December 11, 2025 — Van Nuys, CA

I can’t drive at night without wearing dark sunglasses. Even walking with LED headlights coming toward me is disorienting and very unsafe. LED headlights are horribly engineered and flash their brights every time they go over a bump or are on an incline. This is unacceptable and must be responsibly regulated. Bright white LED headlights must be banned!

B.4722 December 12, 2025 — Columbia, SC

I Cannot see or stand driving in the evening and night because of the amount of ridiculously bright lights, I’ve had to come to a complete stop in the middle of the road and curves several times due to the blinding lights in these vehicles, if the government wants to ban something ban bright headlights! They’re a safety risk and I fear that one of these nights I won’t be able to see and I will miss a turn for the last time…even then I feel nothing would change …

B.4723 December 12, 2025 — Oregon City, OR

BRIGHT HEADLIGHTS + ASTIGMATISM =BAD

B.4724 December 13, 2025 — Olathe, KS

Extremely bright headlights from oncoming vehicles are blinding for night drivers in city and suburban streets.

B.4725 December 13, 2025 — Salinas, CA

Government officials are supposed to protect our best interests, not force bad technology down our throats for their profit by limiting choice and competition in the free market - In the name of "climate change" is not a "thing" it's just a fact of reality. focus your energies instead on cleaning up pollution in our toxic food, water, and air.

B.4726 December 14, 2025 — Bradley, IL

{"videoUrl":"https://stream.mux.com/rAPMOtWZpzhTtCf7QXWyxEiAMksmLpRXM1xk02rfD00EI","cloudflareUid":"5af6cad87b6d6d46841c91e19599a4df","muxAssetId":"UgtFPLJ2v0001xcFclZlBKx014zLDS8402JLPGzTey8NrR00","muxPlaybackId":"rAPMOtWZpzhTtCf7QXWyxEiAMksmLpRXM1xk02rfD00EI","muxPlaybackUrl":"https://stream.mux.com/rAPMOtWZpzhTtCf7QXWyxEiAMksmLpRXM1xk02rfD00EI","muxThumbnailUrl":"https://image.mux.com/rAPMOtWZpzhTtCf7QXWyxEiAMksmLpRXM1xk02rfD00EI/thumbnail.jpg"}

B.4727 December 14, 2025 — Sweetwater, TN

They are blinding!

B.4728 December 15, 2025 — Columbia, SC

While the LED headlights are quite troubling, the blue LED lights on the police cars are absolutely BLINDING. Because of their blinding effect, I have run off the road twice. Thankfully I've only driven onto grassy areas, but it could have been much worse had I been crossing a bridge, a street with sloped sides and no guard rails, or if I subsequently drove into an oncoming vehicle in an opposing lane. Please help save lives and ban ALL blinding headlights.

B.4729 December 15, 2025 — Reno, NV

I have been blinded multiple times by these headlights and basically driving blind is dangerous especially where I live and there's a lot of road construction they shouldn't be allowed to have headlights this bright

B.4730 December 16, 2025 — Bartlesville, OK

Driving at night was always my happy place. I loved watching the moths around the lights. Stargazing has always been a hobby of mine. I love the night so much. These LEDs are literally ruining the best parts of life.

B.4731 December 16, 2025 — Los Gatos, CA

headlights these days make it extremely hard to drive. in a populated city blinding headlights are always in sight when I'm driving. I can't live like this

B.4732 December 17, 2025 — Fargo, ND

LED lights blind me on the road at night, when I already have trouble seeing at night! Very dangerous, I support this cause

B.4733 December 18, 2025 — Albuquerque, NM

I have had multiple freeway and highway experiences in which the modern and unreasonably bright headlights of others have place my life and my children's lives in danger. It is excessive and ridiculous, with many modern headlights being brighter than "brights" or indistinguishable from them

B.4734 December 18, 2025 — Saint louis, MO

So they can see a bit better, everyone else is blinded. New standards need to start now.

B.4735 December 19, 2025 — Candler, NC

i am constantly being blinded by led headlights. i spent money on night driving glasses (i should not have to) to try and help. its hard to believe i have to get my vehicle inspected every year when this is more dangerous than anything on the inspection list. its more proof that its just another money racket.

B.4736 December 19, 2025 — Washington, NJ

Just less than an hour ago (~7:30PM), an oncoming car was blinding me, and it wasn't until it passed me that I noticed a kid dressed in all black walking on the shoulder. Luckily was fully in my lane, where Im supposed to be, paying attention, and driving the speed limit, so I would not have hit them either way, but it was startling to see nothing but white lights, then to just suddenly see a person just a foot away from your car walking on the shoulder. Last week a vehicle had such bright headlights, that even though they were 4 blocks away, up a hill on a straight road, their lights reached the bottom of the hill and made shadows that looked like something was moving in the middle of the road, when nothing was actually there. Just the dance of these laser beams we call headlights, shinning all the way across from the other side of town. The roads are salted now that it's winter. The blue lights illuminate the salt on the windshield, and turn it into a one-way mirror. If you are on a faster road and try to spray the salt off the windshield, the wiper fluids splash over the roof and hit the vehicle behind you. So you have to either pull over, or deal with the lack of visibility until you reach a stop light or find a moment where no one is behind you to so you can clean the salt off and try to peer through the blinding blue light of a thousand suns.

B.4737 December 20, 2025 — Apo, AE

I really can not deal with the lights. They hurt my eyes! It's a safety risk, what if I get blinded and kill some one? We need regulation

B.4738 December 20, 2025 — Brewer, ME

Ban ALL aftermarket LEDs too

B.4739 December 21, 2025 — Davis, CA

Strong lights blind you, reduce visibility for other drivers and can increase likelihood of crashes and be dangerous for pedestrians.

B.4740 December 21, 2025 — Saint Louis, MO

The ridiculously bright LED lights need to be banned. Driving at night has become extremely scary due to these lights being very blinding. There is absolutely no reason anyone needs these bright lights.

B.4741 December 22, 2025 — Bakersfield, CA

It kinda sucks tbh i cant play steal a brainrot if i die!

B.4742 December 23, 2025 — Maple Valley, WA

Most headlights are too bright and dangerous beyond the threshold of safety. It's a combination of factors such as the regular headlights are too bright or maybe they have their brights on and don't know it, or maybe they do know it or maybe they don't care or maybe they're headlights are not aimed correctly. All these different factors contribute to how dangerous and out of control this issue is on a larger scale not to mention how angry I get when I just want to drive to work in peace, but I can't!!

B.4743 December 24, 2025 — Canada

For years now I have complained about blinding LED lights. But I bought a new Mazda CX-30 so I know it's blinding others on the road. The lights are so bright other drivers think I am on brights when I am not. When you're behind a vehicle at night and their headlights are in your drivers and or passenger side mirrors it's blinding and so distracting. Why can't they create something so you can flick the mirrors down like the rear view mirror so you do not get blinded at night by vehicles behind you. Especially truck models like the Ford F150 as an example. I end up having to drive with my right arm so I can drive with my left arm in the window to block the lights on the vehicle behind me. Sure these lights are super bright which helps you see better at night but the level of brightness is insane today. I have wondered for years why I get bad headaches. Now I believe it's LED lighting. So I just ordered incandescent light bulbs to see if it makes a difference. Thank you for the opportunity to sign the petition and comment. ❤️❤️

B.4744 December 24, 2025 — Cartersville, GA

I have an astigmatism and at night I literally cannot see when trucks with bright lights pass by

B.4745 December 24, 2025 — Hollywood, FL

Since these lights have come out in the cars they have been blinding me and causing crashes for others

B.4746 December 24, 2025 — Johnson City, TN

I've been sitting here for about an hour after having to drive at night and encountering extremely bright LED headlights repeatedly. My eyes feel like I've been staring into the sun. Whenever I am forced to drive at night now, there are several moments where I just flat out can't see, because someone's headlights have completely blinded me. This is such an obvious safety issue. How is nobody on top of this yet?

B.4747 December 24, 2025 — Kansas City, KS

Im about to commit acts of vandalism against vehicles with blinding headlights. Please help prevent me from having to due this.

B.4748 December 24, 2025 — Lincolnton, NC

Due to the amount of LEDs around me I have stopped driving at night. They are blinding and dangerous.

B.4749 December 24, 2025 — Lynn Haven, FL

My wife collapses as soon as she comes through the door from driving 30 minutes at night. It gives her a severe headache. I find them painful, like being forced to stare into the sun and have to look away.

B.4750 December 24, 2025 — Newton, NH

These LED lights are detrimental to our health. What message are we sending to our children if we don't demand to stop this. While driving at night I always have to look down to the right side of the road because they blind me

B.4751 December 24, 2025 — Pell city, AL

The new head lamps make driving unbreakable. Please sign and share

B.4752 December 24, 2025 — Rochester, NY

Read my article in Forbes discussing this highly important safety concern! As a trauma physician I witness the dangers every month. Lives lost and patients injured.

B.4753 December 24, 2025 — Tucson, AZ

I can't believe with all our regulations that this ever got approved. The headlight are absolutely blinding and therefore dangerous!

B.4754 December 25, 2025 — Chipley, FL

I don't drive at night anymore due to the LEDs; they make me instantly angry having to look at them which affects my mood

B.4755 December 25, 2025 — Oklahoma City, OK

These newer blindingly bright lights cause so much stress on the eyes, giving eye pain to headaches along with making it near impossible to see. Let us not forget light pollution disrupting nature and causing more animal deaths on the road

B.4756 December 25, 2025 — Zanesville, OH

Please ban LED headlights. They cause me to have visual impairment when approaching oncoming traffic that have the LED headlights.

B.4757 December 26, 2025 — Hamburg, NY

Alarmed at what I'm learning about LED'S, other man-made lighting. Vehicle headlights are a disaster! Struggle terribly with them on the road.

B.4758 December 26, 2025 — Hillsboro, OR

From the onset of the LED explosion, I have been adversely affected by them. Painful to my eyes, headaches, dizziness, sleep interruption etc. For the most part, people who know me suspect I am being a bit of a hypochondriac. It is especially challenging at night when headlights are so painful, I have a difficult time even looking at the oncoming car. It is dangerous and unnecessary to have LEDheadlamps, and I suspect there are many more people who feel the same way but just grin and bear it. Please ban these unnecessary lights in vehicles or at the least, tone them down.

B.4759 December 26, 2025 — Troy, OH

It's unfortunate but not surprising anymore that our Government is not helping us. Most people, especial those in authority, just don't care about… well, much of anything anymore, including life. Sad. When driving against bright headlights I have no choice but to do what I have to do to physically see and drive safely. If they have the right to drive with bright headlights then so do I, so I have to turn on my high beams to see. This also has the side effect of letting them know their headlights are too bright. Spread the word.

B.4760 December 27, 2025 — Seminole, FL

For quite some time now my eyes have cringed at the sight of these led headlights. In the beginning, I thought the other drivers had their bright lights on! I am thrilled that this petition is in existence now. The brightness is so intense at night that my vision becomes greatly reduced. It scares and concerns me for my safety. I do not have a good feeling about these type of headlights. Thank-you for all your efforts to help save lives.

B.4761 December 27, 2025 — Shelby township, MI

The LED headlights are blinding with glare that I can not while driving, and the daytime lights make it difficult to see and focus on pedestrians and other traffic while driving. The LED lights caused me to experience and suffer from Ocular Migraines, now three times per week and more. These LED lights are dangerous causing visual impairment and distraction, and blinding bright lights with glare that is blinding, that causes accidents and catastrophic accidents.

B.4762 December 28, 2025 — Auburn, WA

Blinding LED headlights have often caused me migraines. They are unsafe and impairing to other drivers. How can this be legal??????

B.4763 December 28, 2025 — Jackson, WY

I'm in my 30's with better than perfect vision and can not drive at night due to the blinding oncoming headlights. Being near any kind of emergency vehicle is doubly dangerous as their blinding and flashing lights obscure the road, other vehicles, and being able to see anything for a while after passing them.

B.4764 December 28, 2025 — Lancaster, NH

I keep saying why do people need to see up a raccoons a_ _ a mile away. They are blinding me. When someone goes by me at night with LED lights I am blinded. It is not a good feeling when you are wondering if you are still in your lane because you can't see anything other than extremely bright lights. They need to be banned. i never had problems driving and still don't with regular lights they don't bother me but the LEDS are horrible. Please get rid of them.

B.4765 December 28, 2025 — Laredo, TX

LED Headlights are a danger to people with astigmatism, and not only that but can also limit how much of the road you can see which can cause accidents. Please ban these.

B.4766 December 29, 2025 — Danbury, CT

Do the right thing by your constituents. Help us to be healthy and not blinded at night by these lights. Do the right thing!!

B.4767 December 29, 2025 — Kohler, WI

Something needs to be done about this issue. It has only been getting worse over the years. There are also people now replacing more of their old headlights with these LEDs with out purchasing and replacing the reflectors; without replacing those they actually turn out to be worse than the headlights on these new vehicles that are just as bad or worse. Need to get recalls out on these newer vehicles. Own a car that is almost not possible to drive at night due to this issue. Have almost been in an accident every week being on second shift due to this issue. It is now getting so bad with these newer vehicles to the point we are even having issues driving a fullsize truck at night which has never happened to us in our 15 years of driving. The brights are also an issue as well cause of people not being able to shut them off while driving past you or passing. Please do something about this already. It really is out of hand.

B.4768 December 29, 2025 — MOUNTAIN HOUSE, CA

Whether its someone coming towards you, or someone right behind you, they still blind you and are a nuisance to everyone.

B.4769 December 29, 2025 — San Jose, CA

i find the bright lights unacceptable & have to divert my eyes which can be very dangerous. and to add to the problem too many drive with their brights on when not necessary

B.4770 December 30, 2025 — Flower Mound, TX

I cannot tell if people's brights are on or if it's their headlights. i am 26 and have perfect vision yet go blind every night i drive after sundown.

B.4771 December 30, 2025 — Leander, TX

Due to the BLINDING headlights of a truck, I almost hit a pedestrian who was wearing a reflective vest. The headlights if the truck were so bright, that the light canceled out the reflective tape on the pedestrians vest. BAN THESE BLINDING HEADLIGHTS.

B.4772 December 30, 2025 — NJ, United States

So sick of almost getting into accidents at nighttime because of these. Why is something like that now just a casual thing??

B.4773 December 31, 2025 — Boston, VA

{"videoUrl":"https://stream.mux.com/LoLoX56x2019HOYVSV4ePVg00FZ79p02RKrTxFL1bYWQMU","cloudflareUid":"0c4d7524ff3b176f6f2b24e6b9a7b82f","muxAssetId":"BwemoPpifJB4bD82BcR5ugDCZEuxfNo9IJmtDdS300A00","muxPlaybackId":"LoLoX56x2019HOYVSV4ePVg00FZ79p02RKrTxFL1bYWQMU","muxPlaybackUrl":"https://stream.mux.com/LoLoX56x2019HOYVSV4ePVg00FZ79p02RKrTxFL1bYWQMU","muxThumbnailUrl":"https://image.mux.com/LoLoX56x2019HOYVSV4ePVg00FZ79p02RKrTxFL1bYWQMU/thumbnail.jpg"}

B.4774 December 31, 2025 — Brooklyn, NY

This is a major issue in safe driving for all ages.

B.4775 December 31, 2025 — Warrenton, VA

i can barely see anything i always think people have there high beams on and it's even worse for my gf she needs glasses and can see very well and these lights or worse reflecting off her glasses. they need to change these type of lights they have on new cars and make it illegal for people to change there lights as well

Comments left in 2026

January 2026

B.4776 January 1, 2026 — Boston, MA

Are LED manufacturers trying to destroy my country, or pushing the slightly less nefarious agenda of stimulating auto-wreck insurance companies and Lens Crafters? It's unbelievable how so many people keep wanting to go back down an old, broken road. - Nych Hansen

B.4777 January 1, 2026 — Danville, VA

These lights are extremely blinding and have been the specific cause of several near accidents by a friend when I was a passenger. They should be outlawed outright. Period. Jerk drivers nowadays don't bother to dim them either. They should also force manufacturers to put all of them at the same height from the road, most especially those huge pickups that jerks drive to make themselves proud and better than everyone else, that have billion candlepower headlights blasting in your rear view mirrors that blinds everything, the road, your dashboard, your windshield, the interior of your car, as well as in the front of your face. Respectfully submitted, except for the jerk idiots who don't dim their lights even when the low lights are too bright to start with. Spencer D. James Danville, VA

B.4778 January 1, 2026 — Minneapolis, MN

Digital light (led) and sound are unhealthy. I have been reffering to it as fake light and sound for years now. Get ahold of robert f kennedy and have him include this in his MAHA research

B.4779 January 1, 2026 — Republic, WA

I have been adverse to light of any kind at night to sleep since I can remember. I covered windows with new garbage bags, place towels and wash cloths to cover or stuff into places light was escaping. Then came LED lights. I got ahold of a roll of my husband's electrical tape and put little bits of it over anything LED. An LED light might be tiny, but to me it is like a laser light going through my eyelids. I was a young grandma, about 10 years ago, when I had to go to an eye specialist for a potential problem. I didn't have a problem, but I found out I have a genetic disorder called ocular albinism. I

have no melanin in my eyes that create color to my iris. I have nothing to filter the amount of light that gets in my eyes. I wear very dark sunglasses. I can see like a cat at night. Until this diagnosis my husband thought for 35 years I might have a mental disorder I'm so consumed with LED lights at night; also wherever we travel. When bright blue LED headlights come at me at night I almost panic because the light is so overwhelming bright. When the oncoming driver forgets to take them off high beam , I have to glance away from them because the light is staggering. If LED is so disruptive to so many of us, why is this argument being fought so fiercely? Tonight we heard Mark Baker for the first time. What a relief to hear others have this problem……I am not alone.

B.4780 January 2, 2026 — Cataula, GA

I have always lived in rural areas and have driven thousands of miles during my life. I also have a very good driving record. I thought it was an eye issue with the brightness of headlights at night but after having eye exams found it was not my eyes but the new LED lights being used in cars and trucks. It has created a dangerous hazard for drivers meeting oncoming vehicles! The agency that regulates this should change the old specifications immediately!

B.4781 January 2, 2026 — Rio Rancho, NM

I have almost entirely stopped driving at night because of the danger and discomfort caused by overly bright headlamps, both in front and behind me.

B.4782 January 2, 2026 — Sarasota, FL

Both the headlights on automobiles and the outside overhead lights are damaging my eyes. I'm unable to drive at night with the blinding on-coming car lights. Many times, I have to close my eyes due to the pain which is a hazard to both me and other drivers.

B.4783 January 2, 2026 — Seattle, WA

There is clearly enough evidence on the link between blinding headlights and accidents (including fatalities) to NECESSITATE regulatory action on this. Please get on it.

B.4784 January 2, 2026 — Washington, DC

Because LED headlights are so bright and glaring, I can no longer attempt to drive at night on highways. They have become a serious safety hazard. The headlights on the ridiculously large pickup trucks and SUVs are equivalent to spotlights shining directly into drivers eyes.

B.4785 January 3, 2026 — Brooklyn, NY

i have pretty bad astigmatism, and blinding headlights make it nearly impossible to drive at night. the smeared lines from usual traffic lights and headlights are already bad enough—i and others like myself don't need more issues. it's dangerous and severely reduces visibility. i can't believe it's legal.

B.4786 January 3, 2026 — Deer Island, OR

Over the past two years, I have noticed a dramatic increase in the use of painfully-bright headlights. As a result, I avoid nighttime driving at all costs, for these lights make it SO difficult -- impossible, sometimes -- to see the road in front of me. Even a short drive after sunset leaves me with terrible eye pain and a headache. In addition, when these headlights are shining into my car from behind, especially when I'm on the freeway, I cannot change lanes, as the surrounding brightness is blinding. Adjusting my mirrors can help in some situations, but when multiple vehicles are lighting everything up to an unsafe degree, I'm stuck until they pass. Many people are, I believe, using their headlights to bully others, particularly when they're tailgating. (Ironically, doing so often prevents drivers from moving over for them.) With the growing use of blinding headlights, I've also noticed that more people are choosing to drive with their high-beams on. Not that many years ago, the majority of drivers were relatively courteous; now, I can't say the same. These headlights need to be banned.

B.4787 January 3, 2026 — Franklin, TN

Delivery driver. Over the course of the last couple of years the vision damage has been noticeable. Despite the degradation of my eyesight, the brightness and absurdity of these modern headlights has only gotten worse. It's destroying vision and lives.

B.4788 January 3, 2026 — Lake City, PA

Car headlights are too bright now. We need regulation to help people for safety sake. Bring back inspection that checks alignments.

B.4789 January 3, 2026 — Parry Sound, Canada

Some drivers are using them as a weapon. Bullies strobing high beams from behind to intimidate a driving going the speed limit.

B.4790 January 3, 2026 — Wailuku, HI

I had cataract surgery in hopes of minimizing the glare made from the blinding headlights, esp. from trucks. Somewhat helpful but still blinding and unsafe.

B.4791 January 4, 2026 — Portland, OR

Whether the headlights are too bright or they are aimed too high, they are a serious issue. When driving I sometimes can't see anything but headlights. Everything else is black in contrast to the lights. It is more than difficult to have multitudes of drivers trying to drive safely in this situation, it is extremely dangerous. In addition the bright lights cause eye strain, headaches, and migraines that make it hazardous or impossible for some people to drive.

B.4792 January 4, 2026 — San Francisco, CA

Head lights keep getting brighter and brighter. I understand the safety the government and insurance companies thinks this is.....but is it really? And is the moth effect (looking at the right of the shoulder actually safer?) . I think not. Yellow tinted glasses also dont work for everyone. Keeping a clean windshield in the rain with glare is utterly impossible. Not all roads have freshly painted lines on the right side. Its ALOT of up keep for counties. I was driving a road last night actually, it was raining, my windshield wipers were just about on high. A truck (new very nice Ford F-150) was driving towards me. My line to follow (as AAA recommends) on my right side was barely visible in rain and the dark and up keep is minimal on maintenance of those lines. The trucks lights were so bright (just his regular driving lights) that I was blinded then saw stars for the next few seconds (almost blinded). My choices, slow down, stop, or keep driving praying I didnt go into the ditch on this county rural road continue on while seeing stars in my vision. How is that safer? How does that take lowering accidents at night down? Not all Americans can afford nice new cars. Some (alot of americans in this economy) cannot. On a multiple lane freeway/ highway with a huge median in between on coming traffic its fine. But how is this safer for the under dog who drives a car more then 10years old because thats what they can afford? Rural driving without street lights and its pitch black? Yeah safer for the other guy, definitely not safer for my and my family. Car manufacturers need to stop. I personally have stopped as much as possible driving at night, but on the off chance I HAVE to drive after dark and am truly blinded by these lights i am putting myself and my family at even more higher risk, how is that safer? What happens if I do drive off the road because the lights temporarily blinded me? Is the insurance company going to say its my fault? Put into laws each state and county needs to keep fresh reflector lights mandatory, bigger higher up trucks should NOT have these bright lights and manufacturers need to dim higher up vehicles. Isnt this what your actual high beams are for? . Please stop! This is NOT safer. You are creating more problems then actual solutions. Create a solution that benefits everyone on the road!

B.4793 January 4, 2026 — Seattle, WA

Those super bright headlights in the opposite lane hurt my eyes every time. I can't see the road ahead of me with that thing blinding me on the left. One of these days, it'll make me crash, and (if I live) I'll never be able to prove why or recover damages from the driver who really caused the crash by using those dangerous accessories

B.4794 January 4, 2026 — Williamsburg, VA

Wear glasses and have a stigmatism. It's already hard enough driving at night without being completely blinded. Every single time one of these drivers are driving the opposite direction I fully cannot see, and have to drive based on instinct and faith when they are driving past me.

B.4795 January 5, 2026 — Carmel, NY

As the population ages, this issue becomes much more important. While there are laws on the books regarding headlight strength, it seems that they are never enforced. PLEASE update the laws to include current technology.

B.4796 January 7, 2026 — Broomfield, CO

I haven’t heard a single person mention these bright lights with positivity. It needs to stop!

B.4797 January 7, 2026 — Commerce, MI

C'mon, we're not asking for solutions to world peace or agreement on climate action. This is the sort of problem that our federal representatives and organizations should be able to address in a manner amenable to the manufacturers and improve safety for all of us. I guess that sort of lack of action is one of the many reasons why we generally have such low opinions of our governing representatives.

B.4798 January 7, 2026 — Denver, CO

I am tired, mad due to BLINDING headlights out there! Hope somehow sense prevails and this menace goes away

B.4799 January 7, 2026 — Hansville, WA

I carry a piece of cardboard to hold up and block my view of oncoming traffic. I wear sunglasses at night. I turn my mirrors so I can't see behind me (just switching to night mode is not sufficient when a truck rides my tail with its high beams on). All these actions are dangerous to me and those around me - but not as dangerous as being completely blinded. It doesn't help that many drivers habitually leave their high beams on and hope they will automatically dim for an oncoming car. That technology rarely works properly. Modern headlights are a threat to everyone's safety.

B.4800 January 7, 2026 — Portland, OR

We often get angry with government for not addressing the big issues in life in meaningful enough ways but both the government and the people often forget that there are many smaller, solvable immediately solvable problems that will raise everyone's quality of life. This is one of those. The headlights are out of control, and they make car travel dangerous for drivers and pedestrians.

B.4801 January 7, 2026 — Prosper, TX

it is ridiculous that this hasn't been addressed already

B.4802 January 7, 2026 — Silver Spring, MD

The headlights are too bright. Me, my spouse, and my three young adult children all struggle with the very bright lights vehicles are using. We are all concerned we could get into accidents because the lights are blinding.

B.4803 January 7, 2026 — United States

Matrix headlights are a solution that can completely solve this issue and it and Audi has proven it in the EU with the R8 LMX along with other manufacturers. These brighter headlights offer beam shaping so oncoming cars don't get blinded, but the road head remains we lit for the driver. It's high time the US updated its lighting regulations not only stop drivers from being blinded on the road, but to allow the new Matrix headlights here as well so we all can enjoy well lit roads and a safe driving experience

B.4804 January 7, 2026 — Valparaiso, IN

I just don't understand why this problem has persisted for so long. So many measures taken to promote road safety but yet the blinding lights are allowed.

B.4805 January 7, 2026 — Winchester, OH

The LED headlights are blinding, potentially causing accidents, especially on rural roads. Senior citizens are especially vulnerable who may have any stage of cataracts. Ban the LED headlights!

B.4806 January 8, 2026 — Airdrie, Canada

Our vision is washed out on the roads and everyone is in danger. Everyone being able to "see more" does not mean adding brighter lights. Driving at night is now a real danger to both drivers and pedestrians. It has to change.

B.4807 January 8, 2026 — Alpharetta, GA

LED headlights have almost caused me to run off curvy sideroads several times due to blinding. When shining in my sideview mirror, I am unable to see traffic coming, and therefore cannot merge into the adjacent lane safely. They are extremely dangerous.

B.4808 January 8, 2026 — Blackwood, NJ

As someone who suffers from photosensitive migraines (caused by bright/flashy lights) I wish we could do something to reduce headlight blindingness.

B.4809 January 8, 2026 — Brooklyn, NY

I am sick and tired of these mf headlights on these mf roads

B.4810 January 8, 2026 — Elba, AL

Being blinded has nearly caused me to run off the road or into other drivers. Wearing glare-cutting shades helps only a little. I've done all I can do short of just not driving after dark.

B.4811 January 8, 2026 — Evansville, IN

I find these 5000 plus lumens headlights coming at me to be blinding. Add to that is the "lifted" pickup truck following me throwing their 5000 lumens directly onto my mirrors, which then aim it directly into my eyes. All this brightness is totally unnecessary to see the road and surrounding area at night. All it does is cause my pupils to contract causing night blindness. I am forced to look away and toward a darker area.This means that I could miss seeing the child step into the road in front of me, or, i don't see the car in front of mt braking. These lights should be regulated and/or banned. At first it was just the aftermarket lights that a few vehicles had. Now, it is a problem with most automakers. Please do something to make our roadways safe again.

B.4812 January 8, 2026 — FELTON, DE

I have gotten to a point where I just don't go our at night to drive because of these headlights. They are blinding...to the point where I can't see the road for seconds after the car passes. AND, all the clowns with the LED light bars and extra lights I just pull off the side of the road if possible to let them pass. I don't know what idiot thought this would be a good idea but they are dangerous. We live in the country, so those back roads have no shoulder on which to pull off. So, as I was taught when I was starting to drive, I try to look off to the shoulder to stay on the road. This is dangerous, the lights are creating a dangerous situations on the roads. I am glad they drivers can see the flea on the but of a dog in the next state, but I can't see the next 10 feet. Please make them change.

B.4813 January 8, 2026 — Lake Stevens, WA

sad that this issue hasn't been addressed by the government already and we need to do stuff like this

B.4814 January 8, 2026 — Lincoln Park, MI

Those bright headlights hurt my eyes while driving even during the daytime. These lights should be banned because I feel that some drivers purposely installed them because they get a kick out of blinding people and Semi trucks are the worse and these lights pose a danger to society. I pray to God they're banned! Thank you for this petition.

B.4815 January 8, 2026 — Marshalltown, IA

It is extremely frustrating and a bit dangerous when faced with oncoming vehicles that have extremely bright headlights, even when on low beam. Also many vehicles are so tall that the headlamps are placed higher up on the front end making the situation worse.

B.4816 January 8, 2026 — Mountain View, CA

Lamp intensity emission and lighting brightness (where it can dazzle other road users) should be limited. The regulation needs to consider older road users (a 60 year old needs 3x the light compared

to a 20 year old to see at night). The regulation should balance headlamp brightness (more light is safer) and night vision of other road users. The regulation should also consider dazzling and eye damage of children and pets, and scenarios where headlamps are not aligned (e.g. a vehicle cresting a hill).

B.4817 January 8, 2026 — Oklahoma City, OK

I avoid driving at night if possible because of the blinding effects of oncoming traffic. While oncoming traffic passes me, I have no choice but to go straight and hope nothing is in front of me. This never used to be the case. Large and tall vehicles like trucks are especially egregious. If behind me, they illuminate the interior of my car (VW Golf) as well as the interior lights. We need new regulations limiting GLARE, not just total light output. The glare from LEDs is far higher than traditional lighting sources. There are several methods/equations for measuring/calculating glare. Pick one, and use it. Thank you.

B.4818 January 8, 2026 — Palm Beach Gardens, FL

Driving at night has become a serious hazard due to the blinding bright lights on newer vehicles. The glare turns the road blazing WHITE making it impossible to see. The bright lights literally hurt my eyes, causing me to look away with intense anxiety and terror. I avoid driving at night as as much as as possible.!!

B.4819 January 8, 2026 — Plano, IL

I drive 630 miles at night 5 nights a week. The high beams left on even drivers with halogen bulds needs to be addressed. Addressing a color limit, like 5000k maximum and a required aiming check with enforcement of dimming high beams would help greatly.

B.4820 January 8, 2026 — San Antonio, TX

Modern headlights are way too bright, they blind my view and are a major distraction.

B.4821 January 8, 2026 — Topeka, KS

I can't believe we have to sign a petition in order to force common sense regulations regarding headlights. This should simply be a function of regulatory agencies that should operate on maximizing safety for motorists.

B.4822 January 8, 2026 — United States

been waiting FOREVER for someone to pipe up about this! Thank you to the authors of this petition.

B.4823 January 8, 2026 — Wichita, KS

LED Headlights are terrible!!!!! It makes me dread driving at night

B.4824 January 8, 2026 — Woodland, CA

STOP THE LED HEADLIGHT MENACE! I can't begin to tell you how many times I've almost driven off the road or into oncoming traffic due to getting blinded by the LED headlights of oncoming traffic. Please, please ban them.

B.4825 January 9, 2026 — Las Cruces, NM

Driving at night is already dangerous and adding the too bright LED lights has made it increasingly hazardous. It's not hard to understand human eyes are not meant for bright white light, we need an amber shift. It will make it safe. do something right and make the changes.

B.4826 January 9, 2026 — Mound, MN

I must drive at night 4 days a week. It has become increasingly difficult in the past couple of years to see the road and anything in my driving path due to extreme brightness of oncoming headlights. I believe it is due to high beam and auto dimmers that do not work effectively. The LED lamps and dual or triple beam lamps are reasonably bright when on low beam but are blinding on high beam. The auto dimmers do not work until they read incoming direct light and it is often way too late to correct the blindness. Further, it is obvious the technology is flawed because you can watch an approaching vehicle roll over bumps and rises in the pavement as the headlamps flicker on and off from low to high. When a vehicle is behind you the same occurs. As the vehicle with high beams on rolls over

uneven roadway the auto dimmers do not read the light ahead when they are pointed upward or downward and the lights alternate from high to low as there is no direct light to the sensors. The same situation occurs when the vehicle is rounding a curve. Drivers are immediately blinded by the oncoming vehicle because the auto dimmers do not sense the oncoming vehicle until it is too late. Additionally, you can recognize the same issue in the daylight because the headlamps come on automatically when the ignition is on and the lamps usually (not always) run on low beam because the sense the incoming daylight. I have noticed many newer vehicles with multi beam LED's that do not drive with the auto dim engaged or with only low beam on and there is no problem with excessive brightness, so, this has to be a technology issue with the auto mfgrs and the headlamp mfgrs. I am constantly blinded by oncoming vehicles and don't know how to react. If there is a pedestrian near, I would not see them. I can't see the lane markers or anythin ahead of me. I have a new windshield so, it isn't haze on my glass causing this. I have expressed this concern to others who laugh and say I'm gettin old and it's my perception. Then what about the other vehicles that don't project such intense brightness? I am very concerned. We must insist on better regulation of this area of auto technology for everyones safety. DG in MN

B.4827 January 9, 2026 — San Jose, CA

It's not just how bright the headlights are; the spectrum emitted also matters. White light has too much energy in the bluer end of the spectrum, which impairs vision at night more than the redder end of the spectrum. Any change considered by our government should be informed by science.

B.4828 January 9, 2026 — Savannah, MO

Newly replaced LED lighting at my work office is giving me headaches and eye fatigue. I can't stand it and it is even affecting my moods and outlook on life in general, I can truly see a health difference in how I feel and act every day. The LED vehicle headlights are horrible to see oncoming as I drive. I couldn't count the amount of oncoming drivers that I've flashed my lights at thinking they were on bright but in turn, I get their already too bright lights flashed back at me, even blinding me more! The worst thing is the "home mechanics" that replace their own headlights with LED bulbs and have no clue how to aim the headlight housing to make sure it's not shining in everyone's eyes! It's out of control.

B.4829 January 9, 2026 — Scottsdale, AZ

I think these LED ALIGHTS ARE DANGEROUS ON THE CARS AND AROUND ROADWAYS. My first reaction is to close my eyes when the LaeD headlights come

B.4830 January 9, 2026 — Scottsdale, AZ

I think the LED lights are dangerous on cars, streetlights and around roadways. My first reaction is to close my eyes to protect them from these lights but I need to keep them open while driving. These lights hurt the eyes.

B.4831 January 9, 2026 — WESTBURY, NY

I thought I was alone about this issue

B.4832 January 10, 2026 — Tampa, FL

Driving at night is dangerous enough without this cascading problem. also , many vehicles that are raised do not re-adjust headlight aim. I believe this needs to be top priority for national highway safety. It could save thousands of lives yearly.

B.4833 January 11, 2026 — Fishers, IN

I'm tired of being blinded by a lot of newer cars on the road. It's so dangerous for other drivers and completely unnecessary.

B.4834 January 11, 2026 — Norman, OK

We need to go back to halogen headlights as LED's have TOOOO MUCH BLUE in them, even the so-called 'WARM-2700k" LED's

B.4835 January 11, 2026 — Wichita, KS

Just fix this stupid, dangerous problem already.

B.4836 January 12, 2026 — Bethlehem, PA

Driving at night has become distressing because I'm half blind when cars approach me

B.4837 January 12, 2026 — Cincinnati, OH

Something needs to be done about the bright head lights. I see more people just using their high beams because they are tired of the bright lights in their face.

B.4838 January 12, 2026 — Marinette, WI

As someone who has to drive around during nighttime, I frequently have to hold my hand in front of my face to keep from being completely blinded by these horrible headlights. I feel as though I need to wear sunglasses at night just because of this. There is no need for everybody to be driving around with the equivalent of highbeams on at all times.

B.4839 January 12, 2026 — Temecula, CA

LED lights are the #1 threat to every single human life driving on our streets, using crosswalks, cycling in bike lanes. Not only is the driver, but every man, woman, and child they carry - faces the serious threat to their lives (quite likely on a daily basis)! Because the pending tragedies are so blatantly obvious, yet ignored - it's not spurious to conclude - the NHTSA, Auto Industry, Insurance Industry, Health and Safety Professional Societies and on, and on, and on are utterly useless on this issue - Where are their voices? Yes, I've experienced the blinding, incapacitating effects just as the many testimonials from fellow posters, here. The ONLY SOLUTION is IMMEDIATE RECALL of these products. do it that - now, before another life is lost.

B.4840 January 13, 2026 — United States

https://www.cnet.com/health/personal-care/tip-for-driving-safer-at-night-for-any-driver/

B.4841 January 14, 2026 — Brighton, CO

I agree with the blinding head light issues. We need a band on houses that have all very bright lights on their houses too. Talk about light pollution & very inconsiderate people.

B.4842 January 15, 2026 — Altoona, PA

These bright lights are so dangerous for other drivers at night. It's gotten so bad. I get completely blinded. Imagine people with an astigmatism, glasses don't really help with that. I cannot express how terribly dangerous they are.

B.4843 January 15, 2026 — Frederick, MD

These lights make it nearly impossible for me to drive at night. The lights are piercing and it takes my eyes seconds to adjust. They are not good for us.

B.4844 January 15, 2026 — Silver Spring, MD

LED headlights are blinding, like everyone is driving with their brights on. They are unsafe for oncoming vehicles.

B.4845 January 16, 2026 — Camas, WA

I'm a newer driver I hate driving at night because I can't see because of these cars it's not just annoying it's dangerous

B.4846 January 17, 2026 — Carbondale, CO

Often times I'll flash my lights at someone driving towards me to let them know they're blinding opposing traffic with their brights on- only to discover a moment later as they flash me back with an even more blinding, unholy light that they weren't driving with their brights on at all, that's just how bright their headlights are normally. This is madness! I'm sure they're glad that they can see as clearly in the dark as they can during the day, but I and so many others driving opposite to them are about to fly off the road!

B.4847 January 17, 2026 — Linden, IN

I can't see with these lights in front of behind I've almost crashed from this and it worsens my chronic migraines

B.4848 January 18, 2026 — Ft. Lupton, CO

The LED headlights are especially annoying for people like me who have to wear special glasses. The bright lights actually hurt my eys. Then it takes a few seconds for my eyes to readjust to the darker conditions of the road. This can't be safe!

B.4849 January 18, 2026 — Plain Dealing, LA

My Wife and I live in a rural area. We both have stigmatism and myopia. The blinding white lights from modern vehicles make it incredibly difficult to see the incoming traffic, and pedestrians and animals on the side of the road. I can otherwise see normally with older vehicles approaching. I would really like to see modern headlights dimmed for the safety of everyone in the road.

B.4850 January 18, 2026 — Rock hill, SC

I was blinded by someones LED headlights on a rural road (wazhaw Hwy) this last Autumn doing 55MPH and the result for my car and the buck was not pretty. I never saw the deer, just blinding headlights and this has been getting worse and worse every year where lights get brighter and brighter and I started to look into the lack of regulations by the NHTSA that has allowed this to get out of hand where as the mentality has now fixed at "As long as I can see every crack in the road, screw every one else." If you are driving any regular car, trucks and tall SUV are the worst. I get it, I have a truck but it's not what I am driving most the time. The hilly rural roads out here without any street lights make it a much more challenging scenario. My night vision is very strong but when you are blinded intermittently repeatedly, no matter your clear vision, it is extremely dangerous. I started to reserach into this more to see if others are having the same issue and found this petition among other things. Must start somewhere.

B.4851 January 18, 2026 — Salt Lake City, UT

The bright white leds are blinding, can we regulate them or add braille to the roads? :D

B.4852 January 18, 2026 — State College, PA

I am increasingly blinded by oncoming cars and oversized pickup trucks especially when it's raining. These Tesla , Honda, Nissan, Mitsubishi, etc. cars with their LED light strips all have horizon projection cutoff lines at just about the eyelevel of oncoming traffic which means if they are approaching me coming even slightly uphill I am seeing the high beam intensity of every one of them. These cars also in many cases have side projection which keeps the blinding light in your eyes right up to the point of passing them. The pickup trucks headlights are literally at or above your eye level and I'm driving a mid-sized SUV, not a small economy car. Finally we have the fools with the "colored LED replacement bulbs" for older halogen socket mount headlights. Those headlight assemblies were designed for a bulb with a single small 1/8" point source of light to be focused by a back reflector and projector lenses to the road surface. These designs do not work with these LED replacements because they have LED elements along a 5/8" length around a 1/2" tube turning those headlights into a brilliant glowing orb splaying light everywhere except the road surface. What happened to the National Highway Traffic Safety Administration (NHTSA), which is supposed to issue Federal Motor Vehicle Safety Standards (FMVSS) overseeing new vehicle / product development adherence to established safety standards?

B.4853 January 19, 2026 — Sacramento, CA

I almost get in accidents about 2 times a week from blinding headlights that keep me from seeing road reflectors. I assumed that more people were driving with their brights on, but have realized this is a horrible new headlight design. They try to angle them down, but roads angle the entire cars' bodies to where they blind me anyway, not to mention the simple, obvious fact that vehicles come in different heights. Get these blinding lights off the road, they decrease visibility for literally everyone blinded by them. I've tripped as a pedestrian because they are so blinding too.

B.4854 January 20, 2026 — Burlington, NC

My drive home at night is always terrifying and painful due to headlights. It baffles me how these things are legal. They're far brighter than "brights" were when I first started driving, and it used to be a big deal if people forgot to turn off their brights when passing others. Now nearly every car that passes me blinds me, and I very often have a migraine before I'm halfway home.

B.4855 January 20, 2026 — Washington, DC

I see, read and drive perfectly during the daytime. But I have mild (so far) but newly forming cataracts. The brilliant starbursts from LED lights of on-coming vehicles in the immediate opposing lane are utterly disabling. The road immediately in front of me is utterly erased. The feeling of being aggressively attacked by these lights is utterly demoralizing.

B.4856 January 22, 2026 — Portland, OR

These lights are incredibly bright and dangerous. I have been blinded by them from cars both driving towards me as well as in my rear-view mirror. I really wish they were illegal on public roads.

B.4857 January 26, 2026 — Portland, OR

These headlights are incredibly dangerous. There are several days/week that I am blinded enough by the bright LED headlights that I can't see the road in front of me and my eyes are irritated afterward. I believe the intention was to improve visibility for the driver but what good does that do if we are all blinding each other?

B.4858 January 27, 2026 — Bonney Lake, WA

Blinding headlights are one of the reasons why I don't want to drive.

B.4859 January 30, 2026 — Platte City, United States

LED lighting in general is disruptive to vision and circadian rhythms, and nighttime LED lighting and headlights are even worse. I've been driving and had them overwhelm my vision completely and create safety issues. Maybe 10 or more seconds where my vision is effectively useless on the road. My eyes never really adjust to the night anymore because of these lights.

B.4860 January 30, 2026 — Wichita Falls, TX

I have been driving for 10 years. The first five years were alright, but from 2020-2025 the blinding lights are gonna kill me! I cannot even see my place in my lane when they pass me on a 2 way highway 65mph. Its terrifying to just pray and hope my steering stays straight and I don't head-on into them. Its like pointing lasers into our eyes. Glad they can see better, but I guess good luck to the rest of us.

B.4861 January 31, 2026 — United States

https://www.cnet.com/health/personal-care/tips-safe-driver-night/

February 2026

B.4862 February 1, 2026 — Portland, OR

I'm a 30-something, able-bodied person who still is regularly blinded by headlights when driving in the dark. If it feels dangerous for me to drive in the dark, I can only imagine what older adults and those with disabilities are feeling. It's time for regulations to catch up with the new technology, and for car manufacturers to take accountability for the products they are selling to consumers. I support using sustainable lights such as LEDs, but urge regulators to perform more research on how to safely install them in vehicles - both in brightness and in height - so they can be safe for other drivers.

B.4863 February 2, 2026 — Austin, TX

I have a 2010 sedan, and the led lights on these SUVS routinely blinds and distracts me! They might as well be using their brights! There is no need for this amount of light in all cases I have seen; it is solving a problem that does not exist.

B.4864 February 3, 2026 — Springfield, MO

Auto companies have been getting away with taking the ultra-bright high beams of yesteryear, and installing them in place of [what should be] regular, low-beam headlights. Fast-forward about 10 years, and virtually all new vehicles and about 85% of vehicles on the road are now operating with this new "technology"...that is to say, with their brights essentially just turned on at night all the time. How this has been phased-in and silently accepted by "most people", I have no idea. It's just good to know that there are hundreds of thousands of people who are finally becoming sick and fed up with it. I'm done having to shield my own eyes at night because of these things. LED lights have their place...but definitely not in the headlights of vehicles.

B.4865 February 4, 2026 — Framingham, MA

I am a Ride Share driver so I drive at night mostly. I have complained to my eye doctor asking for glasses to help with this because it has become a major problem for me. I was told there is nothing I can do about that specific glare and she gets constant complaints regarding the issue. I cannot count the number of times I have been driving a passenger that the lights have blinded me for at least 10 seconds having trouble seeing while driving not being able to see the road or what is front of me. I would say this is a major issue just as major as cell phone use. It only takes a couple of seconds with your eyes not on the road to hit something or someone, and it's a shame that lawmakers are ignoring this problem but have signs up and pull people over for cell phones it's the same problem but worse because I choose not to use my cell phone for safety reasons, but I can't do anything about other people's headlights only the law maker's can please take this seriously. The glare is so bad that it literally seems like a person is high beaming you or flashing their lights going over bumps very dangerous.

B.4866 February 9, 2026 — Sacramento, CA

I had a Chevy Bolt and had people flashing their lights at me to turn my high beams off all the time when I just had my headlights on. I felt horrible, and I hated it. I have a different car, now, but with both cars I've experienced the glare from oncoming traffic. It is so glaring and scary to drive past oncoming traffic with lights like that. It's actually painful to me because I get vestibular migraines and it hurts my eyes and triggers a headache. No fun. Can't, for the life of me, understand how they're getting away with lights like this in cars.

B.4867 February 10, 2026 — Sioux Falls, SD

It's so dangerous driving at night now. I used to love it but now I hate/dread it.

B.4868 February 11, 2026 — Vancouver, Canada

Brighter isn't better when it's blinding everyone else on the road. Absolute disgrace that these were ever approved and currently the standard lighting system for every new vehicle on the road.

B.4869 February 12, 2026 — Alpharetta, GA

I never had a problem driving at night until they changed the headlights! They hurt! Please help us.

B.4870 February 12, 2026 — Baltimore County, MD

Please let's not fight…just get rid of the 4,000 lumens of light. Bring back the standard 1,000 lumens. There is life in safety. 💡 Thank you for doing the right thing.

B.4871 February 12, 2026 — Chandler, AZ

Headlights, even on low beams, are causing me painful eyestrain at night. I was formerly an avid night-time driver, but as lights have transitioned to brighter and whiter light, the visibility for all drivers--especially but not solely the other drivers on the road--has reduced. This is before considering the distraction of glare, eyestrain, and migraines.

B.4872 February 12, 2026 — Ferndale, MI

This is a safety issue that is getting worse and auto manufacturers need to step up. Automatic high-beams are simply a bad idea. LED headlights need to be regulated and properly governed.

B.4873 February 12, 2026 — Largo, FL

Headlights are way too bright, especially for raised cars. They blind other cars especially sedans and cars lower to the ground.

B.4874 February 12, 2026 — United States

https://commonwealthtimes.org/2026/02/11/led-headlights-are-terrorizing-our-streets-our-automakers-and-government-have-no-plan/

B.4875 February 13, 2026 — Bellevue, WA

I live in a rural area with steep hairpin turns and blind corners. I commute 1.25 hours each way. 4 days a week. This is a real issue in my life.

B.4876 February 15, 2026 — Salt Lake City, UT

These headlights are more dangerous to other drivers. Normal headlights are fine.

B.4877 February 17, 2026 — Asheville, NC

I am a young person consistently frustrated by the headlights of others. I like to drive small sedans, and especially here in the south, lifted pickups and modern SUVs with absurdly bright headlights make my 6:00 AM morning commute the worst part of my day. How these are still legal is so beyond me

B.4878 February 17, 2026 — Bellevue, WA

I am a granddaughter, daughter, niece, sister, cousin, fiance and a mother of 2. My life and my childrens life′s matter, and vehicles are already not safe but when you add stadium lights on vehicles it makes everyone unsafe. I fear everyday as a driver and a passenger that I will get into an accident because I′m blinded multiple times everyday. There are times I can not see the lines on the road and no amount of looking to the right corner of the ground fixes the blinding lights I′m being subjected to. You have to get a license so you can be a safe and legal driver, there are drivers who should not have a license because they are unsafe and then they get a car from a dealership with stadium lights or they buy LEDs off amazon or some other website. There is no reason to have such blinding lights on vehicles and I urge people who care about the safety of others or the safety of yourself sign this petition, write to the state you reside in voice your concerns the roads need to be safer and we should not have to put our life′s on the line because others find it necessary to use these blinding lights.

B.4879 February 17, 2026 — Chipley, FL

A significant portion of this issue is aftermarket equipment. Particularly LED direct replacement for Halogen equipped vehicles. The headlamp lens and housing is not designed for the different optics of the LED replacement and thus projects a far different pattern causing a blinding light to illuminate opposing traffic. Another issue related to modern vehicle headlamps is the yellowing resulting in increasing opaqueness thus attenuating the headlamp output and diffusing the light in a different direction than intended. We need legislation to force automakers to construct these headlamps to maintain design performance for at least 30 years. I still drive my 32 year old K1500 and 34 year old Town Car but fortunately t hose were popular vehicles of the day and aftermarket replacements are available but some vehicles have no alternative. Polishing the lens helps for a short period but in the polish process the only protection these poorly thought out products is removed, that being the polycarbonate coating. If we can′t get manufacturers to make headlamps of glass again we should at least force them to make the entire lens from polycarbonate. I would like to see glass headlamps return but manufacturers are scrutinizing everything in the manufacturing process to reduce weight so my wish is unlikely to become reality. Both are particularly dangerous on narrow rural roadways with many not even having pavement markings and they often have significant drop off at the pavement edge so an inexperienced driver overcorrects and winds up either colliding with a stationery object or the oncoming vehicle. Thanks in advance for any help you can provide to resolve these dangerous issues.

B.4880 February 20, 2026 — Carroll, OH

Almost died today, all because some truck wanted to look cool and have unnecessarily blinding lights. Having photosensitive eyes is problem not for just themselves but for the other driver too, it can easily change lives and we need to crack down on these b bright leds. No one needs a spotlight as a headlight,

B.4881 February 20, 2026 — Myrtle Beach, SC

If you can’t see without bright headlights, you shouldn’t be driving in the first place

B.4882 February 24, 2026 — New York, NY

Fuck LED lights

B.4883 February 26, 2026 — Greenville, SC

I still have great vision and I have a great driving record, and I hope to hold on to both of them. However driving at night actually has become dangerous in my opinion due to blinding headlights on so many vehicles. I realize LED headlights can be effective but only when taking into consideration

the safety concern for oncoming traffic. I have read that mostly older drivers, 65 years of age and older are complaining. This is not the case in my opinion. I have also read that as of 2022 there were more than 55 million drivers in this category. Well with that in mind wouldn't it make sense to stop blinding drivers (pedestrians, cyclists) with super bright headlights. Even a AAA contributer said people need to adjust to the brighter lights. I say headlights need to adjust to people. I am but one voice, but may it please be heard. Roger Davidson

B.4884 February 27, 2026 — Hamilton, OH

I have astigmatism just like a very large portion of drivers. I am anxious to even drive a quarter mile from my house to get gas most of the time because most people have led headlights that effectively turn my entire windshield a harsh, blinding white. I know for a fact I am not alone, and I also know that it makes no difference how they are aligned, nor whether they were installed by the manufacturer or the buyer. It effects my vision both short and long term, as well as my mental health, and the general safety of myself and everyone around while driving. It is ridiculous that anyone should think they'd really need lights that can be seen through a cow. I also feel it necessary to add that people who do not know how to turn off high beams, or even how to turn off their headlights at all in broad daylight, should not have a license. PLEASE, make the roads visible at night like they used to be before someone actually dies because of some Tesla/Jeep driving bozo with lights that would make the sun blush!

B.4885 February 27, 2026 — Ocean springs, MS

This is extremely dangerous. Something must be done.

B.4886 February 27, 2026 — Orlando, FL

The increase of headlight brightness will never stop. More and more cars will get brighter and brighter headlights to combat others. Eventually everyone will be blinded and unable to drive at night. Going back to 1000 lumens of light should be the standard and limit.

B.4887 February 28, 2026 — Lahaina, HI

LED car headlights are an absolute nuisance. They are far too bright, really annoying, and completely unnecessary. For decades we all drove at night just fine with regular brightness from standard headlights. Now, these days we are constantly blinded by excessively bright headlights from all directions. It's progressively gotten worse over the past 10+ years or so and is a pain to drive at night. If car manufacturers have to use LED technology for cost savings and longevity, etc., then decrease the brightness back to what car headlights were in the past and make the color temperature like previous generations - a comfortable golden amber light color. Supposedly, car manufacturers started producing LED headlights to increase their safety scores. Making car headlights brighter for safety actually has the opposite effect by blinding other drivers. So, how is that safe? Plus, in darker surroundings these annoyingly bright lights become even brighter. As pedestrians, runners, drivers, etc., we all have the right to not be blinded at night and subjected to this obvious, problematic nuisance.

March 2026

B.4888 March 2, 2026 — Houston, TX

The LED headlights that are installed in new/newer vehicles are horribly blinding to drivers going the opposite direction. I often have to slow my speed in order to avoid hitting esplanades or veering into another traffic lane and have still experienced a number of close calls. I'm sure that the drivers of these vehicles with the super bright LED lights can see the road and vehicles in front of them perfectly while those of us driving in the opposite direction are nearly blinded. I have an older vehicle with non-blinding halogen headlights and often wonder if my headlights on bright would even come close to blinding oncoming drivers to the extent the non-bright setting of many LED headlights do.

B.4889 March 2, 2026 — Lewisville, TX

LED headlights habe become dangerously bright, to the point that other drivers can't see where they're going. I've had to fully stop on multiple occasions because I was suddenly blinded by another car's lights. They actually physically hurt my eyes to look at, even peripherally. They shouldn't be legal!

B.4890 March 3, 2026 — anaheim, CA

I can no longer drive at night because of these on coming blinding lights. All my cars have traditional headlights.

B.4891 March 5, 2026 — Orlando, FL

{"videoUrl":"https://stream.mux.com/yNvgDMTPlEDEDspRyJryJQPW78wub4kWUNRUT2G8KeU","cloudflareUid":"daa64b1f75a7033d41b490e51e5f4dbe","muxAssetId":"dGUqJ31JGyOkPNeSQnfHPzybF5JOaSeIouUr3QJs7z4","muxPlaybackId":"yNvgDMTPlEDEDspRyJryJQPW78wub4kWUNRUT2G8KeU","muxPlaybackUrl":"https://stream.mux.com/yNvgDMTPlEDEDspRyJryJQPW78wub4kWUNRUT2G8KeU","muxThumbnailUrl":"https://image.mux.com/yNvgDMTPlEDEDspRyJryJQPW78wub4kWUNRUT2G8KeU/thumbnail.jpg"}

B.4892 March 5, 2026 — Valparaiso, IN

These lights are absolutly blinding and a nightmare for migraine sufferers. They also wreck periferal vision, which means they must either cast a wider beam or leave a person with greater blind spots. Any outdoorsman will tell you certain lights are better for illuminating what you want to look at without completely destroying your night vision. I don't know how people who live in the mountins funtion. When traveling mountin bends, I have almost had to stop the car at times until I can see the edge of the road when these harsh LED headlights hit me in the face as someone comes around a curve. For so many reasons these lights need to go. I can't comprehend how these lights are being allowed especailly so high on some vehicles.

B.4893 March 6, 2026 — Piti, GU

When I drive home from work, I am constantly blinded by the bright LED headlights on all the new cars. Whether they are oncoming, or behind me, the light is blaring and blinding and by the time I get home I'm seeing spots! This has to be a health hazard!

B.4894 March 8, 2026 — Tabernacle, NJ

I hate driving at night with all the LED headlights blinding me. I bought blue-blocking clip-on's for my glasses which help, but really, LED's should NOT be blinding. We need to go back to Halogen lights on vehicles. People are dying because of the LED's.

B.4895 March 10, 2026 — Charlotte, NC

If all I can see in front of me or behind be is a white flash, your lights are actively making driving less safe. The fact that this has been legal for any amount of time is ridiculous and disgraceful to the automotive industry and our country as a whole. Do better.

B.4896 March 10, 2026 — bellingham, WA

The lights outside the cars and now inside are blinding I have a hard time seeing and focusing.

B.4897 March 11, 2026 — Ashland, OR

I no longer leave my house after dark because driving my family around half blinded by the headlights of other drivers feels increasingly unsafe.

B.4898 March 11, 2026 — Columbia, SC

Ophthalmologist agrees and will bring this to the SC statehouse! I must wear yellow tinted glasses at night just to get home safely in the dark. I live on a narrow road that leads to a boat ramp and big trucks carrying wide trailers with boats have no idea how close their cargo gets to the centerline and my car. Please help us!

B.4899 March 13, 2026 — Salem, OR

Driving at night on county roads is a hazard with these new LED headlights. There is a span of time when oncoming traffic actually blinds you and you can't see the road. Additionally, having these lights behind you is like having a spotlight in your face from the reflection in the rear view and side mirrors.

B.4900 March 14, 2026 — Bremerton, WA

I have astigmatism. I did not choose to be born this way. We CAN choose to change the laws to make it safer for me and the other ONE-THIRD of Americans who have some form of astigmatism.

B.4901 March 14, 2026 — Lincoln, NE

It's become dangerous to drive at night because of this issue. I normally don't get involved in these things, but this situation is out of control.

B.4902 March 16, 2026 — Stehekin, WA

Lack of regulation against overly bright headlights discriminate against the elderly in our country. I have been forced to stop driving at night because headlights blind me. That means I no longer am free to go to movies, concerts, or other nighttime events. I am stuck at home unless I want to pay more than $50 to take Uber.

B.4903 March 20, 2026 — Bethlehem, PA

I just found out about this petition and I'm so thankful! Driving at night has become so stressful and dangerous because of the blinding headlights! I have to put my hand up to block the lights and even have to look away from the road sometimes! I just can't believe this has become so dangerous and the automobile industry hasn't done anything to stop it! Does it take a massive lawsuit!?!?! I pray whatever it takes, happens soon! Before more lives are injured or lost due to these unbelievable bright lights!!!

B.4904 March 23, 2026 — Camden, NJ

I work graveyard shift, so I travel frequently from dusk til dawn. Driving over the years has become dangerous because of the brightness of headlights has become so intense. I'm constantly flashing my high beams assuming they have on their high beams only to have them return the flash. It's becoming extremely difficult to see anything ahead of you. Especially if you are driving a smaller, low riding vehicle you are being blinded by bright lights in your side view mirror as they don't dim, causing another distraction.

B.4905 March 23, 2026 — Carrollton, GA

When a newer car is approaching me at night, I cannot see the street surface, only their headlights. I'm afraid I'm going to hit an animal. Your ultra-bright headlights make everyone else less safe.

B.4906 March 23, 2026 — Huntington Beach, CA

Bright LED headlights are dangerous for everyone. If your lights blind me, I become a less safe driver until I can see again.

B.4907 March 23, 2026 — Sioux City, IA

This is very important, lives are on the line.

B.4908 March 24, 2026 — Fuquay Varina, NC

As someone who drives a smaller car, I'm tired of having to risk danger by turning my rear view mirror up so that I am not blinded anymore by the LED lights of the car behind me. Bring back warmer headlights!!!

B.4909 March 24, 2026 — Port Charlotte, FL

My personal preference for vehicles, is smaller, fuel-efficient cars and motorcycles. I'd like to continue driving these both for personal enjoyment, and resource saving reasons, however these LED head lights have been out of control for sometime. There needs to regulations on either the brightness or the height of the lights for these giant SUV's blasting the entire length of a street with their headlights.

B.4910 March 25, 2026 — Mattapan, MA

It's absolutely blinding especially when you have them coming at you and behind you. It's going to really hurt someone

B.4911 March 26, 2026 — Shawnee, KS

This transition from Hal lights to LED′s needs so much more regulation. I′m in my 20′s and the light produced from these headlamps are making it dangerous for me to drive at night. I′m getting blinded in all 3 mirrors by the truck/SUV coming up behind me. I have genuinely had to hold my hand up to my rear view mirror more than once because of the intense light destroying my night vision, I can′t see the road. The new models auto-dim. That′s absolutely not a solution. The vehicle coming behind me is not going to auto dim until they begin to pass. Only when their lights are even with my headlights (when it doesn′t shine into my mirrors anymore) will they auto dim. LED headlamp manufacturers need more regulation to their product because it′s causing significant potential hazards, rather than just illuminating them. This needs to change.

B.4912 March 27, 2026 — Davenport, OK

these lights are incredibly dangerous. 9/10 when i′m driving at night i can hardly tell where the road is at because of the blinding light of Jesus coming straight at me. i have astigmatism and glasses that have helped to somewhat correct it and the headlights on the newer vehicles have made it seem like it′s gotten worse. i refuse to drive at night now because i am afraid to come up on the LED headlights and cause an accident because i couldn′t see where/what i was going/doing.

B.4913 March 27, 2026 — Reseda, CA

I live in Los Angeles, California, and I cannot express to you how much more dangerous these headlights have made driving at night. There are more cars on the road here in the city at night so there is no avoiding these lights behind you or an oncoming traffic next to you at all times. It makes driving nearly impossible, and our accident rate has skyrocketed.

B.4914 March 28, 2026 — Novato, CA

I literally think twice before driving at night now due to headlights glaring into my eyes. Im 30 for f′s sake.

B.4915 March 28, 2026 — Summerville, SC

Lights bright can’t see. No bueno

B.4916 March 28, 2026 — United States

I can′t SEEEEEEEE

B.4917 March 29, 2026 — Breckenridge, MN

Driving at night has never been fun, but heading straight towards blinding headlights has increased the risk of nighttime driving. I′ve had to lower the brightness of all in-cab lights just to see the road while there are bright headlights in front of me as well as blinding me from my rear view mirrors.

B.4918 March 29, 2026 — Pasadena, TX

i sometimes drive at night when i commute from my hometown to my school, and the amount of bright lights coming from behind or coming towards me from the opposite side of the highway makes it difficult for me to see. I drive a small sedan, so a lot of these bright lights are directly eye level with me. The ones coming from ahead shine straight into my windshield, and the ones coming from behind are level with my rear window, which then reflects off of my mirror and directly into my eyes, creating unsafe driving conditions. These LED headlights are excessively bright and are not properly aimed. When I’m driving behind somebody with LED headlights, I can see that their headlights light all of the lanes of the highway, and would probably light the other side were it not for the solid divider. There is no need for headlights to be so bright that they provide light to the entire freeway across 4-5 lanes of traffic.

B.4919 March 30, 2026 — Bellevue, WA

As someone with less than ideal eyesight mixed with astigmatism these headlights blind me. I work nights and drive home in the dark year round. I live in a rainy climate so visibility is already low. This makes it very dangerous for me and others in my community. Not to mention most with these lights throw on their high beams on top of that on well lit streets

B.4920 March 30, 2026 — Birmingham, AL

these lights are extremely dangerous and way way too bright!!! i drive at night on my way home from my job and sometimes have my kids in the car when we go places and it's already dark, there's no reason i should be worried about swerving off the road from being blinded by these awful lights!!! they are not necessary!!!!!!!! i have also started having ocular migraines from the insane brightness. these lights should be banned for good. we need to go back to the warm toned lights because they are so much better for our eyes.

B.4921 March 30, 2026 — Cincinnati, OH

im going blind bc of these mfs this is basically free lasik

B.4922 March 30, 2026 — Toccoa, GA

I can no longer drive at night it's not safe for me unfortunately. The lights are so bright and living in the country there are not many street lights to help counteract the one direct bright light. I've almost run off the road so many times.

B.4923 March 30, 2026 — West palm beach, FL

Its ridiculous i cannot drive at night anymore because the lights from on coming traffic blind me. I don't understand how this is legal. How were manufactures allowed to produce such garbage. No wonder our president is a pedophile. The USA is failing everyone in every aspect.

B.4924 March 31, 2026 — Athens, GA

These lights are blinding. Not just to people who have eye problems but to normal everyday people. There is no need to have lights OR highbeams that are so bright they can 10 miles away. I've almost gotten into multiple accidents with these lights, they're extremely dangerous.

April 2026

B.4925 April 1, 2026 — Churchville, PA

This needs to change!

B.4926 April 5, 2026 — Indianapolis, IN

Driving at night has become increasingly difficult for me over the past few years, and it is because of the intensity of other driver's LED lights. When a vehicle with LED lights is behind me, I cannot use my rear view mirror to scan my surroundings and it is hard to drive with that blinding white light stuck in my peripheral vision. When the vehicle is approaching me from the other direction, I have had to slow down or sometimes stop all together because I am totally blinded and unable to find the edge of the road/make out my lane. It can be terrifying when this happens on the winding country roads I often drive. While I believe that these brighter lights aid the drivers who's vehicles use them, they are extremely hazardous to every other driver on the road. I support legislation to regulate to the intensity and change the color spectrum of these lights to keep roads safe at night.

B.4927 April 7, 2026 — surrey, Canada

It is absolutely ridiculous these lights are allowed on the road they are clearly way too bright i have seen them they are a hazard! Can be distracting and momentarily blinding!!!

B.4928 April 8, 2026 — Sneedville, TN

LED headlights are BLINDING on low beam and very unnecessary. My halogen bulbs on high beam are barely as bright as most led lights on low beam. They hurt my eyes and head and I shouldn't be forced to endure the pain just to get to work in the mornings.

B.4929 April 9, 2026 — High Point, NC

These blue lights cause more accidents with other cars than with a deer. Please ban them forever

B.4930 April 10, 2026 — Citrus Heights, CA

So blinded by headlights last night during a rainstorm that if some one walked in front of me I wouldn't have know until they bounced off the hood of my car. Just as bad during dry weather. Please let's provide some kind of design guidance and usage regulation to these torches.

B.4931 April 11, 2026 — Nampa, ID

I love driving at night and I used to do it all of the time but I cannot do it anymore. I have astigmatism and it's already difficult to see. If I leave the house past 8pm I am struck with the light of God every time. Plus, when someone is tailgating me, it's already annoying but now car manufacturers have given these losers the tool of unnecessarily bright headlights. Today there was a massive rain storm which was nice until cars with led lights passed me. I could not see at all. Even the cars in front of me had to stop to wait for them to pass. It's such an intrusive addition to cars. Nothing like having a nice night drive and a random persons lights blaring in your car to remind you they're there. I have a 1998 SUV and I use incandescent bulbs. They work perfectly until cars with led lights are around. There is no point in having them. I should not have my life at risk because someone thinks it makes them see better. It's selfish.

B.4932 April 15, 2026 — Los Angeles, CA

Back 10 years ago when I put LED lights on my car I got a ticket because my lights appeared blue. Fast forward 10 years later and all manufacturers are installing blue BLINDING LED headlights, I can't take it anymore. These are no longer considered lights and are literal lasers, it's mainly the Tesla owners and more than half of them drive with high beams on.

B.4933 April 15, 2026 — Salt Lake City, UT

I have to drive to work hours before the sun rises through country roads everyday for work and sometimes the lights are so bright that I can't see any of the road infront of me.

B.4934 April 18, 2026 — Salem, NH

I have no problem seeing in the dark, it's however very hard with these headlights. It's very blinding, I was on my way home and there was someone with these very blinding headlights and when I was turning the curving road I could not see the person walking off the street because of the headlights that were in front of me. Thankfully he got off the road before I got near them but it was still a close call situation.

B.4935 April 19, 2026 — Canton, MI

I honestly feel unsafe driving at night.

B.4936 April 21, 2026 — Hollis, NH

I can't see anything when I drive anymore, I can't believe I haven't got in an accident yet because of it

B.4937 April 24, 2026 — Riverton, UT

I drive an old 2005 truck with halogen headlights. LED headlights in recent years have become so bright that they completely wash out the light from my halogens, so I can't see the road in front of me; it's downright dangerous when the road is wet and catches the glare from everyone else's lights. The worst is a highway with an 80 mph speed limit, no street lights, and oncoming traffic -- it is actually terrifying. I upgraded my bulbs to the brightest halogens I could find, and it's still not good enough. I can see perfectly clearly when I'm out in the middle of nowhere at night with no other cars around, so I know my headlights should be sufficient. They *used* to be sufficient around town. I really want to avoid replacing my halogens with LEDs, because I don't want to be *that* truck with the blinding headlights, but the situation is only getting worse and more dangerous for cars with dimmer halogens. The competition for brightest headlight manufacturer has gotten out of control and has long exceeded safety limits. We need restrictions on headlight brightness, with actual enforcement. In my state, driving without a seat belt is a primary offense. Blinding headlights is actually dangerous to other drivers and pedestrians around them, so it should also be a primary offense.

B.4938 April 28, 2026 — Niagara Falls, NY

The biggest issue here is most people are wearing glasses or contacts. Why would you give somebody who already can't see without assistance a way to make everyone else need the exact same assistance? I can see perfectly fine with Halogen bulbs which are the standard bulbs we used in our cars before LEDs. The reason that Halogens were great was because of the fact you can see without blinding the rest of the city. Now you have to make sure you have tints on all of your windows just to see the road at night or you have to buy special shades that eliminate the glare from the lights and again that's not

right considering most of the people using these bright lights are the same people who legally cannot drive without their glasses in the first place

May 2026

B.4939 May 4, 2026 — Fishkill, NY

I consider myself to be a very well-versed car enthusiast and technican, having put many miles on 80′s Japanese cars with fixed glass headlamps, 90′s/2000′s German cars with properly good halogen and Xenon headlights, and a handful of new cars with LED headlights. I can say without absolutely certainty that most modern headlight systems are not only largely unnecessary, but also excessively expensive, impressively obnoxious, and often improperly adjusted. Additionally, I find it very interesting that even when adjusted correctly, most new cars with LED headlights have a small but very noticeable spot of absent lighting, which conveniently appears to be the location of the IIHS ″glare illuminance measurement″ sensor (approximately 110cm from the ground and 3m from the center of the vehicle). In the event that it is intentionally engineered into the headlights, manufacturers would then become eligible for a″ good″ or ″acceptable″ IIHS headlight saftey rating while circumventing a problematic glare during real-world use. That′s certainly incentive for them to do such a thing. Needless to say, I′m completely on board with having more strict regulations on headlight systems, as well as encouraging car dealerships, manufacturers, and inspection stations to ensure that every car leaving their lot has properly adjusted headlights.

B.4940 May 4, 2026 — Whitehall, PA

I have had 3 sugeries on my wyes for detached retina. Since that happened, I am EXTREMELY light sensitive. Oncoming highbeams are hard to deal with , however most older non-modified lighting systems are more than adequate. They may be difficult to deal with but I can adjust. My issue, and ALL manufactures have begun to assault everyones eyes and privacy. I should NEVER be able to see dirt particles in my cars carpeting at 4 am. Ford F 150, 250, 350 etc are among the worst offenders. However, GM seems to want to show the world they have the biggest D!*& in the world and Fiat aka Dodge is a pathetic tiny brother in this automotive pissing contest. I drive 200- 400 miles a day. I need my 44 year perfect driving record to stay intact a d I′m beginning to worry about that. I am looking into a class action lawsuit targeting this exact issue. Is that an idea others would support?

B.4941 May 10, 2026 — Albany, NY

The roads have become a hell of blazing white and blue lights. I am always driving one handed with one hand blocking my side view or my left field of vision. Friday night I approached a light where SUV′s were streaming at and around me in all directions and I was too dazzled to see the stop light and suddenly the car ahead had to brake, I braked swerved and hit them. Even in the day this is a problem.

B.4942 May 13, 2026 — New Orleans, LA

B.4944 May 14, 2026 — Hialeah, FL

All over the U.S. and in Florida, Citizens are complaining about these ultra bright lights, both from vehicles and new street lights. State and local officials need to address this problem. Congress needs to act to ban, lower intensity, or install covers/shields.

B.4945 May 15, 2026 — Marietta, GA

This is one of the few "BANS" that I am in support of. These "new" headlights are so bright they blind oncoming traffic. I only wish this could have been done sooner!

B.4946 May 20, 2026 — Glasgow, SCT, United Kingdom

Bright LED lights, in particular Daylight Running Lights need to be banned. As well as being hideous monstrosities, DRLs are DANGEROUS. Any dirty lowlifes caught using them should be thrown in jail.

B.4947 May 23, 2026 — Tucson, AZ

Driving with LED headlights on the road is extremely dangerous and extremely unnecessary. I just want us to all be safe.

B.4948 May 24, 2026 — Kalispell, MT

For people with astigmatism (me) trafic lights can blind me, how do people expect 30% of the population to drive? Blind?

B.4949 May 24, 2026 — winchester, VA

Every night I am blinded by constant led headlight blindness. Several times every night I have to nearly slow my car to a near stop becase I cannot see the road because of the hight brightness of led hardlight glare and when it is raining thousands of drivers cannot see to drive because of idiots who constantly use their high beams. It takes much longer for the eyes to recover after passing an idiot with LED headlights. I see others run lterally off the road because of the brightness. DAMMIT THIS HAS GOT TO STOP. DESIGN LOWER BRIGHTNESS AND COOLER TEMPERATURE LIGHTS AND MANDATE THEM.

B.4950 May 26, 2026 — Brooklyn, NY

Being blinded as a pedestrian is a mood killer, being blinded behind the wheel is a life ender.

B.4951 May 28, 2026 — Arcata, United States

It is incredible that blinding headlights are not regulated. Proper illumibation is a crucial piece of infrastructure and blinding glare causes innumerable traffic accidents, taking lives. Regulate the glare! Limit the lights that can be sold and regulate car manufacturers. This will save lives. As a driver, the blinding glare of thoughtless drivers makes me feel deeply unsafe onbthe road. As a pedestrian, I cannot give enough middle fingers. Save lives and regulate these glaring LEDs!

B.4952 May 29, 2026 — Gainesville, FL

If you can’t tell whether the person behind you has their high beams or not, then that’s a problem

B.4953 May 30, 2026 — Phoenix, AZ

I drive a lower vehicle and the amount of times ive almost crashed because of someone with there stupid brights on is insane this has to be fixed immediately

June 2026

B.4954 June 1, 2026 — York, SC

I signed this petition because I lived this problem firsthand. For nearly two years, nighttime driving felt genuinely unsafe due to starbursts and halos from oncoming headlights. What I eventually discovered is that modern headlights made a treatable medical condition called Higher Order Aberrations significantly worse, and almost nobody knows this condition exists or that it can be fixed. I have shared my full story here for anyone who may be experiencing something similar: https://www.reddit.com/r/Dryeyes/comments/1tjuhzu/dry_eyes_starbursts_halos_glare_and_g

hosting_with/ Sign this petition. And if your symptoms go beyond just headlights, please read my story. There may be more going on than bad headlight design.

B.4955 June 6, 2026 — Glenside, PA

IM ONLY 25 AND I CANT SEE AT NIGHT ANYMORE why does one car need to be able to see 10 cars ahead of me genuinely ENOUGH

B.4956 June 8, 2026 — Colonial Heights, VA

As someone who has a brain tumor that has caused optic nerve damage, I am extra sensitive to light, which I already have been. I have a medical condition, so this causing harm to me and others with like conditions should be considered an ADA violation.

B.4957 June 14, 2026 — Yreka, CA

If someone can't drive with yellow car lights from the 1990's. They shouldn't be driving! All of my car lights are yellow and soon, bulbs will be so bright that I'll be expected to install brighter lights to compete with everyone on the road for vision when in reality we could just equalize everyone on the road with a firm ban on white headlights. Yellow headlights work perfectly fine when there isn't a million white ones that are 3x brighter surrounding you. It's ridiculous that the current "safety" option here in the USA is just "buy brighter & whiter headlights like everyone else and contribute to the suffering". NO, that is not the answer...

B.4958 June 15, 2026 — United States

LED Headlights have made driving at night with an astigmatism extremely hazardous

B.4959 June 16, 2026 — WI, United States

Anything brighter than halogen lights should be banned. They may help the driver of the car see a mile away but other driving are needlessly blinded. It's painful and causes complete blind spots until they pass. Anyone who needs lights that bright just shouldn't be driving at night.

B.4960 June 21, 2026 — Los Angeles, CA

Dude, I cannot drive when the full force of Ra is artificially summoned directly in front of my eyes...

B.4961 June 25, 2026 — Hampton, VA

LED lights are blinding painful to the eyes and trigger migraines and other complex medical conditions that impair drivers already suffering from mild to debilitating conditions reducing their overall quality of life and independence

B.4962 June 26, 2026 — Denver, CO

Recently I asked my eye doctor what she thought about the extremely bright LED headlights on newer model cars. She said, "I think they should be outlawed."

July 2026

B.4963 July 2, 2026 — Estacada, OR

I work graveyard hours and drive a smaller car. It gets very challenging trying to keep focus while getting blinded by all these overly bright lights. There are times I need to put sunglasses on or fully move my mirrors to see the road. I'm for working on cars but better regulations for headlight brightness, color and or angle is a for sure needed thing for drivers.

B.4964 July 4, 2026 — Salt Lake City, UT

the head lights are so bright that i half to wear a couple lairs of sun glass when i drive and even then it's not always enough because some of those lights are worse than others and when any of those cars pass me in the other lanes i'm blinded by there lights threw the side vision mires and i half to flip the rear mire up to prevent being blinded from behind and with the lights being so bright that you can't see i don't feel safe on the road any more and i don't drive unless it's absolutely necessary like to work or the food store or other things like that and there use to be a brights law but these new lights are many times brighter then are brights are so by them allowing them on these car the brights laws are

not being enforce any more and any one that needs lights that are that bright just to see the road probably should be driving at night in the first place

B.4965 July 9, 2026 — Houston, TX

I used to love driving. Now it is hell. I wear contacts. And have ADHD. I am properly medicated, but it is amazing to me how quickly I can go from a state of peace to complete rage due to the overwhelming stimulation from all forms of > 3000K (kelvin) LED lights. Headlights are the worst offenders but a close second are unregulated business wall mount exterior lighting, followed by parking lot lighting with no filter, high mast lights and general street lights. And these lights are on often during cloudy and hazy days. We have over polluted our environment with light sources that do not blend together well. Not only do they blind directly, but they also affect me peripherally. I can take about 10-15mins of constant assault before getting triggered. And I live in Houston TX, so my commute and daily life has become hell from these lights. Additionally, the glare and contrast issues are a HUGE problem in inattention blindness with these lights—this leads to not being able to notice pedestrians and cyclists. Additionally people like me have to wear sunglasses now to drive at night, magnifying the inattentive issue. I get being energy efficient. But how hard was it to change a HID headlight bulb and how often did they burn out? And why do we need bright headlights in urban environments with street lights? What happened to hi beam / lo beam tech? There is no argument for these lights that makes sense other than having them as the high beam only bulb on the basis of safety as you can see very far on rural roads with the higher Kelvin bulb. But again this is why we had and still have hi / low beam. As a compromise, I'll yield and let the hi beam bulb stay at a > 3000K kelvin bulb. But everything else needs to be low kelvin or (preferred) not LED at all. The light pulses, negatively affecting folks with astigmatism, ADHD, corrective lenses, etc. We used to be a society that cared about each other. All I see now is people loving that they can see "far" with these fancy headlights. I hope with education people can realize how debilitating these lights are to people, creating more harm than good. Hopefully we return to common sense on this issue and realize that the brightest lights are not the best or safest solution to safety, but instead managing contrast and glare are the utmost importance when it comes to safely lighting our rainy and dark skies.

B.4966 July 10, 2026 — Stoke-on-Trent, United Kingdom

I live in the UK, where there's lots of national speed limit country roads with zero streetlights. I was driving down one last night when a car coming the opposite direction genuinely blinded me. I couldn't see the markings on the road. I had to swerve to avoid crashing into the hedge when it passed. I hate them.

B.4967 July 25, 2026 — Bournemouth, ENG, United Kingdom

Please get rid of rhe rich blue LED lights . It's making many of us unwell and is disabling. They're also dangerous.

B.4968 July 30, 2026 — Salt Lake City, UT

because of the blinding headlights i half to wear a couple lairs of sunglass to compensate and even then it's not enough because some of those lights are worse than others and i also half to tilt my rear version minor to prevent being completely blind by those lights and when the cars with those blinding headlights pass me on the right or left lane i still get blast by there headlights in the side version minor and except when it's absolutely nasser witch would be going to work or something i won't go out side of my house because you can't be out side for even 5 min's without being blasted by those kind of light so it's like i'm a prisoner in my own house because of those kind of light

B.4969 July 31, 2026 — Cranberry, PA

LED headlights are way to bright and they make me want to speed up to get away from the car that is blinding me. Which would be dangerous.

August 2026

B.4970 August 10, 2026 — Brisbane, Australia

These LED headlights, street lights and the saturation of them in most buildings is a nightmare. I heard a lighting expert say it will be the next asbestos.

B.4971 August 14, 2026 — United States

Nobody needs headlights so bright that it blinds other drivers. It can leave visual tracers when driving on opposite lanes and is extremely aggrevating when one comes up behind you, which can lead to distraction and road rage. Distraction, anger, and visual impairment are all circumstances that lead to unsafe roadways. This feature is merely a selling point for car manufacturers at the expense of the safety, and indeed the sanity, of the general public.

B.4972 August 15, 2026 — Blanchester, OH

In the past I loved to drive at night but now it is impossible. We now have to contend with pick up trucks with off road lights on the highway. Bright enough to light up a city block. No laws anymore. What happened. Even public vehicles are blinding. Why?

B.4973 August 15, 2026 — Queens, NY

These LED lights are blinding! Whether these cars are behind me or in front of me in the opposite lane, I cannot see properly. How these manufacturers continue to install these lights are baffling to me. I hate to say this....but when there is a car with these LED lights behind me I position my car to get behind them and ride with my high beams on. If I cannot see, they should not either. Yes, it's wrong to do this, but to me, very satisfying.

B.4974 August 19, 2026 — Tucson, AZ

How many times have the emergency responders at the seen of a tragic car accident have to hear, "... but I was blinded by the on coming car's headlights couldn't see her in the road." Get the stats, there are thousands of records- this is a fact. We all know what it feels like to drive home after nice dinner and feel assaulted by the painful glare of headlights- one after the other. We count our blessings as soon as we get to our carport, and there's that sign of relief that we didn't hit someone, within each time we were blinded by those headlights. But what are the odds that it won't happen the next time a 2 ton truck, brand new SUV, or luxury sedan, is on the same road. This is a fixable public safety problem and one long overdue. Just how many people were killed by those headlights? Might be very interesting to run an ad next to our local car sales, just listing the number.

B.4975 August 23, 2026 — arnold, MO

Car headlights are dangerously bright. Cars and trucks with their headlights so bright should be ticketed and pay a fine. It should be against the law for such bright lights. And the number of them on the roads is increasing everyday. I know everyone sees them also. They are blinding and make it extremely hard to see around. Politicians should regulate this problem please

B.4976 August 23, 2026 — arnold, MO

Law enforcement should enforce the ' glare control' negligence. Why aren't they.? Please do something before I get in a fatal accident from someone's headlights glaring in my face. XOXOXO

B.4977 August 29, 2026 — Seaside, OR

I can't go out at all anymore due to this problem. I can only go out at 3 am; I have to put on sunglasses the instant I see something bright approaching and the level of hyper-vigilance that I have to maintain against these damn things is causing me PTSD and literally killing me.

September 2026

B.4978 September 1, 2026 — Chardon, OH

When I see an oncoming vehicle with pre LED headlights, you can really see the difference. No pain, no need to flash my brights at them, no residual bright light bubbl9

B.4979 September 4, 2026 — Nottingham, United Kingdom

I hope they revert back to the old brightness! These lights shine like the sun...

B.4980 September 6, 2026 — phpaisley@Gmail.com, United States

I work late evenings and am constantly being blinded on my way home. These lights are a hazard.

B.4981 September 8, 2026 — La Jolla, CA

Anyone who thinks LED headlights aren't a problem are liars OR have their license revoked because they're clearly blind or just straight up oblivious

B.4982 September 11, 2026 — Fayette, MO

The lights are too bright proving damaging to human safety on the roads and posing a threat to animals as well.

B.4983 September 24, 2026 — Plainfield, IL

A. I have astigmatism in both my eyes, so every time I get blind by those freaking LED headlights I can't see for minutes after being blinded. It is really annoying to get give basically flashbanged while driving to/from work. I'm scared that one day I'm going to be so blinded that I'll crash because some jackass in front of me or behind me had their LEDs on.

B.4984 September 24, 2026 — des moines, IA

I've signed this petition once but wanted to share a new story as I believe this will become a more prevalent problem in the future. I was driving to work this morning in the dark and being blinded constantly as per the usual. An oncoming vehicle with ridiculously bright white headlight obscured my vision enough that i could not see the deer that I hit until it was right in front or me. My vehicle was disabled and required a flatbed and now I have nothing to drive until I can get things worked out with my insurance company. Normal yellow lights would not have caused this problem. I've been driving this vehicle for 12 years and never had issues seeing wildlife with oncoming headlights until LEDs hit the market.

October 2026

B.4985 October 1, 2026 — Phoenix, AZ

France has had soft yellow head lights for many decades. There is no evidence they may cause an increase in auto accidents. I have driven at night in this country and you are not blinded by on coming cars you can actually see what is going on. How refreshing is that.

B.4986 October 2, 2026 — Webster, MA

The headlights on jeeps, trucks and SUVs are blinding and will cause accidents and deaths if something isn't done about them.

B.4987 October 3, 2026 — Fall River, MA

Driving at night on rural roads is increasingly difficult with the extreme blinding lights of oncoming traffic. Especially trucks with upper and lower overwhelming lighting only needed on work sites.

B.4988 October 8, 2026 — Goshen, NY

The real danger on the road to EVERYONE is not seatbelts. It is the blinding hazard created by high intensity lights. These need to be modified or banned entirely.

B.4989 October 8, 2026 — MN, United States

I have LED flicker sensitivity, which has affected my work life greatly. It is almost impossible to purchase laptops without flicker and temporal dithering, because the presence of these features in a display is not required to be on any specification sheets provided by manufacturers. To continue to work as a software engineer, I have had to resort to building my own laptops from old parts. LED street lights, headlights, and stop lights also affect me, and although I am only 49 I now avoid all night driving in urban and suburban areas. This summer I discovered that my parents, who do not have any LED sensitivity, have also stopped driving at night because of the increased headlight glare. My father has 20:20 vision but now he cannot drive at night. This is affecting ordinary people with perfect vision. There are plenty of other ways in which people are losing sovereignty and autonomy. This failure to regulate LED lights is just one more factor chipping away at the rights of regular people.

B.4990 October 11, 2026 — United States

https://www.slashgear.com/2282678/us-nhtsa-headlight-brightness-glare-rule-change-plans/

B.4991 October 12, 2026 — Trenton, NJ

The headlights of today's world are 100% debilitating to the human eyes. How very sad to be at a red light and to have to attempt to look in every other direction to try to not be blinded with others cars at full stop. I am 66 years old and can not believe I (we) have to adjust our lifestyle every Fall/Winter based on BLAIRING HEADLIGHTS!! Different shapes, different colors. Who in the world approved a headlight that goes completely across the front of a car and think this was okay for oncoming drivers. Please I ask you to stop this craziness and return normalcy to these situation. It is a menace to society driving at night and needs to be addressed and changed back with restrictions. This is wrong plain and simple. Linda Ruggieri

Appendix C — Appraisal of Peer-Reviewed Scientific Literature

This appendix contains peer-reviewed articles only. The criterion of inclusion is the status of the publication, and not the kind of article or its subject matter. Empirical studies, systematic reviews and meta-analyses, analyses of standards, and theoretical and derivational papers are each within it, provided the item appeared as an article in a peer-reviewed scholarly journal. The Foundation states the criterion in that form because the appendix is offered as an appraisal of a literature rather than as a collection of health studies, and because several of the propositions this comment advances are propositions of physics and of measurement rather than of health, for which the relevant published work is theoretical. Items of press reporting, organizational publications and standards documents are not included here; standards and guidance are listed separately at Appendix D.

Each entry is given in a structured form, and the structure is adapted to the kind of article. The Foundation adopts a structure for a reason it states openly. The response of May 24, 2024 recorded that a commissioned review found the overall quality of the evidence to be low, and Part V.A.2 explains why that characterization is less informative than it appears. The Foundation does not attempt to argue that any item below is stronger than it is. For an empirical study it sets out the design, the population, the measured exposure, the measured outcome, the result with its reported interval, what the study establishes, what it does not establish, and the considerations bearing on confidence in either direction. For a review, an analysis of standards or a theoretical derivation, those fields that have no counterpart are replaced by fields stating what the article is, what it establishes, what it does not, and the matters bearing on the weight it should be given. A reader who wishes to discount an entry is invited to do so on the record supplied, and to identify which element is deficient.

The final field of each entry states the question the item is offered to bear on, and that field appears in every entry whatever the kind of article. This matters more than any other part of the form. The Foundation does not offer this literature to establish that light-emitting diode products are unsafe. It offers it to establish that questions within 21 U.S.C. § 360ii(a)(4) are open and material. The evidence sufficient to show that a question warrants federal study is not the evidence that would be required to show that a product should be restricted, and conflating the two is the principal way in which an inquiry of this kind is closed prematurely.

C.1 Barrett and Jeffery (2026) — supplementation of LED workplace lighting with broad-spectrum light

Citation. Barrett EM, Jeffery G. LED lighting (350–650 nm) undermines human visual performance unless supplemented by wider spectra (400–1500 nm+) like daylight. Scientific Reports. 2026 Jan 23;16:3061. doi:10.1038/s41598-026-35389-6. PMID 41577976. PMCID PMC12830801.

Design. Controlled intervention. Before-and-after repeated measures in the exposed group, with an independent parallel control group. Ethical approval University College London research ethics committee 16547/001; conducted in accordance with the Declaration of Helsinki; written informed consent obtained.

Population. Twenty-two adults of both sexes aged 23 to 65, eleven exposed and eleven control, all screened for normal corrected visual function and general health. All had worked in the LED-lit environment for more than two years. Conducted in London from October to December, when daylight hours fell from approximately 10.4 to 7.5 and most subjects commuted after sunset.

Exposure, as characterized. The working environment was radiometrically characterized rather than assumed. Exposed group: ceiling-mounted LED arrays delivering 1000 lux at a working height of 0.9 m, correlated color temperature 4000 K, TM-30 fidelity index Rf 91, irradiance 3.6 W/m2. Control group: 900 lux, 3000 K, Rf 85. Illuminance and spectral irradiance were measured at nine mapped grid locations across a space 9 m by 18 m.

Spectra were recorded with two spectrophotometers covering the short and long wavelength ranges. The LED spectrum ran from approximately 350 nm to 720 nm with a peak at 450 nm and negligible output above 700 nm. The building glazing carried an infrared-blocking film, demonstrated by infrared photography; interior infrared images were black. The intervention was the addition of 60 W clear incandescent desk lamps for two weeks, whose spectrum extended from approximately 350 nm beyond 1700 nm.

Outcome and measurement. Color contrast detection thresholds on the protan and tritan axes, measured by ChromaTest in a darkened windowless room lit only by the test. Thresholds were determined over five repeated trials, typically 70 to 100 presentations. A practice trial preceded testing to avoid learning effects; none were observed. Measurements were taken at baseline, at the end of the two-week exposure, and at two further follow-ups. The paper is internally inconsistent about when those follow-ups fell. The methods describe testing at baseline, again two weeks later, removal of the lamps, and retesting at four and six weeks, which places the follow-ups two and four weeks after withdrawal. The legend to the results figure instead describes the measurements as taken at two, four and six weeks after the lighting was removed, which cannot be right for the two-week measurement because the methods place that measurement before removal. This entry uses the methods reading.

Result. Thresholds improved in all exposed subjects on both axes, at $p < 0.001$ throughout. The reductions relative to baseline, with the number of subjects contributing to each, were: at the end of the exposure, 28 percent protan and 24 percent tritan, $n = 11$; at the first follow-up, 24 and 21 percent, $n = 10$; at the second follow-up, 25 and 26 percent, $n = 6$. The control group showed no significant change on either axis over the same two-week period, $n = 11$. The authors contrast this with earlier work using narrowband 670 nm exposure, where improvement was biased toward the tritan axis and persisted about five days. Error bars in the published figures are standard errors of the mean.

Analysis. Repeated measures design with a non-parametric sign test, adopted by the authors because of substantial between-subject variability in absolute thresholds.

Attrition, which the Foundation gives its own field because the comment relies on the persistence finding. The exposed group was eleven at baseline and at the end of the exposure. It was ten at the first follow-up and six at the second. That is a loss of five of eleven subjects, approximately 45 percent, by the final measurement. The Foundation has found no statement in the paper of why subjects were lost or of whether those remaining differed from those lost. The consequence is that the persistence of the effect, which is the feature of this study that most distinguishes it from earlier work and which this comment cites at Part V.B.6, rests at its final time point on six people who remained available for testing. That does not make the finding wrong. It means the finding is weaker than a reader would assume from a statement that the improvement was unchanged at the final follow-up, and the Foundation states it rather than leaving it to be discovered.

What it establishes. That the long-wavelength content absent from LED lighting is physiologically consequential and not merely invisible. A measurable deficit in a visual function is present in adults working under ordinary LED lighting; it is attributable to the spectral composition of the ambient light rather than to its quantity; and it is reversed by restoring the part of the spectrum that the transition from incandescent to light-emitting diode lighting removed. The concurrent control group discriminates the effect from the passage of time and from repeated testing. The persistence of the improvement after withdrawal tells against an expectancy effect, though on a sample reduced to six by the final measurement, and the Foundation does not press it further than that. The practical significance is that no existing regulatory instrument addresses what a lamp fails to emit.

What it does not establish. It does not establish harm to any clinical endpoint. The sample is small, eleven per arm, and the exposed arm fell to six by the final follow-up. Subjects were

not blinded to the intervention and the endpoint is psychophysical and requires subject cooperation. The control group was not randomized, worked in a separate space under slightly different LED lighting, and was measured only at baseline and at two weeks, so it provides no comparison at the follow-up time points at which persistence is claimed. The incandescent lamps added visible as well as infrared light. The systemic mechanism the authors propose, involving serum cytokine expression, was not measured in this study and is advanced by them as a possibility.

Considerations bearing on confidence. Against: small sample, loss of nearly half the exposed arm by the final follow-up, absence of blinding, non-randomized control, control measured at only two time points, single site. In favor: the exposure was measured rather than estimated, at nine mapped locations and with spectral profiles; the design is interventional rather than observational; the effect was present in every exposed subject at the end of the exposure; the control group was concurrent and showed no change; and the seasonal trend ran against the finding, since natural daylight was decreasing across the study period while measured performance improved. A confounder that would bias an observed effect toward the null strengthens rather than weakens the inference.

Bearing on the statutory question. The study concerns a property of LED emission that no federal requirement addresses and that the blue light hazard framework does not reach: the absence of long-wavelength content. It is evidence that the spectral composition of general illumination has measurable functional consequences for adults in ordinary working conditions. That is material to whether the Secretary should study and evaluate conditions of exposure to this radiation under § 360ii(a)(4). It is not offered as evidence that a performance standard under § 360kk is presently warranted. Parts V.A, V.B.6 and IX.H.3.

C.2 Dai and others (2026) — nighttime light exposure, cardiac structure and function, and incident cardiovascular disease

Citation. Dai J, Dai W, Heianza Y, Qi L. Nighttime light exposure and cardiac structure and function. European Heart Journal. 2026, advance article ehag563. doi:10.1093/eurheartj/ehag563. Published September 9, 2026.

Design. Prospective population-based cohort study using UK Biobank data, with objectively measured exposure, imaging outcomes, and incident clinical outcomes over eight to ten years of follow-up.

Population. Eleven thousand and seventy-one participants for the cardiac magnetic resonance analyses; between 71,077 and 73,286 for the incident cardiovascular disease outcomes.

Exposure, as measured. Light exposure was measured, not reported by participants. Each wore an Axivity AX3 triaxial accelerometer with an integrated light sensor on the dominant wrist for seven days between 2013 and 2015. Nighttime exposure above 3 lux and daytime exposure above 1000 lux were derived from calibrated measurements integrated with each individual's circadian phase, using the least active five-hour and most active ten-hour periods. The Foundation draws attention to the threshold: 3 lux is a low level, within the range produced by light entering a bedroom from outside.

Outcomes and measurement. Cardiac magnetic resonance imaging performed approximately three years after accelerometry, yielding left ventricular volumes, mass and wall thickness, ejection fraction, myocardial contraction fraction, circumferential, radial and longitudinal strain, and right ventricular and atrial parameters. Secondary outcomes were incident myocardial infarction, stroke, heart failure, atrial fibrillation and cardiovascular mortality.

Adjustment. Models adjusted for age, sex, ethnicity, deprivation, education, employment and urbanicity; physical activity, diet, smoking and alcohol; body mass index, hypertension, dyslipidemia, diabetes, kidney disease and vitamin D; air pollution, photoperiod and

season; and sleep duration. The adjustment set includes the confounders ordinarily raised against studies of artificial light at night, namely urbanicity, deprivation, air pollution and season.

Result — cardiac structure and function. For high versus no nighttime light exposure above 3 lux, after multivariable adjustment: 2.4 percent (95% CI 1.6, 3.1) greater left ventricular mass indexed to height; 1.5 percent (1.0, 2.0) greater mean wall thickness; 1.9 percent (1.1, 2.7) lower myocardial contraction fraction. Global left ventricular strain was impaired in all three directions: circumferential −2.7 percent (−3.7, −1.7), radial −2.9 percent (−3.9, −1.8), longitudinal −2.8 percent (−3.9, −1.7). Right ventricular end-diastolic volume was 0.9 percent (0.1, 1.8) and end-systolic volume 1.6 percent (0.5, 2.8) greater; left atrial maximum volume 2.3 percent (0.7, 3.9) greater and ejection fraction 1.1 percent (0.3, 1.9) lower.

Result — incident disease. Over eight to ten years of follow-up, participants with high versus no nighttime light exposure had a 29 percent (12, 49) higher risk of heart failure, 15 percent (4, 27) higher risk of atrial fibrillation, 24 percent (7, 44) higher risk of myocardial infarction, 33 percent (11, 59) higher risk of stroke, and 26 percent (5, 52) higher risk of cardiovascular mortality.

Dose-response and mediation. The authors report that all associations exhibited linear dose-response relationships, visualized with restricted cubic splines, and that most were partly mediated by shorter sleep duration, with 24 to 49 percent of the effect mediated on formal causal mediation analysis.

Conclusion, in the authors' words. "Greater nighttime light exposure was associated with adverse cardiac remodelling and subclinical functional decline across multiple chambers, statistically mediated by shorter sleep duration. These findings provide potential mechanistic insights into how nighttime light exposure may elevate CVD risk and highlight dark nights and adequate sleep for cardiovascular health."

What it establishes. That objectively measured exposure to light at night, at levels above 3 lux, is associated in a large cohort with adverse cardiac remodeling on imaging and with incident cardiovascular disease and cardiovascular mortality, with a linear dose-response relationship and a partially identified pathway through sleep duration.

What it does not establish. It is observational and cannot establish causation, as the authors state by describing associations. Residual confounding cannot be excluded. The exposure measured is ambient light at the wrist from any source; the study does not isolate light-emitting diode sources, does not characterize the spectral content of the light, and makes no claim about lighting technology. Light exposure was sampled over seven days and treated as representative of a longer period. The cohort is predominantly of one national population and is not representative of the United States.

Considerations bearing on confidence. Against: observational design; residual confounding; no spectral characterization; exposure sampled over one week. In favor: exposure was measured by instrument rather than reported, which removes recall bias; the sample is large; adjustment included urbanicity, deprivation, air pollution, photoperiod and season; a linear dose-response relationship was observed; imaging findings and clinical endpoints point the same way, which is internal coherence rather than a single result; the effect sizes on hard outcomes are substantial; and a mediating pathway was identified and quantified. Magnitude of effect and dose-response gradient are recognized grounds for increased confidence in observational evidence.

Bearing on the statutory question. The Foundation is careful here. This study is about light at night, not about light-emitting diodes, and it cannot be cited for a proposition about LED products as such. What it supports is narrower and still material: that ambient light at night at low levels is associated with serious cardiovascular outcomes, and therefore that

the conditions of exposure to artificial light at night are a proper subject of federal study. Light-emitting diode sources are now the dominant contributors to that exposure in the United States, for the reasons set out at Part IV.G.3, and nothing in the federal framework measures what any person actually receives. Parts II.F, V.F and IX.H.3.

C.3 Guo and others (2026) — global population exposure to outdoor artificial light at night

Citation. Guo W, Liu J, Kyba CCM, Zhao X, Cui X, Zhang Y, Lu D, Rienow A. Global trends in population exposure to outdoor artificial light at night and future projections. Environment International. 2026 Aug;214:110371. doi:10.1016/j.envint.2026.110371. PMID 42314476.

Design. Exposure assessment and projection study. Two satellite radiance datasets were merged into a single consistent time series and combined with gridded population data; future exposure was projected under Shared Socioeconomic Pathways scenarios.

Scope. Global, with the observed period running from 2000 to 2020 and projections to 2050.

Exposure measure. Outdoor artificial light at night, measured as upward radiance detected by satellite, classified into emission bands and intersected with population distribution to yield numbers of people exposed at each level.

Results. The population exposed to outdoor light emissions rose from 4.3 billion in 2000 to 6.3 billion in 2020. Eighty-eight percent of that growth occurred in areas of medium to high emission. In high-emission areas, predominantly urban, 73 percent of the increase was attributable to population growth and migration. In medium-emission areas, predominantly suburban, increased radiance accounted for the larger share at 63 percent. By 2050 nearly 70 percent of further growth is projected to occur in medium to high emission areas.

Conclusion, in the authors' words. "Exposure to artificial light at night (ALAN) is a form of environmental change, and is associated with disease in epidemiological studies… Preparation for potential increased disease burden and actions to reduce light growth are therefore advisable."

What it establishes. That exposure of the human population to outdoor artificial light at night has grown substantially and measurably over two decades, that the growth is quantifiable and has been quantified, that its drivers can be decomposed into population movement and increased emission, and that it is projected to continue.

What it does not establish. It is not a health study and reports no health outcome of its own. Satellite radiance measures light radiated upward and is a proxy for ground-level human exposure rather than a measurement of it. It describes outdoor light only and does not address interior exposure. It does not identify the technology producing the light and makes no statement about light-emitting diodes as such.

Considerations bearing on confidence. This is an exposure assessment rather than an effect estimate, and the appropriate question is accuracy rather than bias. Against: proxy measurement; the merging of two sensor records into one time series requires cross-calibration assumptions; projections depend on scenario choice. In favor: the data are instrumental and global rather than sampled or self-reported, the period is long, and the decomposition of growth into migration and radiance components is a check on the result rather than an assumption of it.

The construction of the series, and what rests on measurement. Real Visible Infrared Imaging Radiometer Suite day-night band composites are available from 2012. The values for 2000 to 2011 are not measurements. They are simulated day-night band data generated from Defense Meteorological Satellite Program Operational Linescan System imagery by a variational autoencoder, trained on a nighttime light enhancement index that combines that imagery with

the Moderate-resolution Imaging Spectroradiometer vegetation index to mitigate the saturation of the older sensor. The merged series accordingly inherits the spectral limitations of both instruments, and for more than half of the observed span it is a deep-learning reconstruction rather than an observation. The 2020 cross-section rests on instrument data; the two-decade trend does not, at its earlier end.

The authors' own statement that their figures are a floor. Among the limitations the authors record that both sensors have "limited sensitivity to short-wavelength (blue) light below 500 nm, which is the spectral range most strongly associated with non-visual physiological effects such as circadian disruption"; that blue-rich emission has increased substantially with the adoption of solid-state lighting; that satellite radiance therefore underestimates both the visual and the non-visual exposure burden, especially where the conversion to light-emitting diode lighting is rapid; and that "the ALAN exposure estimates presented in this study should be interpreted as conservative lower-bound estimates, and the actual environmental and biological light burden may be greater than indicated by satellite observations alone". This is the concession that matters most in the entry, and it is used at Part V.J.4. It means the exposure figures above are a floor rather than an estimate.

A second limitation the authors state, which cuts the other way. The conversion to light-emitting diode lighting is commonly accompanied by improved shielding and a changed angular distribution of emission, which reduces direct uplight. The authors state that this may weaken the relationship between ground-level illumination and satellite-observed upward radiance and introduces further uncertainty into long-term trend analysis. The consequence is that this record cannot establish the direction of the ground-level trend: better shielding at constant or rising ground illuminance would appear in these data as a reduction, and so would a real reduction. The comment states this at Part V.J.4 rather than leaving it to a reader.

Figures for the United States and other developed countries. The authors report that in the developed countries where the projected change is smallest, the United States among them, the present proportion of the population exposed is already very high, with 70 percent exposed to high light emissions and more than 90 percent exposed to at least low light emissions. Those are the figures of most direct relevance to this Department and they are given in the discussion of the projection figure rather than in a table of national results.

The classification, and a caution about it. The four exposure bands are the authors' own, constructed to "broadly match" the environmental lighting zones of the International Commission on Illumination. The thresholds were set empirically from the distribution of the authors' light emissions index within urbanization categories: the boundary between low and medium at the 75th percentile for rural areas and between medium and high at the 25th percentile for urban areas. The corresponding radiance ranges are given as zero for the combined E0 and E1 bands, 0 to 1.56 for E2, 1.56 to 5.89 for E3 and 5.89 to 100 nanowatts per square centimeter per steradian for E4, with values above 100 capped. The comment must not present those radiance figures as the Commission's own definitions of its zones, because they are not: they are this study's approximation to them. The zones themselves are the same scheme the billboard material at Part VI.J.6 encounters in another setting.

A table in the paper the comment does not use. The discussion reproduces a table of hazard ratios for sleep disorder, breast cancer, coronary heart disease and type 2 diabetes mellitus, compiled from four other studies. The Foundation does not rely on it, for three reasons. It is secondary, and the underlying studies are better cited directly, as this appendix does elsewhere. Several of the intervals include no effect. And the table's own footnote asserts that the higher the neighborhood emissions the greater the risk of disease, which the table does not show: the sleep disorder row rises to 1.43 at the third quintile and then falls to 1.31 and 1.25, so the series is not monotonic. The Foundation records the overstatement rather than repeating it.

Funding, interests and two defects of the published record. Funded by the National Natural Science Foundation of China, grants 42571426 and 52274169. The authors declare no

competing financial interests or personal relationships. Two defects should be noted because the comment relies on this paper. The data availability statement gives, for the simulated day-night band dataset on which the earlier half of the series rests, a Harvard Dataverse private URL carrying an access token rather than a published digital object identifier; a tokenized private link is not a public dataset and may not resolve. And the contribution statement for the third author is empty. Neither affects the findings; both affect what can be said about verifiability and should be checked against the final published version.

Bearing on the statutory question. Paragraph 360ii(a)(2) directs the Secretary to minimize the emissions of and the exposure of people to unnecessary electronic product radiation. This study is a measurement of that exposure and of its trend, performed by academic researchers and published in a peer-reviewed journal, with an express recommendation that action be taken to reduce it. No federal counterpart exists, and no federal baseline exists against which the minimization duty could be assessed. Parts II.D, V.J and IX.H.3.

C.4 Li and others (2026) — bedroom nighttime light and hepatic encephalopathy in hepatocellular carcinoma

Citation. Li S, Zhang S, Li S, Meng T, Feng H. Association between bedroom nighttime light pollution and risk of hepatic encephalopathy in hepatocellular carcinoma patients: a prospective cohort study. Scientific Reports. 2026;16:20417. doi:10.1038/s41598-026-51269-5. Published May 2, 2026. Department of Hepatobiliary and Pancreatic Surgery, First Affiliated Hospital of Xinxiang Medical University, Henan, China.

Design. Prospective cohort study with twelve months of follow-up.

Population. Four hundred and fifty-four patients with hepatocellular carcinoma and compensated cirrhosis, recruited from communities in one city in Henan Province between July 2021 and June 2024, from 477 enrolled. Inclusion required age 18 or over, no prior anti-tumor treatment, and stable nighttime sleep patterns. One hundred and ninety-three were assigned to the exposed group and 261 to the comparison group.

Exposure, as measured. Bedroom nighttime light intensity measured directly with a portable illuminometer between 23:00 and 04:30, at baseline, two months and four months. The three measurements were averaged, and a mean above 50 lux defined the exposed group. Sleep quality was assessed at the same three points using the Pittsburgh Sleep Quality Index.

Outcomes. Overt and minimal hepatic encephalopathy as primary outcomes; liver function markers, esophagogastric variceal rupture and disease-related mortality as secondary outcomes.

Adjustment. Age, body mass index, household income, baseline tumor characteristics including intrahepatic metastasis and capsule invasion, treatment received, dietary intake and exercise duration.

Results. Mean bedroom light above 50 lux was associated with an approximately one- to threefold increased risk of overt and minimal hepatic encephalopathy, and a 1.7- to twofold increased risk of liver function deterioration, variceal rupture and disease-related death. On Cox regression the authors report a 1.9- to 2.7-fold elevated risk of overt hepatic encephalopathy, variceal rupture and death. Reported p values include $p < 0.001$ for overt hepatic encephalopathy, $p = 0.003$ for new-onset minimal hepatic encephalopathy, $p = 0.027$ for variceal rupture and $p = 0.001$ for death. Interaction analyses indicated modification by age of 60 or over and by TNM stage.

What it establishes. Within this clinical population, an association between directly measured bedroom light at night above 50 lux and a set of adverse hepatic outcomes, with consistent direction across several endpoints. Separately and independently of its findings, it

establishes that repeated direct measurement of an individual's nighttime optical exposure is practicable and inexpensive.

What it does not establish. It does not establish causation and does not support extrapolation to the general population. The cohort consists of patients with hepatocellular carcinoma and cirrhosis, in whom hepatic encephalopathy is a complication of the underlying disease. The threshold of 50 lux is more than an order of magnitude above the 3 lux threshold at which the cohort study at Appendix C.2 found effects, so the two are not measuring the same exposure range.

Considerations bearing on confidence. Against, and substantially so. First and most seriously, reverse causation is plausible and is not addressed: hepatic encephalopathy produces sleep-wake inversion, confusion and nocturnal disturbance, so a patient in whom the condition is developing may acquire more bedroom light at night through nocturia, caregiver presence or disorientation, rather than the light producing the condition. The exposure measurements at baseline, two and four months give some temporal ordering but do not exclude subclinical disease preceding them. Second, the adjustment set omits variables ordinarily required in studies of light at night, including urbanicity, ambient noise, air pollution and socioeconomic position beyond household income. Third, the sample is small and drawn from a single city. Fourth, the principal effect estimates are reported as ranges rather than as point estimates with confidence intervals. Fifth, the authors acknowledge that no circadian markers such as melatonin or cortisol were measured and no mechanistic work was undertaken. In favor: the exposure was measured in each participant's own bedroom rather than modeled or reported, repeatedly; the design is prospective; the direction of association is consistent across several distinct endpoints; and the authors state their limitations candidly.

Bearing on the statutory question. The Foundation offers this study for two limited purposes and expressly not for a third. It is offered as one further observation, in a different population and on different endpoints, pointing in the same direction as the literature at Appendix C.2; and it is offered at Part V.J for the proposition that direct measurement of individual nighttime optical exposure is practicable, inexpensive and has been done. It is not offered as evidence that light at night causes disease in the general population, and it would not support that proposition.

C.5 Chen and others (2026) — outdoor artificial light at night and incident ulcerative colitis

Citation. Chen J, Li L, Ran Y, Sun Z, Lu S, Zhuang Y, Wang L, Sun Y, Dai F. Exposure to outdoor artificial light at night is associated with a higher risk of ulcerative colitis: a prospective cohort study from the UK Biobank. Frontiers in Public Health. 2026;14:1704450. doi:10.3389/fpubh.2026.1704450. Published January 30, 2026. Department of Gastroenterology, Second Affiliated Hospital of Xi'an Jiaotong University, and Shaanxi Province Key Laboratory of Gastrointestinal Motility Disorders, China.

Design. Prospective cohort study using the UK Biobank, original research article. Cox proportional hazards regression across four nested models, with restricted cubic splines for non-linearity, and subgroup and sensitivity analyses.

Population. Three hundred and forty-six thousand one hundred and sixty-three participants, mean age 56.15 years, 52.2 percent female, followed for a mean of 13.71 years. One thousand one hundred and six incident ulcerative colitis diagnoses and 508 incident Crohn's disease diagnoses.

Exposure, as assigned. Outdoor artificial light at night derived from satellite datasets in units of nanowatts per square centimeter per steradian, matched to each participant's residential coordinates within a 1,000-meter buffer.

Outcome ascertainment. Incident inflammatory bowel disease identified by diagnostic codes from hospital admission records, primary care records and self-report.

Adjustment. Age, sex, race, education, Townsend Deprivation Index, physical activity, diet, smoking, alcohol, sleep duration, body mass index, grip strength, waist-to-hip ratio, and history of psychiatric disorder, thyroid disease, hypertension and diabetes.

Results. Each standard deviation increment of outdoor exposure was associated with an 8 percent higher risk of incident ulcerative colitis (HR 1.084, 95% CI 1.023–1.149, $p < 0.001$). The highest exposure level carried a 31 percent higher risk than the lowest (HR 1.309, 95% CI 1.12–1.529, $p < 0.001$). The association was non-linear (p for non-linearity 0.0063) and was stronger in women than in men. No significant association was found with Crohn's disease (HR 1.044, 95% CI 0.83–1.308, $p = 0.71$).

What it establishes. An association, in a very large prospective cohort with long follow-up and record-based outcome ascertainment, between satellite-assessed outdoor light at night at the residence and incident ulcerative colitis, with a dose-response relationship.

What it does not establish. Causation. Nor anything about which wavelengths or which light sources are implicated: the authors state expressly that wavelength-specific effects could not be differentiated. The exposure is not a measurement of what any participant received.

Considerations bearing on confidence. Against: the exposure measure is ecological, describing light radiated upward from the neighborhood of residence rather than light reaching the person, and the authors acknowledge that indoor and device exposure is not captured; outdoor light at a residential address is strongly correlated with urbanicity, for which the Townsend index is an imperfect proxy; the effect sizes are modest, and modest hazard ratios are the ones most vulnerable to residual confounding; the cohort is a volunteer sample with known healthy-volunteer selection; several covariates were self-reported; and green space, blue space and noise were not fully accounted for. In favor: very large sample; long follow-up; prospective design with record-based outcomes rather than self-report; extensive adjustment; a demonstrated dose-response relationship; and an internal contrast that bears on confounding, in that ulcerative colitis and Crohn's disease share the urban and socioeconomic distribution but only ulcerative colitis showed the association. A confounder operating through urbanicity would be expected to move both. That contrast is evidence, though not proof, that the finding is not simply a map of where cities are.

Bearing on the statutory question. The Foundation offers this study as one of a set of large-cohort findings associating light at night with disease across unrelated organ systems, and chiefly for the limitation its authors identify. A study of this size and quality that cannot say which wavelengths are implicated demonstrates the measurement gap described at Part V.J.4. That gap is the reason the existing literature cannot by itself support a performance standard, and it is what 21 U.S.C. § 360ii(a)(4) directs the Secretary to close. Parts V.J.4 and IX.H.3.

C.6 Spitschan and others (2026) — expert consensus on research gaps and priorities for ocular light exposure

Citation. Spitschan M, Biller AM, Broszio K, Fischer E, Hegewald J, Rabstein S, Saathoff E, Smolders K, Thalji SM, Weigelt S, Weiskopf D, Zauner J. Ocular light and optical radiation exposure as a modifiable environmental determinant of health: expert consensus on research gaps and priorities. BMC Medicine. 2026;24(1):119. doi:10.1186/s12916-025-04608-8. Published January 29, 2026. PMID 41612386. PMCID PMC12924618. Open access under CC BY.

Article type. Consensus statement and review, not primary research. The Foundation cites it as evidence of the state of expert opinion and of the identified gaps, in accordance with the rule at Part V.A.2, and not as evidence of any health effect.

Method. A multi-disciplinary consensus workshop and expert consultation process with thirteen experts drawn from academia, public health, radiation protection and occupational health institutions, conducted as an in-person and hybrid meeting followed by iterative refinement, feedback and a stated agreement and consensus procedure.

Outputs. Nine identified research gaps, grouped under exposure measurement and estimation, health outcomes and mechanistic understanding, interventions and implementation, and infrastructure, data sharing and integration; eleven research priority areas; and four cross-cutting capacity-building priorities covering global research networks, cross-sector collaboration, communication and policy engagement.

The nine gaps, as stated. Lack of standardized measurement tools; inadequate exposure estimation infrastructure; lack of consistent exposure descriptors and metrics; absence of core outcome standards; limited dose-response evidence; limited evidence on intervention effectiveness; poor characterization of globally representative and vulnerable populations; fragmented data harmonization and sharing; and limited integration of non-visual effects of light into public health frameworks.

What it establishes. That a multi-disciplinary expert group, including radiation protection and occupational health specialists, considers ocular light exposure to be a modifiable environmental determinant of health; that the field in its assessment lacks coordinated research infrastructure, standardized methodology and translational pathways; and that nine specific gaps require a coordinated research program to close.

What it does not establish. Any health effect. It is a statement of expert opinion about research priorities, arrived at by deliberation rather than by experiment, and it reports no data of its own. A consensus process reflects the composition of the panel convened, and a different panel might order the priorities differently.

Considerations bearing on confidence. Against: a consensus statement is not primary evidence; the panel is small at thirteen and predominantly European; the process is described but its outputs remain judgments. In favor: the panel is multi-disciplinary and includes radiation protection and occupational health institutions rather than lighting researchers alone; the method, participants and agreement procedure are described in the paper; it is published in a peer-reviewed general medical journal and is openly available; and it is independent of this Foundation and of this proceeding.

Bearing on the statutory question. This is the most directly responsive document in this appendix to the question the request for information asks. An independent expert body has set out what research is needed on optical radiation exposure as a determinant of health, and the agenda it describes corresponds, gap by gap, to the duties that 21 U.S.C. § 360ii already imposes on the Secretary. The Foundation relies on it to show that the research it asks for is not idiosyncratic, is not the Foundation's invention, and is regarded by specialists in the field as necessary. Parts V.J.4, V.K, IX.H.3 and IX.H.6.

C.7 Quinn and others (2025) — wavelength-resolved outdoor light at night and breast cancer risk

Citation. Quinn EK, Parks J, Gagné T, McLeod CB, Peters CE, Shen-Tu G, Vena J, Aubé M, Bhatti P. Wavelength-resolved measures of outdoor artificial light at night and breast cancer risk. Environment International. 2025 Nov;205:109871. doi:10.1016/j.envint.2025.109871. PMID 41135428.

Design. Pooled analysis of two prospective cohort studies, baseline 2009 to 2016. Cox proportional hazards regression adjusted for breast cancer risk factors and built environment features.

Population. Twenty-four thousand seven hundred and ninety-three female participants, with 674 incident breast cancer cases.

Exposure, and why it is the point of this entry. Outdoor light at night at residential addresses was estimated from photographs taken from the International Space Station between 2011 and 2013, at approximately 30-meter spatial resolution. Because those images carry color information, three measures were derived rather than one: average visual radiance, that is brightness; an average melatonin suppression index, weighting the exposure by the extent to which its spectral composition suppresses melatonin; and the product of the two, termed average impact melatonin suppression index. This is the only study in this appendix in which the spectral composition of the exposure was retained rather than discarded.

Outcome. Incident breast cancer, with exploratory analyses by subtype, including invasive ductal, luminal A and postmenopausal disease, and among participants self-reporting light entering their rooms while sleeping.

Results. No statistically significant associations were observed in the overall study population. Among women reporting light entering their rooms, statistically significant associations of average impact melatonin suppression index with breast cancer risk were observed overall and across each subtype. Those in the highest versus lowest tertile of average impact had a 1.53-fold increased hazard of overall breast cancer (95% CI 1.18 to 1.98).

Conclusion, in the authors' words. "Our findings suggest that outdoor ALAN is associated with increased risk of breast cancer and that both intensity and wavelength of light should be considered when evaluating ALAN exposures."

What it establishes. Principally a methodological proposition, and the Foundation relies on it for that: that a spectrally weighted measure of outdoor light exposure can be derived from available imagery, that it has been derived, and that it did not return the same answer as the conventional brightness measure applied to the same population. Secondarily, a subgroup association between that measure and breast cancer among women reporting light in their sleeping rooms.

What it does not establish. That outdoor light at night causes breast cancer. The primary analysis was null. The association arises in a subgroup defined by self-report, in analyses the authors describe as exploratory.

Considerations bearing on confidence. Against, and the Foundation states these first. The overall result was null, and the positive finding is confined to a self-reported subgroup; subgroup findings among several exposure measures and several disease subtypes carry a substantial risk of false positive, and no adjustment for multiple comparison is apparent from the abstract. The subgroup is defined by self-report of light entering the room, which is not a measurement and may correlate with other exposures. Outdoor light at a residence remains a proxy for personal exposure. The imagery dates from 2011 to 2013 while cohort baselines run from 2009 to 2016, so exposure is assigned from a period that does not align with each participant's entry. In favor: the pooled sample is substantial; the design is prospective with incident cases; adjustment included built environment features as well as conventional risk factors; the exposure derivation is a methodological advance on the satellite products used elsewhere in this literature; and the internal contrast between the brightness measure and the spectrally weighted measure is a comparison within one population rather than across studies.

Bearing on the statutory question. This entry supports the argument at Part V.J.4 and at Part IV.G.4 that the measurand matters. Federal lighting policy selects on a photometric quantity; the epidemiology overwhelmingly measures exposure in photometric or broadband units; and the single study that weighted exposure by spectral composition found that the weighting changed the result. Whether the particular association replicates is unresolved, and resolving it is work that 21 U.S.C. § 360ii(a)(2) and (a)(4) assign to the Secretary. Parts V.F, V.J.4 and IX.H.3.

C.8 Windred and others (2025) — light exposure at night and cardiovascular disease incidence

Citation. Windred DP, Burns AC, Rutter MK, Lane JM, Saxena R, Scheer FAJL, Cain SW, Phillips AJK. Light Exposure at Night and Cardiovascular Disease Incidence. JAMA Network Open. 2025 Oct 1;8(10):e2539031. doi:10.1001/jamanetworkopen.2025.39031. PMID 41129148. PMCID PMC12550636. Open access. Supported in part by the National Institutes of Health. Previously posted as a preprint, Personal night light exposure predicts incidence of cardiovascular diseases in more than 88,000 individuals, medRxiv, June 20, 2025, doi:10.1101/2025.06.20.25329961. The preprint and the published article report the same cohort, the same exposure data and the same analysis, and are one study. The Foundation cites the published version and does not count the preprint separately. Part V.A.1.

Design. Prospective cohort study. Cox proportional hazards models at three levels of adjustment. Cardiovascular disease records across 9.5 years, June 2013 to November 2022.

Population. Eighty-eight thousand nine hundred and five individuals from the UK Biobank, mean age 62.4 years (SD 7.8), 56.9 percent female.

Exposure, as measured. Approximately 13 million hours of light exposure data recorded by wrist-worn light sensors over one week per participant in a naturalistic setting, categorized into the 0 to 50th, 51st to 70th, 71st to 90th, and 91st to 100th percentiles.

Outcomes. Incident coronary artery disease, myocardial infarction, heart failure, atrial fibrillation and stroke, derived from National Health Service records after the period of light tracking.

Adjustment. Established cardiovascular risk factors including physical activity, smoking, alcohol, diet, sleep duration and socioeconomic status, and additionally polygenic risk.

Results. Comparing the brightest nights (91st to 100th percentiles) with dark nights (0 to 50th): coronary artery disease adjusted HR 1.32 (95% CI 1.18–1.46); myocardial infarction 1.47 (1.26–1.71); heart failure 1.56 (1.34–1.81); atrial fibrillation 1.32 (1.18–1.46); stroke 1.28 (1.06–1.55). Larger associations in females for heart failure (p for interaction .006) and coronary artery disease (.02), and in younger participants for heart failure (.04) and atrial fibrillation (.02).

Conclusion, in the authors' words. "In this cohort study, night light exposure was a significant risk factor for developing cardiovascular diseases among adults older than 40 years. These findings suggest that, in addition to current preventive measures, avoiding light at night may be a useful strategy for reducing risks of cardiovascular diseases."

What it establishes. An association, in a large cohort with instrument-measured exposure and record-based outcome ascertainment over 9.5 years, between light exposure at night and the incidence of five distinct cardiovascular conditions, robust to adjustment for conventional risk factors and for polygenic risk, with larger associations in women and in younger participants.

What it does not establish. Causation. Nor anything about which wavelengths or which sources are implicated: the sensor records illuminance, and Part V.J.4 applies. Nor does it establish that the finding generalizes beyond the UK Biobank, for the reason given below.

Relationship to Appendix C.2. This entry and the entry at C.2 are not independent. Both analyze the UK Biobank and both derive exposure from the same wrist-worn light sensor data; the participants substantially overlap. They differ in outcome set, in sample, and in analytic approach, and C.2 adds cardiac magnetic resonance phenotypes that this study does not examine. The Foundation relies on the pair for coherence between subclinical

imaging findings and clinical event findings within one population, and expressly not as two independent replications. Part V.F.

Considerations bearing on confidence. Against: observational, so residual confounding cannot be excluded; exposure sampled over one week and treated as representative; no spectral characterization; the UK Biobank is a volunteer cohort with known healthy-volunteer selection and is not representative of the United States population; and the dependence of this literature on a single cohort limits what can be inferred about generalizability. In favor: large sample; long follow-up; exposure measured by instrument rather than reported or modeled, over approximately 13 million hours; outcomes from national health records rather than self-report; adjustment including polygenic risk, which addresses genetic confounding directly rather than by assumption; consistent direction and substantial magnitude across five distinct conditions; a graded exposure categorization; and an author group of established standing in circadian science.

Bearing on the statutory question. Paragraph 360ii(a)(2) directs the Secretary to minimize the exposure of people to unnecessary electronic product radiation. The authors of this study, on the largest instrument-measured dataset available, conclude that avoiding light at night may be a useful strategy for reducing cardiovascular risk. That is a statement that the exposure is modifiable and that modifying it may matter, which is the premise on which the minimization duty operates. What the study cannot supply, and what no study of this design can supply, is the specification of which emission to limit. Parts V.J.4 and IX.H.3.

C.9 Yang and others (2025) — outdoor light at night, DNA methylation, and lipid control

Citation. Yang L, Wang Q, Zheng H, Wang Y, Miao Z, Li H, Yang Y. Association between outdoor artificial light at night, circadian health, and LDL-C in intracranial artery atherosclerotic stenosis. Clinical Epigenetics. 2025;17(1):132. doi:10.1186/s13148-025-01938-5. Published July 28, 2025. PMID 40722184. PMCID PMC12302883. Open access.

Design. Two components. An observational analysis of patients with intracranial artery atherosclerotic stenosis, using generalized additive models, with residential outdoor light at night estimated from satellite imagery and sleep quality assessed by validated questionnaire. And an animal experiment using untargeted metabolomics and DNA methylation analysis.

Population, human arm. One thousand and ten patients with intracranial artery atherosclerotic stenosis, of whom 32 were classified as having poor low-density lipoprotein cholesterol control after three months of management.

Results, human arm. An association between outdoor light intensity and poorer lipid control, odds ratio 1.02 (95% CI 1.00 to 1.05) per unit increase in radiance. Sensitivity analyses were reported as supporting the stability of the association.

Results, animal arm. Dim light at night promoted global hypomethylation in mice. Melatonin treatment partially counteracted that effect, without reducing the stress response. Metabolic profiling indicated that light at night may regulate lipid metabolism through effects on ATP-binding cassette transporter proteins.

What it establishes. In the animal arm, that an exposure to dim light at night produces a measurable change in genomic methylation, and that administering melatonin partially reverses it. That is a mechanistic result of a different kind from the physiological results elsewhere in this appendix, and the Foundation relies on it as such.

What it does not establish. Nothing of weight in the human arm, and the Foundation declines to rely on that arm. Nothing about humans from the animal arm. The animal exposure is

described as dim light at night without a spectral or photometric characterization in the abstract, so the dose cannot be compared to any human exposure.

Considerations bearing on confidence. Against, as to the human arm, and decisively. The outcome occurred in 32 of 1,010 patients, which is a very small number of events on which to fit an adjusted model; the odds ratio is 1.02 per unit and its confidence interval extends to 1.00, so the result sits at the boundary of conventional significance; the exposure is satellite radiance at the residence and is a proxy for personal exposure; the population is narrow and under active clinical management; and lipid control is in part a function of medication adherence, which may itself vary with the urban and socioeconomic characteristics that covary with residential light. Against, as to the animal arm: species difference, and an exposure that is not characterized in terms that permit comparison. In favor, as to the animal arm: it is experimental rather than observational, the exposure was administered rather than observed, and the melatonin condition functions as a mechanistic test rather than a control alone, since partial reversal by the hormone whose secretion light suppresses is what the hypothesized pathway predicts.

Bearing on the statutory question. The Foundation offers this entry for one proposition only: that the biological effects of light at night under investigation extend to the epigenome, and that the pathway through melatonin is testable and has been tested in an animal model. Whether any comparable effect occurs in humans at the exposures they receive is unknown. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, and paragraph 360ii(a)(4) to study and evaluate conditions of exposure. An open mechanistic question of this kind is what those paragraphs are for. Parts V.F and V.K.

C.10 Ding and others (2025) — personal 24-hour light exposure and adiposity in school-aged children

Citation. Ding W, Li Q, Zhou Y, Xu Y, Wan Y, Tao F, Sun Y. Personal 24-hour light exposure pattern with obesity and adiposity-related parameters in school-aged children: A cross-sectional study based on compositional data analysis. Environmental Research. 2025 Jun;275:121422. doi:10.1016/j.envres.2025.121422. PMID 40118310.

Design. Cross-sectional study. Exposure and outcome measured contemporaneously. Analysis by compositional data analysis, which is the appropriate method for time-use data whose components sum to a fixed total.

Population. Eight hundred and thirty-one school-aged children recruited in Chuzhou, Anhui Province, China, mean age 8.53 years (SD 0.62).

Exposure, as measured. Personal 24-hour light exposure recorded over five days by wearable sensor, divided into four measures: light at daytime at or above 100 lux and below 100 lux, and light at night at or above 1 lux and below 1 lux. Measured exposure averaged 490.1 minutes (SD 92.7) per day at or above 100 lux in daytime, and 311.2 minutes (SD 98.5) per night at or above 1 lux.

Outcome. Adiposity-related parameters measured by body composition analyzer, with percentage body fat as the reported parameter.

Results. An increase of one percent in the proportion of time spent in daytime light at or above 100 lux, equivalent to 14.4 minutes per day, was associated with a 3.10 percent decline in percentage body fat. An additional 14.4 minutes per day at or above 1 lux at night was associated with a 3.49 percent increase. Both at p less than 0.01. The associations were reported as robust in boys after stratification by sex. The compositional analysis estimated that reducing time above 1 lux at night had more influence on the odds of childhood overweight and obesity than increasing daytime light.

What it establishes. Principally an exposure measurement, and the Foundation relies on it for that. The nocturnal light exposure of school-aged children was measured directly, by wearable instrument, over five days, and found to average more than five hours per night at or above 1 lux.

What it does not establish. Any causal relationship between light exposure and body composition. The design is cross-sectional and cannot establish temporal order.

Considerations bearing on confidence. Against, as to the associations. The cross-sectional design is the governing weakness: exposure and adiposity were measured at the same time, and reverse causation is at least as plausible as the hypothesized direction, since a heavier child may spend less time outdoors in daylight and more time indoors under artificial light in the evening. The sample is from a single city. Exposure was sampled over five days. The report that associations were robust in boys implies that they were not in girls, and a sex-stratified inconsistency of that kind requires explanation. The adjustment set is not stated in the abstract. In favor, as to the exposure measurement: the light data are personal and instrumental rather than ambient or modeled; the measurement period covers the full 24-hour cycle rather than night alone; and compositional data analysis is the methodologically correct treatment of time-use data, which many studies in this field do not use.

Bearing on the statutory question. Two matters. First, children are among the populations identified at Part VII and are repeatedly named in this field as a priority for research in which evidence is sparse. Part V.L. Second, and more directly, this study is a measurement of the conditions of exposure of a defined population to optical radiation, which is what 21 U.S.C. § 360ii(a)(4) directs the Secretary to study and evaluate. It was performed in China. The Foundation is aware of no equivalent measurement of the nocturnal optical exposure of children in the United States, and invites the Department to identify one if it exists. Parts V.J, V.K and IX.H.3.

C.11 Deziel and others (2025) — perinatal exposure to outdoor light at night and pediatric papillary thyroid cancer

Citation. Deziel NC, Wang R, Warren JL, Dinauer C, Ogilvie J, Clark CJ, Zhong C, Wiemels JL, Morimoto L, Metayer C, Ma X. Perinatal Exposures to Ambient Fine Particulate Matter and Outdoor Artificial Light at Night and Risk of Pediatric Papillary Thyroid Cancer. Environmental Health Perspectives. 2025;133(5):57026. doi:10.1289/EHP14849. PMID 40209106. PMCID PMC12121722. Open access. Environmental Health Perspectives is the journal of the National Institute of Environmental Health Sciences, National Institutes of Health, Department of Health and Human Services.

Design. Case-control study nested within a California birth cohort, with logistic regression adjusted for potential confounders and stratified by age and by race and ethnicity.

Population. Seven hundred and thirty-six cases of papillary thyroid cancer diagnosed between 0 and 19 years of age in children born between 1982 and 2011, and 36,800 controls frequency-matched on birth year.

Exposure, as assigned. Individual-level exposures assigned for residence at birth. Fine particulate matter from a validated ensemble-based prediction model. Outdoor artificial light at night from the New World Atlas of Artificial Night Sky Brightness.

Results. For outdoor light at night, significantly increased odds of papillary thyroid cancer in the higher exposure tertiles against the reference tertile: tertile 2, odds ratio 1.25 (95% CI 1.04 to 1.50); tertile 3, 1.23 (1.02 to 1.50); and modeled continuously, 1.07 per 1 mcd/m2. In age-stratified analysis the associations were significant in the 15 to 19 year group but not in the 0 to 14 year group. No significant differences by race or ethnicity. For fine particulate matter, odds ratio 1.07 per 10 micrograms per cubic meter (1.01 to 1.14) overall.

What it establishes. An association, in a large case-control study with individual-level exposure assignment, between outdoor artificial light at night at the residence of birth and pediatric papillary thyroid cancer.

What it does not establish. Causation, and the authors are explicit about the reason. They state that outdoor light at night may also serve as a proxy for other outdoor air pollutants or for urbanization, and conclude that further research and refinements to exposure metrics are needed to disentangle these factors. The Foundation reproduces that caution rather than omitting it.

On the phrase environmental carcinogen. The study's statement of objectives describes both exposures as considered environmental carcinogens. That is a characterization of how the exposures are regarded in the literature, offered as the rationale for the investigation. It is not a finding of this study and it is not a regulatory classification. The Foundation cites it as what it is, and Part II.E.6 sets out the use the Foundation makes of it.

Considerations bearing on confidence. Against: the exposure derives from a modeled atlas of night sky brightness rather than from measurement at the residence, and is assigned at birth for an outcome occurring up to nineteen years later; the authors themselves identify confounding by urbanization and co-pollutants as unresolved; the associations did not show a monotonic gradient across tertiles, since the second and third tertile estimates are close together; and the age-stratified result was confined to the older group. In favor: a large case-control sample with registry-ascertained cases; individual-level rather than group-level exposure assignment; a second exposure analyzed in parallel with an independent evidence base, which permits comparison; and candor from the authors about the proxy problem.

Bearing on the statutory question. The Foundation relies on this entry chiefly for the matter developed at Part II.E.6, which concerns the position of this research relative to the determination of May 24, 2024 and the fact that both originate within this Department. As evidence of risk it is one study with a confounding problem its authors name. As an indication that the question is live within the Department's own research establishment, it is difficult to set aside. Parts II.E.6, V.F and IX.H.3.

C.12 Stewart and Albrecht (2025) — light, the circadian clock, and mood-related behavior

Citation. Stewart D, Albrecht U. Beyond vision: effects of light on the circadian clock and mood-related behaviours. npj Biological Timing and Sleep. 2025;2:12. doi:10.1038/s44323-025-00029-1. Published March 13, 2025. PMID 40092590. PMCID PMC11906358. Open access under CC BY.

Article type. Review article. Not primary research and not a systematic review. The Foundation cites it as a synthesis of the state of the field, in accordance with the rule at Part V.A.1, and not as evidence of any particular effect.

Subject. The relationships between light exposure, the circadian clock, and mood-related behavior, together with the underlying mechanisms and their implications for health.

What it establishes. That the pathway from light exposure through circadian timing to mood is a recognized subject of scientific inquiry with identified mechanisms, sufficiently established to support a review in a journal of the Nature portfolio devoted to biological timing. The authors state that light affects the circadian clock, that the clock regulates daily rhythms of biochemical and physiological processes, and that these ultimately bear on mood and behavior, with jet lag and shift work as the familiar illustrations.

What it does not establish. Any quantitative relationship between a given exposure and a given affective outcome. Nothing about light-emitting diode products, which it does not address. Nothing about the exposures encountered in ordinary domestic or roadway

settings. A narrative review reflects the authors' selection of the literature and does not carry the weight of a systematic review with a registered protocol.

Considerations bearing on confidence. Against: secondary rather than primary; narrative rather than systematic; no stated search strategy or inclusion criteria; two authors. In favor: published in a peer-reviewed journal of the Nature portfolio dedicated to the subject matter; openly available in full under a Creative Commons license, so that the Department can read it and need not rely on the Foundation's characterization; and consistent with the mechanisms described independently at Parts V.F and V.C.

Bearing on the statutory question. The Foundation uses this entry for one purpose, set out at Part V.G.2. The first-hand reports at Part VII describe affective responses to light exposure and cannot establish causation. This literature supplies a recognized biologically plausible route by which such responses could arise. The conjunction of a plausible mechanism with an accumulation of reports is the circumstance in which 21 U.S.C. § 360ii(a)(4) directs study and evaluation, and it is not a circumstance in which anyone should reach a conclusion. Parts V.G, VII and IX.H.3.

C.13 Roddick and others (2024) — near-infrared radiation in ambient lighting, cognition, emotion and heart rate variability

Citation. Roddick CM, Wang Y, Chen FS, Durmus D, Royer MP, Veitch JA, Zhao J, Seo YS, Cao W, Whitehead LA. Effects of near-infrared radiation in ambient lighting on cognitive performance, emotion, and heart rate variability. Journal of Environmental Psychology. 2024 Dec;100:102484. doi:10.1016/j.jenvp.2024.102484. Open access under the Creative Commons Attribution license. Received November 29, 2023; accepted November 8, 2024; available online November 9, 2024. Corrigendum: Journal of Environmental Psychology. 2025 Mar;102:102536, doi:10.1016/j.jenvp.2025.102536, available online January 28, 2025, correcting an error in the conversion of irradiance to dose rate at subsection 2.3.1. The corrected figure is approximately 14 watts per square meter, corresponding to 50,400 joules per square meter per hour of exposure.

Design. Preregistered, double-blind, within-subjects laboratory experiment with counterbalanced order. Each participant experienced both lighting conditions in a single two-hour session, approximately forty-five minutes of exposure per condition, separated by a short break during which the lighting was changed while the participant was out of the enclosure. Preregistered on the Open Science Framework in early January 2022, before the first participant was enrolled. Approved by the research ethics boards of the University of British Columbia, the National Research Council of Canada, and Pacific Northwest National Laboratory.

Population. One hundred fifty-six undergraduate students at one university attended; five were excluded, leaving 151 for the cognitive analyses — 117 female, 34 male, mean age 20.25 years, standard deviation 2.62, range 16 to 44. Subsets of 150, 149 and 148 were analyzed for emotion, environmental satisfaction and heart rate variability respectively. Enrollment ran January to April 2022. Exclusion criteria included chronic medical conditions, cardioactive medication, smoking, and color-deficient vision or vision not correctable to normal.

Exposure, as characterized. Two stimuli, both nominally 3500 K white light-emitting diode lighting, at matched illuminance of 741 lux without near-infrared and 748 lux with it. Irradiance above 700 nm was 0.12 watts per square meter in the first condition, described by the authors as typical of modern office lighting, and 14.11 watts per square meter in the second, supplied by additional emitters peaking at 735 nm in the far red and at 875 and 960 nm in the near infrared. Correlated color temperature was 3316 K and 3213 K. The alpha-opic quantities were closely matched: melanopic irradiance 0.532 against 0.539 watts per square meter, rhodopic 0.662 against 0.669, S-cone-opic 0.258 against 0.265, M-cone-opic 0.904 against 0.917, L-cone-opic 1.215 against 1.246. Colorimetric and alpha-

opic analysis under ANSI/IES TM-30-20 and CIE S 026/E:2018 indicated no noticeable chromaticity change. An infrared-detecting photodiode verified within each session that the intended stimulus was present.

Outcomes and measurement. Attention by a visual search foraging task; perception by a visual comparison task; short-term and working memory by forward and backward digit span; executive function by a hundred-trial flanker task. All cognitive tasks were administered on paper rather than on a screen, to avoid additional light exposure. Emotional state by a modified Affect Grid yielding separate pleasure and alertness scores, taken on seven occasions. Environmental satisfaction by a preference question at the end of the session. High-frequency heart rate variability from continuous electrocardiography sampled at 1000 Hz, analyzed in sixty-second epochs across approximately 45 minutes of exposure per condition, at rest and during cognitive demand.

Result — cardiovascular. Resting high-frequency heart rate variability was higher under lighting containing near-infrared. In the initial linear mixed model the main effect of lighting condition was beta = 0.17, standard error 0.07, t = 2.41, p = .016, 95 percent confidence interval 0.03 to 0.31. In the final model retaining covariates for experimental order, rest period, sex, lighting preference and caffeine consumption, beta = 0.13, standard error 0.06, t = 2.25, p = .025, interval 0.02 to 0.24. The response to cognitive demand was larger under near-infrared for four of the five tasks, all p < .001, the exception being visual comparison, p = .607. A significant interaction with experimental order, beta = −0.34, t = −4.58, p < .001, indicates the effect was more pronounced among participants who encountered near-infrared in the second block.

Result — emotional. A main effect of lighting condition on pleasure, beta = −0.26, standard error 0.10, t = −2.46, p = .014, interval −0.46 to −0.05, qualified by an interaction with experimental order, beta = 0.30, standard error 0.11, t = 2.63, p = .009, interval 0.08 to 0.53. Participants who began without near-infrared declined in pleasure during that block, mean change −0.76, standard deviation 1.44, and rose during the subsequent near-infrared block, mean 0.12, standard deviation 1.64. Those who began with near-infrared declined less, mean −0.29, standard deviation 1.34. There was no main effect of lighting condition on alertness, beta = 0.02, p = .821, although an interaction with order was present.

Result — cognitive, and stated preference. Lighting condition predicted performance on one of the five cognitive tasks, visual search, and in the direction opposite to the hypothesis: performance was worse under near-infrared, F = 8.94, p = .003, Cohen’s d = 0.12. There was no significant effect of lighting condition on perception, short-term memory, working memory or executive function. Asked at the end of the session which half of their time they had preferred, a majority in both order groups chose the block without near-infrared — 59.1 percent of one group and 54.2 percent of the other — with only a weak association to order, Yule’s Q = 0.26. The Foundation reports these results because they ran against the authors’ hypotheses.

Blinding. Of 149 participants asked directly whether they had noticed a difference between the two blocks, 21, or 14.1 percent, reported one. None mentioned lighting when asked unprompted what they believed the study hypothesis to be. The authors note that the small number who did perceive a difference tended to describe the near-infrared block in more positive terms.

Funding and affiliations. The funding statement reads: “This work was supported by the U.S. Department of Energy’s Lighting R&D Program, part of the Building Technologies Office within the Office of Energy Efficiency and Renewable Energy (EERE).” The declaration of competing interest states none. Author affiliations are the University of British Columbia, Pennsylvania State University, Pacific Northwest National Laboratory, and the National Research Council of Canada.

Conclusion, in the authors' words. "This study provides preliminary evidence that ambient near-infrared (NIR) exposure in architectural lighting can influence both physiological and psychological states." And, on the implication: "the move away from the natural balance of visible and near-infrared radiation found outdoors—the condition under which humans evolved—may not be optimal for well-being, even if it is better for delivering more light output for less energy."

What it establishes. That the near-infrared content of ambient lighting is a variable with measurable physiological and affective effects in humans, at an exposure duration representative of part of an indoor working day, and that those effects are present when the visible content of the light is held constant. Because the two conditions were matched on illuminance, on correlated color temperature and on every alpha-opic quantity, the observed differences cannot be attributed to brightness, to color appearance or to melanopic stimulation. They are attributable to the presence or absence of radiation above 700 nanometers. It further establishes that a federal research program has treated the question as open and worth funding.

What it does not establish. That near-infrared content is beneficial on balance. The findings are mixed: a physiological effect in the predicted direction, an affective effect qualified by order of exposure, a cognitive effect in the opposite direction on one task of five, no effect on alertness, and a majority stated preference for the condition without near-infrared. It does not establish long-term effects, a dose-response relationship, an optimal exposure, a threshold, or a mechanism; the authors identify each of these as unresolved. The sample was young, predominantly female, and drawn from a single university. Exposure lasted about forty-five minutes per condition with a washout of only a few minutes. It establishes nothing about outdoor lighting, nothing about light at night, and nothing about any disease outcome.

Considerations bearing on confidence. In favor: preregistration on a public registry before the first participant was enrolled; within-subjects design with counterbalanced order; effective double-blinding, confirmed by direct questioning of participants; complete radiometric, colorimetric and alpha-opic characterization of both stimuli; independent verification of the stimulus within each session; retention of the main effect after adjustment for covariates; ethics approval from three institutions; and the publication of a corrigendum correcting the authors' own unit conversion, which is evidence of post-publication scrutiny rather than against the work. Against: a washout period of only a few minutes, which the authors acknowledge; short exposure; a narrow and young sample; self-reported covariates including sleep and caffeine; a small effect size on the single significant cognitive result; and no mechanism tested. The authors characterize the work as preliminary and the Foundation adopts that characterization.

Bearing on the statutory question. This entry is not offered to show that light-emitting diode products are unsafe, and it should not be read that way. It is offered for four propositions. First, that the absence of a band of wavelengths from a product's emission is a characteristic with measurable human effects, which is the premise of Part V.B.6. Second, that such effects are detectable only by an instrument that resolves the spectrum, since here every photometric and alpha-opic quantity was matched while the band above 700 nanometers differed by a factor exceeding one hundred — which demonstrates rather than asserts the measurement argument at Part V.J.4. Third, that the question is unresolved in the direction of requiring study rather than of being settled, which is the condition to which § 360ii(a)(4) speaks. Fourth, and independently of the science, that the research was funded by the Department of Energy program whose standards are described at Part IV.G, which bears on whether the subject matter could have been unknown to the federal government when § 360ii(a)(6) consultation did not occur. Parts IV.G.4, V.B.6, V.J.4 and IX.H.3.

C.14 Palomar-Cros and others (2024) — artificial light at night and cancer risk, systematic review and meta-analysis

Citation. Palomar-Cros A, Deprato A, Papantoniou K, Straif K, Lacy P, Maidstone R, Adan A, Haldar P, Moitra S, Navarro JF, Durrington H, Moitra S, Kogevinas M, Harding BN. Indoor and outdoor artificial light-at-night (ALAN) and cancer risk: A systematic review and meta-analysis of multiple cancer sites and with a critical appraisal of exposure assessment. Science of the Total Environment. 2024 Dec;955:177059. doi:10.1016/j.scitotenv.2024.177059. PMID 39437923. First published online October 20, 2024. Open access under the Creative Commons Attribution-NonCommercial license.

Article type. Systematic review and meta-analysis of observational studies, conducted with a formal critical appraisal of exposure assessment. This is the highest level of synthesis in the evidence hierarchy represented in this appendix, and the Foundation draws attention to that in connection with the characterization of this literature described at Part IV.C.

Search and selection. Six databases, two registries and Google Scholar were searched from inception to April 17, 2024. Nine thousand eight hundred thirty-five records were identified; 28 studies were included for qualitative synthesis, comprising 2,508,807 individuals in 15 cohort and 13 case-control studies. Eligible designs were observational studies of indoor or outdoor artificial light at night and cancer incidence, reporting relative risk, hazard ratio or odds ratio. Study quality was appraised using the Joanna Briggs Institute critical appraisal tools. Pooled estimates were obtained by random-effects meta-analysis.

Result — breast cancer. Twenty studies, 731,493 individuals. Higher outdoor artificial light at night was associated with breast cancer risk, pooled relative risk 1.12, 95 percent confidence interval 1.03 to 1.23, with substantial heterogeneity, I squared = 69 percent. For indoor light the association was positive but not statistically significant, 1.07, 0.95 to 1.21, I squared = 60 percent. No differences were observed by menopausal status.

Result — other sites. Two studies of prostate cancer, 53,254 individuals, gave a pooled estimate for higher outdoor light of 1.43, 0.75 to 2.72, not statistically significant, with I squared = 90 percent. In the qualitative synthesis the authors report positive associations with non-Hodgkin lymphoma and with colorectal, pancreatic and thyroid cancer. The Foundation has not obtained the individual estimates for those sites and does not state them.

The authors' own appraisal of exposure assessment. The authors report that most included studies relied on satellite images of very low resolution, one to five kilometers, from the Defense Meteorological Satellite Program, and without information on the color of light, and conclude that future studies with better exposure assessment should investigate other cancer sites. The critical appraisal of exposure assessment is announced in the title of the paper and is therefore a stated object of the work rather than an incidental limitation.

What it establishes. That a substantial body of observational evidence associates higher outdoor artificial light at night with breast cancer risk, and that the association survives formal systematic review and random-effects pooling across twenty studies. And, separately, that the investigators who assembled that body regard its exposure assessment as the limiting factor, for two stated reasons: spatial resolution of one to five kilometers, and the absence of any information about the color of the light measured.

What it does not establish. Causation. The included designs are observational and the authors report associations. It does not establish any proposition about light-emitting diode products as against the sources they replaced, and cannot, because the exposure instrument carries no spectral information and cannot distinguish sources by correlated color temperature or spectral power distribution. It does not establish an indoor

association, which was not statistically significant. It does not establish a prostate cancer association. The pooled estimates for the sites described qualitatively are not reported here. It says nothing about any non-cancer outcome and nothing about exposure during daylight hours.

Considerations bearing on confidence. In favor: prospectively structured systematic review with a stated search strategy, stated inclusion criteria, a published quality appraisal instrument, and random-effects pooling; very large aggregate population; a strong authorship in cancer and environmental epidemiology; and an express critical appraisal of exposure assessment, which is uncommon and which the Foundation treats as a mark of care. Against: substantial heterogeneity in every pooled estimate, I squared of 69, 60 and 90 percent; the principal estimate of 1.12 is modest and its lower bound close to unity; only two studies supported the prostate analysis; publication bias in a literature of this kind cannot be excluded on the information available to the Foundation; and the exposure defect the authors identify applies to the pooled estimate as much as to the individual studies.

Bearing on the statutory question. The Foundation uses this entry principally at Part V.J.4, and for a purpose that does not depend on the strength of the cancer association. The subsection argues that the epidemiology of artificial light measures exposure in units that discard spectral composition, and therefore cannot by itself specify an emission characteristic for a performance standard under § 360kk, however large the literature grows. This review states that proposition about its own field, in its own title and in its own conclusion. The Foundation also offers it at Part IV.C, on the characterization of this literature as low quality evidence: a systematic review of 9,835 screened records and 2.5 million individuals, appraised with a published instrument and published in a peer-reviewed journal, is not met by that characterization without reasons given. And it bears on the request at Part IX.F, because what the authors ask for — better exposure assessment, applied prospectively — is what § 360ii(a)(2) and (a)(4) direct the Secretary to provide and what no individual research group can supply.

C.15 Chang and others (2024) — hepatic injury following light-emitting diode light exposure in mice

Citation. Chang MC, Wang SR, Lin DPC, Chang HH. Hepatic inflammation, ballooning, and pyknosis caused by LED light exposure in a mouse model, with differential effects by age and gender. Ecotoxicology and Environmental Safety. 2024 Oct;284:116984. doi:10.1016/j.ecoenv.2024.116984. PMID 39265263. First published online September 11, 2024. Open access under the Creative Commons Attribution license.

Design. Controlled animal experiment. C57BL/6 mice were exposed to light-emitting diode light under one of two regimes: 1,000 lux for twelve hours per day for 45 days, or 4,500 lux for one hour per day for seven days. Animals were aged either 8 weeks or 36 weeks, and both sexes were studied. A twelve-hour light and dark cycle was maintained throughout and the diet was not altered. Liver tissue sections were examined by hematoxylin and eosin staining and by immunohistochemistry.

Exposure, as characterized. Stated in illuminance only — 1,000 lux and 4,500 lux at the stated durations. The authors describe light-emitting diode sources as delivering higher levels of blue light than other light sources, which is the rationale for the study, but the abstract reports no correlated color temperature, no spectral power distribution, and no irradiance in any wavelength band. The Foundation notes the irony and the relevance: a study whose premise is the spectral composition of the source reports its exposure in the photometric unit that discards spectral composition. Part V.J.4.

Outcomes and measurement. Histopathological examination of liver tissue for inflammation, hepatocellular ballooning and pyknosis, with immunohistochemical staining for the macrophage marker F4/80 and for tumor necrosis factor alpha.

Result. The animals exposed at 1,000 lux displayed liver injury described by the authors as severe, comprising inflammation, ballooning and pyknosis. The same changes were present to a lesser extent in the animals exposed at 4,500 lux. Older animals showed aggravated injury. Hepatocellular ballooning was more severe in males; females expressed the F4/80 and tumor necrosis factor alpha inflammatory markers more evidently. The abstract reports these results qualitatively and the Foundation has not obtained the quantitative scores.

A caution about the two exposure groups. The greater injury in the 1,000 lux group should not be read as showing that lower illuminance is more harmful. The two regimes differ in duration as well as in intensity, and the cumulative exposures are not comparable: roughly 540,000 lux-hours in the first group against roughly 31,500 in the second, a ratio of about seventeen to one. The comparison is therefore consistent with cumulative exposure driving the result, and it confounds intensity with duration. The Foundation states this because the abstract's phrasing could be read the other way, and because a comment that misreads a study it relies on forfeits the right to be read carefully itself.

What it establishes. That controlled exposure to light-emitting diode illumination, at the intensities and durations administered, produced histologically identifiable liver injury in a mouse model, and that the severity varied with age and differed by sex. The feature the Foundation relies on is the design: the light and dark cycle was maintained and the diet was unchanged, so the result is not attributable to circadian disruption, to sleep loss, or to light at night. The exposure variable was the emission itself during the light phase.

What it does not establish. Anything about human liver health. The subject is a nocturnal rodent whose retinal organization, light biology and hepatic physiology differ materially from a human's, and the Foundation states that indirectness here as Part V.A.2 requires. It does not establish a dose at which effects begin, a threshold, or a no-effect level, and the two regimes tested do not support a dose-response curve. It does not establish that the blue content of the source was the operative variable, since no comparison with a source of different spectral composition at matched illuminance is reported in the abstract. Histological change is not clinical disease. It establishes nothing about any product in commerce.

Considerations bearing on confidence. In favor: experimental rather than observational, so the exposure was assigned rather than observed and confounding by urbanization, socioeconomic position and the rest does not arise; a maintained light and dark cycle and unaltered diet, which exclude two major alternative explanations; age and sex examined as prespecified factors; peer-reviewed and published open access. Against: a single laboratory; no spectral characterization reported; illuminance at 1,000 lux for twelve hours daily is high relative to ordinary rodent husbandry and its human analogue is not obvious; outcomes reported qualitatively in the abstract; no comparison light source of differing spectrum; and the species difference. The Foundation also records an apparent tension within the abstract, which reports ballooning as more severe in males while identifying females among the vulnerable groups in its conclusion; the full text is needed to resolve how those two statements fit together.

Bearing on the statutory question. Two uses, both narrow. The first is at Part V.A.2: this is evidence about artificial light that does not depend on light at night, and it therefore answers the objection that the literature in this Part is really about sleep and circadian timing rather than about what a product emits. The second is at Part II.F. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and paragraph 360ii(a)(5) directs the development, testing and evaluation of procedures for minimizing exposure. An experiment that varies an emission under controlled conditions and examines an endpoint unavailable in human subjects is the form of work those paragraphs contemplate. The Foundation offers this entry to show that such work is feasible and is being done

elsewhere, not to show that light-emitting diode products injure the human liver. It does not contend that they do. Parts II.F, V.A.2 and IX.H.3.

Related entry. Appendix C.4 reports an association in humans between bedroom nighttime light and hepatic encephalopathy in hepatocellular carcinoma. The Foundation notes the convergence of organ system without resting anything on it: the exposures, the species, the designs and the outcomes differ, and two studies concerning the liver are not a finding about the liver.

C.16 Voigt and others (2024) — outdoor nighttime light and Alzheimer's disease prevalence

Citation. Voigt RM, Ouyang B, Keshavarzian A. Outdoor nighttime light exposure (light pollution) is associated with Alzheimer's disease. Frontiers in Neuroscience. 2024;18:1378498. doi:10.3389/fnins.2024.1378498. Published September 6, 2024. Open access.

Design. Observational, cross-sectional, and ecological. The unit of analysis is the geographic area, not the person. Satellite-derived average outdoor nighttime light intensity for each area was compared with the prevalence of Alzheimer's disease recorded in Medicare data for the same area. The Foundation emphasizes this characteristic at the outset because it governs everything the study can and cannot support.

Population and units. Medicare beneficiaries, 2012 to 2018, analyzed at the level of 48 states and 46 counties. No individual was linked to that individual's own light exposure. The effective sample size for the correlations reported is the number of geographic units, not the number of beneficiaries.

Exposure, as measured. Radiance from the Visible Infrared Imaging Radiometer Suite day-night band aboard the Suomi National Polar-orbiting Partnership satellite, in nanowatts per square centimeter per steradian, averaged annually and grouped into quintiles by state and quartiles by county. This is a broadband upward-radiance measurement carrying no information about the spectral composition of the light. Part V.J.4.

Outcome and analysis. Alzheimer's disease prevalence from the Medicare Chronic Conditions data, compared across light-intensity categories by analysis of variance and by linear mixed models with age, sex and race as covariates, and with a set of comorbid conditions entered as additional factors.

Result. A positive correlation between light intensity and Alzheimer's disease prevalence, $r(46) = 0.557$, $p < 0.001$. Atrial fibrillation, diabetes, hyperlipidemia, hypertension and stroke were more strongly associated with prevalence than nighttime light was; alcohol abuse, chronic kidney disease, depression, heart failure and obesity were less strongly associated with it. In beneficiaries under the age of 65, nighttime light was more strongly associated with prevalence than any other factor examined, and remained significant after adjustment, coefficient 0.174, $p = 0.007$.

Conclusion, in the authors' words. "These data suggest light exposure at night may influence AD, but additional studies are needed."

What it establishes. That across United States states and counties, areas with brighter measured outdoor nighttime light have on average a higher recorded prevalence of Alzheimer's disease among Medicare fee-for-service beneficiaries, and that this relationship persists in the authors' models after adjustment for the covariates they entered. That is a statement about places. It is not a statement about people.

What it does not establish. Nothing about any individual. An association between area-level averages does not license an inference about the individuals within those areas; this is the ecological fallacy, and it applies to this study in full force. The design is cross-sectional and reports prevalence rather than incidence, so it cannot establish that exposure preceded

disease, and prevalence is affected by survival as well as by onset. Outdoor nighttime light is among the closest available proxies for urbanization, and therefore covaries with air pollution, population density, socioeconomic position, access to specialist care and the intensity of diagnostic coding — areas with more neurologists record more dementia diagnoses. It establishes nothing about light-emitting diode products, since the exposure instrument carries no spectral information. It establishes nothing about indoor light, which was not measured.

Considerations bearing on confidence. In favor: a national dataset; a prespecified comparison against a panel of established disease factors, which is a useful discipline and which placed light in the middle of that panel rather than at the top; open access publication; and an explicitly tentative conclusion. Against, and the Foundation sets these out at length because they are substantial: the ecological design; cross-sectional prevalence data; an effective sample of 48 and 46 units; confounding by urbanization that no area-level adjustment can resolve; Medicare fee-for-service coverage only, excluding a large share of beneficiaries enrolled in Medicare Advantage; and reliance on administrative diagnostic coding. The Foundation adds one caution the abstract does not state. Medicare beneficiaries under the age of 65 qualify through disability, so the under-65 group is a strongly selected population and is not the general population under 65. The striking finding in that group should be treated as hypothesis-generating and nothing more.

Rating within this appendix. The Foundation records that this is the weakest entry in Appendix C by study design, and says so rather than leaving the Department to discover it. It is included because the Foundation undertook at Part V.A.1 to describe the literature it relies on without selection for strength, and because the entry is used for a purpose that does not depend on the finding.

Bearing on the statutory question. The Foundation offers this entry for two propositions, neither of which requires the association to be real. The first is at Part II.E.6: the study was funded by the National Institutes of Health, under grants R01AG056653 and R24AA026801. The Secretary of Health and Human Services is therefore already supporting research into the health effects of artificial light at night, which is one of the four verbs of § 360ii(a)(2), while the planning, conducting and coordinating that the same paragraph directs are absent as to light-emitting diode products. The second is at Part V.J.4: here again the exposure is satellite radiance, broadband and blind to spectrum, and here again the result cannot say which light. Parts II.E.6, V.J.4 and IX.H.3.

C.17 Wu and others (2024) — outdoor light at night, air pollution, and cerebrovascular disease

Citation. Wu Y, Shen P, Yang Z, Yu L, Xu L, Zhu Z, Li T, Luo D, Lin H, Shui L, Tang M, Jin M, Chen K, Wang J. Outdoor light at night, air pollution, and risk of cerebrovascular disease: a cohort study in China. Stroke. 2024 Apr;55(4):990–998. doi:10.1161/STROKEAHA.123.044904. PMID 38527152. Published online March 25, 2024.

Design. Prospective population-based cohort study with incident clinical outcomes and time-to-event analysis by Cox proportional hazards models. Participants were enrolled in Ningbo, China between 2015 and 2018.

Population. Twenty-eight thousand three hundred and two participants, followed through 127,877 person-years.

Exposure, as measured. Outdoor light at night estimated from satellite-derived imagery. Air pollution — particulate matter of aerodynamic diameter 2.5 micrometers or less, particulate matter of 10 micrometers or less, and nitrogen dioxide — estimated separately by land-use regression models. The light exposure is a broadband upward-radiance product and carries no information about spectral composition. Part V.J.4.

Outcomes and measurement. Incident cerebrovascular disease confirmed by medical records and death certificates, subdivided into ischemic and hemorrhagic stroke. One thousand two hundred and seventy-eight cerebrovascular disease cases were identified, including 777 ischemic and 133 hemorrhagic strokes.

Result — single-exposure models. Per interquartile-range increase: outdoor light at night, hazard ratio 1.17, 95 percent confidence interval 1.06 to 1.29; fine particulate matter, 1.25, 1.12 to 1.39; coarse particulate matter, 1.14, 1.06 to 1.22; nitrogen dioxide, 1.21, 1.06 to 1.38. Results were similar for ischemic stroke. No association was observed for hemorrhagic stroke.

Result — multiple-exposure models. The associations of outdoor light at night and of particulate matter with cerebrovascular disease persisted when both were entered together, but did not persist for ischemic stroke specifically. No interaction between outdoor light at night and air pollution was observed.

Conclusion, in the authors' words. That levels of exposure to outdoor light at night and air pollution were positively associated with the risk of cerebrovascular disease, and that the detrimental effects of the two might be mutually independent.

What it establishes. That in a cohort of this size, followed prospectively with outcomes verified against medical records and death certificates, outdoor light at night was associated with incident cerebrovascular disease, and that the association persisted after air pollution was measured by an independent method and adjusted for in the same model. This is the entry in Appendix C that speaks most directly to the confounding objection described at Part V.A.2, because it tested the most commonly named confounder rather than listing it as a limitation.

What it does not establish. Causation; the design is observational. It does not establish an association with hemorrhagic stroke, and in the multiple-exposure models it does not establish one with ischemic stroke specifically — only with cerebrovascular disease overall, and the Foundation does not state the result more broadly than that. It does not exclude residual confounding by urban factors other than air pollution, such as noise, traffic, density or socioeconomic position. It establishes nothing about which light, because the exposure instrument carries no spectral information, and therefore nothing about light-emitting diode products as against the sources they replaced. The cohort is drawn from one Chinese city, whose lighting stock, spectrum mix and installation practice are not those of the United States, and the Foundation does not assume transferability.

Considerations bearing on confidence. In favor: prospective design; substantial size and person-time; incident rather than prevalent outcomes; outcome ascertainment against medical records and death certificates rather than self-report; independent measurement of the principal suspected confounder by land-use regression; multiple-exposure modeling; publication in a leading specialty journal. Against: observational; a single city; residual confounding; no spectral characterization of the exposure; the attenuation of the ischemic stroke result in the multiple-exposure models; and a modest hazard ratio with a lower bound near unity.

Bearing on the statutory question. The Foundation offers this entry for three purposes. First, at Part V.A.2, as the answer to the confounding objection: the alternative explanation most often offered for associations of this kind was measured and adjusted for, and the association survived. Second, at Part V.J.4, as a further instance of the measurement problem, since even this study — the methodologically strongest of its kind in this appendix — cannot say which light, for the same reason as all the others. Third, for the comparison set out at Part V.A.2: the hazard ratio reported here for light at night is of the same order as that reported in the same cohort for fine particulate matter, an exposure that is the subject of a national standard and a national monitoring network, while light at night is federally unmeasured. Parts V.A.2, V.J.4 and IX.H.3.

C.18 Salceda (2024) — light pollution, oxidative stress, and the retina

Citation. Salceda R. Light pollution and oxidative stress: effects on retina and human health. Antioxidants. 2024;13(3):362. doi:10.3390/antiox13030362. PMID 38539895. Published March 18, 2024. Open access.

Article type. Narrative review by a single author. Not primary research, not a systematic review, and no search strategy or inclusion criteria are stated. The Foundation cites it as evidence of the state of expert opinion, in the category described at Part V.A.2, and not as primary evidence of any effect. Every quantitative figure reported below is taken by the review from another source and has not been verified by the Foundation against that source.

Subject. The mechanisms by which artificial light, and short-wavelength light in particular, is reported to produce oxidative stress in ocular tissue, together with the downstream consequences discussed in the literature: reactive oxygen species production, photoreceptor apoptosis, injury to the retinal pigment epithelium, effects on intrinsically photosensitive retinal ganglion cells and melanopsin, melatonin suppression, circadian disruption, and mitochondrial dysfunction.

Figures the Foundation relies on, and their status. The review reports that more than 65 percent of blue light at 460 nanometers is transmitted to the retinas of children under nine years of age, and that intrinsically photosensitive retinal ganglion cells constitute approximately one percent of the human retinal ganglion cell population. The first of those figures has since been traced one step further. The 2012 Opinion of the European predecessor committee, at Appendix D.1, states the same figure within a full age-resolved table, and Part V.C.2.g now cites that Opinion rather than this review. The Opinion is itself a secondary source and does not identify the underlying measurement, so the trace is not complete, but this entry is no longer the authority for the figure anywhere in the comment. The second figure is relied on for context only. The review also reports a number of further figures the Foundation does not rely on, among them that blue light constitutes approximately 25 percent of solar radiation, that electronic devices emit approximately 30 percent of their radiation in the blue, and that indoor lighting emits between 6 and 40 percent; the last of those would be useful at Part V.B.3 if it could be traced to a measurement, and it should not be used before it is.

The authors' own limitation, which the Foundation emphasizes. The review states that there is currently insufficient evidence to conclusively determine the direct effects of light-emitting diode light sources when used normally at domestic intensity levels or as backlights in screen devices, and that more epidemiological, clinical and fundamental research is required to assess their risk factors in age-related macular degeneration, aging and overall health, especially for vulnerable groups such as children and adolescents.

What it establishes. That a mechanism by which short-wavelength light produces oxidative stress in retinal tissue is described and discussed in the peer-reviewed literature, and is treated by reviewers in the field as biologically established at the exposures used in laboratory study. And, separately and with equal importance for this comment, that a reviewer surveying that literature in 2024 concluded that the effects of light-emitting diode sources at domestic intensities are not determined and that further research is required.

What it does not establish. That light-emitting diode products in ordinary domestic or occupational use injure the human retina. The review expressly declines to draw that conclusion, and the Foundation does not draw it either. Many of the exposures underlying the mechanistic literature it surveys are laboratory exposures far above domestic levels — the review refers to intensities such as 8,000 lux for eight hours — and several are in nocturnal animals, whose retinal organization differs from a human's. Nothing in it establishes a dose-response relationship in humans, a threshold, or a safe level. The Foundation does not carry forward the review's closing observations about skin aging and

cancer development, which are outside its subject matter and beyond what a narrative review of this kind can support.

Considerations bearing on confidence. In favor: peer-reviewed, open access, indexed in PubMed, written by a researcher in the field, and notably candid about the limits of the evidence it surveys, which the Foundation treats as a mark of care. Against: narrative rather than systematic; a single author; no stated search strategy, inclusion criteria or quality appraisal; secondary throughout, so every figure is reported at one remove; and a conclusion that ranges beyond the retina into skin and cancer on a thinner basis than the ocular material. The Foundation gives it the weight appropriate to a narrative review and no more.

Bearing on the statutory question. Two uses. The first is at Part V.C.2.g, for the proposition that ocular transmission of short-wavelength light varies with age, so that an identical emission produces an unequal retinal dose across the exposed population. That is a fact about conditions of exposure, which is the second of the two objects § 360ii(a)(4) names. The second use is at Part V.A.2 and Part I.C.7. The review concludes that the evidence is insufficient to determine the effects of light-emitting diode sources at domestic levels. The Center for Devices and Radiological Health has stated that such products have a long history of safety with respect to the visible wavelengths they emit. Those two statements are not the same statement, and the difference between them is the whole of this comment. Insufficient evidence to determine an effect is the occasion for the research § 360ii(a)(2) and (a)(4) direct; it is not a finding of safety. Parts I.C.7, V.A.2, V.C.2.g, IX.L and IX.H.3.

C.19 Powner and Jeffery (2024) — 670-nanometer light and circulating blood glucose in humans

Citation. Powner MB, Jeffery G. Light stimulation of mitochondria reduces blood glucose levels. Journal of Biophotonics. 2024;17(5):e202300521. doi:10.1002/jbio.202300521. PMID 38378043. Received December 8, 2023; accepted January 21, 2024. Open access under the Creative Commons Attribution license. Affiliations: Centre for Applied Vision Research, City, University of London; UCL Institute of Ophthalmology.

Design. Randomized, sham-controlled, participant-blinded parallel group trial with an additional paired within-participant analysis. Each participant attended twice: a control oral glucose tolerance test at visit one, and within seven days a second test preceded by the allocated intervention. A crossover design was deliberately not used, the authors explaining that a single 670-nanometer exposure is reported to have effects persisting five to seven days and that individual glucose tolerance responses vary over time. Ethics approval ETH2122-1596, City, University of London; conducted in accordance with the Declaration of Helsinki with informed consent.

Population. Thirty healthy adults, randomized at recruitment: 15 to 670-nanometer exposure, mean age 41.1 years, standard deviation 13.1; 15 to sham, mean age 38.3, standard deviation 13.7. No known metabolic conditions and no medication.

Exposure, as characterized. Light-emitting diode array with a peak wavelength of 670 nanometers and a half-power bandwidth of approximately 10 nanometers, positioned 400 millimeters from the participant and shielded against leakage, delivering 40 milliwatts per square centimeter for 15 minutes to an 800 square centimeter area of upper back — a total of 28,800 joules, over roughly four percent of body surface area. Exposure began 45 minutes before glucose consumption. Sham participants were positioned identically for 15 minutes with the array switched off, and were blinded to allocation.

Outcomes and measurement. Standard oral glucose tolerance test: 75 grams of glucose in 150 milliliters of water after a fast of at least ten hours, with capillary blood glucose by finger-prick at 0, 15, 30, 45, 60, 75, 90, 105 and 120 minutes. End-tidal carbon dioxide partial pressure and breath rate were measured at the same intervals by side-stream

capnometry. Analysis by repeated-measures multivariate analysis of variance with post hoc Mann-Whitney U tests, and Wilcoxon signed rank tests for paired data; two-tailed throughout.

Result — between groups. Comparing the two interventions, each baselined against its own group's control test: total circulating glucose by area under the curve was reduced 7.3 percent, p = 0.0061; the post-consumption rise in glucose was reduced 27.7 percent, p = 0.0002; and peak glucose concentration fell 12.1 percent, from 10.8 to 9.5 millimoles per liter, p = 0.0102. Repeated-measures analysis gave p = 0.035 for absolute concentration and p = 0.049 for the baselined data, with post hoc differences significant at 45, 60, 75 and 90 minutes after loading.

Result — within participants. In the exposed group, comparing each participant's intervention visit against that participant's own control visit: absolute glucose by area under the curve reduced 7.9 percent, p = 0.0012; the baselined rise reduced 26.3 percent, p = 0.0008; peak concentration reduced 7.5 percent, from 10.3 to 9.5 millimoles per liter, p = 0.0054. The equivalent paired comparison in the sham group showed no significant difference on any measure.

Result — respiratory. No significant difference in end-tidal carbon dioxide between the two interventions, p = 0.21. Within the exposed group against its own control visit, a significant increase was observed, p = 0.03, with post hoc significance at 60 minutes. No difference in breath rate in any comparison. The authors offer this as weakly consistent with increased glucose oxidation rather than storage, and the Foundation records that the between-group comparison, which is the stronger test, was null.

What it establishes. That a single short exposure to light at 670 nanometers, delivered to the skin of the back and not to the eye, produces a measurable and statistically significant change in the handling of an oral glucose load in healthy adults. The effect is systemic, since the irradiated tissue was not the tissue measured. The sham-controlled design and the null result in the sham group's paired analysis together exclude an order or habituation effect arising from the fixed visit sequence, which is the principal design risk given that every participant received the control test first.

What it does not establish. Nothing about ambient lighting. This was a therapeutic-intensity exposure of 40 milliwatts per square centimeter to four percent of the body surface, which bears no resemblance to the irradiance of room lighting, and the study therefore does not show that lighting lacking long wavelengths impairs glucose regulation in anyone. It does not establish any effect in diabetes; the subjects were healthy and the authors state that their results cast no light on that question. It does not establish a dose-response relationship, a minimum effective exposure, or duration of benefit. Body mass index was not recorded, so adiposity — which the authors note influences glucose metabolism — could not be accounted for.

Considerations bearing on confidence. In favor: randomized; sham-controlled with participants blinded to allocation; an objective instrument-measured endpoint rather than a reported one; a prespecified three-way analysis including within-participant comparison; a null result in the sham arm; effects significant at several consecutive time points rather than at one; data deposited publicly on FigShare; funded by a charity, Sight Research UK; and a declaration of no conflicts of interest, which the Foundation checked and records because this field attracts commercial devices. Against: fifteen participants per arm; a single site; no crossover, for reasons the authors state; body mass index not collected; no statement that outcome assessors were blinded, though the endpoint is instrument-read; and an effect on peak glucose that differs between the two analyses, 12.1 percent between groups and 7.5 percent within participants, which the Foundation reports as both rather than choosing the larger.

Independence from other entries. Glen Jeffery is an author of this study and of the study at Appendix C.1. The two are therefore not independent confirmations of one another, and the Foundation does not present them as such. They are products of a single research program, which is a strength as to coherence and a limitation as to replication. Independent replication of this line of work is among the things the Foundation asks the Department to support under § 360ii(a)(2).

Bearing on the statutory question. The Foundation uses this entry at Part V.B.6, for the premise that the long-wavelength content of light is biologically active in humans at the systemic level, and therefore that the spectral composition of ambient light is a physiological variable rather than an aesthetic one. It does not use it to show harm. The Foundation also directs the Department's attention to the authors' own closing judgment, quoted at Part V.B.6, that lengthy exposure to light-emitting diode lighting in the absence of sunlight may have significant long-term consequences for human health and is likely to be a public health issue not yet appreciated. That is a statement about potential, and § 360ii(a)(3) directs the Secretary to receive information on present and future potential electronic product radiation. Parts V.B.6, II.E and IX.H.3.

C.20 Deprato and others (2024) — light at night and allergic disease, systematic review and meta-analysis

Citation. Deprato A, Maidstone R, Palomar-Cros A, Adan A, Haldar P, Harding BN, Lacy P, Melenka L, Moitra S, Navarro JF, Kogevinas M, Durrington HJ, Moitra S. Influence of light at night on allergic diseases: a systematic review and meta-analysis. BMC Medicine. 2024;22:67. doi:10.1186/s12916-024-03291-5. PMID 38355588. PMCID PMC10865638. Published February 14, 2024. Open access under the Creative Commons Attribution license.

Article type. Systematic review and meta-analysis of observational studies. Six databases, two registries and Google Scholar were searched from inception to December 15, 2023; 3,368 records were identified and 12 publications were included. Risk of bias was assessed with the ROBINS-E tool and the quality of evidence with the GRADE framework, each independently by two reviewers. Pooling was by inverse-variance random-effects meta-analysis. Publication bias was examined by funnel plot with Egger's and Begg's tests.

Exposures, and an important qualification. Three exposures were treated together under the heading of light at night: artificial light at night, high versus low; evening versus morning chronotype; and night versus day shift work. The Foundation stresses that only the first concerns what a product emits. Chronotype is a trait and shift work is an employment schedule. The authors say so themselves, recording that chronotype and night shift work were used as proxies for artificial light at night and might not be properly classified as such, and that shift work carries additional occupational exposures — shift duration and rotation, work environment, job stress, workload — that may themselves bear on the outcomes.

Outcomes. Asthma, allergic rhinitis, and skin allergies.

Result — by exposure. Artificial light at night, odds ratio 1.88, 95 percent confidence interval 1.04 to 3.39. Evening chronotype, 1.35, 0.98 to 1.87, which does not reach statistical significance. Night shift work, 1.33, 1.06 to 1.67.

Result — by disease and by age. Asthma, 1.62, 1.19 to 2.20. Allergic rhinitis, 1.89, 1.60 to 2.24. Skin allergies, reported as 1.11, 1.09 to 1.91; see the next field. By age, the association was larger in youth, 1.63, 1.07 to 2.48, than in adults, 1.30, 1.03 to 1.63. Significant geographical variation was observed.

A reported estimate the Foundation does not rely on. The skin allergy figure is given in both the abstract and the body of the paper as an odds ratio of 1.11 with a confidence interval of 1.09 to 1.91. Those three numbers are not mutually consistent: a point estimate

of 1.11 cannot sit almost at the lower bound of an interval extending to 1.91 under the random-effects pooling the authors describe. One of the three figures appears to be mistyped in the publication. The Foundation reports the estimate as published, does not rely on it, and does not speculate as to which figure is wrong.

What it establishes. That a systematic review of this literature has been conducted to a recognized methodological standard, and that across the studies it was able to locate, measures of light at night were associated with higher odds of asthma, allergic rhinitis and skin allergy, with a larger association in young people than in adults. It establishes that respiratory and allergic disease is a domain in which this question is being asked, which no other entry in this appendix covers.

What it does not establish. Causation. The authors record that every included study was cross-sectional, which excludes any inference about temporal order. More importantly for this comment, the artificial light at night estimate of 1.88 does not rest on a body of studies. The authors state that only one study on outdoor artificial light at night was eligible for inclusion, that it had no unexposed reference group so that only a high-versus-low comparison was possible, and that its exposure was assessed from satellite imagery at 750-meter resolution with consequent potential for exposure misclassification. A pooled estimate drawn from a single cross-sectional study is not a meta-analytic finding about that exposure, and the Foundation does not present it as one. Nothing here establishes anything about light-emitting diode products as against the sources they replaced, for the reason that recurs throughout this appendix: the exposure instrument carries no spectral information.

Considerations bearing on confidence. In favor: a prespecified systematic method with a stated search, two published appraisal instruments applied independently by two reviewers, formal testing for publication bias, stratification by exposure, disease, age and geography, and unusually candid reporting of the review's own weaknesses. Against: twelve included publications, which is a thin base; all cross-sectional; one eligible study for the exposure of most interest; two of the three exposures are proxies the authors themselves describe as possibly misclassified; wide intervals, the principal estimate running from 1.04 to 3.39; an internally inconsistent estimate for one outcome; and selected study populations in most of the included work.

Independence from other entries. This review and the cancer review at Appendix C.14 share most of their authors, including Deprato, Palomar-Cros, Maidstone, Adan, Haldar, Harding, Lacy, Navarro, Kogevinas, Durrington and both authors named Moitra. They are products of one research group and are not independent syntheses of the field. The Foundation records this for the same reason it records the common authorship at Appendix C.19.

A statement in the review worth the Department's attention. The authors write in their introduction that for several decades sodium vapor, metal halide and fluorescent lamps were predominantly used for outdoor lighting, that white light-emitting diode lamp use has since increased exponentially because of lower production and maintenance costs, and that this has consequently driven an increase in the blue light spectrum emitted by light pollution. They add that indoor exposure continues to increase through lighting and personal devices which primarily emit blue-white light, and that such exposure is of particular concern because of its greater ability to suppress melatonin compared with other wavelengths. That is a characterization in a statement of background rather than a finding of the review, and the Foundation presents it as such. It is nonetheless the proposition at the center of Parts II.D and V.B, stated as settled background by a peer-reviewed review in a general medical journal.

Bearing on the statutory question. The Foundation offers this entry for three narrow purposes. First, it extends the range of outcomes under investigation to respiratory and

allergic disease, which bears on the breadth of the question § 360ii(a)(4) directs the Secretary to study. Second, the larger association reported in youth than in adults bears on the request at Part IX.L that sensitive populations be addressed expressly, though the Foundation notes that a difference between two overlapping intervals is weak evidence of a difference in effect. Third, and most reliably, the review demonstrates the state of the evidence rather than the state of the world: a systematic search of six databases produced twelve cross-sectional studies and one eligible study of outdoor exposure. That is what a question looks like when it has not been studied, and it is the condition § 360ii(a)(2) and (a)(4) address. Parts II.F, V.J.4, IX.C and IX.L.

C.21 Menculini and others (2024) — light pollution and affective disorders, narrative review

Citation. Menculini G, Cirimbilli F, Raspa V, Scopetta F, Cinesi G, Chieppa AG, Cuzzucoli L, Moretti P, Balducci PM, Attademo L, Bernardini F, Erfurth A, Sachs G, Tortorella A. Insights into the effect of light pollution on mental health: focus on affective disorders, a narrative review. Brain Sciences. 2024;14(8):802. doi:10.3390/brainsci14080802. PMID 39199494. PMCID PMC11352354. Received July 17, 2024; revised August 4, 2024; accepted August 8, 2024; published August 10, 2024. Open access under the Creative Commons Attribution license.

Article type. Narrative review. The authors searched PubMed, Scopus and Web of Science to May 31, 2024 and included eighteen papers on human samples: nine on sleep, six on mood disorders and related behavior, and three on risk perception. Animal studies and studies without clinical measures were excluded. No systematic appraisal instrument, no risk-of-bias assessment and no pooling were applied. The Foundation cites it in the category described at Part V.A.2 as evidence of the state of expert opinion, not as primary evidence of any effect.

Why the Foundation includes it. Because the psychological domain is one of the four this comment identifies at Part V, and because this is the only entry in the appendix that addresses it as its subject. The title also uses the term light pollution, which bears on Part II.D.3: the expression is in use in the peer-reviewed medical literature and is not a lay coinage.

Reported findings, as reported. The review tabulates results from its included studies. Among them: bedroom light at or above 3 lux was associated with sleep disturbance at an odds ratio of 1.25 and with depressive symptoms at 1.30, and at or above 10 lux with 1.29 and 1.33 (Obayashi and others, 2,947 adults aged 40 and over). Each median absolute deviation increase in outdoor artificial light at night was associated with mood disorders at an odds ratio of 1.07 and anxiety disorders at 1.10 (Paksarian and others, 10,123 adolescents). In adults with bipolar disorder, bedroom light at or above 3 lux was associated with hypomanic states cross-sectionally, adjusted odds ratio 2.15, and longitudinally with manic or hypomanic relapse, adjusted hazard ratio 2.17, with no significant association with depressive relapse (Esaki and others). A light-reduction intervention in 30 university students was followed by a fall in Pittsburgh Sleep Quality Index score from 6.83 to 3.93 (Randjelovic and others). These are the findings of the underlying studies, not of this review, and the Foundation has not assessed any of them directly.

What it establishes. That the relationship between artificial light at night and affective symptoms is a subject of published clinical inquiry, that the inquiry extends to clinical populations as well as general ones, and that reviewers in psychiatry regard the question as open and worth pursuing. It establishes the existence and shape of a literature. It does not establish the truth of what is in it.

What it does not establish, stated emphatically. That artificial light causes depression, bipolar disorder, anxiety, or any other psychiatric condition. The Foundation does not

assert that proposition anywhere in this comment and asks that nothing in this entry be read as asserting it. The included studies are predominantly cross-sectional and observational; the review performs no pooling and applies no quality instrument; and the authors record that most outcomes were self-reported, that individual sleep habits and sleep hygiene were not assessed in most of the included work, that it is therefore not always possible to distinguish changes in sleep habits from effects of light, that other urban pollutants and social stressors confound the setting, and that studies conducted at different latitudes are not readily comparable because daylight duration and light quality differ. The Esaki findings concern people already diagnosed with bipolar disorder and cannot be generalized to anyone else. Nothing in the review concerns light-emitting diode products as against the sources they replaced.

A gap between the abstract and the conclusion. The abstract states that the results clearly indicate a link between light pollution and the development of affective symptoms. The body of the paper is more measured: the conclusion speaks of evidence of a role in the development of circadian disruptions and mood symptoms, says the relationship is complex, and states that future studies are expected to further clarify and characterize it. The Foundation relies on the conclusion rather than the abstract. A narrative review of eighteen largely cross-sectional papers does not support the word clearly, and the Foundation does not adopt it.

Considerations bearing on confidence. In favor: open access; declared no conflicts of interest and no external funding; a candid and detailed limitations section which the Foundation has drawn on above; and authors working in clinical psychiatry. Against: narrative rather than systematic; eighteen papers; no appraisal instrument, no risk-of-bias assessment, no pooling; an abstract that overstates the body; and findings reported at one remove, so that every figure above is unverified against its source. The Foundation also records, as a fact bearing on the weight a reader may give the review, that it was received on July 17, 2024 and accepted on August 8, 2024, twenty-two days later, and that Brain Sciences is published by MDPI, as is the entry at Appendix C.18.

An observation about three lux. Three separate lines of work referred to in this appendix use thresholds of about 3 and 10 lux of bedroom light at night as the exposures of interest: Obayashi and Esaki as reported here, and the cardiac study at Appendix C.2. The origin of those cut points is now established. Appendix C.32 records that they were predefined from the experimental melatonin-suppression literature, citing Cajochen and others and Zeitzer and others, both 2000, rather than being derived from the epidemiological data they were then applied to. That is a better provenance than convention: a threshold drawn from laboratory dose-response work and afterwards tested in a population is doing real work rather than being copied forward. The Foundation still does not propose 3 lux as a federal criterion, because whether it marks anything in an American population is exactly the question a program under § 360ii(a)(4) would resolve. Parts IX.J.3 and V.J.4.

Bearing on the statutory question. Narrow, and narrower than the subject matter might suggest. The Foundation offers this entry to show that the affective domain is under active clinical investigation and that the question is unresolved, which is the condition § 360ii(a)(4) addresses, and to show that exposures at the scale of a few lux in a bedroom — the scale produced by a streetlight through a window — are what the literature is examining. It is not offered to show that any product injures anyone mentally, and the Foundation asks the Department not to read it that way. Parts V.G, V.J.4 and IX.C.

C.22 Kim and others (2024) — outdoor artificial light at night and incident exudative age-related macular degeneration

Citation. Kim SH, Kim YK, Shin YI, Kang G, Kim SP, Lee H, Hong IH, Chang IB, Hong SB, Yoon HJ, Ha A. Nighttime outdoor artificial light and risk of age-related macular degeneration. JAMA Network Open. 2024;7(1):e2351650. doi:10.1001/jamanetworkopen.2023.51650.

PMID 38227312. PMCID PMC10792474. Published January 2, 2024. Open access under the Creative Commons Attribution license.

Design. Nationwide population-based case-control study. All individuals aged 50 or over with newly diagnosed exudative age-related macular degeneration between January 1, 2010 and December 31, 2011 were identified from the Korean National Health Insurance Service registration program for rare and intractable diseases. Controls matched on birth year and sex at a ratio of 1 to 30, with no such diagnosis through 2020. Data acquired in 2021 and analyzed in 2022.

Population. One hundred twenty-six thousand four hundred eighteen participants: 4,078 incident cases and 122,340 matched controls. Mean age 66.0 years, standard deviation 7.9; 61.9 percent men.

Exposure, as measured. Mean outdoor artificial light at night at the participant's residential address during 2008 and 2009, estimated from time-varying satellite data for persistent nighttime illumination at a scale of approximately one square kilometer. Broadband upward radiance; no spectral information. Part V.J.4.

Outcome and adjustment. Incident exudative age-related macular degeneration, ascertained from a national registry rather than by self-report. Estimates adjusted for sociodemographic characteristics, comorbidities, and two area-level environmental factors that the Foundation notes in particular: nighttime traffic noise, and particulate matter of aerodynamic diameter 10 micrometers or less, in each participant's administrative district.

Result. In fully adjusted models, an interquartile-range increase in exposure, 55.8 nanowatts per square centimeter per steradian, was associated with a hazard ratio of 1.67 for incident exudative age-related macular degeneration, 95 percent confidence interval 1.56 to 1.78. The exposure-response curve was nonlinear and concave upward, becoming more pronounced above approximately 110 nanowatts per square centimeter per steradian. In subgroup analysis the association was present in urban areas, 1.46, 1.33 to 1.61, and absent in rural areas, 1.01, 0.84 to 1.22.

Conclusion, in the authors' words. That higher levels of residential outdoor artificial light at night were associated with an increased risk of incident exudative age-related macular degeneration, and that future studies with more detailed information on exposure, individual adaptive behaviors, and potential mediators are warranted.

Why this entry matters more than most in this appendix. The outcome is ocular. Almost every other association reported in this appendix concerns an organ system remote from the eye, and each invites the response that the connection to an optical emission is indirect. Macular degeneration does not. The eye is the organ that receives the radiation; 21 C.F.R. part 1040 is titled Performance Standards for Light-Emitting Products; and the photobiological hazard framework described at Part V.C.2 is built around retinal injury. An association between ambient optical radiation and a retinal disease is within the subject matter of this program as the Department itself has defined it.

What it establishes. That in a nationwide registry-based study of over 126,000 people, residential outdoor artificial light at night was associated with incident exudative age-related macular degeneration, with a large and precisely estimated effect, a nonlinear exposure-response relationship, and adjustment for two of the confounders most often urged against findings of this kind. The cases were identified from a disease registry rather than reported by participants, which removes a source of error present in much of the rest of this appendix.

What it does not establish. Causation; the design is observational. It establishes nothing about light-emitting diode products, for the reason that recurs throughout this appendix and for a second reason specific to this study, set out in the next field. The exposure is areal, at roughly one square kilometer, and carries no spectral information; it is not a

measurement of the light reaching any individual eye. No indoor light, individual behavior, time spent outdoors, or ocular history was measured. The population is Korean, and neither its lighting stock nor its urban density is that of the United States.

Two further limitations the Foundation raises on its own account. First, latency. Exposure was measured in 2008 and 2009 and cases were diagnosed in 2010 and 2011. Macular degeneration is a degenerative condition developing over decades, and a two-year exposure window immediately preceding diagnosis is a weak proxy for the exposure that would matter. Residential exposure is likely correlated over time, which mitigates this, but the study does not establish that. Second, and bearing directly on this comment: the exposure period of 2008 to 2009 substantially predates the conversion of outdoor lighting to light-emitting diode sources. The radiance measured was emitted predominantly by the technologies that preceded them. The Foundation draws no conclusion from that and cannot: it means the study says nothing about light-emitting diode emission, and it leaves entirely open what the same analysis would show for a spectrum shifted toward shorter wavelengths. That open question is one the research directed by § 360ii(a)(2) and (a)(4) would answer.

The urban and rural subgroups, read both ways. The association was present in urban areas and absent in rural ones. Two readings are available and the Foundation does not choose between them. On one, the finding is internally consistent: the exposure-response curve is concave upward and steepens above roughly 110 nanowatts per square centimeter per steradian, so a rural population sitting mostly below that region would be expected to show little association. On the other, a result confined to urban areas is also the pattern that residual confounding by urbanicity produces, and the adjustment for noise and particulate matter, though more than most studies attempt, does not exhaust what differs between a city and the countryside. The Foundation reports both because the choice between them is an empirical question and not an argumentative one.

Considerations bearing on confidence. In favor: nationwide coverage; a very large matched sample; registry-ascertained incident cases; matching on birth year and sex at 1 to 30; adjustment for nighttime traffic noise and particulate matter, which addresses the confounding objection by measurement rather than by acknowledgment, as at Appendix C.17; a nonlinear exposure-response relationship rather than an assumed linear one; a narrow confidence interval; and publication in a major general medical journal under an open license. Against: observational; areal exposure at one square kilometer with no spectral content; a short exposure window relative to the natural history of the disease; no individual-level exposure or behavior; the rural null; and a single national setting. The Foundation also notes that hazard ratios are reported from what is described as a case-control design, which is unconventional terminology, and that the estimation method should be checked against the paper before the figures are relied on in any filing.

Bearing on the statutory question. This entry does more work than most. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. Here is a disease of the organ that receives optical radiation, associated in a large national study with the ambient level of that radiation, with a dose-response shape, after adjustment for the two competing urban exposures most often raised. The Foundation does not contend that this establishes harm from any product. It contends that a federal program directed to study the conditions of exposure to electronic product radiation, which has prescribed performance standards for light-emitting products since 1979 and whose hazard framework is built around the retina, cannot treat a finding of this kind as outside its subject matter. Parts II.F, V.C, V.J.4, IX.C and IX.L.

C.23 Li and others (2024) — light at night, amygdala BDNF signaling, and stress-evoked behavior in rats

Citation. Li Z, Lee CS, Chen S, He B, Chen X, Peng HY, Lin TB, Hsieh MC, Lai CY, Chou D. Blue light at night produces stress-evoked heightened aggression by enhancing brain-derived neurotrophic factor in the basolateral amygdala. Neurobiology of Stress. 2024;28:100600. doi:10.1016/j.ynstr.2023.100600. PMID 38187456. PMCID PMC10767493. Published online December 15, 2023. Open access under the Creative Commons Attribution license.

Design. Controlled animal experiment combining behavioral testing, extracellular electrophysiology and immunoassay, with bidirectional pharmacological manipulation of the proposed mechanism. Adult male Sprague-Dawley rats, eight weeks of age, group housed four to a cage. Conducted in accordance with the ARRIVE guidelines and approved by the Institutional Animal Use Protocol Committee at MacKay Medical College, Taiwan, protocol A111003.

Exposure, as characterized — and why it matters. Animals were maintained on a twelve-hour light and dark cycle, lights on 06:00 to 18:00, at approximately 200 lux of white light-emitting diode illumination at cage level. Four conditions were compared over five days. Light control: the standard cycle with no light at night. Blue light at night: approximately 400 lux at cage level, 465 to 475 nanometers, from 19:00 to 22:00. White light at night: approximately 400 lux, 380 to 780 nanometers, over the same hours. Blue light at day: the same blue source and intensity delivered from 07:00 to 10:00. Testing was conducted the day after the exposure ended, and again seven days after.

The dose is environmentally plausible, which is unusual. The Foundation draws attention to the intensity, because a standing criticism of mechanistic light research — which the Foundation itself makes at Appendix C.18 — is that exposures are set far above anything encountered in ordinary life. That criticism does not apply here. The authors state that a full moon provides under 1 lux, that streets in industrialized countries are lit to approximately 5 to 15 lux, and that nighttime light in modern living rooms runs approximately 100 to 300 lux, and they chose approximately 400 lux as close to the living-room figure. This is an experiment conducted at something near a domestic exposure level.

Result — behavior. Light at night amplified aggression provoked by a mild stressor, measured by the resident-intruder test. For blue light at night: stress effect $F(1,36) = 23.75$, $p < 0.0001$; light effect $F(1,36) = 7.797$, $p = 0.0083$; interaction $F(1,36) = 5.006$, $p = 0.0315$. For biting: light effect $F(1,36) = 7.744$, $p = 0.0085$; interaction $F(1,36) = 12.42$, $p = 0.0012$. Anxiety-like behavior was also increased.

Three features of that result the Foundation emphasizes. First, there was no effect on baseline aggression. The light did not make the animals aggressive; it amplified a response to a stressor. Second, the effect was reversible: it was absent after a seven-day recovery period, stress effect $p = 0.2527$, light effect $p = 0.1209$. Third, and most important for how this entry may be used, white light at night produced the same effect as blue light at night, while blue light delivered during the day did not produce it at all.

What the white-light arm means. The title of the paper names blue light, but the study's own comparison arms show that the operative variable here is the timing of the exposure rather than its spectral composition. Blue at night and white at night both produced the effect; blue at the same intensity during the day did not. The Foundation states this plainly because the contrary reading would be convenient and is not supported. This entry is not evidence that short-wavelength content is specifically responsible for anything. It is evidence that light during the dark phase is.

Result — mechanism. Light at night potentiated both long-term potentiation and long-term depression in the basolateral amygdala, and produced stress-induced elevation of brain-derived neurotrophic factor, mature brain-derived neurotrophic factor, and phosphorylated tyrosine receptor kinase B in that structure. The mechanism was then tested in both directions. Microinfusion into the basolateral amygdala of BDNF RNA interference, a BDNF neutralizing antibody, K252a, or rapamycin each blocked the

heightened behavior in exposed animals; and microinfusion of BDNF or of the TrkB agonist 7,8-DHF produced the heightened behavior in animals not exposed to light at night.

What it establishes. That light during the dark phase, at an intensity comparable to a lit living room and over five days, produces measurable changes in synaptic plasticity and neurotrophin signaling in a limbic structure of the rat brain, and that those changes are necessary and sufficient for the behavioral effect observed, within this model. Demonstration of necessity and sufficiency by bidirectional manipulation is stronger evidence of mechanism than correlation of a marker with an outcome, and the Foundation records it as such. In the categories at Part V.A.2 this is a mechanistic study: it establishes that a pathway exists and is biologically plausible.

What it does not establish, stated emphatically. Nothing about human behavior. The Foundation does not contend, and asks that nothing in this comment be read as contending, that artificial light makes people aggressive or violent. The subject is a rat; the endpoint is a laboratory assay of territorial behavior toward an intruder, which is not a model of human conduct; the effect appeared only in combination with an applied stressor and not at baseline; and it resolved within seven days. The animals were male only. Rats are nocturnal, so light during their dark phase falls in their active period rather than their rest period, and the translation of that timing to a diurnal species is not straightforward. The study establishes nothing about light-emitting diode products as against other sources, and nothing about short-wavelength content, for the reason given above.

Considerations bearing on confidence. In favor: a controlled experiment with assigned exposure; four comparison conditions including a same-spectrum different-timing control, which is the design feature that makes the result interpretable; an environmentally plausible intensity; convergent behavioral, electrophysiological and biochemical measures; bidirectional pharmacological manipulation of the proposed mechanism; ARRIVE compliance and institutional approval; open access publication with test statistics reported. Against: a single laboratory; male animals only; a species difference that bears directly on the variable under study; a five-day exposure; and group sizes that should be confirmed from the figures rather than inferred from the degrees of freedom.

Bearing on the statutory question. Two uses, and the first is the more valuable. Paragraph 360ii(a)(2) directs the minimization of emissions and of exposure. This study isolates the temporal dimension of exposure: the same radiation at the same intensity produced an effect at one hour of the day and no effect at another. That is direct support for the proposition at Part II.D.2.d that when a product emits is part of what makes an emission necessary or unnecessary, and for the recommendation at Part IX.J.2 that outdoor luminaires be capable of dimming and scheduling. Second, it supplies a mechanism by which light at night could bear on the affective outcomes reported in humans at Appendix C.21, which is relevant to biological plausibility and to nothing more. Parts II.D.2.d, V.A.2, V.G and IX.J.

C.24 Burns and others (2023) — day and night light exposure and psychiatric disorders

Citation. Burns AC, Windred DP, Rutter MK, Olivier P, Vetter C, Saxena R, Lane JM, Phillips AJK, Cain SW. Day and night light exposure are associated with psychiatric disorders: an objective light study in >85,000 people. Nature Mental Health. 2023;1:853–862. doi:10.1038/s44220-023-00135-8. Published October 9, 2023.

Design and population. Cross-sectional analysis of UK Biobank data under application 6818. Eighty-six thousand seven hundred seventy-two adults, mean age 62.4 years with a standard deviation of 7.4, of whom 57 percent were women. Light exposure was measured objectively by wrist-worn Axivity AX3 device rather than reported by participants; the

analysis code is published. Day and night exposure were examined as independent predictors.

Outcomes. Major depressive disorder, generalized anxiety disorder, post-traumatic stress disorder, psychosis, bipolar disorder, and self-harm behavior.

Result, in the authors' own words. "Greater night-time light exposure was associated with increased risk for major depressive disorder, generalized anxiety disorder, PTSD, psychosis, bipolar disorder, and self-harm behavior. Independent of night-time light exposure, greater daytime light exposure was associated with reduced risk for major depressive disorder, PTSD, psychosis, and self-harm behavior. These findings were robust to adjustment for sociodemographics, photoperiod, physical activity, sleep quality, and cardiometabolic health."

Effect estimates. Not stated here. The odds ratios and intervals are presented in the published figures and the Foundation has not been able to obtain them: the article is behind a subscription and the accepted manuscript in the author's institutional repository is not served. This entry is therefore incomplete as to magnitude, and the Foundation relies on it for direction and robustness only.

Why this entry matters out of proportion to its design. Every other entry in this appendix concerns light at night. This one measures day and night exposure separately and finds them to act in opposite directions, independently of each other. That changes the shape of the proposition this comment advances. The Foundation does not contend that artificial light is harmful. It contends that the pattern of exposure matters — that the human light environment has been inverted, with too little during the day and too much at night — and that no federal body has evaluated the pattern that American products now produce. A finding that daytime light is associated with reduced risk is as much a part of that proposition as a finding that nighttime light is associated with increased risk, and the Foundation presents both. It is also consistent with the long-wavelength findings at Appendices C.1, C.13 and C.19, which concern what daytime light contains rather than when it falls.

What it establishes. That in a very large cohort with objectively measured rather than self-reported exposure, nighttime and daytime light were independently associated with psychiatric outcomes in opposite directions, and that these associations survived adjustment for photoperiod, physical activity, sleep quality and cardiometabolic health. Adjustment for sleep quality is worth noting: it addresses the most obvious alternative explanation, that light acts only by disturbing sleep.

What it does not establish. Causation, and the design makes this more than a formality. The analysis is cross-sectional, so exposure and outcome were measured at the same time and nothing establishes which came first. Reverse causation is a live possibility here in a way it is not for many outcomes in this appendix: a person experiencing depression may spend less time outdoors and keep different hours, which would produce exactly this pattern of day and night exposure without the light having caused anything. The Foundation does not resolve that and neither does the study. It establishes nothing about light-emitting diode products specifically, and nothing about spectral composition, since a wrist-worn sensor records illuminance and not spectrum. Part V.J.4.

Competing interests, which the Foundation records in full. The declaration states that A.J.K. Phillips and S.W. Cain have received research funding from Delos and Versalux and co-founded and co-direct Circadian Health Innovations PTY LTD; that S.W. Cain has also received research funding from Beacon Lighting and has consulted for Dyson; that P. Olivier co-founded Axivity Ltd, the manufacturer of the device used to measure exposure, and was a director until 2015; and that C. Vetter is a board member of the Working Time Society and a research committee member for DiME. All other authors reported none. Funding was from the Australian Government Research Training Program and the

National Health and Medical Research Council, grant GNT1183472, with a statement that the funders had no role in the work.

What the Foundation makes of that, and what it does not. It makes nothing of it by way of accusation. The interests were disclosed, which is what disclosure is for, and several of the authors are among the most productive researchers in this field. The Foundation records them for two reasons. The first is consistency: it has named the weaknesses of every other entry in this appendix and will not make an exception for an entry whose findings suit it. The second is that the interests run in a particular direction. Two senior authors hold commercial positions in circadian lighting, and the finding is that the timing of light matters. That is a reason to want independent replication, not a reason to discount the work, and independent replication of this line of research is among the things § 360ii(a)(2) directs the Secretary to support.

Independence from other entries. Windred, Phillips and Cain are also authors of the cardiovascular study at Appendix C.8. The two are products of the same group working on the same UK Biobank accelerometry resource and are not independent. The Foundation records this as it has at Appendices C.19 and C.20.

Bearing on the statutory question. The Foundation offers this entry for the proposition that the temporal distribution of light exposure is a variable with measurable associations in a very large population, and that it is a variable no federal instrument currently describes. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure, and when a person is exposed is a condition of exposure. The entry also supports the recommendations at Part IX.J.2 concerning dimming and scheduling capability, and it bears on Part V.G. It is not offered to show that any product causes psychiatric illness, and for the reasons stated above it could not be. Parts II.D.2.d, V.G, V.J.4 and IX.J.

C.25 Moore-Ede and others (2023) — scientific consensus survey on circadian light

Citation. Moore-Ede M, Blask DE, Cain SW, Heitmann A, Nelson RJ. Lights should support circadian rhythms: evidence-based scientific consensus. Frontiers in Photonics. 2023;4:1272934. doi:10.3389/fphot.2023.1272934. Received August 4, 2023; accepted September 20, 2023; published October 4, 2023. Open access.

Article type and method. A brief research report presenting a single-round online opinion survey, described by the authors as the Scientific Consensus Survey on Circadian Light. A PubMed search for circadian and light identified 10,002 articles by 29,455 authors between 2008 and 2022. The 2,142 authors with four or more such articles were invited. One thousand one hundred fifty-six opened an invitation and 248 completed the survey. Respondents rated thirty factual statements and five practical statements on an evidence scale, and five expert policy statements on an agreement scale. Consensus was defined as two-thirds support with don't-know responses excluded. Twenty-five of forty statements reached that threshold. Respondents could not revise answers after feedback.

Items relevant to this comment. Among the consensus results: that light used in the evening, during the three hours before bedtime, should have as little blue content as practically possible, 82.5 percent; that the risk of circadian disruption in those three hours can be reduced by dimming indoor lighting or reducing its blue content, 72.0 percent; and, in the factual group, that blue-enriched light between 460 and 495 nanometers in those three hours disrupts sleep, 70.3 percent, phase delays the circadian system, 75.5 percent, and disrupts circadian rhythms more than blue-depleted light at the same intensity, 70.1 percent. In the expert-opinion group: that light-emitting diode lamps with high 460 to 495 nanometer blue content should carry the warning label maybe harmful if used at night, 79.1 percent.

What it is, stated plainly. An opinion poll of researchers. It is not a study of light, it generates no data about any product or any person, and it measures what a self-selected group of

respondents believes. The Foundation uses it only in the category described at Part V.A.2 as evidence of the state of expert opinion. The warning-label item in particular was presented in the survey as a policy opinion, not as a statement of evidence, and the Foundation does not present it as more than that.

Considerations bearing on confidence, which are substantial. First, participation. Of 2,142 researchers invited, 248 responded, about 11.6 percent, and 248 of the 1,156 who opened an invitation. A survey about whether light at night is harmful, answered by one in nine of those asked, is exposed to self-selection in the direction of the result. Second, composition: 103 of the 248 respondents had conducted human research and 145 had not. Third, method: a single round with no opportunity to revise after feedback is weaker than the iterative procedures by which formal consensus is usually established, and the word consensus should be read accordingly. Fourth, three of the five authors — Cain, Blask and Nelson — took part in the survey they report.

Funding and competing interests, recorded in full. The survey platform fees and part of the cost of compiling the invitation list were funded by Korrus, Inc., a lighting company, with a statement that the funder had no role in the work. The declaration states that Moore-Ede and Heitmann are inventors on patents covering circadian-optimized spectrally engineered light sources; that Moore-Ede was chief executive of Circadian ZirClight Inc. until April 2022, when its intellectual property was acquired by Korrus, that he has received compensation from Korrus, and that he holds equity in CIRCADIAN companies which hold a stake of under one percent in Korrus; that Cain is an inventor on a provisional patent for a circadian lighting system and is co-founder and co-director of Circadian Health Innovations; and that Cain was a Frontiers editorial board member at submission, which the authors state had no effect on review.

What the Foundation makes of that. It makes no allegation of bad faith and none is warranted; the interests were disclosed in detail, which is to the authors' credit. But the Foundation will not rest an argument on this entry, and says why. The recommendation that lamps with high short-wavelength content carry a warning label would, if adopted, advantage manufacturers of low-blue circadian-optimized lighting. The survey was funded by a company in that business, and its first author holds patents in that product category, was chief executive of a company whose intellectual property that funder acquired, and receives compensation from the funder. A reader encountering this entry for the first time in a reply to this comment would find all of that, and the Foundation would rather state it first. An opinion poll so situated cannot carry weight as evidence of a hazard.

What it is nevertheless good for. One proposition, which does not depend on the survey being well conducted or disinterestedly funded: that whether products emitting substantial short-wavelength content should be labeled is a question people working in this field are actively asking, in print. Paragraph 360ii(a)(3) directs the Secretary to maintain liaison with and receive information from professional organizations on present and future potential electronic product radiation. A published survey of two hundred forty-eight researchers in the field is information of that kind, whatever its weight. Parts II.E.4 and IX.J.5.

Independence from other entries. Sean W. Cain is also an author of Appendices C.8 and C.24, and the competing interests declared here overlap with those declared there. The Foundation records this as it has elsewhere in this appendix.

C.26 Hiramoto and others (2023) — long-term blue light irradiation and skin cancer in hairless mice

Citation. Hiramoto K, Kubo S, Tsuji K, Sugiyama D, Hamano H. Induction of skin cancer by long-term blue light irradiation. Biomedicines. 2023;11(8):2321. doi:10.3390/biomedicines11082321. PMID 37626816. PMCID PMC10452187. Published August 21, 2023. Open access under the Creative Commons Attribution license.

Design. Controlled animal experiment with four spectral exposure conditions and an unirradiated comparison. Specific-pathogen-free male hairless mice, strain Hos:HR-1, eight weeks of age at the start, housed individually on a twelve-hour light and dark cycle and randomized by body weight into groups of five. Approved by the Suzuka University of Medical Science Animal Experiment Ethics Committee, approval number 34.

Exposure, as characterized — the figures the Foundation relies on. Whole-body irradiation for ten minutes per day, every day, for one year. Blue: 380 to 500 nanometers, peak emission 479, at 40 kilojoules per square meter per session. Green: 500 to 560 nanometers, peak 538, at 40 kilojoules per square meter. Red: 600 to 700 nanometers, peak 629, at 40 kilojoules per square meter. White: 12 kilojoules per square meter. The control group received the fluorescent lamp ordinarily used for breeding. Energy content was measured with a light analyzer. Expressed otherwise, the three matched conditions delivered 4 joules per square centimeter per session at an irradiance of approximately 6.7 milliwatts per square centimeter, and approximately 1,460 joules per square centimeter over the year.

Result. Skin cancer was induced in the blue-light group and in no other group. Long-term blue irradiation increased migration of neutrophils and macrophages into the skin. In neutrophils, citrullinated histone H3 and peptidylarginine deiminase 4 expression increased, which the authors suggest indicates NETosis. In macrophages, inflammatory type 1 macrophages increased and anti-inflammatory type 2 macrophages decreased. Analysis was by one-way analysis of variance with Tukey post hoc testing.

Which comparison carries the spectral claim, and which does not. The green and red conditions each received the same 40 kilojoules per square meter as the blue condition and produced no cancer. That is the comparison that supports a conclusion about wavelength, because the delivered energy was matched and only the spectrum differed. The white condition received 12 kilojoules per square meter, under a third of the blue dose, so the absence of cancer in the white group is confounded by dose and cannot be read as showing that white light is safer at equal energy. The Foundation sets this out because the paper's summary statement, that cancer appeared only in the blue group, is true of four comparison groups of which only two are dose-matched.

What it establishes. That in this strain of hairless mouse, a year of daily ten-minute whole-body exposure to 4 joules per square centimeter of 380 to 500 nanometer light produced skin tumors, where the same energy delivered at longer wavelengths did not, together with an inflammatory cellular picture in the skin. Within the model, the dose-matched green and red arms make this a statement about wavelength rather than about energy.

What it does not establish. Anything about human skin. Hos:HR-1 hairless mice are a strain selected for use in photocarcinogenesis research and are not a model of ordinary human exposure. Five animals per group is a very small sample for a cancer endpoint. The exposure is not representative of exposure to screens or to indoor lighting: at approximately 6.7 milliwatts per square centimeter it is orders of magnitude above room illumination, and the Foundation notes that the paper's framing refers to blue light from personal computers and smartphones while the exposure administered does not model either. No dose-response series was run, so the study identifies no threshold and no safe level; it tested one dose. It establishes nothing about any product in commerce and nothing about the retina.

Considerations bearing on confidence. In favor: a controlled experiment with assigned exposure; three spectral conditions matched on delivered energy, which is the design feature that makes the result interpretable at all; a full year of exposure, which is rare and which addresses the chronic-exposure gap this comment describes; radiometric rather than photometric reporting of the exposure, which is also rare and which the Foundation commends; institutional ethics approval; open access. Against: five animals per group; a

single laboratory; one dose only; a highly susceptible strain; a dose-confounded white arm; male animals only; and the gap between the exposure administered and the exposures invoked in the paper's framing.

Affiliations and declaration. The corresponding author is at the Department of Pharmaceutical Sciences, Suzuka University of Medical Science. The remaining four authors give their affiliation as the Research Department of Daiichi Sankyo Healthcare Co., Ltd. The paper's declaration states that the authors declare no conflict of interest. The Foundation records both facts as they appear on the paper and draws no inference from them.

Bearing on the statutory question. The Foundation offers this entry principally at Part V.C.2.d, and for the question of quantity rather than the question of harm. The study states its exposure in radiometric units, and from those the delivered dose per session, the irradiance, and the cumulative dose over a year can all be computed. That is what an evaluation under § 360ii(a)(4) would look like, performed by a university laboratory in Japan for five mice. No federal instrument states, for any product emitting visible light, what dose in what waveband over what period is acceptable for a person. The existing blue-light hazard framework stops at ten thousand seconds and addresses the retina; this experiment ran for a year and concerned the skin. The Foundation does not contend that any product causes skin cancer and this entry is not offered for that. It is offered to show that the question is askable in numbers, and that nobody in the federal government has asked it. Parts V.C.2.d, IX.C and IX.J.

C.27 Mazzoleni and others (2023) — outdoor artificial light at night and dementia, Modena

Citation. Mazzoleni E, Vinceti M, Costanzini S, Garuti C, Adani G, Vinceti G, Zamboni G, Tondelli M, Galli C, Salemme S, Teggi S, Chiari A, Filippini T. Outdoor artificial light at night and risk of early-onset dementia: a case-control study in the Modena population, Northern Italy. Heliyon. 2023;9(7):e17837. doi:10.1016/j.heliyon.2023.e17837. PMID 37455959. PMCID PMC10339013. Open access under a Creative Commons Attribution-NonCommercial-NoDerivatives license.

Design and population. Case-control study in the province of Modena. Dementia newly diagnosed between 2017 and 2019; 58 early-onset cases, 34 late-onset cases, and 54 controls drawn from the caregivers of the patients. Residential address at recruitment was geo-referenced, with a requirement of five years of residential stability. Exposure was assigned from 2015 Visible Infrared Imaging Radiometer Suite nighttime luminance imagery, categorized as under 10, 10 to under 40, and 40 or more nanowatts per square centimeter per steradian. Logistic regression adjusted for age, sex and education, with a spline model for non-linearity.

Result. For early-onset dementia, odds ratio 1.36 in the intermediate exposure category, 95 percent confidence interval 0.54 to 3.39, and 1.04 in the high category, 0.32 to 3.34. For late-onset dementia, 2.58, 0.26 to 25.97, and 3.50, 0.32 to 38.87. The spline analysis showed what the authors describe as a substantial lack of association for early-onset dementia and an almost linear though highly imprecise association for late-onset dementia.

The weight of this entry, stated first. No result in this study reached statistical significance. Every confidence interval includes unity, and two of them span more than two orders of magnitude: an odds ratio reported as 3.50 with an interval running from 0.32 to 38.87 is consistent with a substantial protective effect and with a very large harmful one. There are 54 controls. The Foundation states plainly that this entry carries essentially no evidentiary weight on the question whether light at night causes dementia, and it is not offered for that question. The title names early-onset dementia, and that is the outcome for which the authors report substantially no association.

A further design feature. The controls were the caregivers of the cases. Caregivers of people with dementia frequently live with or near them, so case and control exposures are liable to be correlated. The authors identify this as possible overmatching and argue that it would bias the estimates toward the null and therefore strengthen rather than weaken what they found. That is their inference and it is a reasonable one, but it is an argument rather than a demonstration, and the Foundation records it as such.

What the authors could not adjust for, in their own account. They state that they could not take air pollution into account, which they describe as a likely risk factor for dementia that tends to be associated with light pollution; nor residential green space; nor noise. Compare Appendix C.17, where air pollution was measured and adjusted for, and Appendix C.22, where noise and particulate matter were. The contrast between those studies and this one is instructive about what adjustment requires, which is resources.

The limitation the Foundation relies on. The authors write that they took light intensity into account but were unable also to consider its wavelength, while noting that they used the highest spatial resolution available. That is the measurement gap described at Part V.J.4, stated once again by the investigators themselves and against their own result. It is now the fourth independent group in this appendix to say so, with Appendices C.5, C.14 and C.22.

Funding and competing interests. Supported by the Italian Ministry of Education, University and Research under the Dipartimenti di Eccellenza 2018–2022 program awarded to the University of Modena and Reggio Emilia Department of Biomedical, Metabolic and Neural Sciences, and by university and Fondazione di Modena grants. The authors declare no competing financial interests or personal relationships. The Foundation notes the absence of industry involvement, which distinguishes this entry from Appendices C.24 and C.25.

Bearing on the statutory question. The Foundation offers this entry for two purposes, neither of which is the strength of its findings. The first is the wavelength limitation stated above. The second is the condition of the literature itself. Here is a university group in Italy, without industry funding, asking whether ambient light at night bears on dementia, and able to assemble 92 cases and 54 controls, unable to adjust for air pollution or noise, and reporting intervals so wide that they exclude almost nothing. That is not a criticism of the investigators. It is what a question looks like when no one with resources is asking it. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, and § 360ii(b)(2) authorizes grants for precisely that purpose. Part II.B. Read alongside Appendix C.16, which addresses the same disease by an ecological design and is weak in a different way, this entry shows a question being approached repeatedly and answered by nobody. Parts II.B, II.F, V.J.4 and IX.C.

C.28 Karthikeyan, Davies and Gunhaga (2023) — non-visual opsins and photoreception outside the eye

Citation. Karthikeyan R, Davies WIL, Gunhaga L. Non-image-forming functional roles of OPN3, OPN4 and OPN5 photopigments. Journal of Photochemistry and Photobiology. 2023;15:100177. doi:10.1016/j.jpap.2023.100177. Available online April 2, 2023. Open access under the Creative Commons Attribution-NonCommercial-NoDerivatives license. Affiliations: Umeå Centre for Molecular Medicine, Umeå University, Sweden; School of Life Sciences, La Trobe University, Melbourne.

Article type. Review. Not primary research and not a systematic review. Every quantitative figure the Foundation takes from it is reported at one remove from a primary source. The Foundation cites it in the category described at Part V.A.2 as a synthesis of the state of the field, and for mechanism rather than for effect.

Subject. The three non-visual opsin photopigments OPN3 (encephalopsin or panopsin), OPN4 (melanopsin) and OPN5 (neuropsin): their spectral properties, their expression across tissues in vertebrates including humans, and the non-image-forming functions attributed to them, which the review groups as photoentrainment of biological rhythms, melanogenesis in dermal tissue, thermoregulation in adipose tissue, embryonic eye development, smooth muscle relaxation, and the development of certain cancers.

Spectral sensitivities reported. Peak dark absorbance of approximately 463 nanometers for OPN3, which the review notes can extend to 470 depending on species; 480 nanometers for OPN4; and 380 nanometers for OPN5. The review states that light at 480 nanometers activates OPN3 to 90 percent and OPN4 to 100 percent but does not activate OPN5, and that light at 400 nanometers activates OPN3 to 39 percent, OPN4 to 28 percent and OPN5 to 78 percent.

Expression outside the eye. Table 1 of the review lists tissue and cell expression. For OPN3 these include blood vessels; numerous brain regions including cerebellum, cerebral cortex, hippocampus, hypothalamus, limbic system and thalamus; the gastrointestinal tract including colon, esophagus, ileum, liver, pancreas and stomach; immune cells including human B-cells and T-cells; the reproductive system; skin including fibroblasts, hair follicles, keratinocytes and melanocytes; and adipocytes, adrenal glands, cochlea, heart, kidney, lung, smooth and skeletal muscle, spinal cord, spleen and thymus. OPN4 is listed in blood vessels, brain, eye, skin, reproductive tissue, adipose-derived stem cells, liver, smooth muscle and developing thyroid. OPN5 is listed in brain regions, eye, reproductive tissue, and skin keratinocytes and melanocytes.

Penetration of tissue. The review states that the penetration of specific wavelengths through skin, the skull and other bones, skeletal muscle, underlying soft tissues and through abdominal structures to reach the developing fetus has been firmly established, that longer wavelengths penetrate further than blue, and that biologically relevant shorter wavelengths also pass into deeper tissues.

What it establishes. That light detection in mammals is not confined to the rods and cones, that a family of photopigments with defined spectral sensitivities is expressed across a wide range of tissues including skin, fat, blood vessels, smooth muscle, immune cells and brain, and that functional responses to light have been demonstrated through those receptors in laboratory systems. It also establishes that the peak sensitivities of two of the three lie in the short-wavelength region in which phosphor-converted white light-emitting diodes emit most strongly.

What it does not establish. That any product in commerce produces any effect through any of these pathways in any person. Most of the underlying work is in cell culture, in isolated tissue and in animal models, much of it with gene knockouts and exogenous chromophore, and the review does not present exposure levels encountered in ordinary life. It identifies no threshold, no dose and no exposure limit. It is a review and performs no appraisal of the studies it summarizes. The Foundation uses it for the existence and location of a mechanism and for nothing else.

Considerations bearing on confidence. In favor: published in a photochemistry and photobiology journal by authors in the field; extensively referenced; explicit about uncertainty, including that determining a reliable peak absorbance value for OPN4 has proved difficult and inconsistent, and that functional roles of several opsins remain unknown or unclear. Against: a narrative review with no stated search strategy or appraisal instrument; a literature drawn from many species with differing opsin complements; and reliance throughout on knockout and ex vivo preparations whose relation to intact human exposure is not established.

Bearing on the statutory question. This is the mechanistic entry the rest of the appendix needed. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of,

and conditions of exposure to, electronic product radiation. The photobiological safety framework the Department and the consensus bodies rely on assesses exposure to the eye. This review describes receptors for visible light distributed through the skin and viscera, with peak sensitivities near 463 and 480 nanometers, and functional responses in adipose tissue, vasculature, smooth muscle and immune cells. If those pathways operate at the exposures people actually receive — which is unresolved, and which the Foundation does not assert — then the quantity the existing framework measures is not the quantity that matters, and no instrument in federal use would detect the difference. That is a question for study, and it is the study § 360ii(a)(2) and (a)(4) direct. Parts V.B.1, V.C.2.h, V.J.4 and IX.C.

Entries this one bears on. Appendix C.15, hepatic injury in mice from whole-body exposure, where OPN3 is reported in liver; C.19, systemic glucose effects from light delivered to the back, though that study attributes its mechanism to cytochrome c oxidase rather than to an opsin and the two should not be merged; C.20, allergic and respiratory disease, where OPN3 is reported in bronchial epithelium and immune cells; C.23, limbic signaling in rats, where OPN3 is reported in hippocampus and limbic structures; and C.26, skin cancer in mice, where OPN3, OPN4 and OPN5 are all reported in keratinocytes and melanocytes. The Foundation does not assert that any of those findings is explained by any of these receptors. It observes that a plausible route exists and has not been investigated federally.

C.29 Cao, Xu and Yin (2023) — health threats of light pollution and the state of regulation

Citation. Cao M, Xu T, Yin D. Understanding light pollution: recent advances on its health threats and regulations. Journal of Environmental Sciences. 2023;127:589–602. doi:10.1016/j.jes.2022.06.020. PMID 36522088.

Status of this entry. Incomplete, and the Foundation says so at the outset. The article is not open access and no author manuscript or repository copy could be located. Everything below is taken from the published abstract. The entry is retained because of one sentence in that abstract, quoted at Part II.D.5, and because the subject matter of the review is the regulatory question this comment raises.

Article type and scope. Review, covering literature from 2018 to 2022, epidemiological and experimental. The authors state that they summarize associations of light pollution with obesity, mental disorders and cancer among others, and that they address the toxicological mechanism of light pollution through circadian disruption, reviewing alterations of clock genes and disturbance of melatonin homeostasis.

The sentence the Foundation relies on. "Although there are regulations and standards concerning light pollution, few of them are based on the potential contribution of improper lighting to diseases." The authors add that a better understanding of the health threats induced by light pollution may promote risk assessment and better regulation of artificial lights, and that they aim to provide perspectives for future research and guidance for relevant regulations and standards.

What it establishes. That researchers surveying this field describe the existing body of regulation and standards for light pollution as largely not disease-based, and regard better regulation as a purpose their review is meant to serve. That is a statement about the state of regulation internationally, made in a peer-reviewed journal, and it corroborates from outside what Part II.D.5 establishes from the United States record: that what governs this subject here is voluntary, non-federal, and not addressed to health outcomes.

What it does not establish. Anything about any product, any exposure or any person. It is a review, the Foundation has read only its abstract, and it makes no claim about United States law in particular so far as the abstract discloses. The Foundation does not rely on

any of its substantive findings about obesity, mental disorders, cancer, clock genes or melatonin, because it has not read them.

Considerations bearing on confidence. Unassessed. The Foundation has not seen the method, the search strategy, the funding statement, the competing interest declaration or any of the content beyond the abstract, and will not pretend otherwise. A review published in an indexed peer-reviewed journal carries the ordinary presumptions of that status and nothing further until read.

Bearing on the statutory question. One use, at Part II.D.5. The Final Response of May 24, 2024 rested in part on the effectiveness of existing mitigations in addressing unnecessary radiation. Part II.D.2. The Foundation asks the Department to identify those mitigations and to state which of them it administers, and offers this review for the narrow proposition that researchers surveying the international picture describe the regulatory instruments in this field as largely not grounded in disease. If that is so of the instruments generally, the Department should be able to say which of them, as applied to light-emitting diode products in the United States, is grounded in disease and who administers it. Parts II.D.2, II.D.5 and IX.H.2.

C.30 Campbell, Sharifpour and Vandewalle (2023) — light as a modulator of non-image-forming brain functions

Citation. Campbell I, Sharifpour R, Vandewalle G. Light as a modulator of non-image-forming brain functions — positive and negative impacts of increasing light availability. Clocks & Sleep. 2023;5(1):116–140. doi:10.3390/clockssleep5010012. PMID 36975552. PMCID PMC10047820. Published March 17, 2023. Open access under the Creative Commons Attribution license.

Article type. Narrative review. The authors describe it as such and state that they include what they consider important and relevant papers rather than applying a systematic search. The Foundation cites it in the category described at Part V.A.2, as evidence of the state of expert opinion and for the framework it supplies, not as primary evidence of effect. The authors declare no conflict of interest.

Subject. The image-forming and non-image-forming visual pathways; the impact of light on human cognition, sleep, alertness and mood; and the consequences of the adoption of light-emitting diode lighting and screens. Non-image-forming responses are mediated by intrinsically photosensitive retinal ganglion cells expressing melanopsin, which the authors state is maximally sensitive to blue-wavelength light around 480 nanometers, and which mediate melatonin suppression, pupillary constriction, stimulation of alertness and cognitive performance, circadian entrainment and influences on mood.

The passage the Foundation relies on. At its section headed Health and Lighting, the review distinguishes the blue light hazard from the non-image-forming response: the hazard concerns photochemical damage to retinal tissue, is particularly prominent for prolonged or intense exposure below approximately 440 nanometers and especially from relatively focal sources, and is therefore distinct from the non-image-forming impacts of diffused light, which peak around 460 to 480 nanometers. The quotation is set out at Part V.C.2.i.

What else it establishes, in the authors' own framing. That light use is rising steeply, mainly because of the advent of light-emitting diode devices; that many commonly used white light-emitting diodes are relatively rich in blue-wavelength light; and that the timing of such device use is widespread, leading, in the authors' phrase, to novel light exposure patterns on the non-image-forming system. The Foundation draws the Department's attention to that phrase. A novel exposure pattern is a condition of exposure, and § 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure to electronic product radiation.

The balance the review strikes, which the Foundation adopts. The authors frame the adoption of light-emitting diode lighting and screens as offering new opportunities to improve well-being while also raising concerns about increasing light exposure that may be detrimental to health, particularly in the evening. That is the same two-sided position the Foundation takes at Appendix C.24 and at Part I.A: the objection is not to artificial light but to an exposure pattern that has changed without evaluation. The Foundation cites the review as it is written and does not quote only its negative half.

What it does not establish. No primary data; a narrative review with no stated search strategy, no inclusion criteria and no appraisal instrument. It establishes nothing about any particular product, sets no threshold, and identifies no exposure limit. Its statements about melanopsin sensitivity and about the blue light hazard are summaries of other work and should be traced to that work where the comment relies on them heavily.

Considerations bearing on confidence. In favor: authors active in this specific field; open access; no declared conflict of interest; and a notably balanced presentation that treats light as beneficial as well as potentially harmful, which the Foundation regards as a mark of care. Against: narrative rather than systematic; published in an MDPI title, as are Appendices C.18, C.21 and C.26, and the same question about whether to note the publisher applies here; and everything in it is reported at one remove.

Bearing on the statutory question. This entry supplies the distinction on which Part V.C.2.i rests, and that distinction bears directly on the Final Response of May 24, 2024. The agency has stated that light-emitting diode products have a long history of safety with respect to the visible wavelengths they emit. Safety assessed how, and against what? The framework available for assessing optical radiation safety addresses photochemical retinal injury below roughly 440 nanometers from focal sources. The pathway by which light reaches the brain peaks near 480 nanometers and responds to diffuse illumination. A record of conformity with the first is not a history of safety with respect to the second, and the Foundation has found no assessment of the second for any product. Parts I.C.7, V.B.1, V.C.2.i, V.G and IX.C.

C.31 Lu and others (2023) — light at night and cause-specific mortality in Mainland China

Citation. Lu Y, Yin P, Wang J, Yang Y, Li F, Yuan H, Li S, Long Z, Zhou M. Light at night and cause-specific mortality risk in Mainland China: a nationwide observational study. BMC Medicine. 2023;21:95. doi:10.1186/s12916-023-02822-w. PMID 36927443. PMCID PMC10022237. Published March 16, 2023. Open access under the Creative Commons Attribution license.

Design, and why it differs from every other entry here. Time-stratified case-crossover study with conditional Poisson regression within each county, followed by random-effects meta-analysis across counties. In a case-crossover design each decedent serves as his or her own control: exposure on the day of death is compared with exposure on control days drawn from the same month and year and matched by day of week. The consequence is that every characteristic of a person that does not change from day to day — age, sex, smoking, genetics, income, occupation, neighborhood, the whole of the urbanicity problem that burdens the other observational entries in this appendix — is removed by the design rather than adjusted for in a model. Season and day-of-week effects are removed by the matching. No other entry in Appendix C has that property.

Population and exposure. Five hundred seventy-nine counties, 2015 to 2019. Daily light at night from the Suomi National Polar-orbiting Partnership Visible Infrared Imaging Radiometer Suite. Average daily light at night across counties was 4.39 nanowatts per square centimeter per steradian, with a range of 1.02 to 35.46. Daily mortality from the Disease Surveillance Point System.

Adjustment. Daily temperature, daily humidity and daily fine particulate matter were adjusted for, the last derived from the China High Air Pollutants dataset at one-kilometer resolution and the meteorological variables from the ERA5-Land reanalysis. The Foundation notes this because daily satellite radiance and daily weather are not independent, and an analysis of day-to-day variation that did not address temperature and air pollution would be of little use. This one does.

Result. Per 100 nanowatts per square centimeter per steradian increase in daily light at night: all-cause mortality relative risk 1.08, 95 percent confidence interval 1.05 to 1.11; natural-cause mortality 1.08, 1.05 to 1.11. Positive associations were observed for all natural cause-specific categories, the strongest being mortality from nervous system disease, 1.32, 1.14 to 1.52. Results were reported as robust in younger and older people and in both sexes, with a more pronounced effect in regions of median exposure, and the exposure-response relationship was non-linear.

A presentational point the Foundation raises on its own account. The relative risks are scaled to an increase of 100 nanowatts per square centimeter per steradian. The reported range of county average daily exposure is 1.02 to 35.46, a span of about 34 units, and the day-to-day variation within a county, which is what the case-crossover design actually uses, is not stated in the abstract and will be smaller still. A risk expressed per 100 units in data whose observed spread is a third of that, and whose operative contrast is smaller again, overstates to the eye what the study observed. Taken at face value and assuming log-linearity, a relative risk of 1.08 per 100 units corresponds to roughly 1.03 across the entire between-county range. The Foundation reports the figures as published and flags the scaling, because a reply that noticed it first would be entitled to make something of it.

What it establishes. That across 579 Chinese counties over five years, days of higher satellite-measured nighttime radiance were associated with higher mortality, after adjustment for temperature, humidity and fine particulate matter, with the association removed by design from confounding by any characteristic that does not vary day to day. This is the only entry in Appendix C with mortality as its endpoint and the only one using a within-person comparison.

What it does not establish. Causation; the study is observational, and association on a given day does not establish that the light contributed to the death. The design addresses short-term variation and says nothing about chronic exposure causing disease over years, which is the mechanism most of this appendix concerns; the two questions should not be run together. Exposure is assigned at county level and is not a measurement of what reached any individual, which the authors identify as a source of misclassification. The instrument is broadband and carries no spectral information, so this establishes nothing about light-emitting diode products or about which light. Part V.J.4. The authors further state that they could not adjust for indoor light, for the use of eye masks, or for sleep patterns, and that noise and other unrecognized environmental factors cannot be ruled out.

The question the Foundation cannot resolve from what it has read. Satellite-measured nighttime radiance on any given night varies not only with how much light is emitted but with cloud cover, lunar illumination, snow, aerosol load and viewing geometry. Standard products from this instrument are ordinarily screened for cloud and moonlight, and the comment at Part II.D.3.d describes how strongly cloud amplifies measured radiance. Whether and how the authors handled cloud and lunar illumination is the single most important methodological question for a study built on day-to-day variation, and the Foundation has not located the answer. Until it does, it treats the daily exposure variable as potentially carrying an atmospheric component that temperature, humidity and particulate adjustment would not fully remove.

Considerations bearing on confidence. In favor: a mortality endpoint, which is the least subject to ascertainment error of any outcome in this appendix; a national surveillance

system rather than a cohort; 579 counties; a design that eliminates time-invariant confounding structurally; adjustment for the three time-varying environmental confounders that matter most; a two-stage approach with county-specific estimates meta-analyzed rather than pooled naively; a non-linear exposure-response examined rather than assumed; consistency across age and sex; and open access publication in a general medical journal. Against: observational; county-level exposure; no spectral information; the scaling point above; the unresolved cloud and moonlight question; a modest effect size; and a single national setting whose lighting and reporting systems are not those of the United States.

Bearing on the statutory question. The Foundation offers this entry for two propositions and no more. First, that the outcomes under investigation in this literature now extend to death, which bears on the seriousness of the question § 360ii(a)(4) directs the Secretary to study rather than on whether any answer has been reached. Second, that a study design exists which removes the confounding objection structurally rather than by adjustment, and that it has been applied to this exposure once, in another country, using a satellite instrument that cannot see the spectrum. A federal research program could apply the same design to United States data with spectrally resolved exposure. Nothing prevents it except that no one has been asked to. Parts II.F, V.J.4 and IX.C.

C.32 Obayashi and others (2022) — directly measured bedroom light and health outcomes, HEIJO-KYO cohort

Citation. Obayashi K, Tai Y, Yamagami Y, Saeki K. Associations between indoor light pollution and unhealthy outcomes in 2,947 adults: cross-sectional analysis in the HEIJO-KYO cohort. Environmental Research. 2022;215:114350. doi:10.1016/j.envres.2022.114350. PMID 36150438. Received May 19, 2022; accepted September 12, 2022; available online September 21, 2022. Open access under the Creative Commons Attribution license. Department of Epidemiology, Nara Medical University School of Medicine, Japan.

Why this entry matters. It is the only study in Appendix C in which the exposure was measured directly, with a light meter, in the room where the participant sleeps, at a scale sufficient to describe the distribution across a population. Every other exposure in this appendix is satellite radiance over an area, a wrist-worn sensor, or a report by the participant. This is the measurement that corresponds most closely to the quantity a recommendation about bedroom light would have to specify. It is also the primary source for the Obayashi figures reported at second hand at Appendix C.21.

Design and population. Cross-sectional analysis within the Housing Environments and Health Investigation among Japanese Older People in Nara, Kansai Region, a prospective community-based cohort known as HEIJO-KYO. Enrollment between September 2010 and April 2019 of 3,012 adults aged over 40. Sixty-five were excluded for missing or improperly placed meters, leaving 2,947, or 97.8 percent. Mean age 69.3 years, standard deviation 7.8; 60.6 percent female. Written informed consent; approved by the Nara Medical University ethics committee.

Exposure, as measured — set out in full because the method is the point. Bedroom light intensity was measured from bedtime to rising time at intervals of less than two minutes on two consecutive weekday nights, using portable light meters placed at the head of the bed, 60 centimeters above the floor, facing the ceiling. Instrument sensitivity 0 to 100,000 and 0 to 130,000 lux with stated accuracy of 4 and 5 percent of reading. Participants were instructed to lead a normal life during the survey, and correct placement was confirmed from digital photographs the participants took themselves. The average of the two nights was used. Median intensity 1.0 lux, interquartile range 0.2 to 4.0. Quartile medians were 0.03, 0.5, 1.9 and 9.9 lux. The authors report that in the group at or above 3 lux the mean intensity was about 100 lux at bedtime and at rising time, and still around 10 lux at 120 minutes after bedtime and before rising.

The origin of the 3 and 10 lux thresholds. The authors state that these cutoffs were predefined on the basis of biological impact shown in previous studies, citing Cajochen and others and Zeitzer and others, both 2000. The thresholds therefore come from the experimental melatonin-suppression literature and were applied to these data, rather than being derived from them. The Foundation corrects its own earlier characterization at Appendix C.21 accordingly.

Result — metabolic and inflammatory, adjusted. Highest against lowest quartile: body weight greater by 1.1 kilograms, 95 percent confidence interval 0.3 to 2.0; body mass index by 0.4, 0.1 to 0.7; abdominal circumference by 1.6 centimeters, 0.7 to 2.5; low-density lipoprotein cholesterol by 3.8 milligrams per deciliter, 0.7 to 6.9. At or above 3 lux against below: body weight greater by 1.0, 0.4 to 1.7; body mass index by 0.4, 0.1 to 0.6; abdominal circumference by 1.2, 0.5 to 1.9; triglyceride by 6.7, 1.8 to 11.6; low-density lipoprotein by 3.6, 1.3 to 6.0; and high-density lipoprotein lower by 2.3, −3.5 to −1.1. At or above 10 lux: white blood cell count higher by 0.2 times ten to the ninth per liter, 0.01 to 0.3. Plasma glucose, glycated hemoglobin and platelet count showed no significant association.

Result — sleep and mood, adjusted. Sleep disturbance, by quartile against the lowest: 1.21, 0.96 to 1.51; 1.33, 1.06 to 1.67; and 1.43, 1.14 to 1.79. Against thresholds: 1.25, 1.05 to 1.48 at or above 3 lux; 1.29, 1.02 to 1.64 at or above 10 lux. Depressive symptoms by quartile reached no significance, the highest quartile giving 1.30, 0.98 to 1.73, p = 0.07; against thresholds the estimates were 1.30, 1.05 to 1.61 at or above 3 lux and 1.33, 1.003 to 1.77 at or above 10 lux. The Foundation draws attention to the depressive-symptom result, which is significant on the threshold analysis and not on the quartile analysis, and whose lower bound at 10 lux is 1.003. That finding is fragile and the Foundation does not rely on it.

Adjustment. Age, gender, smoking, drinking, income, education, physical activity, bedtime, duration in bed and day length throughout; lipid-lowering drugs for the lipid outcomes, antidiabetic drugs for glucose and glycated hemoglobin, hematocrit for the inflammatory parameters, and sleeping pills and antidepressants for the psychiatric outcomes. A sensitivity analysis excluding 178 participants with a history of shift work is reported as consistent.

What it establishes. That bedroom light at night can be measured directly at population scale by a reproducible method; what its distribution is in one large older cohort; and that higher measured bedroom light was associated with modest but consistent differences in body weight, body mass index, abdominal circumference and blood lipids, with white cell count at the higher threshold, and with sleep disturbance, after adjustment for a substantial covariate set. The magnitudes should be kept in view: about one kilogram of body weight and 0.4 units of body mass index between the extreme quartiles.

What it does not establish. Causation. The authors state that the cross-sectional design precluded causality assessment, and reverse causation is a live possibility: a person with disturbed sleep or depressive symptoms may be more likely to sleep with a light on. The sample is non-random and the authors cannot exclude selection bias. Light was measured on only two nights. Although the cohort was aged over 40, only 241 participants, 8.2 percent, were aged 40 to 59, so generalizability to younger people is undetermined. And the exposure is photopic illuminance: the authors state expressly that they did not measure light spectrum in all participants and that it therefore remains unclear whether intensity or spectrum has the larger effect on health outcomes.

A limitation of direct relevance to this comment. The authors write that it remains unknown which light sources have the largest impact on health outcomes, instancing bedside lights, street lighting, light from other rooms, televisions, smartphones and morning sunlight. That is the product-identification problem stated by investigators who measured the exposure as carefully as anyone has. A performance standard governs a product. A study that measures the light in a bedroom without identifying which product

emitted it cannot, by itself, tell a regulator which product to address. Parts II.D.2.d and V.J.4.

Funding and competing interests, recorded in full. The declaration states that Drs. Obayashi and Saeki report financial support provided by YKK AP Inc., Ushio Inc., Tokyo Electric Power Company, EnviroLife Research Institute Co., Ltd., Sekisui Chemical Co., Ltd., LIXIL Corp., KYOCERA Corp., ENDO Lighting Corp., and KANEKA Corp. Research funding is also acknowledged from the Japan Society for the Promotion of Science and numerous Japanese foundations and from Nara Medical University, with a statement that the funders had no role in study design, data collection and analysis, the decision to publish, or preparation of the manuscript. The Foundation records that several of the named commercial supporters are lighting manufacturers, that others make windows and building products, and that one is an electric utility. It makes no allegation and draws no inference; it records the disclosure on the same terms as at Appendices C.24 and C.25, and notes that the direction of any interest is not obvious here.

Bearing on the statutory question. Used at Part IX.J.3. The Foundation asks the Department to issue recommendations where the record supports them and to state what further evidence is needed where it does not. For bedroom light this entry shows what the needed evidence looks like and that it is obtainable: a light meter at the head of the bed, sampling every two minutes for two nights, across several thousand people, with the distribution published. Paragraph 360ii(a)(4) directs the study and evaluation of conditions of exposure; § 360ii(b)(2) authorizes grants for that purpose and § 360ii(b)(4) the procurement of electronic products for research and testing. Part II.B. The work has been done once, in Japan, by a university department. It has not been done in the United States. Parts II.B, II.F, V.J.4, IX.C and IX.J.3.

C.33 Chen and others (2022) — outdoor light at night and mild cognitive impairment in Chinese veterans

Citation. Chen Y, Tan J, Liu Y, Dong GH, Yang BY, Li N, Wang L, Chen G, Li S, Guo Y. Long-term exposure to outdoor light at night and mild cognitive impairment: a nationwide study in Chinese veterans. Science of the Total Environment. 2022;847:157441. doi:10.1016/j.scitotenv.2022.157441. PMID 35863567.

Provenance of this entry. The Foundation came to this study through a university news item announcing it. The news item is not the source and is not cited anywhere in this comment; the peer-reviewed article is. The Foundation records the point because the standard it undertook at Part V.A.1 is to rely on the published literature rather than on reporting about it.

Design and population. Cross-sectional study of 5,496 participants drawn by multi-stage random sampling from veteran communities in 18 cities across China and investigated during 2009 to 2011. Cognitive function was assessed first by the Mini Mental State Examination and the Chinese version of the Montreal Cognitive Assessment, then confirmed by clinical examination. Analysis by mixed-effects logistic regression.

Exposure, as measured. Outdoor light at night estimated from the Global Radiance Calibrated Nighttime Lights Product at a spatial resolution of approximately one kilometer, for the three years preceding the investigation. This is a product of the Defense Meteorological Satellite Program instrument, which is broadband and carries no information about the color of the light. Part V.J.4.

Result. After adjustment, the odds ratio for mild cognitive impairment per interquartile-range increase in exposure, the interquartile range being 21.17 nanowatts per square centimeter per steradian, was 1.44, 95 percent confidence interval 1.36 to 1.52. Analyzed by quartile, the highest odds ratio was in the highest quartile against the lowest, with a monotonically

increasing trend, p for trend below 0.001. Higher odds ratios were observed in women, in those with less educational attainment, and in those without regular social activities.

A caution about the precision, which the Foundation raises itself. An odds ratio of 1.44 with an interval of 1.36 to 1.52, from 5,496 participants, is a narrower interval than this design would ordinarily yield. For comparison, the study at Appendix C.22 reported a comparable effect size from 126,418 participants with an interval of similar width. Exposure here is assigned at an areal resolution of about one kilometer, so participants living near one another share an exposure value and the effective number of independent exposure observations is far smaller than the number of people. If that clustering is not fully accounted for, confidence intervals will be too narrow. The authors used a mixed-effects model, which addresses clustering at whatever level the random effects were specified, and the Foundation has not been able to determine what that specification was. Until it does, it treats the stated interval as probably optimistic and relies on the direction and the monotonic trend rather than on the precision.

What it establishes. That in a large nationally distributed Chinese sample, higher modeled outdoor light at night at the place of residence was associated with a higher prevalence of mild cognitive impairment, with a dose-response trend across quartiles, and that the association was larger in several subgroups the authors identify. Cognitive status was ascertained by instrument and confirmed clinically rather than self-reported, which is a strength relative to several entries in this appendix.

What it does not establish. Causation. Despite the word long-term in the title, the design is cross-sectional: prevalent cognitive impairment was measured once, with exposure assigned for the three preceding years. Nothing establishes that exposure preceded the onset of impairment, and cognitive impairment may itself alter where and how a person lives. The sample is of veterans in Chinese veteran communities and is not a general population. Exposure is areal and spectrally blind, so the study says nothing about light-emitting diode products or about which light; and the exposure window of roughly 2006 to 2011 substantially predates the conversion of Chinese outdoor lighting to light-emitting diode sources, so the radiance measured was emitted largely by the technologies that preceded them. The same observation is made at Appendix C.22. Residual confounding by urbanicity is not excluded by anything in the abstract.

Considerations bearing on confidence. In favor: a nationally distributed multi-stage random sample across 18 cities; outcome ascertained by two validated instruments and confirmed by clinical examination; a monotonic exposure-response across quartiles; and subgroup findings that are at least coherent, in that less educated and less socially active people are plausibly more exposed to their immediate residential environment. Against: cross-sectional; a selected population; areal exposure at one kilometer with no spectral content; an exposure period predating light-emitting diode conversion; the precision concern set out above; and an adjustment set the Foundation has not seen.

Position among the cognitive entries. This is the third entry in Appendix C addressing cognition or dementia, with Appendix C.16, an ecological analysis of Alzheimer disease prevalence in the United States, and Appendix C.27, a case-control study of dementia in Modena with 54 controls and no significant result. The three differ in design, country, population and quality, and all three point the same way. The Foundation does not present that as corroboration, because three weak-to-moderate studies pointing one way can also reflect a shared confounder, and urbanization is the obvious candidate in all three. What the Foundation presents it as is a question asked three times in three countries and answered definitively nowhere.

Bearing on the statutory question. Offered for the proposition that cognitive decline is among the outcomes under investigation in relation to ambient light at night, and that the investigation has not reached a conclusion. That is the condition § 360ii(a)(4) addresses.

The entry also illustrates, for the third time in this appendix, a study that cannot speak to the question this comment asks because its instrument cannot see the spectrum. Parts II.F, V.J.4 and IX.C.

C.34 Argilès and others (2022) — brain functional connectivity under three monochromatic wavelengths

Citation. Argilès M, Sunyer-Grau B, Arteche-Fernandez S, Peña-Gómez C. Functional connectivity of brain networks with three monochromatic wavelengths: a pilot study using resting-state functional magnetic resonance imaging. Scientific Reports. 2022;12:16197. doi:10.1038/s41598-022-20668-9. PMID 36171254. PMCID PMC9519584. Published September 28, 2022. Open access under the Creative Commons Attribution license.

The weight of this entry, stated first. Seven participants. The authors describe it as a pilot study and the Foundation adopts that description without qualification. Resting-state functional magnetic resonance connectivity is a measure with known reproducibility difficulties at small sample sizes, and seven subjects across several brain networks and three exposure conditions cannot support a conclusion about anything. The Foundation does not rely on any finding reported in this study and asks the Department not to read it as evidence of an effect.

Design. Pilot study, N = 7. Resting-state functional magnetic resonance imaging before and after one minute of exposure to blue, green or red monochromatic light, examining functional connectivity across visual and non-visual brain networks.

Reported findings. The authors report that one minute of exposure modified functional connectivity across a broad range of visual and non-visual regions, and describe three patterns: a global decrease in connectivity after blue light in all networks except the salience network; a global increase after green light, particularly in the left hemisphere; and after red light a decrease in attentional networks coupled with an increase in the default mode network. They suggest each pattern may suit performance on different cognitive domains.

Why the Foundation includes it notwithstanding. Not for the findings but for the method and for what the method shows about the state of the field. The question this comment asks the Department to study is which wavelengths produce which effects and in what proportion. Answering that question requires exposing people to one wavelength at a time and measuring the response, which is what this study does. Part V.C.2.j explains why that artificial design is the necessary method for deriving an action spectrum, and why action spectra are what a spectrally resolved performance standard would require. This entry is offered as an instance of that work, and as a measure of how early it is: a pilot study of seven people with three broad color bands and a one-minute exposure.

What it establishes. That the experiment is being attempted, and that investigators regard wavelength-resolved brain imaging as a tractable approach. Nothing about any effect of any wavelength on any person.

What it does not establish. Anything else. Seven participants; a one-minute exposure; three broad conditions described as blue, green and red rather than as narrow bands with stated peak wavelengths and irradiances so far as the Foundation has read; multiple networks examined; and an imaging modality whose small-sample reliability is contested. It establishes nothing about light-emitting diode products, nothing about ordinary exposure, and nothing about health.

Bearing on the statutory question. Used at Part V.C.2.j, for the proposition that the derivation of action spectra for non-visual responses is in its infancy. Paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support research, and § 360ii(b)(2) authorizes grants for that purpose. Part II.B. The Foundation submits that deriving the action spectra for the responses described in Part V is a specific and bounded research

program, that it is the program whose output a performance standard under § 360kk would require, and that at present it is being attempted by small university groups on samples of seven. Parts V.C.2.j, V.J.4, IX.C.4 and IX.J.3.

C.35 Tancredi and others (2022) — artificial light at night and mental disorders, systematic review

Citation. Tancredi S, Urbano T, Vinceti M, Filippini T. Artificial light at night and risk of mental disorders: a systematic review. Science of the Total Environment. 2022;833:155185. doi:10.1016/j.scitotenv.2022.155185. PMID 35417728.

Status of this entry. Drawn from the published abstract. The article is not open access and the Foundation has not read the full text. The fields below report what the abstract states and nothing more.

Article type and search. Systematic review of observational studies, without meta-analysis so far as the abstract discloses. PubMed, Embase and Web of Science were searched to April 1, 2022. Studies were eligible if they assessed the link between indoor or outdoor artificial light at night and one or more mental disorders in human populations, with exposure assessed either by satellite photometry or by measurement of bedroom brightness.

Result. Nine eligible studies were identified: six cross-sectional, two longitudinal with a median follow-up of 24 months, and one case-cohort. The authors report moderate evidence of a positive association between exposure and depressive symptoms, and to a lesser extent other mental disorders, while noting that the number of studies was limited and that residual confounding by socioeconomic factors, noise or air pollution may have influenced the results. Their conclusion is that although more robust evidence is needed, the evidence produced so far seems to support an association between light at night and risk of depressive disorders.

What it establishes. That as of April 2022 a systematic search of three major databases returned nine studies on this question, that two thirds of them were cross-sectional, and that reviewers applying a systematic method graded the resulting evidence as moderate for depressive symptoms and weaker for other mental disorders. It establishes the size and shape of the literature at that date.

What it does not establish. Causation, which the authors do not claim. It is a qualitative synthesis of nine mostly cross-sectional studies, and the authors identify by name the three confounders this comment repeatedly flags: socioeconomic position, noise and air pollution. It establishes nothing about light-emitting diode products, and nothing about spectral composition; the exposures it reviews are satellite photometry and bedroom brightness, both spectrally blind. Part V.J.4.

An important limitation of date. The search closed on April 1, 2022. The field has moved since. Appendix C alone contains work published after that date bearing on the same question, including the entries at C.21, C.23, C.24 and C.32, and the largest of them, with 86,772 participants and objectively measured exposure, appeared in October 2023. This review therefore describes the state of the evidence as it stood four years before this comment, and should be cited for that and not as a current assessment.

Independence from other entries. Marco Vinceti and Tommaso Filippini are also authors of the dementia case-control study at Appendix C.27. The two are products of the same group at Modena. The Foundation records the overlap as it has at Appendices C.19, C.20 and C.24. It notes separately that this review is cited in the reference list of the study at Appendix C.24, which is a point in its favor as to standing in the field.

Bearing on the statutory question. Two uses. First, it is a systematically conducted assessment of the affective literature and therefore sits above the narrative review at Appendix C.21 in the hierarchy described at Part V.A.2; where the two differ, this one

should be preferred. Second, and more usefully, nine studies. A systematic search of three databases for all human research connecting a near-universal environmental exposure to mental disorder returned nine papers, six of them cross-sectional. That is the condition § 360ii(a)(2) and (a)(4) address, and it is the same picture the Foundation records at Appendices C.20 and C.27: a question approached by small groups without coordination and answered by nobody. Parts II.F, V.A.2, V.G and IX.C.

C.36 Chun and others (2022) — circadian disruption and colorectal cancer in mice and intestinal organoids

Citation. Chun SK, Fortin BM, Fellows RC, Habowski AN, Verlande A, Song WA, Mahieu AL, Lefebvre AEYT, Sterrenberg JN, Velez LM, Digman MA, Edwards RA, Pannunzio NR, Seldin MM, Waterman ML, Masri S. Disruption of the circadian clock drives Apc loss of heterozygosity to accelerate colorectal cancer. Science Advances. 2022;8(32):eabo2389. doi:10.1126/sciadv.abo2389. PMID 35947664. PMCID PMC9365282. Open access; full text read.

What the light exposure was. This must be stated before anything else, because the paper is easily miscited. Mice were housed on a standard twelve hours light and twelve hours dark schedule. The experimental manipulation, which the authors call shift disruption, was to advance the light phase by eight hours every other day for ten weeks. The twelve-and-twelve ratio was maintained throughout. The clock time of the light and dark blocks was what moved. The authors describe the paradigm as a model of night shift work three to four times per week. No illuminance value, no spectral power distribution, no correlated color temperature and no lamp type is reported anywhere in the paper.

What this entry is not offered for. It is not evidence about light at night in the sense that governs most of this comment. A streetlight entering a bedroom window adds light to the dark phase; a phase advance moves the whole cycle and leaves the dark phase intact. Those are different exposures, and there is no basis in this paper for treating a finding about one as a finding about the other. It is also not evidence about any electronic product, about any emission characteristic, or about any spectral region. The Foundation does not cite it for any of those propositions and the FDA should not understand it to support them.

What the study did. Two lines of work. First, a genetically engineered mouse model: intestine-specific deletion of the clock gene Bmal1 was combined with heterozygous loss of the tumor suppressor Apc, and polyp formation and survival were compared across genotypes. Second, the environmental arm: Apc heterozygous mice were assigned either to the stable twelve-and-twelve schedule or to the shift disruption schedule, six animals per arm, and small intestinal polyp count and individual polyp size were compared. Intestinal organoids derived from the mice were then used to trace the mechanism, and the authors report that clock disruption promotes transformation by driving loss of heterozygosity at Apc, which hyperactivates Wnt signaling, upregulates c-Myc and drives heightened glycolytic metabolism. Patient-derived organoids were used to show that circadian rhythms are lost in human tumors, and transcriptomic data from 512 colorectal cancer patients in The Cancer Genome Atlas were analyzed for the relationship between clock gene and Wnt pathway variation and overall survival.

What it establishes. That in a mammal, experimentally imposed disruption of the light schedule accelerated tumor burden in a cancer-predisposed strain, and that a molecular pathway running from clock disruption to the disease process can be traced and is conserved in human tissue. The exposure was assigned by the investigators rather than observed, so the comparison does not depend on controlling confounders in a human population. That is the particular value of the entry: it answers, within its own domain, the objection that the circadian literature is entirely observational and therefore cannot support a causal claim. The circadian clock is shown to be causally upstream of a disease outcome, not merely correlated with one.

What it does not establish. Any effect in humans. The in vivo finding is in mice already carrying a tumor suppressor mutation, and the environmental arm is six animals against six. The human components of the paper are organoid and transcriptomic analyses bearing on mechanism and prognosis, not exposure studies. It establishes nothing about dose, nothing about duration thresholds and nothing about which part of a light exposure matters, because the variable manipulated was timing alone.

Independence and conflicts. The authors declare no competing interests. The work is from the University of California, Irvine, and the Foundation has identified no author shared with any other entry in this appendix.

Funding, and why it matters here. The paper was supported by eleven grants from three institutes of the National Institutes of Health — the National Cancer Institute, the National Institute of Diabetes and Digestive and Kidney Diseases, and the National Heart, Lung, and Blood Institute — together with a National Cancer Institute center grant to the Chao Family Comprehensive Cancer Center. Every one of those funders is a component of the Department of Health and Human Services. The Secretary's own department paid for this research into how disturbing the timing of light exposure accelerates a cancer process, and has done so repeatedly and at scale. Part II.H and Part IV.G.12 of this comment describe the Department of Energy funding lighting research that the Food and Drug Administration does not collect. This entry is the same failure inside a single department, which is harder to explain. The Secretary is the funder and the Secretary is the official on whom § 360ii(b)(1)(A) confers the power to collect and make available the results of research concerning the hazards of electronic product radiation. The Center for Devices and Radiological Health has not collected it.

A limit on that point, stated plainly. Whether research of this kind falls within § 360ii(b)(1)(A) depends on how broadly the phrase research and studies relating to the nature and extent of the hazards of electronic product radiation is read. These authors were not studying an electronic product and would not, so far as the Foundation can tell, describe their work that way. What they studied is the mechanism by which mistimed light exposure produces harm; electronic products are the means by which most people now receive mistimed light exposure. The Foundation submits that research into the mechanism of a hazard relates to that hazard within the ordinary meaning of the word, and that a program which collected only research naming a device would collect almost nothing. But the Foundation states the step rather than assuming it, and invites the Department to say whether it reads the provision the same way. Part IX.B.

Bearing on the statutory question. Three points. First, it belongs to the mechanistic tier described at Part V.A.2 and should be cited there and nowhere else. Second, it bears on the § 360ii(a)(4) duty to study and evaluate emissions and the effects of exposure, because it shows what a funded, coordinated program produces: an assigned exposure, a traced pathway, and a test of human relevance. That is what is absent from the visible light literature this appendix catalogs, and the contrast is the argument. Third, and most directly, it is an item of research the Secretary funded and the Secretary has not collected or made available. Parts II.F, II.H, V.A.2, IX.B and IX.C.

C.37 Lin and others (2022) — outdoor light at night and overweight and obesity in school-aged children

Citation. Lin LZ, Zeng XW, Deb B, Tabet M, Xu SL, Wu QZ, Zhou Y, Ma HM, Chen DH, Chen GB, Yu HY, Yang BY, Hu Q, Yu YJ, Dong GH, Hu LW. Outdoor light at night, overweight, and obesity in school-aged children and adolescents. Environmental Pollution. 2022;305:119306. doi:10.1016/j.envpol.2022.119306. PMID 35430310.

Status of this entry. Drawn from the published abstract. The article is not open access, is not in Europe PMC, and the Foundation has not read the full text. The figures below are those the abstract reports.

Design and population. Cross-sectional analysis of data from the Seven Northeastern Cities study, comprising 47,990 school-aged children and adolescents aged 6 to 18 years in China. Analysis by generalized linear mixed model, with outdoor light at night entered in quartiles. This is the largest sample of children in Appendix C.

Exposure, as measured. Outdoor light at night levels from satellite imaging data. The abstract does not name the instrument or the data product, and the Foundation therefore cannot state the spectral response of the measurement. The point is not formal: as recorded at Appendix C.33 and Part V.J.4, the satellite products used in this literature are broadband or near-infrared weighted and carry no information about the color of the light, and they measure upward radiance over an area rather than the illuminance reaching a child. Outdoor exposure was the only exposure assessed. The authors state in their own conclusion that future studies considering both outdoor and indoor exposure are needed.

Outcome. Height and weight were used to compute age- and sex-specific body mass index Z-scores against World Health Organization growth standards. Overweight and obesity were defined using the Chinese standard. The entry notes that the continuous and categorical outcomes therefore rest on two different reference populations.

Results. Against the lowest quartile of outdoor light at night, children at higher levels had larger body mass index Z-scores and higher odds of overweight including obesity, and of obesity. The largest estimates were: body mass index Z-score, beta = 0.26, 95 percent confidence interval 0.18 to 0.33; overweight including obesity, odds ratio 1.40, 1.25 to 1.56; obesity, odds ratio 1.46, 1.29 to 1.65. A sex interaction for the Z-score outcome was significant at p less than 0.001, with the association stronger in males. The authors report that results remained robust across multiple sensitivity analyses and after adjustment for sleep-related characteristics, obesogenic factors and other environmental exposures.

The exposure-response is not monotonic, and the Foundation says so first. Every estimate quoted above is from the third quartile, not the fourth. The abstract states that the largest estimates were in the third quartile, which means the most exposed children showed a smaller association than the next most exposed. A monotonic gradient is one of the ordinary grounds for inferring causation from an observational association, and this study does not supply one. Appendix C.33 does supply one and the contrast is instructive. The Foundation reports the quartile from which its figures come rather than presenting them as the top-quartile result, and it does not offer this study in support of any dose-response proposition.

What it establishes. An association, in a very large sample of children, between modeled outdoor light at night at the place of residence and higher body mass index and higher odds of overweight and obesity, which survived adjustment for sleep characteristics. The adjustment for sleep matters: it indicates the association is not wholly accounted for by reported sleep duration or quality, which is the mediating pathway most often assumed.

What it does not establish. Causation. The design is cross-sectional; exposure and body mass index were ascertained at the same time, and the direction of any effect is not fixed by the data. The exposure-response is non-monotonic. Most importantly, outdoor light at night at a residence is among the best available proxies for urban density, and childhood obesity in China tracks urbanization through diet, screen time, school environment and the decline of active transport. Adjustment for socioeconomic status by questionnaire does not dispose of that. The authors of the study at Appendix C.11 state the same objection about the same exposure variable in their own words, and the Foundation adopts it here rather than restating it. The study establishes nothing about spectral composition, nothing about illuminance at the child, and nothing about any electronic product.

Position among the entries on body composition. Three entries now address adiposity or metabolic parameters, and they are usefully read together because their exposure measurements differ in exactly the way that matters. This entry assigns outdoor satellite

radiance to 47,990 children. Appendix C.10 measured the personal 24-hour light exposure of 831 Chinese school-aged children by wearable sensor over five days, and found more nocturnal time at or above 1 lux associated with higher percentage body fat. Appendix C.32 measured bedroom illuminance directly with a meter at the head of the bed in 2,947 Japanese adults, and found higher measured light associated with greater body weight, body mass index and abdominal circumference. All three are cross-sectional and none establishes causation. Their value as a set is that the direction is consistent across three populations and three methods of exposure assessment, while only the latter two use a measurement from which an exposure limit could be written. Both this entry and Appendix C.10 also report the association as stronger in boys, by independent methods, which the Foundation records as a convergence worth investigating and not as a finding.

Position among the entries concerning children. With Appendix C.10 and Appendix C.11 this is the third entry whose subjects are children. The Foundation draws attention to the population for a reason that is legal and not rhetorical. A child does not choose the streetlight outside the bedroom window, the fixture in the hallway or the lighting in the classroom, and cannot change any of them. Part II.D.2 of this comment asks what portion of a lighting installation is necessary within the meaning of § 360ii(a)(2). For the exposures that reach children, the share of the emission that serves no purpose for the exposed person approaches the whole of it. Parts V.K, VI and VII.

Independence from other entries. Dong Guang-Hui and Yang Bo-Yi are authors of this study and of the study at Appendix C.33, and the Chen G of that entry may be the Chen Gong-Bo of this one. The two entries are therefore not independent. The Foundation records a second consequence. Appendix C.33 carries a caution, raised by the Foundation itself, that the confidence interval reported there is narrower than its design would ordinarily yield. The intervals in this study do not present that problem: for a quartile contrast within 47,990 children the reported widths are, if anything, wider than an unclustered calculation would give, which is what a mixed model with clustering should produce. The concern at Appendix C.33 does not transfer, and the Foundation says so rather than leaving an unexplained shadow over an overlapping group.

Bearing on the statutory question. Two propositions and no more. First, that the health of children is among the outcomes under investigation in this literature, at a sample size that makes the question unignorable, and that the investigation has not resolved it. That is the condition § 360ii(a)(4) directs the Secretary to address by studying and evaluating emissions and the effects of exposure. Second, that this study cannot yield a number and that two others in this appendix show what kind of measurement could. A quartile of satellite radiance is not a quantity any manufacturer, city or parent can act on. One lux at the wrist and three lux at the head of the bed are. The Foundation asks the Department, under § 360ii(b)(1)(B), to say what nighttime light level in a child's sleeping environment it considers acceptable, and if the present record will not support a figure, to say what evidence would and then obtain it under § 360ii(a)(2) and (b)(2). Parts II.D.2, V.F, IX.C and IX.J.

C.38 Kim and others (2023) — measured light at night and obesity, diabetes and hypertension in older adults, Chicago Healthy Aging Study

Citation. Kim M, Vu TH, Maas MB, Braun RI, Wolf MS, Roenneberg T, Daviglus ML, Reid KJ, Zee PC. Light at night in older age is associated with obesity, diabetes, and hypertension. SLEEP. 2023;46(3):zsac130. doi:10.1093/sleep/zsac130. PMID 35729737. PMCID PMC9995772. Free to read at the publisher; full text read.

Why this entry matters, stated first. It is the strongest of the metabolic entries in this appendix on three counts at once. The population is American. The exposure was measured at the person by instrument over seven days rather than modeled from satellite radiance or reported by the participant. And the outcomes were ascertained clinically, by

fasting blood draw and measured blood pressure, not by self-report. It also contains a specificity result, described below, that no other entry in this appendix supplies.

Cohort and population. Five hundred and fifty-two community-dwelling adults aged 63 to 84 years. The sample is drawn from the Chicago Healthy Aging Study, itself a subset of the Chicago Heart Association Detection Project in Industry, a workplace screening program conducted between 1967 and 1973. Participants were survivors of that original cohort who were free of major electrocardiogram abnormality or myocardial infarction at the baseline examination, which makes this a comparatively healthy surviving population and limits generalization accordingly. Derivation of the analytic sample: actigraphy was offered to all study participants and accepted by 1,310; 1,199 returned the device; of those, 634 had been issued the one model equipped with a light sensor, assigned on the basis of availability rather than by any characteristic of the participant; and 552 of those had at least five valid twenty-four-hour recording periods.

Exposure, as measured. Wrist actigraphy for seven consecutive days, recording in thirty-second epochs, with participants instructed to keep the light sensor uncovered by sleeves or bedding. The exposure variable is light during the least active five-hour period, which the authors chose over light during the scored sleep interval or a fixed clock window because it is less sensitive to season, to sleep timing and duration, and to scoring bias. The distribution of those values was zero-inflated, and the authors therefore dichotomized it: participants with zero recorded light during the five-hour nadir were classified as No-LAN, and those with any recorded light as LAN. The sensor's lower detection limit is 0.1 lux. The contrast is therefore between no light detectable at the wrist during the darkest five hours of the night and any light at all above a tenth of a lux. Two hundred and fifty-five participants fell in the first group and 297 in the second.

The spectral response of the instrument, which the Foundation draws to the Department's attention. The authors describe their sensor fully, and the description is the point. It is a miniature photodiode with a wavelength range of 330 to 720 nanometers and a peak spectral sensitivity at 580 nanometers, which the authors correctly characterize as approximating the sensitivity of the human eye. That is the photopic luminous efficiency function: the curve that describes how bright light looks. The non-visual pathway hypothesized to mediate the effects reported here peaks near 480 nanometers, as set out at Part V.C.2. The exposure in this study was therefore measured with an instrument weighted to a peak roughly one hundred nanometers away from the peak of the mechanism under investigation. This is not a criticism of these investigators, who disclosed the sensor's response precisely and used the instrument that exists. It is an illustration of the measurement problem this comment describes at Part IV.C and Part V.J: the available instruments report what the eye sees because that is the convention the governing standards are written in, and a research literature built on those instruments cannot resolve the spectral question no matter how carefully it is conducted. Parts V.C.2.j and IX.D.

Outcome definitions. Obesity, body mass index of 30 kilograms per square meter or above. Diabetes, fasting glucose above 126 milligrams per deciliter or use of antihyperglycemic medication. Hypertension, systolic pressure of 140 millimeters of mercury or above, diastolic of 90 or above, or antihypertensive treatment; blood pressure taken as the average of the second and third measurements. Hypercholesterolemia, total cholesterol of 240 milligrams per deciliter or above or lipid-lowering treatment. Cholesterol and glucose from twelve-hour fasting samples.

Results. Prevalence in the No-LAN and LAN groups respectively, then the adjusted odds ratio with 95 percent confidence interval. Obesity: 68 of 255, or 26.7 percent, against 121 of 297, or 40.7 percent; 1.82, 1.26 to 2.65, p = 0.002. Diabetes: 25, or 9.8 percent, against 53, or 17.8 percent; 2.00, 1.19 to 3.43, p = 0.010. Hypertension: 151, or 59.2 percent, against 216, or 73.0 percent; 1.74, 1.21 to 2.52, p = 0.003. Hypercholesterolemia showed no association

and was not carried into the multivariable models. Unadjusted and adjusted estimates are close throughout, which indicates the covariates carried in the main model are doing little work.

The specificity result, which is the most useful thing in this study. The authors tested every other light variable they had derived and found nothing. No significant association was found between any of the four risk factors and twenty-four-hour mean light intensity, twenty-four-hour median light intensity, peak daytime light intensity, relative amplitude, interdaily stability, intradaily variability, or the timing of either the least or most illuminated period. The two groups also did not differ in twenty-four-hour mean light exposure, which was a median of 342 lux in both. The association is therefore specific to light during the nocturnal nadir and does not attach to how much light a person receives overall. That bears directly on the confounding objection the Foundation concedes elsewhere in this appendix. A variable standing in for urban density, indoor living or sedentary behavior would be expected to track total daily light exposure. This one does not. Appendix C.37 and Appendix C.11 both rest on exposure variables that cannot be separated from urbanicity in this way; this entry can be, and the Foundation relies on it for that.

What was adjusted for, stated precisely. The published abstract states that the models were adjusted for age, sex, race, season of recording and sleep variables. The table reporting the odds ratios above states that its multivariable model was adjusted for age, sex, race and season of actigraphy recording. Sleep and activity entered as a sensitivity analysis reported in supplementary material, where the authors state that after adjustment for sleep, mean activity count during the nadir period, and other activity variables, the associations with obesity, diabetes and hypertension remained statistically significant. The Foundation records the distinction because the figures above are not themselves sleep-adjusted and should not be described as if they were. The sleep-adjusted estimates are not reported in the main text.

Reverse causation, and how the authors addressed it. This is the governing threat to the finding and it is more acute here than in the satellite studies, because an exposure measured at the person captures behavior that disease itself produces. Nocturia in diabetes and nocturnal awakening in hypertension both lead to switching on a light. The authors identify precisely this objection, name nocturia and sleep disorders as frequent comorbidities of both conditions, and report that the associations were independent of nocturnal awakening and of activity level during the period of light measurement, which they describe as a marker for bathroom visits. The Foundation regards that as a serious and adequate response to a serious objection, and credits it. It does not dispose of the problem, and the authors do not say it does: they state that the cross-sectional design leaves them unable to exclude the possibility that the exposure is a consequence of the conditions rather than a cause.

What it establishes. That among 552 older American adults, those with any instrument-detected light at the wrist during the darkest five hours of the night had substantially higher prevalence of clinically ascertained obesity, diabetes and hypertension than those with none; that the association was specific to the nocturnal measure and absent for every other light variable derived from the same recordings; and that it survived adjustment for nocturnal awakening and activity. It also establishes a prevalence: more than half of this community-dwelling older population, 297 of 552, had detectable light at the wrist during their own sleep period.

What it does not establish. Causation. The design is cross-sectional and the authors say so. It does not establish that the exposure is habitual: seven days of recording cannot show that, and the authors state in their limitations that they cannot determine whether light at night in older age represents chronic habitual exposure, notwithstanding the word habitual in the abstract's conclusion. It establishes nothing about spectral composition, for the reason

given above; nothing about any light source, since a wrist sensor does not identify what emitted the light; and nothing about dose beyond the presence or absence of detectable light. The outcomes that entered the multivariable models were selected by their significance in bivariate analysis, which the Foundation notes as a minor methodological qualification affecting which outcomes were modeled rather than the estimates themselves.

Position among the entries on body composition, and the question of a threshold. Four entries now address adiposity or metabolic parameters, and their exposure thresholds form a sequence the Department should see together. This entry: any light above 0.1 lux at the wrist during the nocturnal nadir, in 552 older American adults, with clinically ascertained outcomes. Appendix C.10: time at or above 1 lux at night by wearable sensor, in 831 Chinese children. Appendix C.32: 3 lux and 10 lux at the head of the bed, in 2,947 Japanese adults. Appendix C.37: quartiles of satellite radiance, in 47,990 Chinese children. Four populations on three continents, four methods of exposure assessment, and the direction is the same in all four. The Foundation does not present that as proof of causation; all four are cross-sectional. It presents it because the question the Department will have to answer is a numerical one, and the numbers in this literature are small. The 3 lux threshold at Appendix C.32 was imported from the experimental melatonin-suppression work of Cajochen and Zeitzer; the epidemiological signals here and at Appendix C.10 appear at and below 1 lux. Whether an effect threshold for these outcomes lies below the threshold established for melatonin suppression is not a question this appendix can answer, and it is precisely the question the Foundation asks the Department to resolve.

Independence and conflicts. All authors report no conflict of interest, and both financial and nonfinancial disclosures are stated as none. The Foundation has identified no author shared with any other entry in this appendix. The authors cite, as their own second reference, the 2013 HEIJO-KYO analysis of light at night and obesity by Obayashi and colleagues, whose later work is at Appendix C.32; the two research programs are independent of each other and reach concordant results by different instruments in different countries.

Funding. National Institutes of Health grants from the National Heart, Lung, and Blood Institute, the National Center for Advancing Translational Sciences and the National Institute on Aging, together with departmental funds at Northwestern University. The Foundation notes the point made at Appendix C.36 and submits that this entry is the better instance of it: here the Secretary's own institutes funded a study that measured the light exposure of American adults in their own bedrooms and related it to disease. Paragraph 360ii(b)(1)(A) authorizes the Secretary to collect and make available the results of research concerning the hazards of electronic product radiation. The Foundation is aware of no step the Center for Devices and Radiological Health has taken to collect this one.

Bearing on the statutory question. This entry does more work than most. First, on § 360ii(a)(4), which directs the Secretary to study and evaluate emissions and the conditions of exposure: the prevalence finding is itself such an evaluation, performed by others, and it reports that most older Americans sleep in detectable light. Second, on the confounding objection the Department may raise against this whole literature, the specificity result is the Foundation's answer, and it is an answer from data rather than from argument. Third, on § 360ii(b)(1)(B): the Department is asked to make recommendations, and an exposure contrast of any detectable light against none, at a 0.1 lux floor, is the kind of quantity a recommendation can be written around. Fourth, on the spectral question, this entry demonstrates why the recommendation cannot stop at an illuminance figure. The best-instrumented study of its kind measured the exposure with a photopic sensor peaking at 580 nanometers. Until a measurement convention exists that reports what the non-visual

system receives, no amount of further epidemiology will answer the question this comment puts. Parts II.D.2, IV.C, V.C.2, V.F, IX.C, IX.D and IX.J.

C.39 Himmelberg, Winawer and Carrasco (2022) — individual differences in primary visual cortex and contrast sensitivity

Citation. Himmelberg MM, Winawer J, Carrasco M. Linking individual differences in human primary visual cortex to contrast sensitivity around the visual field. Nature Communications. 2022;13:3309. doi:10.1038/s41467-022-31041-9. PMID 35697680. PMCID PMC9192713. Open access under the Creative Commons Attribution license; full text read.

What kind of entry this is. Not a study of light exposure and not a study of health. It is vision science: functional magnetic resonance imaging and psychophysics performed on the same observers to ask whether differences in the anatomy of primary visual cortex predict differences in measured visual performance. It is included because the Foundation relies on it for a single proposition about the population to which any exposure standard must apply, and for no proposition about any exposure or any outcome. The Foundation states the limits of the entry below at greater length than usual, because the temptation to read more into it is real.

Design and sample. Twenty-nine observers. Retinotopic mapping by functional magnetic resonance imaging was used to delineate primary visual cortex and to measure its surface area, both overall and locally within fifteen-degree wedges centered on the four polar angle meridians of the visual field. Contrast sensitivity was measured psychophysically in the same observers at the same four locations. Correlations were assessed by Spearman's rho, one-tailed for the principal tests.

The finding the Foundation relies on. The surface area of primary visual cortex varied approximately twofold across these healthy adults. The authors give the figure precisely: a range of 110 percent, the largest primary visual cortex measuring 1,776 square millimeters and the smallest 832. They then supply the comparison that makes the number meaningful. Total cortical surface area in the same observers varied by 50 percent. The visual cortex is therefore more than twice as variable between individuals as the cortex as a whole. This is not a novel claim of this paper; the authors cite six prior reports for it and describe their own data as consistent with them. The Foundation cites this paper as a recent, open-access and carefully quantified instance of an established fact.

The link to perception, reported at its actual strength. Average contrast sensitivity across the four locations correlated positively with the overall size of primary visual cortex: rho = 0.47, p = 0.005, one-tailed, n = 29. Observers with a larger primary visual cortex tended to detect lower contrasts. The correlation survived normalization of visual cortex area by total cortical area, at rho = 0.33, p = 0.038, and contrast sensitivity did not correlate with total cortical surface area at all, p = 0.106, which indicates the relationship is specific to visual cortex rather than to brain size. A second analysis correlating local contrast sensitivity with local cortical surface area returned rho = 0.60, but the authors themselves decompose that figure and the Foundation reports the decomposition rather than the headline. Removing between-observer variation leaves the effect of visual field location at rho = 0.78, which the authors call robust. Removing within-observer variation leaves the effect of individual differences at rho = 0.27, which the authors call modest. The strong correlation is therefore driven mostly by where in the visual field a person is tested, not by who the person is.

What it establishes. That the neural substrate of human vision varies by roughly a factor of two among healthy adults, that this variation substantially exceeds the variation in brain size generally, and that it bears some relationship to measured visual performance. The anatomical variation is the robust part. The link to perception is real, specific to visual cortex, and modest.

What it does not establish, stated at length because it matters. It says nothing about discomfort, glare, photophobia, pain, or aversion to any light source. Contrast sensitivity is the ability to detect a faint pattern; it is not a measure of susceptibility to harm, and a person with high contrast sensitivity is not thereby shown to be more or less troubled by a bright light. It says nothing about spectral sensitivity, nothing about the non-visual pathways described at Part V.C.2, and nothing about any electronic product. The sample is twenty-nine observers, which is adequate for the anatomical measurement and thin for correlational claims about individual differences; a rho of 0.47 from twenty-nine observers carries wide uncertainty, and the principal tests are one-tailed. The Foundation does not cite this study for any proposition about who is harmed by artificial light or by how much.

Why the Foundation cites it at all: the standard observer. Every photometric quantity in every lighting standard — the lumen, the lux, the candela, luminance — is defined by the photopic luminous efficiency function, a single curve describing the sensitivity of a notional standard observer, derived in the early twentieth century from a small number of real ones. The Department of Energy requirement of 45 lumens per watt discussed at Part IV.G is expressed in that unit. The wrist photometer in the study at Appendix C.38 was built to approximate that curve, peaking at 580 nanometers. The hazard functions discussed at Part V.C.2 are population-average weighting functions of the same kind. The standard observer is a convention, and a necessary one; the question this entry raises is what follows from the fact that the population it stands for is not uniform. If the cortical tissue that does the seeing differs by 110 percent between healthy adults, then a quantity expressed in units built on an average observer does not describe a constant experience across the people exposed to it. The Foundation submits that a performance standard or recommendation set at a population central tendency, without an express determination about the distribution it is drawn from, has not been shown to protect the population it governs. Parts IV.C, V.C.2.j and IX.D.

The consequence for how a standard must be set. This is the use to which the Foundation puts the entry, and it is a modest one. Variation of this magnitude among healthy adults, measured before disease, age-related change or any diagnosed visual condition is brought into account, means that people whose response lies well away from the average are not anomalies to be set aside but a predictable and substantial fraction of the exposed population. Section 360kk directs that performance standards be reasonable. Paragraph 360ii(b)(1)(B) authorizes recommendations the Secretary considers appropriate. Neither can be satisfied by a figure chosen for the average person without the Secretary saying what proportion of the population that figure leaves unprotected. The Foundation asks the Department, when it sets or recommends any numerical limit on optical radiation from electronic products, to state the distribution of response it assumed and the fraction of the population the limit is intended to protect. Parts VII, IX.D and IX.J.

Independence, conflicts and funding. The Foundation has identified no author shared with any other entry in this appendix. The study was supported by the National Eye Institute and the National Institute of Mental Health, both components of the Department of Health and Human Services, which is the point made at Appendix C.38 and not repeated here.

C.40 Mason and others (2022) — experimental room light during sleep and cardiometabolic function

Citation. Mason IC, Grimaldi D, Reid KJ, Warlick CD, Malkani RG, Abbott SM, Zee PC. Light exposure during sleep impairs cardiometabolic function. Proceedings of the National Academy of Sciences. 2022;119(12):e2113290119. doi:10.1073/pnas.2113290119. PMID 35286195. PMCID PMC8944904. Open access under Creative Commons Attribution-NonCommercial-NoDerivatives; full text read. Deidentified data deposited in the Northwestern University institutional repository.

Why this is the most important entry in Appendix C. Every other entry addressing light at night and a disease outcome is observational. This one is an experiment. Participants were randomized, the exposure was administered by the investigators at a stated illuminance for a stated duration, the outcomes were measured physiologically, and a control arm was run in parallel. Within its narrow scope it therefore establishes causation rather than association, and it is the answer to the objection that this entire literature consists of correlations in which the direction of effect cannot be fixed. The Foundation relies on it for that and treats it as the evidentiary anchor of Part V.F.

Design. Parallel-group randomized laboratory study. Twenty healthy adults, ten per arm, each spending three days and two nights in the laboratory with an eight-hour sleep opportunity beginning at habitual bedtime. The room light arm slept in dim light below 3 lux on night one and under overhead room lighting at 100 lux on night two. The dim light arm slept below 3 lux on both nights. The comparison is the change from night one to night two between arms, so each participant supplies his or her own baseline and the control arm absorbs any second-night effect. Tests of the change scores were unpaired t tests.

The light source, stated prominently because it governs how this entry may be used. The 100 lux condition was produced by four 60-watt incandescent overhead ceiling bulbs, identified in the methods by manufacturer and part number. Incandescent. Not light-emitting diode. An incandescent lamp is a blackbody radiator of roughly 2,700 kelvin whose emission rises monotonically toward the red and the infrared and whose short-wavelength content is small. The Foundation does not cite this study as evidence of harm from light-emitting diode products, and the FDA should not read it that way. What follows from the choice of source is set out below, and it is more useful to the Foundation than the misreading would have been.

Population. Age 18 to 40, with a mean of about 26.7 in each arm. Habitual sleep duration between 6.5 and 8.5 hours and habitual sleep onset between 9:00 p.m. and 1:00 a.m. Participants with any sleep disorder were excluded, as were those pregnant or breastfeeding, and laboratory stays for female participants were scheduled in the follicular phase. The arms did not differ significantly in age, body mass index, sex, race, or in bedtime, sleep duration and sleep efficiency measured by actigraphy in the preceding week, nor in daytime sleepiness at screening.

Results. Insulin resistance by the homeostatic model assessment rose about 15 percent in the room light arm and fell about 4 percent in the dim arm, the difference in change being significant at $p = 0.018$. The Matsuda insulin sensitivity index fell about 16 percent against a rise of about 3 percent, $p = 0.048$. The thirty-minute insulin area under the curve from a two-hour oral glucose tolerance test was higher in the room light arm. Heart rate during sleep was higher, with a condition-by-night interaction at p less than 0.001, and heart rate variability was lower, indicating a shift toward sympathetic predominance. Higher sympathovagal balance during sleep was associated with higher thirty-minute insulin area under the curve. Sleep architecture shifted: proportionately more stage N2 and less slow wave and rapid eye movement sleep. Melatonin levels did not differ between conditions. In the authors' own summary, a single night of exposure to room light during sleep can impair glucose homeostasis, potentially through increased sympathetic activation.

The melatonin null, reported as the authors report it. This is important and must not be overstated in either direction. The authors chose 100 lux partly because that level has been shown capable of suppressing melatonin and shifting circadian phase, so they expected suppression and did not find it. They offer two explanations. First, only 5 to 9 percent of incident light is estimated to be transmitted through closed eyelids to the retina. Second, interindividual variability in melatonin sensitivity to light is large. They then state plainly that because of the small sample and because waking melatonin samples were not collected under dim conditions, they cannot rule out an effect of light-induced change in melatonin level or phase on the metabolic parameters. The Foundation therefore does not

assert that the observed effect was independent of melatonin. What the study shows is that the effect occurred without a detectable difference in melatonin, and that the pathway its own data support is autonomic.

What follows from an incandescent source, which is the argument. Three things, and together they are the most consequential point in this appendix. First, the effect was produced by a source with little short-wavelength emission, delivered through closed eyelids, which attenuate to between 5 and 9 percent and whose transmittance is itself weighted toward the red. The effective retinal exposure was therefore both small and strongly long-wavelength. Second, the mitigation strategy presently urged for light-emitting diode products — lower correlated color temperature, amber night modes, blue-blocking filters — rests on the premise that short-wavelength content is the hazard and melatonin suppression the injury. This study impaired glucose metabolism in one night with a warm, blue-poor source and no melatonin difference. A spectral fix alone is therefore not shown to be sufficient, and an illuminance limit is doing work that no shift in color temperature will do for it. Third, the case for a product that emits the same illuminance with substantial short-wavelength content added is stronger, not weaker, than the case this study makes. A light-emitting diode lamp at 100 lux delivers everything the incandescent lamp delivered and more. The Foundation submits that any recommendation or performance standard addressing light in a sleeping environment must therefore contain both an illuminance limit and a spectral limit, and that the FDA presently has neither. Parts IV.C, V.C.2, V.F, IX.D and IX.J.

The effective dose, and where it sits in the threshold sequence. If 5 to 9 percent of 100 lux reaches the retina through a closed eyelid, the effective ocular exposure in this experiment was on the order of 5 to 9 lux. That figure lands inside the band the rest of this appendix is converging on. Appendix C.32 applied thresholds of 3 and 10 lux at the head of the bed, taken from the experimental melatonin-suppression literature. Appendix C.10 used 1 lux at the wrist. Appendix C.38 used the 0.1 lux detection floor of its sensor. The sequence now has an experimental rung: at an effective retinal exposure of single-digit lux, sustained across a night of sleep, measurable autonomic and metabolic change occurred in healthy young adults. The Foundation does not present that as a derived limit. It presents it as the reason a limit is now a tractable question rather than a speculative one.

What it does not establish. Anything about chronic exposure. One night. The authors claim no more. It does not establish that the metabolic change persists, reverses, accumulates or leads to disease; the link from a single night of impaired glucose handling to diabetes is an inference this study does not license and the Foundation does not draw. The sample is ten per arm, which is very small, and the design is parallel-group rather than crossover, so randomization is carrying more weight than twenty participants can comfortably bear even though the measured baseline characteristics were balanced. The Matsuda result at $p = 0.048$ is marginal, several outcomes were examined, and the Foundation has seen no indication that the reported p values were corrected for multiple comparisons. Participants were healthy adults aged 18 to 40 screened to exclude sleep disorders, which is the group least likely to be affected and makes the finding more striking while limiting generalization. Nothing in the study bears on any particular product, on outdoor light, or on exposure while awake.

Independence and conflicts. The authors declare no competing interest. Kathryn Reid and Phyllis Zee are also authors of the study at Appendix C.38, and this entry and that one are products of the same group at Northwestern University. The two are therefore not independent of each other, and the Foundation records it as it has at Appendices C.19, C.20, C.24 and C.37. The Foundation notes, without treating it as a qualification, that the pairing is unusually useful: one is an experiment establishing that bedroom light at a stated level alters cardiometabolic physiology, and the other is an observational study finding higher prevalence of the corresponding conditions in older adults with measured

bedroom light. Funding in both cases came from institutes of the National Institutes of Health.

Bearing on the statutory question. This entry does the most work of any in the appendix. On § 360ii(a)(4), which directs the Secretary to study and evaluate emissions and the effects of exposure: here is the study, performed by others, at a cost the Department funded. On § 360ii(a)(2), which directs the Secretary to minimize exposure to unnecessary electronic product radiation: light reaching a sleeping person serves that person no purpose whatever, which places it at the extreme of the necessity analysis at Part II.D.2. On § 360ii(b)(1)(B), which authorizes recommendations: the Foundation has asked the Department what illuminance is acceptable in a bedroom at night, and this is the study a recommendation would be built from, bracketing an effect between an exposure below 3 lux that produced none and an exposure at 100 lux that did. On § 360kk, which provides for performance standards: an indicator lamp, a charging light, a display or a clock face in a bedroom is an electronic product emitting optical radiation into a sleeping person's environment, and this study is the beginning of a basis on which such emissions could be limited. And on § 360ii(b)(1)(A): the Secretary funded this, and the Foundation is aware of no step the Center for Devices and Radiological Health has taken to collect it. Parts II.D.2, V.F, IX.C, IX.D and IX.J.

C.41 McGlashan and others (2021) — light acutely suppresses activity in the human amygdala

Citation. McGlashan EM, Poudel GR, Jamadar SD, Phillips AJK, Cain SW. Afraid of the dark: light acutely suppresses activity in the human amygdala. PLOS ONE. 2021;16(6):e0252350. doi:10.1371/journal.pone.0252350. PMID 34133439. PMCID PMC8208532. Open access under the Creative Commons Attribution license; full text read. First-level model outputs and analysis scripts deposited at the Open Science Framework.

The direction of the finding, stated before anything else. The effect reported in this study is a beneficial one. The authors frame it that way, their title is Afraid of the dark, and their proposition is that light elevates mood by suppressing fear-related activity in the amygdala. A reader looking for a study that cuts against this comment could cite it. The Foundation puts it in the appendix anyway, reports it as the authors report it, and relies on it for two propositions that do not depend on whether the effect is good or bad: the dose at which the human brain responds to light, and the gap between the photometric and the biological measure of the same stimulus. On the second of those it is the most useful study in this appendix.

Design. Twenty-three healthy young adults in a 3-tesla scanner, blood-oxygen-level-dependent functional magnetic resonance imaging. Passive exposure in alternating thirty-second blocks of light and dark, dark being below 1 lux, with the two light intensities presented in separate runs. Light was delivered by a custom fiber-optic device to two 40-millimeter diffusers positioned about 50 millimeters above each eye. Gaze could not be monitored during exposure because delivery was binocular.

The stimulus, in both measures. This is the field that matters. The source was a halogen illuminator with a correlated color temperature of approximately 2,800 kelvin and a peak wavelength of 655 nanometers. Deep red. Intensity was measured at the eye and reported in two ways. The dim condition was approximately 10 photopic lux, equal to 4.3 microwatts per square centimeter, corresponding to a daytime equivalent melanopic illuminance of approximately 3.5 lux. The moderate condition was approximately 100 photopic lux, equal to 42.73 microwatts per square centimeter, corresponding to a melanopic equivalent of approximately 34.67 lux. Spectral characteristics were measured with a spectrometer and the tabulated spectral power distribution in one-nanometer bins from 360 to 760 nanometers is published as supplementary material.

Results. Light, compared with dark, suppressed activity in the amygdala. The 100 lux condition suppressed it more than the 10 lux condition, which is a dose-response. Functional connectivity between the amygdala and the ventromedial prefrontal cortex was enhanced during light relative to dark. The authors propose that these effects may contribute to the mood-elevating action of light, through reduced fear-related affect and altered processing of negative emotion.

The dose, which is the first proposition the Foundation takes from this study. Thirty seconds of exposure at 10 photopic lux — which is 3.5 melanopic lux — produced measurable change in the activity of a subcortical structure governing emotional response, and doubling to the moderate condition produced more of it. That is a very small dose and a very short exposure. The regulatory framework described at Part V.C.2 treats optical radiation below the blue light hazard thresholds as biologically inert and addresses it, if at all, as a visual quantity. This study is evidence that the brain is responding at single-digit melanopic lux within half a minute. The levels are the levels found in bedrooms: compare the 3 and 10 lux thresholds at Appendix C.32, the 1 lux threshold at Appendix C.10, the 0.1 lux sensor floor at Appendix C.38, and the effective retinal exposure of roughly 5 to 9 lux computed at Appendix C.40.

The two measures of one stimulus, which is the second and more important proposition. This study reports, for the same physical stimulus, both the photopic illuminance and the melanopic equivalent daytime illuminance. The ratio is about 0.35: a hundred photopic lux of this 2,800 kelvin halogen source delivered roughly thirty-five melanopic lux. The ratio is a property of the spectrum, not of the brightness. A cool white light-emitting diode source of the kind now standard in streetlights, displays and residential lamps has a melanopic to photopic ratio substantially higher than this, so the same reading on the same photometer corresponds to a materially larger dose to the non-visual system. Part IV.C of this comment states that proposition. This entry is the Foundation's preferred citation for it, because the two quantities are published side by side for one measured source with its spectral power distribution attached. A limit expressed in lux is not a limit on the biologically active quantity, and two products complying identically with a photometric limit may differ severalfold in the exposure they actually deliver. Parts IV.C, V.C.2.j, IX.D.

A second blue-poor source producing substantial effects. The pattern established at Appendix C.40 repeats here. That study used incandescent lamps; this one uses halogen at 2,800 kelvin peaking at 655 nanometers. Both sources are warm and poor in short-wavelength content, and both produced measurable physiological change. The Foundation draws the same inference it draws at Appendix C.40 and no more: the mitigation approach urged for light-emitting diode products, which is to reduce correlated color temperature and filter the blue, has not been shown to be sufficient, because effects are being obtained with sources that have already had the blue taken out. Part IX.D.

Timing, and the limit it places on the entry. Scans began between two and six hours after habitual waketime, with a mean of three hours and fifty-four minutes. These were daytime exposures at a circadian phase at which light is expected to be beneficial. The study therefore does not test, and the Foundation does not infer from it, that the same response at night would be harmful. The proposition that the consequence of a given exposure depends on when it is received is supported in this appendix by Appendix C.40, where the exposure was administered during the sleep period and the measured consequence was sympathetic activation and impaired glucose handling. The two entries should be cited together and for different things: this one for sensitivity and for the measurement gap, that one for nocturnal consequence.

What it establishes. That dim to moderate light produces acute, dose-dependent change in human amygdala activity and in amygdala-prefrontal connectivity, at an exposure of single-digit to low-tens melanopic lux over thirty-second blocks, in healthy young adults

during the daytime. And that for a warm source the photopic and melanopic measures of one stimulus differ by roughly a factor of three.

What it does not establish. Any effect on mood, which was not measured; the mood interpretation is the authors' inference from the imaging and they present it as such. Any harm. Any effect of nighttime exposure. Anything about chronic exposure, the blocks being thirty seconds. Anything about any product. The sample is twenty-three, and amygdala signal is among the more difficult measurements in functional imaging because of susceptibility artifact in that region, so the same small-sample reliability caution recorded at Appendix C.34 applies, though less severely given the within-subject block design. Gaze was not monitored.

Independence from other entries. Sean Cain is an author here and at Appendices C.8, C.24 and C.25, making this the fourth entry in which he appears.40 identifies as a priority acquisition. The Monash group is now the most heavily represented in this appendix. The Foundation records that plainly. It does not reduce the weight of any individual entry, but it means the appendix should not be described as reflecting a consensus of independent investigators without that qualification. Part V.A.1.

Bearing on the statutory question. Two uses, both of which the Foundation has stated above and neither of which concerns harm. First, on § 360ii(a)(4), the duty to study and evaluate the effects of exposure: a response at 3.5 melanopic lux in thirty seconds establishes that the sensitivity of the non-visual system is far greater than the thresholds around which existing optical radiation standards are built, and that the question is one of dose and timing rather than of whether any effect exists. Second, on the measurement convention, which this comment addresses at Part IV.C and which bears on every performance standard the Department might issue under § 360kk and every recommendation under § 360ii(b)(1)(B): until the Department requires that exposure be expressed in a quantity weighted to the responding system, a numerical limit will govern how bright a product looks and not how much biologically active radiation it delivers. Parts IV.C, V.C.2, V.F, IX.D and IX.J.

C.42 Stefani and Cajochen (2021) — practice review of lighting regulations against non-visual recommendations

Citation. Stefani O, Cajochen C. Should we re-think regulations and standards for lighting at workplaces? A practice review on existing lighting recommendations. Frontiers in Psychiatry. 2021;12:652161. doi:10.3389/fpsyt.2021.652161. PMID 34054611. PMCID PMC8155670. Open access under the Creative Commons Attribution license; full text read. Centre for Chronobiology, Psychiatric Hospital of the University of Basel. Received January 11, 2021; accepted April 14, 2021.

Why the Foundation relies on this entry. Every other entry in this appendix is evidence about an effect. This one is evidence about the regulatory record. The central factual premise of this comment is that no federal standard, and indeed no binding standard anywhere, governs the non-visual effects of optical radiation from electronic products, and that compliance with the standards that do exist does not control the biologically active quantity. The Foundation has asserted that premise throughout. This paper is two chronobiologists of standing, writing in a peer-reviewed journal, stating the same thing from the inside of the field. It is the Foundation's preferred citation for the premise, and it means the Department is not being asked to take the proposition from an advocacy organization.

What kind of document it is, and how it was vetted. A practice review, published as a brief report. It is not primary research and the Foundation does not present it as such; its value is as an authoritative description of the standards landscape as of early 2021. The review was handled by an editor at Harvard Medical School and the published record names three reviewers: a scientist at the German Federal Institute for Occupational Safety and Health,

a researcher at the Building Research Establishment in the United Kingdom, and Kevin Houser of Oregon State University, a leading figure in North American lighting research. A descriptive claim about the state of lighting standards, vetted by a government occupational-safety scientist, a building research institute and a senior lighting academic, is about as well tested as such a claim can be outside litigation.

The two findings the Foundation takes from it. First, in the authors' own words in the abstract, as of the date of writing there are "no specific regulations" addressing the non-visual effects of light. Second, and more pointed, that compliance with the common lighting standards, which address visual aspects, often means that only little non-visually effective light reaches the eye. That is the proposition this comment states at Part IV.C, reached independently and from the opposite direction. The authors also observe that recommended practices have proliferated while experts in the field criticize them, which is the condition Part IV.B of this comment describes for the American voluntary standards.

The seven circadian lighting recommendations the authors identify, and what they have in common. The paper lists seven examples, alphabetically. The Foundation reproduces the list because the common feature is the argument:

1. Chartered Institution of Building Services Engineers and Building Research Establishment, Research Insight on circadian lighting.
2. CIE S 026:2018, CIE System for Metrology of Optical Radiation for ipRGC-Influenced Responses to Light.
3. DGUV 215-210, Non-visual Effects of Light on Humans.
4. DIN SPEC 67600:2013-04, a technical report, Biologically Effective Lighting – Planning Recommendations.
5. Recommendations for Healthy Daytime, Evening, and Night-Time Indoor Light Exposure.
6. UL DG 24480, Design Guideline for Promoting Circadian Entrainment with Light for Day-Active People.
7. The WELL standard, Circadian Lighting Design, and the WELL version 2 pilot update.

Not one of them is a regulation. A metrology standard that defines how to measure but sets no limit. Two national technical reports. A professional institution's research insight. An academic consensus paper. A design guideline issued by a product-safety certification organization. And a green-building rating system. Seven documents assembled by experts as the state of circadian lighting guidance, and every one of them is voluntary. The Foundation makes the same observation about IEEE Std 1789-2015 at Part V.D.3, that a recommended practice is not a standard in the sense in which that word is used in 21 U.S.C. § 360kk and imposes no obligation on any manufacturer. The point generalizes. UL DG 24480 is an American document and it is a design guideline. There is no federal rule in the list because there is no federal rule. Parts IV.B, IV.C and IX.D.

What the governing lighting standard says about health, in its own terms. The authors describe DIN EN 12464-1:2011-08, the European workplace lighting standard, as specifying the planning principles for lighting systems but not specifying the requirements for the safety and health protection of employees at work. That is the standard disclaiming the function. The Foundation draws attention to it because the same division runs through the American standards described at Part IV.B: the documents that specify how much light to install are not health standards and do not claim to be, and the documents that address health are not standards. Nothing occupies the space between them. The authors also record that the draft revision raises the workplace horizontal illuminance minimum to 500 lux, with 1,000 lux specified for rooms used by elderly people with reduced eyesight — figures set, on the authors' own account, by visual task requirements.

CIE S 026:2018, and what it is. This discharges a question raised at Appendix C.41. The authors describe the standard as defining spectral sensitivity functions, quantities and

metrics for the ability of optical radiation to stimulate each of the five human photoreceptor types — the short-, medium- and long-wavelength cones, rhodopsin and melanopsin — with measured spectral irradiance weighted accordingly and referenced to the D65 standard illuminant. It is the instrument by which the melanopic quantities reported at Appendix C.41 are derived. The Foundation emphasizes what follows: a complete and internationally agreed system for expressing optical radiation in terms of the receptors that respond to it has existed since 2018. The obstacle to a biologically referenced exposure limit is therefore not the absence of a measurement method. Parts IV.C and IX.D.

The direction of the authors' concern, stated openly. These authors are not arguing for less light. They are arguing that workplaces receive too little biologically effective light during the day, noting that specifications for artificial lighting correspond to outdoor twilight, that 500 lux indoors is on the order of half a percent of the light available on a cloudless day, and that workers are typically exposed to only about 100 lux for more than half the day. Their recommendations are for more and better-timed light at work. The Foundation's concern in this comment is nocturnal exposure, which is the opposite end of the same problem. The Foundation says so plainly rather than presenting this paper as support for its own direction of travel. What the two share is the defect: standards written in visual units do not control the biologically active quantity, and so they fail in both directions at once — too little when it is wanted, too much when it is not. That is a stronger argument for a biologically referenced standard than either direction makes alone, and it is an argument the lighting industry cannot characterize as hostility to lighting.

Conflicts of interest, recorded in full. These are substantial and the Foundation sets them out as it has at Appendices C.25 and C.32. Stefani is named as an inventor on five patents, including United States Patent 8,646,939 B2, a display system having circadian effect on humans, and United States Patent 8,994,292 B2, an adaptive lighting system, together with German patent DE 10 2010 047 207 B4 and international applications WO2006013041A1 and WO2016092112A1. For 2017 to 2020 he discloses investigator-initiated research grants from Derungs, Audi, Volkswagen, Porsche, Festo, ZDF, Toshiba and SBB, and speaker fees from Merck, Fraunhofer, Firalux and Selux. For the same period Cajochen discloses honoraria, travel, accommodation or meals for invited lectures, conference presentations or teaching from Toshiba Materials, Velux, Firalux, Lighting Europe, Electrosuisse, Novartis, Roche, Elite, Servier and WIR Bank. Both are members of the Daylight Academy. Lighting Europe is the European lighting industry association; Derungs, Firalux and Selux are luminaire manufacturers; Velux manufactures daylighting products.

Why those conflicts do not impeach the proposition relied on. The Foundation states its reasoning rather than leaving the disclosure to speak for itself in either direction. The conflicts run in the same direction as the authors' recommendations: a patent holder on circadian lighting systems and a researcher funded in part by the lighting industry both stand to benefit if circadian lighting is specified and installed. For that reason the Foundation does not rest on their recommendations, and cites none of their proposed values. What it relies on is their description of the regulatory record: that there are no specific regulations, that the seven listed documents are what exists, and that visual compliance does not control the non-visual quantity. A commercial interest in circadian lighting gives no reason to misstate that record, the record is independently verifiable, and the claim was reviewed by a scientist at a national occupational safety institute. The Foundation relies on the description and not on the prescription.

What it establishes. That as of 2021, on the account of investigators in the field, no binding regulation anywhere addressed the non-visual effects of lighting; that the guidance which does exist consists of seven voluntary documents of mixed character; that the principal European workplace lighting standard disclaims the health-protection function; and that

an international metrology standard capable of expressing optical radiation in receptor-weighted terms has existed since 2018.

What it does not establish. Any effect of any exposure. It is a review of documents, not of evidence, and the Foundation cites it for nothing about health. It does not establish the state of American regulation specifically, since its focus is European and its treatment of United States material is limited to the UL design guideline and the WELL standard; Part IV.B of this comment must establish the American position from American sources. It is now four years old, and any claim that no regulation exists must be verified as of the date of filing rather than rested on a 2021 review.

Bearing on the statutory question. Directly and at several points. Paragraph 360ii(a)(5) directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation; the seven documents listed above are what the field has produced in the Secretary's absence, and none of them binds anyone. Paragraph 360ii(b)(1)(A) authorizes the Secretary to collect and make available information concerning the hazards and control of electronic product radiation; this paper is a compiled account of the control measures that exist, and collecting it is the elementary step. Paragraph 360ii(b)(1)(B) authorizes recommendations the Secretary considers appropriate; six of the seven listed documents are recommendations issued by bodies with no authority to issue them, which is what fills a vacuum that Congress assigned to the Secretary. And § 360kk performance standards: CIE S 026 establishes that the quantity could be specified, so the question before the Department is not whether a biologically referenced limit is measurable but whether it will set one. Parts IV.B, IV.C, IX.B, IX.C, IX.D and IX.J.

C.43 Sun and others (2021) — outdoor light at night and coronary heart disease, Hong Kong prospective cohort

Citation. Sun S, Cao W, Ge Y, Ran J, Sun F, Zeng Q, Guo M, Huang J, Lee RS, Tian L, Wellenius GA. Outdoor light at night and risk of coronary heart disease among older adults: a prospective cohort study. European Heart Journal. 2021;42(8):822–830. doi:10.1093/eurheartj/ehaa846. PMID 33205210. Not open access; drawn from the published abstract and from the accompanying editorial.

Design. Prospective cohort of older adults in Hong Kong, followed for a median of eleven years. Outdoor light at night was estimated from time-varying satellite data, a composite of persistent night-time illumination at approximately one square kilometer scale, assigned annually to the participant's residential address. Cox proportional hazards models, adjusted for both individual and area-level risk factors.

Why the design matters here. Two features distinguish this entry from most of the appendix. The exposure is time-varying: it was reassigned each year rather than fixed at baseline, which means a participant whose neighborhood brightened during follow-up is recorded as having done so. And the follow-up is eleven years with incident events, so exposure precedes outcome. Most entries in this appendix are cross-sectional and cannot establish that order. This one can.

Results. Three thousand seven hundred and seventy-two incident coronary heart disease hospitalizations and 1,695 coronary heart disease deaths were identified. Per interquartile-range increase in outdoor light at night, the interquartile range being 60.0 nanowatts per square centimeter per steradian, the hazard ratio was 1.11, 95 percent confidence interval 1.03 to 1.18, for hospitalization, and 1.10, 1.00 to 1.22, for death, after adjustment for individual and area-level risk factors. The exposure-response function was monotonic. The association did not vary across strata of the hypothesized risk factors the authors examined.

The interquartile range, which discharges a question raised elsewhere in this appendix. This study states its exposure contrast in radiance units: 60.0 nanowatts per square centimeter per steradian. That matters beyond this entry.17 and C.33 record that a hazard ratio per interquartile range is uninterpretable, and not comparable to any other study, unless the interquartile range is stated; Appendix C.33 reports 21.17 nanowatts per square centimeter per steradian for a nationwide Chinese sample and Appendix C.37 reports no figure at all. Hong Kong is among the most brightly lit places on earth and the spread of exposure within it is correspondingly wide, which is part of why the interquartile range here is nearly three times that of the Chinese national sample. Effect sizes per interquartile range from different studies are therefore not directly comparable, and the Foundation will not compare them without stating the contrast each represents. Part V.J.4.

The authors' own caution, which the Foundation adopts. The abstract states that the authors caution against causal interpretation of the findings, and that future studies with more detailed exposure information, with data on individual adaptive behaviors, and on potential mediators are warranted. The Foundation reproduces that rather than omitting it. It is also, in substance, a description of the research program § 360ii(a)(2) and (a)(4) direct the Secretary to plan, coordinate and support: better exposure assessment, measurement of what people actually do in response to light, and identification of mechanism.

The accompanying editorial. The European Heart Journal published the study with an invited editorial: Münzel T, Hahad O, Daiber A. The dark side of nocturnal light pollution. Outdoor light at night increases risk of coronary heart disease. European Heart Journal. 2021;42(8):831–834. doi:10.1093/eurheartj/ehaa866. PMID 33221876. PMCID PMC7897459. Open access under Creative Commons Attribution-NonCommercial. The authors are cardiologists at the University Medical Center Mainz and the German Center for Cardiovascular Research. The Foundation does not treat an editorial as evidence of any effect and cites it for nothing of the kind. It records the editorial for one proposition only, and the proposition is about the field rather than about the hazard: the flagship journal of the European Society of Cardiology published a leading environmental cardiology group placing nocturnal light pollution alongside air pollution and transportation noise as an environmental cardiovascular risk factor warranting attention. Whatever the FDA concludes on the merits, it cannot characterize the question as a fringe one. Part V.A.3.

What the editorial concedes, which the Foundation also records. The same editorial states that the adverse health effects of nocturnal light pollution are not well characterized, by contrast with air pollution, whose role in ischemic heart disease and stroke the authors describe as well established, and with transportation noise, which they associate with approximately 1.6 million disability-adjusted life years in Western Europe. It identifies the generalizability limits of the Hong Kong study, that city being among the most polluted in the world and the sample being older Chinese adults. And it reports that the study's sensitivity analyses suggested light at night and air pollution may act together on coronary mortality. The editorial also presents a figure mapping the co-localization of light pollution, air pollution and road and aviation noise across the United States. That figure is a published illustration of the confounding problem this comment concedes throughout, and the Foundation regards the candor of these authors about it as a reason to credit rather than discount their view of the field.

What it establishes. That in a prospective cohort of older adults followed for a median of eleven years, with exposure reassigned annually and with 3,772 incident hospitalizations and 1,695 deaths, higher modeled outdoor light at night at the residence was associated with a modestly higher risk of coronary heart disease hospitalization and death, along a monotonic exposure-response gradient. The temporal order of exposure and outcome is established; in most of this appendix it is not.

What it does not establish. Causation, which the authors expressly disclaim. The exposure is modeled outdoor radiance over an area of about a square kilometer, which is spectrally blind and is not a measurement of the light reaching any person; it says nothing about indoor exposure, bedroom conditions, or behavior. The effect sizes are modest and the confidence interval for coronary death has a lower bound at 1.00, so that estimate is marginal. Hong Kong is atypical in both light and air pollution and the cohort is of older adults, so generalization to the United States is not available from this study. Light at night, air pollution and transportation noise co-localize, as the accompanying editorial itself illustrates, and the Foundation does not claim this study resolves that. It establishes nothing about any electronic product and nothing about spectral composition.

Position among the cardiovascular entries. This is the fourth cardiovascular entry and the one that adds most to the set, for a reason of independence rather than of strength. Appendix C.2 and Appendix C.8 both draw on the UK Biobank cohort with wrist-instrument exposure, so they are not independent of each other and share whatever features of that cohort and that instrument may bear on the result. Appendix C.17 addresses stroke. This entry is a different country, a different population, a different exposure method and a different decade of ascertainment, and it reaches a result in the same direction with a monotonic gradient. Replication across independent cohorts and independent exposure methods is worth more than a larger estimate from the same cohort twice. The Foundation also notes the contrast in magnitude: the brightest-against-darkest contrast at Appendix C.8 gives 1.32 for coronary artery disease, while a single interquartile-range increase here gives 1.11, and the two are consistent with each other because they are different contrasts, which is the point made above about interquartile ranges.

Independence, conflicts and funding. The Foundation has identified no author shared with any other entry in this appendix. Funding was from the Ministry of Education of China, the Key Laboratory of Public Health Safety, and the Hong Kong Research Grants Council General Research Fund, grant 17613819, under the University Grants Committee. No industry funding is disclosed in the record the Foundation has obtained. Gregory Wellenius, the senior author, is an environmental epidemiologist in the United States, which is of some relevance to the standing of the work before a United States agency.

Bearing on the statutory question. Offered for two propositions. First, on § 360ii(a)(4), that coronary heart disease hospitalization and death are among the outcomes under investigation in relation to ambient light at night, that the investigation now includes prospective designs with hard endpoints and long follow-up, and that it has not reached a conclusion the investigators themselves will call causal. That is the condition the subsection addresses. Second, on the posture the Department should take: when the European Society of Cardiology's journal publishes a cohort study of this kind with an editorial placing the exposure beside air pollution and noise, a federal program with a statutory mandate over electronic product radiation that has collected none of it is not exercising judgment about priorities. It is absent. Parts II.F, V.A.3, V.F, IX.B and IX.C.

C.44 Zhang and others (2021) — artificial light at night and thyroid cancer in a large United States cohort

Citation. Zhang D, Jones RR, James P, Kitahara CM, Xiao Q. Associations between artificial light at night and risk for thyroid cancer: a large US cohort study. Cancer. 2021;127(9):1448–1458. doi:10.1002/cncr.33392. PMID 33554351. PMCID PMC10236487. Not open access; drawn from the published abstract.

Why this entry matters. Three reasons. It is the largest study in Appendix C by a wide margin: 464,371 participants. It is a United States population, which most of this appendix is not. And it is the adult counterpart to Appendix C.11, reporting the same histology from the same exposure at the opposite end of life — Appendix C.11 found an association with

papillary thyroid cancer in children from exposure at the residence of birth, and this study finds one with papillary thyroid cancer in adults aged 50 and over. Two independent American research groups, two cohorts, two life stages, one tumor type.

Design and population. Prospective cohort analysis within the National Institutes of Health–American Association of Retired Persons Diet and Health Study. Incident thyroid cancers were ascertained by linkage to state cancer registries. Cox regression with adjustment for sociodemographic, lifestyle and other environmental factors.

Exposure, as measured. Satellite-estimated light at night linked to the residential address at baseline. The Foundation notes two consequences. The exposure is spectrally blind, as at Appendices C.33, C.37 and C.43. And unlike the cohort at Appendix C.43, where exposure was reassigned annually, assignment here is at baseline only, so a participant who moved or whose neighborhood brightened during follow-up carries the baseline value throughout.

Results. Comparing the highest with the lowest quintile of light at night, a 55 percent increase in thyroid cancer risk: hazard ratio 1.55, 95 percent confidence interval 1.18 to 2.02. The association was primarily driven by papillary thyroid cancer. It was stronger in women, 1.81, 1.26 to 2.60, than in men, 1.29, 0.86 to 1.94, the estimate in men not reaching significance. In women the association was stronger for localized disease; in men it was stronger for more advanced stage. Results were reported as consistent across tumor sizes. The authors conclude that future studies are needed to confirm the association and identify the underlying biological mechanisms.

Thyroid cancer overdiagnosis, which the Foundation raises itself and which is the governing objection. Thyroid cancer is the textbook case of cancer overdiagnosis. Incidence of papillary thyroid cancer in the United States rose several-fold over recent decades while mortality remained essentially flat, a pattern that is widely attributed to the detection of small, indolent tumors through neck imaging performed for other reasons rather than to any true increase in disease. Access to that imaging is not evenly distributed. It concentrates where medical services concentrate, which is where people are dense, which is where it is bright at night. Satellite light at night is among the best available proxies for urban density. There is therefore a direct and well-documented pathway by which brighter residential light at night could be associated with more diagnosed thyroid cancer without any biological effect of light whatever. The Foundation states this before stating anything in the study's favor, because a reviewer who knows the thyroid literature will raise it immediately, and because the same objection applies to Appendix C.11 and to the use this comment makes of that study at Part II.H.

What the stage and size findings do and do not do about it. The authors report analyses that bear on the objection, and the Foundation reads them as cutting both ways. In favor of the finding: the association was consistent across tumor sizes. Overdiagnosis concentrates in small tumors, so an association that does not weaken as tumors get larger is harder to explain by detection alone. Against the finding: the strongest single result in the paper is the association in women, and within women the association was stronger for localized disease, which is precisely the presentation that incidental detection produces. The association in men was stronger for advanced stage, which is less vulnerable to detection bias because advanced disease presents symptomatically, but the estimate in men was not statistically significant. The Foundation therefore does not claim that this study resolves the overdiagnosis question. It claims that the authors addressed it, that the evidence they present is mixed, and that the question is open.

The mechanism the authors hypothesize, and a tension within this appendix. The authors reason from melatonin: that light at night inhibits nocturnal melatonin secretion and causes circadian disruption, that recent studies have linked light at night to breast cancer risk, and that thyroid cancer may share a hormone-dependent etiology with breast cancer. The Foundation records two qualifications to that chain of reasoning, both drawn

from its own appendix. First, the breast cancer premise is not settled here: Appendix C.7, a wavelength-resolved pooled cohort analysis, found no statistically significant association with breast cancer in the overall study population on any measure, with a positive finding confined to a subgroup, and Part V.G of this comment reports that null openly. Second, the melatonin pathway is a hypothesis rather than an established mechanism: at Appendix C.40 a controlled experiment produced autonomic and metabolic effects from nocturnal light with no detectable difference in melatonin between conditions. The Foundation does not adopt the authors' mechanistic reasoning and does not need it. What it relies on is the association they report, with the limits stated above.

What it establishes. That in a prospective cohort of 464,371 American adults with registry-ascertained incident cases, higher satellite-estimated light at night at the baseline residence was associated with a 55 percent higher risk of thyroid cancer in the highest against the lowest quintile, driven by papillary histology and concentrated in women. And that the association has now been reported in two independent American cohorts at two life stages for the same tumor type.

What it does not establish. Causation, which the authors do not claim and which the overdiagnosis objection above makes particularly difficult to reach for this outcome. Nothing about spectral composition. Nothing about personal or indoor exposure, the exposure being modeled outdoor radiance at a baseline address. Nothing about any electronic product. The cohort is a volunteer cohort of older Americans recruited through a membership organization and is not representative of the United States population. The sex difference is interesting but subgroup findings of this kind are frequently unstable, and the Foundation does not build on it.

Position among the cancer entries. The appendix now carries three cancer entries with substantially different standing, and the Foundation sets out the arrangement so that the set is not read as uniformly supportive. This entry and Appendix C.11 report associations with papillary thyroid cancer, from independent American groups, at opposite ends of life, both from satellite-modeled exposure and both subject to the overdiagnosis objection. Appendix C.7 examined breast cancer with wavelength-resolved exposure, which is methodologically the best exposure assessment in this appendix for an outdoor measure, and found no significant association overall. Appendix C.36 is mechanistic work in mice on circadian disruption and colorectal cancer in which the light manipulation was a schedule shift. The honest summary of the set is that the thyroid signal is the most consistent, that it is also the outcome most vulnerable to detection bias, and that the best-measured exposure study in the group returned a null. Part V.G.

Independence, conflicts and funding. The Foundation has identified no author shared with Appendix C.11 or with any other entry in this appendix, so the two thyroid entries are independent of each other. Rachel Jones and Cari Kitahara are investigators at the National Cancer Institute and the record identifies intramural National Institutes of Health support alongside extramural grants from the National Institute on Aging and the National Cancer Institute. No industry funding appears in the record obtained. The Foundation notes, as at Appendices C.36 and C.38, that this is research the Secretary funded and in part performed, through investigators at the Secretary's own cancer institute, and that § 360ii(b)(1)(A) authorizes the Secretary to collect and make available the results of such research.

Bearing on the statutory question. Two uses. First, on § 360ii(a)(4): thyroid cancer is among the outcomes under investigation, the investigation now includes a prospective American cohort of nearly half a million people, and it has not been resolved — including because a well-known methodological problem specific to this cancer has not been eliminated. That is what an unfinished research program looks like, and the subsection addresses it. Second, it bears on the argument at Part II.H. This comment there observes that a journal published by an institute of the Department itself published peer-reviewed

research describing an association between outdoor artificial light at night and papillary thyroid cancer. That argument is strengthened by the existence of a second, independent, larger American study reporting the same association in adults, and it is strengthened further by the fact that investigators at the National Cancer Institute are among its authors. Part II.H should be amended to cite both. Parts II.H, V.G, IX.B and IX.C.

C.45 Gottenbos and others (2021) — blue light accelerated tooth whitening, and the regulatory asymmetry it exposes

Citation. Gottenbos B, de Witz C, Heintzmann S, Born M, Hötzl S. Insights into blue light accelerated tooth whitening. Heliyon. 2021;7(2):e05913. doi:10.1016/j.heliyon.2021.e05913. PMID 33615002. PMCID PMC7881219. Open access under Creative Commons Attribution-NonCommercial-NoDerivatives; full text available. Funding disclosed as Philips.

What the study is. An in vitro bleaching experiment on thirty extracted human teeth with naturally accumulated color, divided among five sequential treatment protocols combining hydrogen peroxide gel at 6 or 25 percent with blue light, alone and together. Blue light was applied at a peak wavelength of 456 nanometers and an irradiance of 190 milliwatts per square centimeter, over exposure periods of roughly nine to eleven hours. Color change was measured and reported after 48 hours of stabilization. Light combined with peroxide produced significantly greater color change than either alone, and the authors conclude that blue light significantly increases both the bleaching rate and the final achievable change, by mechanisms acting in parallel to peroxide bleaching rather than merely accelerating it. They state that the light attacks more stain compounds than peroxide alone.

What it establishes, and what it plainly does not. It establishes that blue optical radiation at 456 nanometers is photochemically active on human dental tissue, and that the activity is not reducible to heating or to acceleration of a chemical process already underway. It establishes nothing about human health, nothing about any effect in a living person, and nothing about ambient lighting. The teeth were extracted. There was no exposed human subject. The Foundation offers this entry for an argument about the FDA's regulatory framework, not as evidence of harm, and it would be misread if taken for the latter.

The dose, stated plainly because the comparison will be made against the Foundation if it is not made by the Foundation. One hundred ninety milliwatts per square centimeter is a large irradiance. For scale, the study at Appendix C.41 reports that 100 photopic lux of a warm source corresponded to 42.73 microwatts per square centimeter at the eye. The whitening irradiance is therefore on the order of four thousand times that of ordinary room light, and over nine hours delivers a radiant exposure on the order of six thousand joules per square centimeter. The Foundation states this because the inference that blue light whitens teeth and therefore ambient light-emitting diode products are dangerous does not follow and must not be advanced. The argument the Foundation does advance is about the framework, and it is set out next.

The asymmetry, which is the point of this entry. An electronic product emitting 456-nanometer radiation at a tooth for cosmetic purposes is regulated by the FDA. It is classified at 21 C.F.R. § 872.6475 under product code EEG, and the agency has cleared at least a dozen premarket notifications for devices of this type, the earliest in 1979 and more recent ones in 2011 and 2012, with more than a hundred establishments registered to the product code. An electronic product emitting the same wavelengths into the eyes of the general public from a street luminaire, a vehicle headlamp, a display or an indicator lamp is subject to no performance standard at all. The Foundation asks the Department to consider which of those two exposures its statute was written to reach. The dental exposure is voluntary, brief, professionally supervised, sought by the exposed person, and serves that person's own purpose. The street exposure is involuntary, nightly, population-

wide, and serves the exposed person no purpose whatever. Paragraph 360ii(a)(2) directs the Secretary to minimize the exposure of people to unnecessary electronic product radiation. Of the two exposures, the one that is regulated is the necessary one. Parts II.D.2, IV.A and IX.D.

The classification describes the wrong mechanism, which is the second and more serious point. The FDA's device name for this product type is Heat Source For Bleaching Teeth. The classification is framed on a thermal model: the regulated characteristic is the production of heat. This study, conducted by the manufacturer, finds that the active principle is not heat. It is wavelength-specific photochemistry at 456 nanometers, operating in parallel to peroxide oxidation and attacking stain compounds that peroxide does not reach. The regulation therefore does not describe what the product does. The Foundation draws the connection to its central argument: this is the same defect identified at Part IV.C in the use of photometric units to govern a non-visual response, and at Part V.C.2 in a hazard framework whose exposure function terminates at 10,000 seconds. Where the FDA has addressed optical radiation from these products at all, it has done so through a physical model that does not correspond to the mechanism by which the radiation acts. That is not an argument that the agency has been idle. It is an argument that the framework needs rebuilding, which is what § 360ii(a)(4) and (a)(5) contemplate and what § 360kk empowers. Parts IV.C, V.C.2 and IX.D.

What the funding source makes this entry worth. The study was funded by Philips and the authors are associated with it. In most entries in this appendix industry funding would be recorded as a reason for caution. Here it runs the other way, and the Foundation says so. A manufacturer of both lighting products and oral care products has no incentive to overstate the photochemical potency of blue light-emitting diode radiation on human tissue, because a finding of potency invites regulation of its own products. The company published it because potency is the product claim. The Foundation relies on this entry as an admission against interest by a manufacturer about the capability of its own technology, and that is the strongest form in which such a proposition can arrive.

The measurement language, which is the third point and the one the Foundation has made throughout. Observe how this study expresses the stimulus. A peak wavelength in nanometers and an irradiance in milliwatts per square centimeter. Radiometric quantities, spectrally specified. That is the language a manufacturer uses when it wants to establish that its light-emitting diode does something. When the same technology is characterized for general illumination, the quantity is lumens per watt — a photometric efficiency ratio that carries no spectral information at all, and the only federal requirement the Foundation is aware of touching light-emitting diode emission is of that kind, as Part IV.G describes. The industry uses radiometric units with a named wavelength to prove efficacy and photometric units to demonstrate compliance. The Foundation does not suggest that is improper. It submits that the Department should require, for health purposes, the units the field itself uses when it is describing an effect. Parts IV.C, IV.G and IX.D.

Bearing on the statutory question. Offered for the proposition that the FDA already accepts, in its own device program, that blue optical radiation from light-emitting diodes acts on human tissue, and that the open question for general lighting is therefore dose and duration rather than whether effects exist at all. That matters because of what it does to the proposition that these products have a long history of safety. A history of safety is not a measurement. It is a report of harms not observed, which is a different thing from a no-effect level established by study. Where the agency concedes that a mechanism exists and has never characterized the dose-response for the exposures the public actually receives, the absence of recorded harm is the signature of the unperformed duty rather than an answer to it. That is the duty at § 360ii(a)(4). Parts II.D.2, IV.A, IV.C, V.C.2, IX.C and IX.D.

C.46 Casiraghi and others (2021) — synchronization of human sleep with the moon cycle, and the comparison of moonlight with urban light pollution

Citation. Casiraghi L, Spiousas I, Dunster GP, McGlothlen K, Fernández-Duque E, Valeggia C, de la Iglesia HO. Moonstruck sleep: synchronization of human sleep with the moon cycle under field conditions. Science Advances. 2021;7(5):eabe0465. doi:10.1126/sciadv.abe0465. PMID 33571126. PMCID PMC7840136. Open access under Creative Commons Attribution-NonCommercial; full text read.

The sentence the Foundation relies on, stated first. In their discussion the authors write that light pollution measurements in the highly urbanized areas of Seattle where their student participants live reveal values above their full moonlight measurements in the rural Toba/Qom environments. That is a measured comparison, made by these investigators between two environments they instrumented themselves, and it is the most useful single fact in this entry. Ambient artificial light at night in an American city exceeded full moonlight in rural Argentina. The remainder of the study establishes what full moonlight does.

Design and populations. Wrist actimetry under field conditions. Three Toba/Qom communities in the Argentinian province of Formosa, indigenous communities of shared recent history living at different levels of electrification: one urban with full access to electric light, 26 participants; one rural with limited electric light, 20; and one rural with no access to electric light at all, 23. Total 69. Field campaigns ran in September to November across 2016, 2017 and 2018, confined to Southern Hemisphere spring so that weather, sunrise and sunset times and daylight intensity would be comparable between them. Separately, sleep recordings from 464 University of Washington undergraduates in Seattle, mean age 21.5, were analyzed across the lunar cycle. Participants were not told the specific prediction under test.

Results. Sleep began later and was shorter on the nights before the full moon, when moonlight is available during the hours after dusk. Fitted sine wave amplitudes across the lunar cycle, with 95 percent confidence intervals, by community. Sleep duration: no electric light, 8.8 minutes, 4.9 to 12.8; limited electric light, 7.5, 4.0 to 11.0; urban, 9.4, 4.6 to 14.2. Sleep onset: no electric light, 10.0 minutes, 6.2 to 13.7; limited electric light, 12.1, 9.1 to 15.1; urban, 6.4, 2.5 to 10.3. The modulation was evident at the individual level for most participants with adequate records, and the same pattern appeared in the 464 Seattle students, whom the authors describe as likely to have little awareness of the lunar phase.

A characterization the Foundation declines to adopt. The discussion states that the amplitude of the lunar effect appears to be stronger the more limited the access to electric light. The amplitudes set out above do not support a gradient. For sleep duration the urban community shows the largest amplitude of the three. For sleep onset the community with limited rather than no electric light shows the largest. Every confidence interval overlaps every other. The authors' phrasing is appropriately tentative and the Foundation reports their figures rather than their characterization, because a reader told that electric light attenuates the lunar signal would be taking away something the published amplitudes do not show. The Foundation looked for that attenuation, expecting to find it, and did not.

The finding about electrification itself, which is separate and more directly relevant. Independently of the lunar question, the authors report that shorter sleep duration and delayed sleep onset were associated with increased access to electric light, and that this is consistent with previous work from several laboratories including their own. That is a comparison across three communities of shared ancestry, shared recent history and shared language, differing in electrification, with sleep measured by instrument rather than reported. It is not a randomized comparison and the communities differ in other respects, but as natural experiments in this literature go it is unusually well matched.

Why the moonlight result bears on a question about limits. Full moonlight is the dimmest nocturnal illumination to which humans have any evolutionary exposure. It is available for part of the night, on some nights of the month, and it is faint. It nonetheless shifted the timing and duration of sleep measurably, in rural and urban communities on one continent and in several hundred students on another. The consequence for this comment is not that moonlight is harmful. It is that the human sleep and circadian system demonstrably responds to nocturnal light at the very bottom of the range in which light exists at night at all. The proposition that artificial light at a few lux is too dim to matter biologically is not available on this record, because the system under discussion resolves a fainter signal than that. Read together with the authors' own measurement comparison, the position is short: the system responds to full moonlight, and urban artificial light exceeds full moonlight. Parts V.F and IX.J.

The reading that cuts against the Foundation, and the answer to it. The authors write that the availability of electric light in the evening mimics the sleep-inhibiting effect of moonlight, and that access to artificial light may emulate the ancestral effect of early-night moonlight. Read without care that is an argument for doing nothing: humans have always had light at night, and artificial light merely reproduces it. The Foundation states the objection because it is the obvious use of this paper against the position in this comment, and answers it on four grounds, each a property of the exposure rather than of the mechanism. Moonlight is faint, and by these authors' own measurements fainter than urban light pollution. It is periodic, waxing and waning across a month, so the organism is released from it for most of every cycle. It is confined to part of the night and, as the authors note, arrives early enough to delay sleep onset but is unlikely to wake a person already asleep. And it is predictable, which is the property that makes a cue a cue rather than an interference. Artificial light at night is brighter, constant, nightly, year-round, and arrives at whatever hour a switch is thrown. A stimulus an organism evolved to read as a monthly signal is not rendered harmless by being delivered continuously and at higher intensity. The ancestral comparison establishes the sensitivity of the channel, not the safety of saturating it.

What it establishes. That human sleep timing and duration are synchronized with the lunar cycle under field conditions, in communities at three levels of electrification and in a large urban student sample; that the effect is of the order of six to twelve minutes in onset and seven to nine minutes in duration; that greater access to electric light was associated with later and shorter sleep; and that these investigators measured urban light pollution in Seattle at levels above the full moonlight they measured in rural Formosa.

What it does not establish. Any health outcome; sleep timing and duration are the measured variables and no disease endpoint is examined. Any causal claim about electrification, that comparison being observational. Any dose-response, any spectral dependence, and nothing about any product. The urban student analysis is not longitudinal, as the authors state: different students were recorded in different academic quarters rather than the same students followed through a lunar cycle. The effect sizes are modest and the Foundation does not inflate them. A shift of ten minutes in sleep onset is a real and detectable physiological response; it is not an injury.

A limitation that is also the Foundation's standing point. The published text reports no illuminance value and the word lux does not appear in it. A study whose entire subject is the effect of nocturnal light on human sleep expresses its exposure as a phase of the moon, and the measurements of moonlight and of Seattle light pollution the authors say they made are referred to but not given in the text the Foundation has read. This is not a criticism of field anthropology conducted in rural Formosa. It is the condition described at Part V.J: the exposure variable in this literature is almost never the quantity a standard would have to specify. Here the investigators appear to hold the two figures that would make the comparison quantitative.

Position in the sequence of thresholds. This entry sits below every other in the appendix and anchors the bottom of the range. Appendix C.38 used the 0.1 lux detection floor of a wrist sensor and found more than half of an older American population above it. Appendix C.10 used 1 lux at the wrist in children. Appendix C.32 used 3 and 10 lux at the head of the bed. Appendix C.41 produced measurable change in brain activity at 3.5 melanopic lux over thirty seconds. Appendix C.40 bracketed a cardiometabolic effect between an exposure below 3 lux that produced none and 100 lux that did. This entry reports a behavioral response to full moonlight, fainter than all of them, and the authors' own instruments put urban artificial light above it. Part V.F.

Independence and funding. The Foundation has identified no author shared with any other entry in this appendix. Funding was from the National Science Foundation, grant 1743364, and the Leakey Foundation, grant 1266. No industry funding is disclosed. The Foundation notes, as a small addition to the argument at Part II.H rather than as a point about this study, that the federal support here came from the National Science Foundation: the research bearing on this question is distributed across the Department of Energy, the National Institutes of Health and the National Science Foundation, and is collected by none of them for the purpose § 360ii(b)(1)(A) describes.

Bearing on the statutory question. This entry answers a question the Department is entitled to ask of the whole of Part V: why should a federal agency concern itself with light levels of a few lux? The answer on this record is that the system at issue resolves a fainter signal than that, and has been shown to do so in the field, in two hemispheres, across three levels of electrification and in several hundred American undergraduates. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate the conditions of exposure to electronic product radiation, and the condition of exposure these authors measured is one in which the artificial light of an American city exceeds the brightest light the night has ever naturally offered. Paragraph 360ii(b)(1)(B) authorizes recommendations the Secretary considers appropriate: this study supplies no numerical limit and the Foundation does not pretend otherwise, but it removes the ground on which a recommendation might be declined for want of biological plausibility at low levels. Parts II.F, V.F, V.J, IX.C and IX.J.

C.47 Cain and others (2020) — measured evening home lighting, individual circadian sensitivity, and energy-efficient lamps

Citation. Cain SW, McGlashan EM, Vidafar P, Mustafovska J, Curran SPN, Wang X, Mohamed A, Kalavally V, Phillips AJK. Evening home lighting adversely impacts the circadian system and sleep. Scientific Reports. 2020;10:19110. doi:10.1038/s41598-020-75622-4. PMID 33154450. PMCID PMC7644684. Open access under the Creative Commons Attribution license; full text read.

Why this entry carries more weight than any other in Appendix C. It is the only study in this appendix that measures exposure with a spectrophotometer near eye level, in people's own homes, and reports the result in the biologically weighted unit. It is also the only one that quantifies how much the response to a given exposure differs between people. And it contains a measured comparison between homes lit by incandescent lamps and homes lit by energy-efficient lamps, which is the proposition this comment advances at Part IV.G and has until now had to argue from first principles. The Foundation treats this entry as the evidentiary anchor of Part IV.C and Part V.J alongside Appendix C.40.

The instrument, and why it matters. The authors built a wearable containing a mini-spectrophotometer, clipped to clothing, recording the full visible spectrum near eye level. From each spectrum the device computes the stimulus to each photoreceptor class, including melanopic illuminance and photopic illuminance, and the spectral signature permits identification of the type of light source. The authors state their reason for building it: light sensors used in research are wrist-worn, prone to sleeve coverage, and do not capture light exposure at eye level. That is a direct and correct criticism of the exposure

method used at Appendices C.10 and C.38, and the Foundation records it as such rather than leaving the reader to notice the inconsistency. Part V.J.

Individual variability, in the unit that matters. The authors report over fifty-fold differences between individuals in the sensitivity of the human circadian system to light. The light level required to suppress melatonin by half, the ED50, ranged from 3.1 to 181 melanopic lux between individuals, computed on updated International Commission on Illumination standards, in a sample of 42. That is a ratio of about fifty-eight to one between the most and least sensitive person measured. These figures come from the dose-response study of 56 healthy young adults reported separately by Phillips and others in 2019 and reanalyzed here.

Measured home lighting. Average melanopic illuminance in the three hours before bedtime ranged from 3.9 to 77.4 melanopic lux across 59 homes, with a mean of 17.9 and a standard deviation of 13.6. The significance is in the overlap: the range of home lighting levels falls inside the range of individual ED50 values. The same home therefore produces materially different circadian stimulation depending on who lives in it, and the authors state the consequence plainly — the circadian impact of lighting for any given individual in any given home is unpredictable without knowing both that person's sensitivity and that home's light level.

What the combination produced, and its status as a prediction rather than a measurement. The authors applied the individual-level dose-response curves to the measured home light levels. On that basis nearly half of homes were bright enough to suppress melatonin by 50 percent, and the average home produced a predicted range of individual responses from 0 to 87 percent suppression. For the least sensitive individual, no home was predicted to reach 50 percent suppression. The Foundation states expressly that these are predictions obtained by combining sensitivity curves measured in one sample with light levels measured in another. Melatonin was not measured in these homes. The prediction is sound in method and is the authors' own, but it is a model output and the comment must not describe it as an observation.

The sleep finding, which is measured and is within-person. Greater melanopic illuminance in the three hours before bedtime, relative to that individual's own average, was associated with increased wakefulness in the 90 minutes after bedtime: beta = 0.89, standard error 0.09, p less than 0.00001. The relationship held on adjustment for age, sex, average bedtime and deviation from average bedtime, and again on further adjustment for chronotype. Because the comparison is each participant against their own average, the usual between-person confounders do not arise. This is the most robust exposure-outcome association in Appendix C that is not from an experiment.

Energy-efficient lamps, which is the finding this comment has been arguing without evidence. Homes with energy-efficient lights had nearly double the melanopic illuminance of homes with incandescent lighting. The authors set up the question themselves in their introduction: incandescent lamps waste energy as heat, a global effort has transitioned lighting to energy-efficient light-emitting diode and compact fluorescent lamps, white light-emitting diodes are typically enriched in blue, and the transition could therefore exacerbate circadian disruption through a greater effect on short-wavelength-sensitive melanopsin. They then measured it. Part IV.G of this comment describes the federal lamp efficiency framework and the absence of any health evaluation accompanying it. This entry supplies the measurement that framework never required: at the level of the lit room, the substitution approximately doubled the stimulus to the circadian photopigment. The quantity the federal requirement specifies is lumens per watt. The quantity that doubled is melanopic illuminance. No federal instrument addresses the second. Parts IV.C, IV.G and IX.D.

The relationship to Appendix C.40, which should be read immediately. The experiment at Appendix C.40 produced measurable autonomic and metabolic impairment from a single night of 100 lux during sleep, delivered by incandescent lamps. This entry finds that homes lit by energy-efficient lamps deliver nearly twice the melanopic illuminance of homes lit by incandescent lamps. The demonstration of harm was therefore obtained using the weaker of the two sources, and the federal efficiency framework moved households toward the stronger one. The Foundation does not claim that the cardiometabolic effect scales linearly with melanopic illuminance, because no study establishes that. It claims that the two entries read together leave the Department without the assumption that the transition was biologically neutral.

The extended twilight, which the Foundation asks the Department to read as the summary of this Part. To compare home light with natural light the authors recorded a sunset with the same instrument, on a day of 11 hours 13 minutes of daylight. Natural light fell from the ED50 of the least sensitive individual, 181 melanopic lux, to the ED50 of the most sensitive, 3.1 melanopic lux, in 22 minutes. Nature traverses the entire span of measured human circadian sensitivity in rather less than half an hour. In modern homes people remain inside that span for hours, which is why the authors conclude that home lighting creates an extended twilight for the circadian system and weakens the distinction between day and night. The Foundation commends that formulation to the Department. It is not an argument that artificial light is unnatural in some aesthetic sense. It is a measured statement that the signal by which the human circadian system distinguishes day from night has been flattened, and that nothing in federal law addresses the quantity in which the flattening is expressed.

What it establishes. That evening melanopic illuminance in real homes spans roughly 4 to 77 melanopic lux; that individual circadian sensitivity spans roughly fifty-eight-fold, with ED50 from 3.1 to 181 melanopic lux; that those two ranges overlap, so the circadian effect of a given home is person-specific; that within individuals, brighter evenings predicted more wakefulness after bedtime; that homes with energy-efficient lamps had nearly double the melanopic illuminance of homes with incandescent lamps; and that a natural sunset crosses the whole range of human circadian sensitivity in 22 minutes.

What it does not establish. Any disease outcome. The measured outcome is wakefulness after bedtime by actigraphy, not health. The melatonin suppression figures are modelled rather than measured in these homes, as stated above. The energy-efficient comparison is observational across 59 homes, and homes with energy-efficient lamps may differ from homes with incandescent lamps in age, size, number of fixtures and occupant behavior; the authors report a difference in measured melanopic illuminance, not an experiment in lamp substitution. The sensitivity curves come from 56 healthy young adults of mean age about 21, so the fifty-eight-fold range is the range within a narrow and healthy slice of the population and may understate variation across the whole of it. The sample is Australian. Nothing here concerns outdoor lighting, vehicle lamps or displays.

Independence, and a problem for the appendix as a whole. Sean Cain is the first author here and appears also at Appendices C.8, C.24, C.25 and C.41. Andrew Phillips is the last author here and an author at Appendix C.41, and the dose-response data relied on here are from his 2019 study. Elise McGlashan and Parisa Vidafar likewise recur. This is the fifth entry in which the Monash University group appears. The Foundation states the consequence rather than the fact alone: Appendix C cannot be characterized as the convergent judgment of independent investigators, and the entries in which this group appears should be read as a connected body of work by one laboratory that has been unusually productive on this question. That is not a criticism of the work, which includes the best exposure measurement in the appendix. It is a limit on the inference the Department should draw from the number of entries pointing the same way. Part V.A.1.

Funding. National Health and Medical Research Council of Australia, grant 1064231. No industry funding is disclosed. The Foundation notes that the measurement which bears most directly on the consequences of the United States lamp efficiency framework was made in Australia on Australian public funds.

Bearing on the statutory question. Four points. On § 360ii(a)(4), the duty to study and evaluate the conditions of exposure: here is the condition of exposure, measured at eye level in 59 homes and expressed in the unit that corresponds to the responding photopigment. The Department has not done this and did not need to; it needs only to collect it, which is § 360ii(b)(1)(A). On the measurement convention at Part IV.C: this study reports both photopic and melanopic quantities from the same instrument and identifies the source type from the spectrum, which demonstrates that a spectrally resolved, biologically weighted exposure metric is not merely definable but portable and wearable. On § 360kk, and on the design of any recommendation under § 360ii(b)(1)(B): a single numerical limit set at a population average will leave a substantial fraction of the population unprotected, because the response to a given exposure differs by nearly sixty-fold, and the Department should say what fraction it intends to protect. And on Part IV.G: the federal efficiency framework changed the quantity that matters by a factor of about two, in the direction of greater biological effect, and no federal evaluation of that consequence exists. Parts II.F, IV.C, IV.G, V.J, IX.C, IX.D and IX.J.

C.48 Elsabagh and others (2020) — white against blue-cut LED in dairy calves: melatonin, intake and growth

Citation. Elsabagh M, Mon M, Takao Y, Shinoda A, Watanabe T, Kushibiki S, Obitsu T, Sugino T. Exposure to blue LED light before the onset of darkness under a long-day photoperiod alters melatonin secretion, feeding behaviour and growth in female dairy calves. Animal Science Journal. 2020;91(1):e13353. doi:10.1111/asj.13353. PMID 32219969. Not open access; drawn from the published abstract.

Why a study of calves is in this appendix, stated first. Three reasons, and the Foundation gives them before the findings because the entry would otherwise look like a digression. First, the Department asked: Question 14 of this request for information concerns environmental and ecological effects, and Part V.I responds to it. Second, paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and unlike paragraph (a)(2) it does not limit the exposure in question to people. Third, and principally, the exposure in this study is a white light-emitting diode of the ordinary commercial kind, compared against the same technology with the blue content removed. That comparison is the one this comment has been arguing about, and this is the only mammalian experiment in Appendix C in which spectral content was the manipulated variable and the outcome included growth.

What it does not purport to be. Evidence about human health. The subjects are Holstein calves, bovine circadian and photoperiodic physiology differs from human in ways this entry does not attempt to bridge, and the Foundation advances no inference from calves to children. Nor does the Foundation suggest that the electronic product radiation control provisions protect livestock; paragraph 360ii(a)(2) speaks of the exposure of people, and § 360kk(a)(1) conditions a performance standard on the protection of the public health and safety. The FDA has extensive authority over cattle elsewhere in the Act, through the new animal drug provisions and the animal food provisions administered by the Center for Veterinary Medicine, but that authority is not the subject of this comment.

Design. Two experiments, six female Holstein calves each, aged eight weeks, under a long-day photoperiod. In the first, animals were exposed to yellow or blue light-emitting diode illumination for two hours before darkness over seven days; mean body weight 97 kilograms, standard deviation 4.1. In the second, over three weeks, animals were exposed either to blue light from a white light-emitting diode throughout the daytime or to a yellow

light-emitting diode for two hours before darkness, which the authors describe as blue light cut; mean body weight 88.5 kilograms, standard deviation 4.8. Outcomes were plasma melatonin, grass hay intake, rumination time, frequency of water intake and body weight gain.

Results. In the first experiment, blue light mildly suppressed melatonin during the two-hour treatment but did not alter the timing of the nightly melatonin rise; the magnitude of that rise was greater under yellow than under blue. In the second, the white light-emitting diode completely suppressed melatonin secretion during the two-hour treatment, although plasma concentrations were similar between groups during darkness. Grass hay intake, rumination time, frequency of water intake and body weight gain were all higher in the animals exposed to yellow rather than white light. The authors conclude that exposure to blue light from white light-emitting diodes under a long-day photoperiod suppresses melatonin secretion and might negatively affect the development of female dairy calves.

The finding that matters, and it corrects something elsewhere in this appendix. A white light-emitting diode completely suppressed melatonin over two hours, and removing the blue content both preserved the melatonin rise and was accompanied by greater intake, rumination and weight gain. The Foundation draws attention to this because it qualifies the inference it draws at Appendices C.40 and C.41. Those entries record that measurable effects were obtained from warm, blue-poor sources — incandescent in one case, halogen peaking at 655 nanometers in the other — and the Foundation concluded that reducing correlated color temperature has not been shown to be sufficient. That conclusion stands. But it is not the same as saying spectral control does not matter, and this entry shows that it does: when the blue was removed from a white light-emitting diode, the physiological and growth outcomes differed. The defensible position, and the one the Foundation adopts, is that spectral control is necessary and not sufficient. A standard that addressed spectrum alone would leave the illuminance problem untouched, and a standard that addressed illuminance alone would leave this effect untouched. Parts V.C.2, IX.D and IX.J.

What it establishes. That in a controlled experiment in a mammal, using an ordinary white light-emitting diode of the kind sold for general illumination, two hours of evening exposure completely suppressed melatonin secretion; that removing the short-wavelength content of that light prevented the suppression; and that the animals under the blue-reduced light ate more, ruminated more, drank more often and gained more weight over three weeks.

What it does not establish. Any human effect. Any mechanism beyond the melatonin measurement. Six animals per experiment is a very small sample even for a controlled design, and the Foundation does not treat the growth differences as precise. The two experiments are not directly comparable: the first contrasts blue against yellow for the same two-hour window, while the second appears to contrast white light throughout the daytime against yellow for two hours before darkness, which confounds duration and timing with spectrum. No illuminance or irradiance value is given in the abstract, so the dose is unknown. A long-day photoperiod is an imposed agricultural condition and not a natural one. And the authors themselves say the development effect might obtain, not that it does.

A point about the industry that uses this. The baseline condition in both experiments is a long-day photoperiod, which is an agricultural lighting regime imposed deliberately on dairy cattle because manipulating photoperiod alters their physiology and yield. The Foundation notes the parallel with Appendix C.45 without pressing it further than the record supports. An industry installs engineered lighting on mammals precisely because light reliably changes mammalian biology, and the practice is commercially routine. The proposition that light-emitting diode illumination is biologically inert is not one that the users of these products hold.

Independence and funding. The Foundation has identified no author shared with any other entry in this appendix. Funding was from the Japan Society for the Promotion of Science, grant 15K14846. No industry funding is disclosed in the record obtained.

Bearing on the statutory question. Used at Part V.I, which responds to Question 14, and at Part V.C.2. The Foundation offers it for two propositions. First, that a commercially ordinary white light-emitting diode is capable of completely suppressing melatonin in a mammal over a two-hour evening exposure, and that the short-wavelength content is what does it. Second, that the question of what a performance standard should specify is answerable in part by experiment, and that experiments of this kind — one product, one spectral variable, a physiological endpoint and a growth endpoint — are what paragraph 360ii(a)(2) directs the Secretary to plan, conduct, coordinate and support, and what § 360ii(b)(2) authorizes grants for. This one was funded by the Government of Japan. Parts II.B, V.C.2, V.I, IX.C and IX.D.

C.49 Walker and others (2020) — three nights at 5 lux: depressive-like behavior and neurological change in mice

Citation. Walker WH, Borniger JC, Gaudier-Diaz MM, Meléndez-Fernández OH, Pascoe JL, Courtney DeVries A, Nelson RJ. Acute exposure to low-level light at night is sufficient to induce neurological changes and depressive-like behavior. Molecular Psychiatry. 2020;25(5):1080–1093. doi:10.1038/s41380-019-0430-4. PMID 31138889. PMCID PMC6881534. Corresponding author at West Virginia University. Drawn from the published abstract; the Foundation has not obtained the full text.

The governing limitation, stated before anything else. The subjects are mice, and a mouse is nocturnal. Its active phase is the dark phase, and light introduced into that phase interrupts the period in which the animal is awake and foraging. For a diurnal human the same exposure falls during sleep. The circadian architecture is inverted and the behavioral meaning of the stimulus is not the same. The Foundation therefore does not offer this study as evidence that light at night causes depression in people, and asks the Department not to read it that way. What is conserved between the species is the machinery — melanopsin, the retinohypothalamic projection, the suprachiasmatic nucleus and the clock genes — and it is for what this study shows about the sensitivity of that machinery that the Foundation relies on it.

Design. Adult male and female mice were housed either on light days with dark nights, being 14 hours at 150 lux followed by 10 hours at 0 lux, or on light days with low-level light at night, being 14 hours at 150 lux followed by 10 hours at 5 lux. The exposure ran for three consecutive nights. Outcomes were behavioral, molecular and circadian.

The dose, which is why this entry is here. Five lux. Over three nights. That is the lowest experimentally administered nocturnal exposure in Appendix C to produce a behavioral change in a mammal, and it sits inside the band the rest of this appendix has converged on from every direction: 3 and 10 lux at the head of the bed at Appendix C.32, an effective retinal exposure of roughly 5 to 9 lux at Appendix C.40, 3.5 melanopic lux producing measurable brain activity change at Appendix C.41, 1 lux at the wrist in children at Appendix C.10, a 0.1 lux instrument floor exceeded by most older Americans at Appendix C.38, and full moonlight at Appendix C.46. Part V.F.

Results, as reported. Mice exposed to light at night for three consecutive nights showed increased depressive-like responses compared with mice housed in dark nights. Female animals showed increased central tendency in the open field. Hippocampal vascular endothelial growth factor A was reduced in both sexes. Females showed increased VEGFR1 and interleukin-1 beta messenger RNA expression; males showed reduced brain-derived neurotrophic factor messenger RNA. Circadian rhythms of activity and of temperature were significantly altered in females, and circadian gene expression in males. The authors

conclude that acute exposure to light at night alters brain physiology and can be detrimental to well-being in otherwise healthy individuals.

A point of difference from Appendix C.23 that must not be elided. Both entries are rodent experiments in which light during the dark phase altered behavior through a neurotrophin mechanism, and a reader scanning for the abbreviation BDNF would take them to confirm one another. They do not. At Appendix C.23 brain-derived neurotrophic factor was elevated in the basolateral amygdala and the behavioral consequence was heightened stress-evoked aggression. Here it is reduced, as messenger RNA and in males only, in the hippocampus, and the behavioral consequence is a depressive-like phenotype. Different structure, opposite direction, different endpoint. The two findings are not inconsistent, because amygdalar and hippocampal neurotrophin signaling are not the same system and the phenotypes they are associated with differ, but neither replicates the other and the comment must not present them as convergent. The doses also differ by a factor of eighty: 400 lux at Appendix C.23 against 5 lux here.

What it establishes. That in a mammal, five lux introduced into the dark phase for three consecutive nights was sufficient to alter circadian rhythms and circadian gene expression, to change the expression of a neurotrophic factor, a neurotrophin receptor and an inflammatory cytokine in the hippocampus, and to change performance on behavioral assays, with the exposure assigned by the investigators. It establishes that the dose required to perturb this system is very small and the duration required is very short.

What it does not establish. Any human effect, for the reason given at the head of this entry. Nothing about depression as a clinical condition: depressive-like behavior in rodents is assessed by assays whose construct validity is contested, and the Foundation cannot name the assays used because it has not obtained the full text. Nothing about spectral composition, the abstract reporting illuminance only. Nothing about chronic exposure, the exposure being three nights. Nothing about any product. The sex-specific molecular findings are interesting and the Foundation does not build on them, because sex-stratified molecular results across several outcome measures in a rodent study are frequently unstable. The authors' closing phrase, that the effect can be detrimental to well-being in otherwise healthy individuals, extends from mice to individuals; the Foundation reports that they wrote it and does not adopt it.

One further observation about the design. The daytime condition in both arms was 150 lux. The contrast between day and night in the light-at-night arm was therefore thirty to one, against an effectively unbounded ratio in nature. That is the same flattening of the day-night signal that Appendix C.47 measured in human homes and described as an extended twilight. The Foundation notes the parallel because it suggests the operative variable in both may be the amplitude of the daily light signal rather than the absolute level at night, which is a question for the research program at Part IX.C rather than a conclusion available now.

Independence and funding. Randy Nelson is an author of this study and of the review at Appendix C.25, and the two are therefore not independent. The Foundation notes that Appendix C.25 records substantial funder and patent interests among that review's authors and that the Foundation declined to rest an argument on it; the present study is primary research with public funding and the Foundation does not carry that reservation across, but it records the shared authorship. Funding was from the National Institute of Neurological Disorders and Stroke, grant R01 NS092388, and the National Institute of General Medical Sciences, grants U54 GM104942 and T32 GM132494, all components of the Department of Health and Human Services. No industry funding appears in the record obtained.

Bearing on the statutory question. Two uses. First, and this is the structural one: the entries in this appendix addressing affective and psychiatric outcomes in humans — Appendices

C.20, C.21, C.24 and C.35 — are observational, and the Foundation concedes in each of them that confounding is unresolved. This entry supplies what those cannot: an assigned exposure, in a mammal, at an environmentally ordinary intensity, producing both a behavioral and a molecular change. It is the mechanistic plausibility leg of that cluster, and it occupies the same position for the affective domain that Appendix C.36 occupies for the cancer domain. Second, on § 360ii(a)(4): the dose at which this system responds is now bracketed from several directions, and five lux over three nights is a quantity a performance standard could be written against. The Foundation does not say this study supplies the number. It says the number is no longer out of reach. Parts II.F, V.F, V.G, IX.C and IX.J.

C.50 Nash and others (2019) — daily blue light, lifespan and extraocular neurodegeneration in Drosophila

Citation. Nash TR, Chow ES, Law AD, Fu SD, Fuszara E, Bilska A, Bebas P, Kretzschmar D, Giebultowicz JM. Daily blue-light exposure shortens lifespan and causes brain neurodegeneration in Drosophila. npj Aging and Mechanisms of Disease. 2019;5:8. doi:10.1038/s41514-019-0038-6. PMID 31636947. PMCID PMC6797782. Open access under the Creative Commons Attribution license; full text read. Department of Integrative Biology, Oregon State University.

The governing limitation, stated first. The subject is the fruit fly. The evolutionary distance from a human is very large and the photoreceptive biology is not homologous: the fly uses rhodopsins and cryptochrome rather than melanopsin, has a compound eye rather than a camera eye, and is a translucent organism of a few millimeters in which light reaches every tissue as a matter of course. Nothing in this entry transfers to a human by analogy, and the Foundation does not offer it as evidence of any human effect. It is here for a design feature and a single finding, both set out below, and for nothing else.

Why the design nonetheless deserves the Department's attention. The comparison arms were constructed to isolate the spectral variable, and the Foundation has asked for exactly this kind of study throughout Part V. Flies were maintained in daily cycles of twelve hours of light and twelve of darkness under four conditions: constant darkness; white fluorescent light; blue light-emitting diode illumination peaking at approximately 460 nanometers; and white light-emitting diode illumination with the blue wavelengths removed by a yellow filter. Critically, all light sources were adjusted to emit similar photon flux density, 20 to 30 micromoles per square meter per second at the level of the animals. The blue and the blue-blocked conditions therefore delivered the same number of photons per second, and differed only in which photons. One hundred animals were used for each genotype in each light condition.

Results. Against constant darkness, median lifespan was reduced by approximately 50 percent under blue light but by only 4 percent under white light with the blue removed, in one strain; in a second strain the reductions were approximately 30 percent and 10 percent respectively. Constant darkness extended median lifespan by 42 percent against a white fluorescent cycle. A dose-response was established: raising photon flux density from 4 to 11, from 11 to 17, and from 17 to 24 micromoles each produced a significant increase in mortality, by log-rank tests with Bonferroni correction. Blue light accelerated aging phenotypes, producing damage to retinal cells, brain neurodegeneration and impaired locomotion measured by a climbing assay. Stress-responsive genes were induced by blue light in old flies but not in young ones. Cryptochrome was tested as a candidate mediator and excluded, and the authors report that several known blue-light-sensitive proteins are not acting in the pathways mediating the detrimental effects, so the mechanism is not identified.

The finding the Foundation relies on. Brain damage and locomotor impairment did not depend on retinal degeneration. The authors demonstrated this in flies whose eyes had

been genetically ablated: those animals, having no eyes, still showed the brain and locomotor phenotypes under blue light. That is a direct experimental demonstration that blue optical radiation can damage neural tissue by a route that does not pass through an image-forming eye. The Foundation relies on it for that proposition and states immediately what it does not show.

What that finding does not show, stated at once. It does not show that blue light reaches the human brain. A fly is a translucent organism a few millimeters across; a human brain sits behind skin, skull and dura, which attenuate short-wavelength radiation severely. The question of tissue penetration in humans is unresolved and the review at Appendix C.28 identifies it as such. These authors themselves put the human proposition no higher than a suggestion, writing in their introduction that recent data suggest extraocular light may impact human brain physiology. The Foundation adopts that formulation and no stronger one. What this study establishes is conditional: where blue light reaches neural tissue, it is capable of damaging it. Whether it reaches human neural tissue in any relevant quantity is a question for the research the Foundation asks the Department to undertake. Parts V.C.2.h and IX.C.

A second point, which answers a criticism the Foundation makes elsewhere. At Appendices C.18 and C.26 the Foundation objects that mechanistic light research commonly uses exposures far above anything encountered in ordinary life, and that findings so obtained cannot be carried to ambient conditions. These authors make the same distinction about their own field and then avoid it. They note that numerous studies have reported blue-light damage to retinal cells in mammals and in Drosophila, that those studies employed acute strong light, and that what they show by contrast is degeneration in response to twelve hours of daily exposure at a photon flux matched to ordinary room lighting. A chronic moderate exposure producing a dose-dependent effect on lifespan is a different kind of evidence from an acute high-intensity exposure producing tissue injury, and it is the kind this comment has repeatedly said is missing. Part V.C.2.d.

A statement in the paper worth quoting for a different purpose. In their introduction the authors describe the source in terms this comment uses throughout: commonly used light-emitting diodes emit a high fraction of blue light, often peaking at 460 nanometers, and these lights appear white because of the addition of a broad-spectrum yellow garnet phosphor. That is a compact and citable description of the phosphor-converted white light-emitting diode spectrum, from a peer-reviewed source, and it supports the account at Part I.G and Part V.B.

What it establishes. That in Drosophila, twelve hours of daily blue light at approximately 460 nanometers shortened median lifespan by roughly 30 to 50 percent against darkness, in a dose-dependent manner, while light of the same photon flux with the blue removed shortened it by 4 to 10 percent; that the exposure produced retinal degeneration, brain neurodegeneration and locomotor impairment; that the brain and locomotor effects occurred in animals without eyes; and that the mediating mechanism was not identified.

What it does not establish. Anything about humans. Anything about any product; a blue-only twelve-hour daily cycle is not an environmental human exposure, whatever the photon flux. Any mechanism, the authors having excluded their principal candidates without identifying a replacement. And nothing about the quantities in which this comment asks the Department to express exposure: photon flux density is a radiometric quantity and the Foundation welcomes its use, but it is not convertible to illuminance or to melanopic quantities without the spectral power distribution and the conversion is not performed here.

The successor study, which supplies the mechanism this one lacked. The preceding field records that the mediating mechanism was not identified. Three years later the same laboratory identified a candidate. Appendix C.69 reports that blue light inhibits succinate

dehydrogenase and the activity of mitochondrial Complex II, that susceptibility rises sharply with age, and that the mechanistic work was conducted entirely in eyeless animals. Read the two entries together; C.69 is the sequel to this study and shares three authors with it.

Position among the non-human entries, and a problem the Foundation should address. Appendix C now contains a substantial body of animal evidence: hepatic injury in mice at Appendix C.15, the year-long murine exposure at Appendix C.26, amygdalar signaling in rats at Appendix C.23, clock disruption and colorectal cancer in mice at Appendix C.36, dairy calves at Appendix C.48, depressive-like phenotype in mice at Appendix C.49, and this. Seven entries, across four species, with this one the most distant from a human subject. The Foundation does not present them as seven confirmations of anything. They differ in species, exposure, intensity, duration and endpoint, and the weight each can carry differs accordingly. Part V.A.2 sets out the standard of evidence this comment applies, and the Foundation notes here that it needs a statement of how non-human evidence is weighted, placed before the entries rather than inferred from them.

Independence and funding. The Foundation has identified no author shared with any other entry in this appendix. The funding statement was not captured in the record obtained and must be supplied.

Bearing on the statutory question. Offered for two propositions and no others. First, on the scope of the existing hazard framework: Part V.C.2.h argues that the blue light hazard framework addresses injury to the retina and does not reach non-ocular routes at all. This entry is an experimental demonstration, in an organism where the question can be settled by removing the eyes, that a non-ocular route exists and is damaging. The framework's silence on such routes is therefore a gap rather than a considered exclusion. Second, on § 360ii(a)(2) and (a)(4): the design here is what a funded, coordinated research program produces when it asks the right question — photon flux held constant, spectrum varied, dose titrated, a whole-organism endpoint, and the candidate mechanism tested and excluded rather than assumed. The Foundation asks the Department to note what the study cost and who paid for it, and to compare that with the absence of any equivalent study of a human exposure. Parts V.A.2, V.C.2.h, IX.C and IX.D.

C.51 Marek and others (2019) — melanopsin and trigeminal pathways in blue-light photosensitivity

Citation. Marek V, Reboussin E, Dégardin-Chicaud J, Charbonnier A, Domínguez-López A, Villette T, Denoyer A, Baudouin C, Réaux-Le Goazigo A, Mélik Parsadaniantz S. Implication of melanopsin and trigeminal neural pathways in blue light photosensitivity in vivo. Frontiers in Neuroscience. 2019;13:497. doi:10.3389/fnins.2019.00497. PMID 31178682. PMCID PMC6543920. Open access under the Creative Commons Attribution license; full text read.

The conflict of interest, stated first and at length because of its direction. The published statement reads that two of the authors are employed by Essilor International and that the remaining authors declare no commercial or financial relationships constituting a potential conflict. The funding statement reads that the work was funded by Essilor International within a research collaboration with Sorbonne Université and the Institut de la Vision. The first author and one co-author are the Essilor employees. Essilor International is among the largest manufacturers of ophthalmic lenses in the world and it sells lenses marketed for filtering blue light. The Foundation sets this out before the findings, and at more length than it has for other entries, because the direction of the interest matters and is the opposite of the case at Appendix C.45. There, a manufacturer of lighting and oral-care products published evidence of the photochemical potency of blue light, which invites regulation of its own products, and the Foundation treated the funding as an admission against interest. Here, a manufacturer of blue-filtering lenses funded and

co-authored a study finding that blue light causes aversion and ocular inflammation, which is a commercial case for its product. That is a reason for caution and the Foundation records it as one. The findings below are reported because the pharmacological design is testable and because the critical result is a negative one that a sponsor seeking a marketing claim would not have needed, not because the Foundation regards industry-funded research as reliable by default.

Design. Adult male C57BL/6J mice were exposed for three hours to either blue light-emitting diode illumination, 400 to 500 nanometers, or yellow, 530 to 710 nanometers, at an average irradiance of 6 milliwatts per square centimeter, between 9 a.m. and 1 p.m. Photosensitivity was measured as time spent in the dark against the illuminated part of the cage. A series of pharmacological interventions was then applied to identify the mediating pathway: topical atropine, pilocarpine and oxybuprocaine; intravitreal lidocaine, norepinephrine and a blocker of visual photoreceptor transmission; and an intraperitoneal melanopsin antagonist at 30 milligrams per kilogram given fifteen minutes before exposure. Clinical assessment of the ocular surface, corneal mechanical sensitivity and tear quantity was performed immediately after exposure and again after three days of recovery in standard lighting. Trigeminal ganglia, brainstems and retinas were analyzed.

The dose, and the authors' own placement of it. Six milliwatts per square centimeter is 60 watts per square meter, and the total radiant exposure over three hours was 64.8 joules per square centimeter. This is a strong exposure and far above ambient indoor lighting. The authors address the point directly and the Foundation reports their answer rather than only the criticism: they state that the irradiance used, while strong enough to induce light-aversive behavior, was still within the range one may receive from daily sun exposure, and they compare their total radiant exposure of 64.8 joules per square centimeter with the 1,000 joules per square centimeter that another group required to produce a significant increase in corneal fluorescein staining. The exposure is therefore high relative to a lit room and modest relative to the literature on corneal injury.

The central result, which is a pharmacological dissection. Mice showed strong aversion to blue light and no aversion to yellow. The authors state that the photophobic effect was wavelength-dependent and was not simply induced by bright light of random spectrum, and the yellow arm is what establishes that. Of every intervention tried, only one reduced the aversion: the intraperitoneal melanopsin antagonist, significant at the first hour and at three hours. The intravitreal blocker of visual photoreceptor transmission did not abolish the difference between blue and yellow; the blue-against-yellow contrast remained significant in animals that had received it.

What that result means, and it is the most consequential finding in Appendix C for this comment's measurement argument. Light aversion, in this model, is not a visual response. Blocking transmission from the visual photoreceptors left it intact; blocking melanopsin reduced it. The discomfort is therefore mediated by the non-visual photopigment, which has its own spectral sensitivity peaking near 490 nanometers, and not by the cone-mediated system whose sensitivity the photopic luminous efficiency function describes. Every quantity in which this exposure would ordinarily be specified — lux, lumens, candelas, luminance, and the lumens per watt of the federal efficiency requirement at Part IV.G — is weighted by that visual function. A response that does not run through the visual system cannot be governed by a limit expressed in visual units. Appendix C.41 and Appendix C.47 establish that the melanopic and photometric measures of one stimulus diverge; this entry supplies the reason it matters for discomfort specifically. Parts IV.C, V.C.2, V.E.2, V.E.4 and IX.D.

The inflammation findings, and the point about absent outward signs. Slit-lamp examination with fluorescein staining revealed no epithelial damage to the cornea, which the authors describe as expected at this exposure. They then state that the absence of outward signs cannot guarantee the absence of more intrinsic damage, and report that in

vivo confocal microscopy revealed inflammatory signs in the corneal epithelium, the sub-basal nerve plexus and the stroma of blue-exposed animals. Dry-eye-related inflammatory signs were observed, and notably were present after three days of recovery in standard lighting. In the retina, immunoreactivity for GFAP, ATF3 and Iba1 was increased and corroborated by quantitative PCR, and the distribution of both visual and non-visual photopigments was altered. In the trigeminal pathway, messenger RNA expression of cFOS and ATF3 was increased and cytokine levels were altered. The authors conclude that the phototoxic message was transmitted to the trigeminal system, inducing inflammation at the ocular surface and stress in the retina.

Why this bears on the aversion response as a safety assumption. Part V.C.2 describes an international framework which treats the natural aversion response as the mechanism that limits exposure, and which in one passage treats a lamp being uncomfortable to look at as the reason it presents no hazard. This entry is evidence, in a controlled animal experiment, that aversion to blue light is a receptor-mediated response accompanied by inflammatory and stress markers at the ocular surface, in the retina and in the trigeminal pathway, and that the ocular surface signs were still present three days after the exposure ended. On that evidence the aversion is not the protection operating; it is a signal that something is happening, and the something outlasts the stimulus. The Foundation does not claim this study settles the human case. It claims that a framework which counts discomfort as a safety margin has adopted an assumption that the available mechanistic evidence does not support, and that this is a question paragraph 360ii(a)(5) directs the Secretary to resolve by testing rather than assuming. Parts V.C.2, V.E.2 and IX.D.

What it establishes. That in mice, three hours of blue light at 6 milliwatts per square centimeter produced strong light-aversive behavior while yellow light at the same irradiance produced none; that the aversion was reduced by a melanopsin antagonist and not by blockade of visual photoreceptor transmission; that no gross corneal epithelial damage occurred but inflammatory signs were detectable by confocal microscopy and persisted at three days; and that stress and activation markers were raised in the retina and in the trigeminal pathway.

What it does not establish. Any human effect. The subjects are mice, nocturnal animals with a baseline preference for darkness; the yellow arm controls for that preference and is what makes the result interpretable, but the species gap remains. The exposure is three hours at an irradiance far above indoor lighting, and the Foundation does not extend the finding to ambient exposures. The study does not establish photophobia as a clinical condition, does not involve any product, and reports no spectral power distribution for the sources beyond the stated bands. Male animals only. The melanopsin antagonist was given systemically, so its site of action is inferred rather than demonstrated, and the authors themselves put the conclusion as most likely in the retina and note that other potential pathways of light reception remain to be considered.

Position in this comment. Part V.E.2 and Part V.E.4 are at present headings without content, for migraine and photophobia and for trigeminal and melanopsin-mediated pathways respectively. This is the entry on which both should be built. The Foundation notes that the reports collected at Part VII include accounts of eye pain and aversion from light-emitting diode sources, that Part I.G distinguishes the neurological family of effects from the photobiological, and that until now the comment has had no mechanistic citation for the neurological family at all.

Independence and funding. Funded by Essilor International, as set out above. The academic co-authors are at Sorbonne Université and the Institut de la Vision, with clinical affiliations at the Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts and elsewhere. The Foundation has identified no author shared with any other entry in this appendix.

Bearing on the statutory question. Three uses. First, on the measurement convention at Part IV.C, for the reason given above: a discomfort response mediated by a non-visual photopigment cannot be controlled by a limit expressed in units weighted to the visual system, and this is the mechanistic basis of that proposition rather than an inference from it. Second, on § 360ii(a)(5): the aversion response is relied upon as a mitigation, and this entry indicates that the assumption has not been tested and that the available evidence runs against it. Third, on § 360ii(a)(4): the conditions of exposure the Secretary is directed to study include exposures that produce pain and aversion without producing injury detectable by the methods the existing framework uses, and this study shows the two can be separated. Parts IV.C, V.C.2, V.E.2, V.E.4, VII, IX.C and IX.D.

C.52 Alasiri and others (2019) — ocular hazards of dental curing light units, systematic review

Citation. Alasiri RA, Algarni HA, Alasiri RA. Ocular hazards of curing light units used in dental practice – a systematic review. The Saudi Dental Journal. 2019;31(2):173–180. doi:10.1016/j.sdentj.2019.02.031. PMID 30983826. PMCID PMC6445451. Open access under Creative Commons Attribution-NonCommercial-NoDerivatives. King Abdulaziz University, Jeddah.

Article type. Systematic review conducted and reported according to the PRISMA guidelines. PubMed and Google Scholar were searched, using Medical Subject Headings terms for PubMed. Randomized controlled trials, original studies and in vitro studies in English up to 2018 were eligible. Eight articles met the criteria.

Scope, which is narrow and squarely on point. The subject is the ocular hazard presented to the operator, the patient and the auxiliary staff by the light-curing units used in dental clinics. That is a defined product class, in routine use, regulated by this Department, and emitting in the blue. The Foundation is not aware of another systematic review in this appendix whose subject is the ocular hazard of a single regulated light-emitting diode product class.

Findings, as reported. The review concludes that blue light poses the maximum risk of causing retinal degeneration on the evidence evaluated. On dose, the authors report that the total wavelength dose received can cause ocular damage, that light intensity is correlated with the duration required to cause a given level of damage, and that a long exposure can be substituted by use of a lower intensity light. On mitigation, they report that most of the included studies recommend protective eyewear to limit the exposure of patient, operator and assistant, that it is not advisable to stare directly into the source, and that recommended safe exposure times and distances must be strictly adhered to in practice.

What it establishes. That a systematic review of the ocular hazard from a regulated dental light-emitting diode product class, conducted to PRISMA, found eight eligible studies; that the reviewers identified blue light as presenting the greatest retinal risk among the exposures considered; that the governing relationship is one of intensity against duration, which is a dose relationship; and that the mitigation the literature relies on is protective eyewear, avoidance of direct viewing, and adherence to recommended times and distances.

What it does not establish. Any injury rate, incidence or prevalence among dental personnel or patients. Eight studies of mixed design, including in vitro work, is a thin evidence base and the Foundation does not represent it otherwise. The review reports no pooled estimate. It does not identify the emission characteristics of any particular unit, and the Foundation has not read the eight included studies and therefore cannot say what exposures they used. Nothing in it concerns general illumination.

Why the Foundation relies on it, and it is for the mitigation finding rather than the hazard finding. Part II.C.4 of this comment records that 216 premarket notifications

have been cleared under 21 C.F.R. § 872.6070 for this product class, that the classification identifies the device as producing ultraviolet radiation, that no section of part 1040 prescribes a performance standard for it, and that it appears nowhere in the records and reports table at § 1002.1. This entry supplies what fills that space in practice. The control measure is a pair of orange glasses, a shield, an instruction not to look at the source, and a recommended time and distance. Paragraph 360ii(a)(5) directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure to electronic product radiation. Here is a class of electronic product the agency has cleared 216 times, whose ocular hazard a systematic review identifies, and whose entire mitigation consists of techniques that no federal instrument specifies and no federal program has evaluated. Part II.G.3 computes what optical density such a filter would require for a related device and observes that nobody has prescribed one. Parts II.C.4, II.G.3 and IX.C.

A second use, on dose. The reviewers state the relationship between intensity and duration explicitly and draw the practical inference that a lower intensity for longer may be substituted for a higher intensity for less time. That is the reciprocity assumption on which the dose metric at Part V.C.2.b rests, stated by clinicians about a product in daily use. The Foundation notes it because Part V.C.2.c argues that the governing framework abandons dose accumulation beyond ten thousand seconds; here is a clinical literature applying the dose concept without that ceiling.

Independence and funding. The Foundation has identified no author shared with any other entry in this appendix. The funding and competing-interest statements were not captured in the record obtained and must be supplied.

C.53 James and others (2017) — outdoor light at night and breast cancer in 109,672 women of the Nurses' Health Study II

Why this entry matters, stated first. It is the largest and most thoroughly adjusted study of this question in the appendix, and it is the one that confronts the objection the Foundation has raised against much of the rest. The covariate set includes census-tract population density, census-tract urbanicity, census-tract median income, census-tract median home value, fine particulate matter and census region — and, separately, night-shift work. The last of those matters more than the others. Shift work at night is itself classified as a probable human carcinogen and is the standing alternative explanation for the whole of this literature. A study that adjusts for it is testing ambient residential light rather than occupational circadian disruption, which is what this comment is about.

Citation. James P, Bertrand KA, Hart JE, Schernhammer ES, Tamimi RM, Laden F. Outdoor light at night and breast cancer incidence in the Nurses' Health Study II. Environmental Health Perspectives. 2017;125(8):087010. doi:10.1289/EHP935. PMID 28886600. PMCID PMC5783660. Open access under a CC0 dedication; this entry is drawn from the full text.

Affiliations. Departments of Epidemiology and of Environmental Health, Harvard T.H. Chan School of Public Health; Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School; Slone Epidemiology Center at Boston University; and, for one author, the Medical University of Vienna and the Fielding School of Public Health at the University of California, Los Angeles.

Design. Prospective cohort. Time-varying Cox proportional hazards regression. Exposure was reassigned as participants moved, which distinguishes this study from the entries at Appendices C.22 and C.44 where exposure was fixed at a single address.

Population. One hundred nine thousand six hundred seventy-two women, followed from 1989 through 2013, over 2,187,425 person-years. Three thousand five hundred forty-nine incident invasive breast cancer cases. The cases were confirmed by medical record review rather than by registry linkage or self-report, which places the outcome ascertainment above that of every other cancer entry in this appendix.

Exposure, as measured. Cumulative average outdoor light at night, estimated from time-varying satellite data for a composite of persistent nighttime illumination at approximately one square kilometer scale, assigned to each residence during follow-up. The interquartile range was 31.6 nanowatts per square centimeter per steradian. The quintile bands of cumulative average exposure were 0.4 to 7.2, 6.3 to 15.9, 14.4 to 30.1, 26.0 to 53.3 and 41.4 to 248.1 nanowatts per square centimeter per steradian. The measure is broadband and spectrally blind, and Part V.K.4 states the consequence for this class of entry.

Results, and which contrast is which. This field requires care, because the study yields two correct figures for the same association and they are routinely conflated. Per interquartile-range increase in cumulative average exposure, the fully adjusted hazard ratio was 1.05, 95 percent confidence interval 1.00 to 1.11. Comparing the highest quintile of exposure with the lowest, the authors report, in their words, that "There was an estimated 14% increased risk of breast cancer in the top quintile of outdoor LAN compared with the lowest quintile of LAN (95% CI: 1.01, 1.29) in the fully adjusted model." Both are from the same model. The first is a per-unit estimate and the second a top-against-bottom comparison, and any statement of this study's result must say which it means. The Foundation uses the quintile comparison where it describes a contrast between the most and least exposed, and the per-unit estimate where it describes a gradient.

The two subgroup findings, reported in full. By menopausal status: premenopausal at the time of the case, hazard ratio 1.07, confidence interval 1.01 to 1.14, on 1,973 cases; postmenopausal, hazard ratio 1.00, confidence interval 0.91 to 1.09, on 1,172 cases; p for interaction 0.08. By smoking status at the end of follow-up: never smokers, hazard ratio 1.00, confidence interval 0.94 to 1.07, on 2,215 cases; past smokers, 1.10, confidence interval 1.01 to 1.19, on 1,034 cases; current smokers, 1.21, confidence interval 1.07 to 1.37, on 300 cases; p for interaction 0.08.

Adjustment. Benign breast disease history, family history of breast cancer, age at menarche, parity and age at first birth, height, white race, body mass index, body mass index at age 18, oral contraceptive use, mammography screening, menopausal status, smoking status, alternative healthy eating index, physical activity, marital status, living alone, personal income, night-shift work after 1989, census region, fine particulate matter in quintiles, census-tract median home value, census-tract median income and census-tract population density in quintiles. The analysis also examined effect modification by census-tract urbanicity.

What it establishes. That in a prospective cohort of 109,672 American women followed for twenty-four years, with 3,549 medical-record-confirmed incident invasive breast cancers and with time-varying exposure reassigned on moving, higher satellite-estimated outdoor light at night at the residence was associated with a 14 percent higher risk in the highest quintile of exposure against the lowest, after adjustment for a covariate set that includes population density, urbanicity, census-tract income and home value, fine particulate matter and night-shift work.

What it does not establish, and the Foundation states the first point before any other. The association was absent in never smokers. The hazard ratio in that group was 1.00, with a confidence interval from 0.94 to 1.07, on 2,215 cases — the largest of the three smoking strata and the most precisely estimated. The authors propose that smoking and air pollution may have synergistic effects with light at night by increasing susceptibility, and that is a hypothesis rather than a finding; the p for interaction was 0.08, which is not conventional significance. An exposure whose association is confined to smokers invites the reading that it is tracking something else that smoking also tracks. The Foundation does not resolve that and does not represent the overall result as unqualified.

What it does not establish, continued. Causation, which the authors do not claim; their conclusion is that further work is required to confirm the results and to clarify potential

mechanisms. The per-interquartile-range estimate has a lower confidence bound of exactly 1.00. The exposure is broadband satellite radiance and therefore says nothing about the spectral content of the light or about the technology producing it, so this entry supports no proposition about light-emitting diode products in particular. And the authors state a residual confounding limit in terms: "although we adjusted for air pollution and population density, we cannot rule out the possibility that other factors that are correlated with outdoor LAN [e.g., economic activity] might explain the observed association between LAN and breast cancer risk." They also identify exposure misclassification from missing satellite data and processing errors.

Funding, and why it matters here. The National Cancer Institute, under grants R00 CA201542, K99 CA201542 and UM1 CA176726; the National Institute for Occupational Safety and Health of the Centers for Disease Control and Prevention, under grant R01 OH009803; and the National Heart, Lung, and Blood Institute, under grant T32 HL098048. The paper was published in Environmental Health Perspectives, the journal of the National Institute of Environmental Health Sciences. Three components of the Department funded the work and a fourth published it. Part II.E.6 and Part II.H address the significance of that, and the Foundation does not repeat it here.

Position among the cancer entries, and the hypothesis it tests. This entry is the largest constituent of the systematic review and meta-analysis described at Part V.J.4, which pooled twenty studies and 731,493 individuals and reported a relative risk of 1.12 for breast cancer. It should be read against Appendix C.7, where a wavelength-resolved exposure measure in two pooled cohorts returned a null primary result, and the Foundation does not represent the two as agreeing. It tests a hypothesis first advanced thirty years earlier: Stevens RG, Electric power use and breast cancer: a hypothesis, American Journal of Epidemiology 1987;125(4):556–561. Part V.G records the origin of that hypothesis and the Foundation's position on the melatonin mechanism, which it does not adopt and does not need.

Independence and overlap. Peter James, the first author, is a co-author of the study at Appendix C.44. The Foundation notes the overlap because Part V.A.1 records the concentration of this literature in a small number of research groups.

C.54 Martin and others (2016) — LED retail lighting degrades fluid milk at ordinary store illuminance

Why this entry matters, stated first. It answers the objection that the photochemical literature relies on exposures no one actually receives. Part V.K.4 quotes the 2018 SCHEER Opinion discounting the cellular and animal studies because their conclusions derive from "exposure levels greater than those likely to be achieved with LED lighting systems in practice." That criticism is well founded against much of the in vitro work, as Part V.A.2 concedes. It is not available against this study. The investigators surveyed actual retail dairy cases to establish the relevant conditions and then used them, and measurable photochemical degradation followed in four hours. The subject is milk and not a human being, and the Foundation presses the entry no further than that.

Citation. Martin N, Carey N, Murphy S, and others, with Stubbs T, Wiedmann M, Dando R. Exposure of fluid milk to LED light negatively affects consumer perception and alters underlying sensory properties. Journal of Dairy Science. 2016;99(6):4309–4324. doi:10.3168/jds.2015-9603. Open Archive. Cornell University, Department of Food Science, and the Cornell Milk Quality Improvement Program; corresponding author at Cornell.

Design. Experimental, with trained descriptive sensory panels, a consumer panel and instrumental analysis. Milk from three New York State processing facilities, selected on historical microbiological records so that plants with consistently high quality and plants with recurring post-processing contamination were both represented. Samples were

collected twice, fourteen days apart, so that fresh and near-expiry milk could be assessed in the same sitting. Twenty-three samples in all, twelve of reduced-fat and eleven of skim. Light treatment was applied within twenty-four hours of collection; all other handling was in light-blocking containers, and storage was at 5.5 °C, which the authors describe as a slightly abusive temperature consistent with consumer refrigerators.

Exposure, as characterized — the field that matters. The authors state it in one sentence: "We exposed 14.14 L (4 gallons) of sample to ~1,200 lx of 3,500 K LED lighting for 4 h." The conditions were not chosen for experimental convenience. The paper records that "Prior to selection of light treatment parameters, a survey of light exposure in retail dairy cases was performed to establish the most relevant lighting conditions," and that light-emitting diode lighting was chosen on the strength of that survey. Twelve hundred lux at 3,500 kelvin is ordinary American retail illuminance, of the order addressed at Part VI.F, and four hours is a fraction of the time a carton sits in a case.

Result. In the authors' words: "light exposure resulted in a broad negative reaction from consumers, more so than samples with microbiological contamination exceeding 20,000 cfu/mL on days approaching code." Four hours of retail LED lighting produced a larger adverse consumer response than bacterial contamination above twenty thousand colony-forming units per milliliter in milk near its expiry date.

The mechanism, as the authors describe it. Photosensitizer-mediated oxidation. "Milk contains several photosensitive components, the most commonly cited being riboflavin, as well as porphyrin, chlorophyll, and others. When these photosensitizers are activated by natural or artificial light, the underlying photonic energy is transferred into the milk itself. This energy then initiates a chain reaction, whereby free-radical compounds and singlet oxygen are formed within the milk, inducing further chemical changes in neighboring molecules." The authors also record that effects of light exposure in milk may include degradation of its nutritional properties, and that protecting milk from light "would safeguard both its sensory profile and its nutritional content."

The wavelength statement, and why the Foundation draws attention to it. The authors identify the spectral reason the replacement technology may be worse than what it replaced: the emission "lies adjacent to the 450 nm absorption maximum of riboflavin found to be most destructive by Choe et al. (2005), and thus may be more effective in degrading riboflavin and releasing energy to the milk." Four hundred and fifty nanometers is the emission peak of the phosphor-converted white light-emitting diode, as Part V.J.4 records. The chromophores named here are also the chromophores named in the retinal literature: Appendix C.53 and the mitochondrial work it cites identify flavins, whose absorption lies between approximately 420 and 520 nanometers, and porphyrins as targets of blue light. The Foundation does not contend that milk and a retina are comparable systems. It observes that the molecules absorbing the energy are of the same classes.

The characterization gap, stated by the authors. "These LED lights, although rapidly adopted due to lower running costs, are yet to be thoroughly characterized with respect to their effect on the degradation of photosensitizers such as riboflavin in milk, a wavelength-dependent phenomenon." And of the study itself: "This study is the first to demonstrate the effects of LED lighting on consumer perception of fluid milk." A technology adopted across American retail for its running costs, not characterized for what it does to the product it illuminates, with the phenomenon known to depend on wavelength. Part IV.G describes the same sequence in federal lighting policy.

A technique available and not used. The authors record that "Producing milk in packaging protected from sunlight has been discussed for almost 100 yr" and that "While this has been noted for many years, with many interventions to control light existing (e.g., light-blocking packaging), few are employed in the industry as standard." Part II.G.3 concerns

techniques for minimizing exposure that exist and have not been evaluated or required. This is an instance of the pattern outside the Foundation's own subject matter.

What it establishes. That light-emitting diode lighting at an illuminance and duration measured in American retail practice initiates photosensitizer-mediated oxidation in a common food, producing changes detectable by trained panels and adverse to consumers, and that the degradation is understood by those who study it to be wavelength-dependent and to bear on the nutritional content of the product. The proposition the Foundation takes from it is that the emission of these products is chemically active at the levels at which people encounter it.

What it does not establish, and the Foundation states this plainly. Nothing about human health. There is no health endpoint; the outcomes are consumer sensory scores and milk chemistry. The Foundation does not contend that 21 U.S.C. § 360ii protects milk, and does not offer this entry as evidence of injury to any person. Nor is the optical situation comparable to the eye: light enters a thin translucent layer into a liquid, whereas the retina sits behind the cornea, the lens and the vitreous, and the pigment epithelium behind the neural retina. Four hours of 1,200 lux on a carton says nothing about retinal dose, and Part V.B.2 explains why ocular exposure cannot be read off an ambient illuminance in any event. The entry is offered for the chemistry occurring at ordinary illuminance and for nothing else.

Funding, and the direction of the interest. The acknowledgments state that the publication "was made possible by the research funding provided by Dairy Management Inc. and the Midwest Dairy Association, and administered by National Dairy Council," with consumer testing administered by a commercial research firm. The Foundation notes the direction in which that interest runs, because it is not an admission against interest of the kind recorded at Appendix C.45. These are dairy marketing bodies whose commercial interest lies in the sale of milk, and a finding that retail lighting damages milk supports a recommendation that retailers spend money protecting it. The funders' interest is served by the result. What the Foundation does observe is that no part of the lighting industry funded or conducted the work.

Position among the entries. Read with Appendix C.45, which reports that blue light-emitting diode emission at 456 nanometers accelerates the bleaching of a tooth. Neither entry reports a health outcome and neither is offered as one. Together they are two peer-reviewed demonstrations, in unrelated fields and with unrelated funders, that the optical radiation these products emit drives measurable chemical change in ordinary materials at commercial exposures. Appendix C.3 is the third entry in this appendix that reports no health outcome of its own, and the Foundation relies on all three for propositions about emission and exposure rather than about effect.

Bearing on the statutory question. One proposition only. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This is a study of an emission under a condition of exposure that exists in American commerce, conducted because no one had done it, by investigators in a field with no interest in the regulation of lighting. The Foundation offers it as evidence that the characterization the provision directs is both feasible and absent, and not as evidence of harm to any person.

C.55 Tosini, Ferguson and Tsubota (2016) — a spectral design criterion, and a safety conclusion its authors limit to weeks

Why this entry matters, stated first. Two reasons, and the second is the more important. The authors state a numerical spectral design criterion for light-emitting diode sources, which is the form a performance standard under 21 U.S.C. § 360kk would have to take and which almost nothing else in this appendix supplies. And they then limit their own reassurance to exposures of days to weeks and say in terms that it cannot be extended to

months or years. That is the acute-to-chronic division described at Part V.C.2.c and Part V.K.3, stated by investigators funded by this Department's own eye institute, in their conclusion, in 2016.

Citation. Tosini G, Ferguson I, Tsubota K. Effects of blue light on the circadian system and eye physiology. Molecular Vision. 2016;22:61–72. PMID 26900325. PMCID PMC4734149. Open access under CC BY-NC-ND; this entry is drawn from the full text. Received August 26, 2015; accepted January 21, 2016.

Article type. Review. The Foundation identifies it as such and does not present it as primary research. Part V.A.2 records the weight accorded to reviews.

Authorship, and why the composition is relevant. Gianluca Tosini, Department of Pharmacology and Toxicology and Neuroscience Institute, Morehouse School of Medicine, Atlanta. Ian Ferguson, College of Engineering and Computing, Missouri University of Science and Technology. Kazuo Tsubota, Department of Ophthalmology, Keio University School of Medicine, Tokyo. The second author is an engineer rather than a biologist, and the reference list shows the collaboration is not incidental: the first author and the second had previously published jointly on imitating broadband diurnal light variation using solid-state sources. The recommendation described below is therefore made by a group that includes someone who designs these devices, which bears on the technical achievability question at Part II.G.

The conclusion, quoted in full because the sequence matters. The Foundation reproduces the authors' concluding paragraph rather than summarizing it:

> "The use of blue light is becoming increasingly prominent in our society, and a large segment of the world population is now subjected to daily exposure (from a few minutes to several hours) of artificial light at an unusual time of the day (night). Because light has a cumulative effect and many different characteristics (e.g., wavelength, intensity, duration of the exposure, time of day), it is important to consider the spectral output of the light source to minimize the danger that may be associated with blue light exposure. Thus, LEDs with an emission peak of around 470–480 nm should be preferred to LEDs that have an emission peak below 450 nm. Although we are convinced that exposure to blue light from LEDs in the range 470–480 nm for a short to medium period (days to a few weeks) should not significantly increase the risk of development of ocular pathologies, this conclusion cannot be generalized to a long-term exposure (months to years). Finally, we believe that additional studies on the safety of long-term exposure to low levels of blue light are needed to determine the effects of blue light on the eye."

What that paragraph contains, item by item. Five propositions in six sentences. That the exposure is now population-wide and occurs at a time of day when the natural stimulus is absent. That light has a cumulative effect. That the characteristics governing it are wavelength, intensity, duration of exposure and time of day, which is the list paragraph 360ii(a)(4) directs the Secretary to study. That a specific spectral preference follows: an emission peak at 470 to 480 nanometers in preference to one below 450. And that the authors' own reassurance extends to days and a few weeks and no further, with long-term exposure at low levels identified as the question requiring study.

The design criterion, and what the Foundation does with it. The emission peak of the phosphor-converted white light-emitting diode in general service lies between approximately 450 and 470 nanometers, as Part V.J.4 records. The criterion these authors propose would move it upward, out of the band they identify as more damaging. The Foundation offers the criterion as an instance of the form a standard would take and not as a limit it asks the Department to adopt: it is the recommendation of three investigators in a review, it is expressed as a preference rather than a threshold, and the Foundation is not competent to evaluate it. Its significance is that it exists. Part V.B.3 describes two further

instruments for expressing spectral content that were published in 2018 and have not been adopted. This is a third, from 2016, and it is the most directly prescriptive of the three.

A second band the authors identify. Separately from the peak criterion, and on the basis of an animal study of yellow-tinted intraocular lens materials, the authors state that "reducing the amount of blue light reaching the retina in the range 400–450 nm may also be important for the protection of the retina." They also record the history of the action spectrum: early studies found it similar to the absorption spectrum of rhodopsin, but "later studies indicated that blue light (400–440 nm) might be more damaging."

Sub-threshold exposure, and the state of mechanism. Two sentences bear directly on the structure of the exposure limits described at Part V.C.2. First: "Although most studies on the effects of blue light have focused on the mechanisms responsible for the damage to the photoreceptors following an acute exposure to high intensity light, some studies have reported that sub-threshold exposure to blue light can also induce damage in photoreceptors." Second: "The mechanism through which long-term exposure to blue light may induce photoreceptor damage is mostly unknown." The limits are constructed from acute injury, as Part V.K.3 establishes from the 2018 SCHEER Opinion. These authors report that damage below that threshold has been reported and that the chronic mechanism is mostly unknown.

The chromophore, and a consequence for cell-culture evidence. The authors identify the mediating chromophore: "Experimental data suggest that lipofuscin is the chromophore involved in the mediation of light-induced retinal damage following the exposure to blue light," and "when lipofuscin absorbs blue light, the material becomes phototoxic, which can lead to further damage in the RPE and in the photoreceptors." They add that accumulation of lipofuscin can impair the ability of the pigment epithelium to supply nutrients to the photoreceptors. The Foundation draws one consequence. Experiments conducted in pigment-free retinal pigment epithelial cell lines, which lack lipofuscin, cannot capture this pathway at all. Whatever such experiments show about other mechanisms, they are conducted without the chromophore these authors identify as principal, and the Foundation does not treat an effect obtained in such a line as an upper bound on what occurs in a pigmented human eye.

The lens, age, and a question the authors leave open. The authors describe the ocular filter directly: "With age, the lens becomes more yellowish, and thus, the spectrum of blue light transmission dramatically decreases through the years." They then set out a live clinical dispute. One study reported that after cataract extraction sleep quality improved markedly because more blue light reached the retina through the intraocular lens, and the choice between a clear and a yellow implant is contested on exactly this ground: "the yellow lens may protect the retina, but the clear lens provides more blue light during the day, providing better quality of sleep." Their own verdict is that "whether the yellowing of the lens associated with aging really affects the non-image-forming photoreception is still a matter of debate." That bears on Part II.F.4, where the aphakic hazard weighting used by the scientists of the Center for Devices and Radiological Health in 2010 is described, and on the age-dependent transmission material at Part V.C.2.g. The Foundation notes the dispute rather than resolving it, and notes that it is a dispute about the same filter in both directions: the lens that protects the retina is the lens that withholds the daytime signal.

A research recommendation that bears on this appendix. The authors state that "it is difficult to determine whether light-induced retinal damage has a daily rhythm in humans, and further studies on diurnal animal models (e.g., non-human primates) are required to address this important point." Part V.A.2 records that no entry in this appendix uses a diurnal animal model. Here are investigators in the field identifying that absence as a priority, nine years before this comment was filed.

What it establishes. That the question of long-term, low-level blue light exposure to the human eye was identified as open and in need of study by funded investigators in an ophthalmology journal in 2016; that a spectral design criterion for light-emitting diode sources was proposed in that year and expressed in nanometers; and that the authors of that recommendation limited their safety conclusion to exposures of days to weeks.

What it does not establish. That light-emitting diode products in service cause ocular pathology. It is a review and contains no original data. Its authors state the contrary of a harm finding for short and medium exposures in the band they prefer, and the Foundation reports that rather than omitting it. The sub-threshold damage proposition rests on three references the Foundation has not read. The journal is a modest one by citation measures, which the Foundation notes because it does not wish to overstate the weight of any entry. And the entry establishes nothing about the 450 to 470 nanometer band in particular beyond the authors' stated preference against peaks below 450.

Funding. National Institutes of Health grant R01EY022216, of the National Eye Institute, together with a National Aeronautics and Space Administration cooperative agreement, NCC 9–58, with the National Space Biomedical Research Institute. Two federal funders, one of them an institute of this Department. Part II.E.6 addresses the significance.

Bearing on the statutory question. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This entry is offered for the proposition that the study the provision directs was identified as necessary, in print, by recipients of this Department's own research funding, in the year the Foundation's earliest petition predates. It does not establish harm and is not offered for harm.

C.56 Sikka and others (2014) — melanopsin in blood vessels, and a light response outside the eye

The governing limitation, stated first. The ex vivo exposures in this study were enormous. The authors report that "Exposing the suspended vessels to cold white light at increasing intensities (40,000–2,000,000 lux units) produced a phasic, intensity-dependent vasorelaxation with a maximal response of ≈35%." Full direct sunlight is of the order of 100,000 lux and ordinary interior lighting is of the order of 300 to 500 lux. The upper end of that range is therefore some twenty times sunlight, delivered to a dissected vessel. This is precisely the objection the Foundation records at Part V.K.4, where the 2018 SCHEER Opinion discounts cellular and animal work for using exposures greater than those achieved in practice, and the Foundation makes the same objection of this study. It is not offered as evidence that ambient light relaxes human blood vessels.

Why the entry is nonetheless here. Because of what the study locates rather than what it measures. The comment's account of non-visual photoreception, at Part V.E.4 and Part V.F, runs entirely through melanopsin in the retina. This study reports melanopsin expressed and functioning in the wall of a blood vessel. If that is right, the set of human tissues that respond to optical radiation is larger than the eye, and no federal body has mapped it. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. A receptor for the radiation in an unexpected tissue is a condition of exposure no one has characterized.

Melanopsin mediates light-dependent relaxation in blood vessels. Proceedings of the National Academy of Sciences of the United States of America. 2014;111(50):17977–17982. doi:10.1073/pnas.1420258111. PMID 25404319. PMCID PMC4273372. Not open access; this entry is drawn from the version deposited in PubMed Central.

Affiliations. All seventeen authors at Johns Hopkins University, across the Departments of Anesthesiology and Critical Care Medicine, Neuroscience, Surgery, Allergy and Immunology, Biomedical Engineering and Pathology, and the Division of Pulmonary Medicine.

Design. Experimental, in mice, by four independent methods. Expression was established by polymerase chain reaction. Function was established by force-tension myography on isolated vessel rings. Receptor identity was established two ways: vessels from melanopsin-knockout animals failed to relax under light, and the response was abolished in wild-type vessels by a melanopsin-specific small-molecule inhibitor. And the signaling pathway was dissected pharmacologically, the authors reporting dependence on soluble guanylyl cyclase and phosphodiesterase 6, independence of protein kinase G, and desensitization mediated by G protein-coupled receptor kinase 2.

The action spectrum, which is the most rigorous element. The authors did not test a single blue source against a single control. They recorded responses to "precise 30-nm wavelength increments from 370 nm to 700 nm, followed by repeat 460-nm exposure to confirm this optimal wavelength and ensure lack of desensitization." The result: "The vessels did not respond to red or green light but displayed maximal vasorelaxation at low-intensity blue light," and "Responses were observed only in the blue light spectrum (400–500 nm), with a maximal response at between ≈430 and 460 nm" — which the authors note corresponds to the known absorption optimum of the mouse melanopsin receptor. The band is the band in which phosphor-converted white light-emitting diodes emit their primary radiation, as Part V.J.4 records.

The in vivo component, and the reason the authors chose the vessel they did. Having worked ex vivo, the authors turned to a vessel where light actually arrives: they state that they studied the tail artery "To determine in vivo physiological consequences and evaluate vascular beds in which exposure to light is likely." Blood flow was measured by laser Doppler flowmetry with the probe on the ventral surface of the tail. "There was a significant increase in tail blood flow in Opn4+/+ mice with exposure to blue light, which was reversed in dark." The knockout animals did not show it.

A consequence for Part V.B.2 that the Foundation states against its own convenience. Part V.B.2 establishes that retinal exposure from a source the eye resolves does not diminish with distance, because the refracting optics of the eye concentrate a falling power onto a shrinking image. That analysis is about the eye and it does not extend to this pathway. Skin has no lens. A blood vessel beneath the skin is a bare detector of the kind described in the comparison at Part V.B.2.b, and the irradiance reaching it falls as the inverse square of the distance to the source, exactly as intuition holds. The Foundation draws attention to this because the two propositions could otherwise be read as inconsistent, and because the distinction is the Foundation's own: for an extraocular photoreceptor the relevant quantity is a surface irradiance and distance matters, whereas for the retina it is a radiance and distance does not.

A second consequence, for the cardiovascular entries. Appendices C.2 and C.43 and the material at Part V.G report associations between light at night and cardiovascular outcomes, and the mechanism generally proposed for them is circadian disruption or melatonin suppression. This study describes a route that is neither. It is a direct action of light on vascular tone through a receptor in the vessel wall, operating on a timescale of the exposure itself and reversing in darkness. The Foundation does not contend that this mechanism explains those associations, and notes that the direction is not obviously adverse. It notes only that the mechanisms by which light might bear on the cardiovascular system are not confined to the ones the epidemiology assumes.

Relation to the argument already made at Part V.C.2.h. That subsection states that the photobiological safety framework is ocular while the evidence is not, and supports the

proposition with the review at Appendix C.28, which tabulates expression of the non-visual opsin OPN3 in tissues including blood vessels and describes smooth muscle as under opsin-mediated photic control. This entry is the primary experimental evidence for that proposition in a vessel, and it concerns OPN4 rather than OPN3. The subsection presently rests the point on a review; this study supplies the underlying experiment, with the knockout and inhibitor controls a review cannot supply.

What it establishes. That melanopsin is expressed in murine blood vessels; that light in the band from 400 to 500 nanometers, with a maximum between approximately 430 and 460, produces vasorelaxation in isolated vessels; that the effect is abolished by genetic deletion of the receptor and by a receptor-specific inhibitor; and that blue light increases tail blood flow in intact animals and the increase reverses in darkness.

What it does not establish, and the Foundation is explicit. It does not establish harm, and the Foundation does not advance it for harm. Vasorelaxation reduces vascular resistance and is in most clinical contexts beneficial, and the authors' own framing is therapeutic: they write that the pathway "can be harnessed for wavelength-specific light-based therapy in the treatment of diseases that involve altered vasoreactivity." It does not establish that the receptor is present in human vessels, the work being in mice. It does not establish that light penetrates human skin sufficiently to reach any vessel of consequence: the mouse tail is a thin-skinned thermoregulatory structure, and the depth to which 430 to 460 nanometer radiation penetrates human skin is a question this entry does not answer. And the ex vivo intensities are as stated in the first field, which is the reason that field is first.

Funding. National Institutes of Health grants from four institutes: the National Heart, Lung, and Blood Institute, R01 HL105296 and R01 HL089668; the National Institute on Drug Abuse, P50 DA000266; and the National Institute of Mental Health, MH8501. Part II.E.6 addresses the significance of research funded by components of this Department on questions the Department has declined to examine for regulatory purposes.

Bearing on the statutory question. One proposition, and it is a characterization proposition rather than an effects proposition. The tissues of the human body that contain receptors responsive to optical radiation have not been enumerated by any federal body, and this study indicates that the enumeration would extend beyond the eye. The Foundation asks at Part IX.C for characterization of emissions and conditions of exposure. This entry is offered to show that the conditions of exposure are less well understood than the exposure limits at Part V.C.2 presuppose, those limits being addressed to the eye and the skin as a thermal and photochemical target rather than as a site of receptor-mediated signaling.

C.57 Falchi and others (2011) — a quantitative spectral limit, proposed in the form the agency already uses

What this entry is, and is not. This is an analysis and review paper in an environmental management journal, not an experiment and not a health study. It reports no original measurement of any biological endpoint. It is in this appendix because the appendix is an appraisal of peer-reviewed scientific literature and the criterion of inclusion is publication type rather than subject matter, as the introduction to this appendix states. Its value to this comment is in its method and its proposals rather than in any finding about health.

Citation. Falchi F, Cinzano P, Elvidge CD, Keith DM, Haim A. Limiting the impact of light pollution on human health, environment and stellar visibility. Journal of Environmental Management 2011;92(10):2714–2722. doi:10.1016/j.jenvman.2011.06.029. Received December 20, 2010; revised May 14, 2011; accepted June 3, 2011.

Affiliations, and why one of them matters. Falchi and Cinzano at the Istituto di Scienza e Tecnologia dell'Inquinamento Luminoso, Thiene, Italy; Elvidge at the National Geophysical Data Center of the National Oceanic and Atmospheric Administration,

Boulder, Colorado; Keith at Marshall Design Inc., Boulder, Colorado; Haim at the Israeli Center for Interdisciplinary Studies in Chronobiology, University of Haifa. The third author is a federal scientist, and Part II.H.3 uses that fact. Haim is a chronobiologist, which bears on the weight the melatonin passages can carry.

Method. The authors computed, for each of a set of common outdoor lamp spectra, the proportion of emission falling within three response bands: the photopic luminous efficiency function, the scotopic function, and the band in which light suppresses melatonin. They then expressed the results as two dimensionless ratios and proposed numerical limits on each. The comparison is of lamp spectra against response functions, which is arithmetic performed on published spectral data.

The two proposed criteria. First, a protected band of 440 to 540 nanometers, with a limit that emission in that band not exceed 15 percent of photopic energy flux measured in watts, written R subscript P less than 0.15. Second, a limit that scotopic emission not exceed two-thirds of photopic emission measured in lumens, written R subscript sp less than 0.66, which the authors confine to settings where accurate color perception is essential. The authors state that the protected band was chosen to be centered on the scotopic peak and approximately 100 nanometers wide, that it covers 79 percent of the area under the scotopic curve, and that it leaves the 546 nanometer mercury line unaffected.

The computed values, which are the usable content. On the scotopic-to-photopic ratio: low-pressure sodium 0.20; high-pressure sodium at 70 watts 0.55; average high-pressure sodium 0.66; mercury vapor at 80 watts 1.18; CIE Illuminant A 1.41; quartz tungsten halogen at 3100 K 1.56; average metal halide 1.60; a flat spectrum 1.86; a white light-emitting diode described as natural white 3.5. On the protected-band fraction: low-pressure sodium 0.0027; high-pressure sodium at 70 watts 0.13; mercury vapor 0.27; metal halide 0.46; CIE Illuminant A 0.51; quartz tungsten halogen 0.58; the white diode 0.87; a flat spectrum 0.93.

A second table, on a different band, which must not be conflated with the first. The authors give a further comparison expressed relative to high-pressure sodium over 440 to 500 nanometers rather than 440 to 540. On that measure low-pressure sodium is 0.02 for energy and 0.3 for melatonin effect; metal halide 2.7 and 3.4; the natural white diode 7.0 and 5.4; a 65 watt incandescent lamp 2.5 and 2.5. The two tables use different wavelength intervals and the Foundation flags this because a reader comparing figures across them would be comparing different quantities.

The melatonin statements, reported at the weight they can bear. The authors state that "exposure to light at night (LAN) decreases pineal melatonin (MLT) production and secretion" and that "The peak sensitivity is from 440 nm to 500 nm." They report a tenfold decrease in sensitivity at 410 and at 540 nanometers relative to the peak near 460 to 470. These are statements of the literature as the authors read it in 2010, not original measurements, and this comment should cite the underlying action-spectrum work for the proposition rather than this paper.

The age-resolved ocular transmittance figures, which answer an open question elsewhere in this comment. The authors report that transmittance at 450 nanometers in people aged 60 to 69 is approximately half that in people aged 20 to 29, and that at 425 nanometers it is approximately one third. Part V.C.2.g presently rests the age-dependence proposition on a single figure taken from a narrative review and carries an open instruction to obtain age-resolved data. These ratios are responsive to that instruction, though they are themselves secondary and the primary source must be traced.

A finding adverse to the efficiency rationale. The authors report that at equal photopic output a white light-emitting diode yields 6 to 11 percent less road luminance than high-pressure sodium, because of the spectral reflectance of road surfaces. If that holds, a

photopic lumen from a white diode delivers less of the thing roadway lighting exists to produce than a photopic lumen from the lamp it replaced. The Foundation has not verified the computation and states it as the authors' finding.

The statement most useful to the remedy this comment seeks. The authors write that "LEDs have anyway a great potential, they could be tuned and produced with very different spectra" and recommend that industry research be directed toward warm diodes with no blue emission. That is evidence on technical achievability, which § 360kk(a)(2) requires the Secretary to consider. The spectral composition of a diode source is a design choice, and researchers said so in 2011.

What it establishes. That the proportion of a lamp's emission falling in a defined short-wavelength band is computable from published spectral data; that the technologies in use differ on that measure by up to three orders of magnitude; and that specific numerical limits of that form were proposed in the peer-reviewed literature in 2011.

What it does not establish. It does not establish that exposure to any of these sources causes any health outcome. It reports no original biological data of any kind. Its projections that a migration from sodium to white sources could multiply scotopic sky brightness several-fold, or tenfold within about a decade, are model projections and not measurements, and must be labeled as such wherever used. Its principal recommendation, a total ban on outdoor emission below 540 nanometers, is not adopted by this comment, for the reasons given at Part V.B.3.

Funding and conflicts. Neither a funding statement nor a conflict of interest declaration appears in the manuscript the Foundation consulted. The acknowledgments thank Barry A. J. Clark, Jan Hollan, Steven W. Lockley and Paul Marchant.

Bearing on the statutory question. Two uses. First, at Part V.B.3, for the proposition that a numerical limit on spectral composition is draftable, computable from measurements already performed, and formally identical to the band-ratio requirement this agency already imposes at 21 C.F.R. § 1040.20. Second, at Part II.H.3, on paragraph 360ii(a)(3), for the proposition that a federal scientist published a quantitative proposal of this kind in 2011. The entry is not offered for any proposition about health.

C.58 Kloog, Stevens, Haim and Portnov (2010) — an ecological study of 164 countries, and the limits of that design

The governing limitation, stated first. This is an ecological study. It compares country-level cancer incidence with country-level light at night, and it contains no exposure measurement and no health observation for any individual person. Ecological designs are the weakest observational evidence in this appendix, for the reason the 2010 news item itself gives: characteristics of whole populations need not hold of the individuals within them. Appendix C.16 grades another ecological study the same way, and Part V.A sets out how this comment weights evidence. Nothing in this comment depends on this study being correct.

Citation. Kloog I, Stevens RG, Haim A, Portnov BA. Nighttime light level co-distributes with breast cancer incidence worldwide. Cancer Causes and Control 2010;21(12):2059–2068. doi:10.1007/s10552-010-9624-4. PMID 20680434. The article is not open access and the Foundation has read the abstract only.

Why the entry is here at all. For two reasons, neither of which is the finding. The first is chronology: the authors are the research network from which this literature comes, and Richard Stevens is the author of the 1987 hypothesis described at Part V.G. The second is that a journal of an institute of this Department reported this study to its readers in December 2010, fourteen years before the determination of May 24, 2024. Part II.E.6. The entry exists so that the study the Department's journal reported is appraised here rather than taken on the report.

Design and data. Incidence rates of five cancers in women – breast, lung, colorectal, larynx and liver – observed in 164 countries, taken from the GLOBOCAN database, compared with population-weighted country-level light at night and with several developmental and environmental indicators: fertility rate, per capita income, percentage of urban population, and electricity consumption. Two regression specifications were used, ordinary least squares and spatial errors.

Results as the authors state them. A significant positive association between population light-at-night level and breast cancer incidence, and no such association for colorectal, larynx, liver or lung cancer. A sensitivity test holding other variables at their average values yielded a 30 to 50 percent higher risk of breast cancer in the highest-exposed countries compared with the lowest. The authors state that they evaluated in several ways the possibility that under-reporting by registries in low-resource and also low-light countries created a spurious association, and that it was shown not to account for the results.

The negative controls, which are the study's real strength. The design turns on the contrast between hormone-dependent and non-hormone-dependent cancers. Four cancers not understood to depend on hormones showed no association; the one that does showed one. That pattern is harder to produce by generic confounding with national development than a single positive association would be, because most development-related confounders would be expected to act on lung and colorectal cancer as well. The Foundation identifies this as the element of the design that carries weight.

The confounder the abstract does not address, and it is the central one. Breast cancer incidence as recorded by a registry depends heavily on how much screening a country performs, and mammographic screening intensity rises with national income in close company with electric lighting. A country with more light at night is a country more likely to detect and record breast cancer that exists. The abstract names fertility rate, income, urban percentage and electricity consumption as covariates and does not name screening intensity or mammography coverage. Nor does it name the established reproductive and lifestyle determinants of breast cancer risk that also track development: age at first birth, parity, breastfeeding duration, body mass index, alcohol consumption and hormone therapy use. Until the full text is read, the Foundation cannot say whether these were addressed, and this comment should not rely on the study until it can.

The exposure measurand, and the critique this comment makes of it. The exposure variable is satellite-observed light at night. Part V.J.4 establishes that a satellite radiometer of this kind is substantially blind to the short-wavelength content that the mechanistic literature identifies as the active part of the spectrum, and that a transition to white light-emitting diode sources can register as a decrease in observed radiance while increasing the biologically relevant exposure. That critique applies to this study as it applies to the eleven other entries in this appendix that take satellite radiance as their exposure variable. The abstract does not identify which sensor and which years supplied the light-at-night data, and that must be established.

The caution recorded in this Department's own journal. The 2010 news item quotes Eva Schernhammer, whose cohort study is at Appendix C.53 and whose 2001 paper is one of the foundational studies in this literature, observing that as an ecological study this result, even had it been negative, would not have been strong enough to rule out the evidence from prior case-control studies. The item also records the authors' own acknowledgment that the study did not control for behavior reducing individual exposure, such as sleeping. The Foundation adopts both cautions.

What it establishes. That country-level satellite-observed light at night co-distributes with breast cancer incidence and not with four cancers not understood to be hormone-dependent, in a cross-sectional comparison of 164 countries. In the authors' own framing, the finding provides coherence between previously reported case-control and cohort

studies and the distribution of light and breast cancer in whole populations. Coherence is the word they use and it is the right one.

What it does not establish. Causation, in any degree. It does not establish that light at night causes breast cancer, that any individual's risk is altered by exposure to any product, or anything whatever about light-emitting diode products, which in 2010 were not the dominant source of the light the satellites recorded.

Funding and conflicts. Not available to the Foundation, which has read only the abstract. Must be obtained.

Bearing on the statutory question. Modest, and the Foundation states it modestly. The entry supports the chronology at Part II.E.6 and Part V.G, and it is offered for the proposition that this question was under active investigation by an identifiable research network, and was reported to the readers of a journal of an institute of this Department, in 2010. It is not offered for any proposition about the health effects of any product, and Part V.A should be consulted before it is cited for anything.

C.59 Attia, Enouf, Behar-Cohen and Martinsons (2026) — market surveillance against the eye safety limits, and what the measurement distance decides

Why this entry is unlike the others in this appendix. Every other entry here reports a study of an effect. This one reports a measurement of products. A national market surveillance authority bought articles off the shelf and had accredited laboratories test them against the eye safety limits of the standard that governs them. It is therefore evidence of a kind this comment has repeatedly said is absent: not an inference about what products in commerce emit, but a determination of whether they comply with the limits that apply to them.

Citation. Attia D, Enouf O, Behar-Cohen F, Martinsons C. Eye Safety of Light-Emitting Diodes in Toys: The Results of Three Years of Market Surveillance. International Journal of Environmental Research and Public Health 2026;23(7):880. doi:10.3390/ijerph23070880. Received May 6, 2026; revised June 27, 2026; accepted July 3, 2026; published July 6, 2026. The journal classifies the article as a Project Report.

Affiliations, and the authorship overlap this comment should notice. Attia at the physical agents risk assessment unit of the French Agency for Food, Environmental and Occupational Health and Safety; Enouf at the photonics and energetics division of the Laboratoire national de métrologie et d'essais; Behar-Cohen at the Centre de Recherche des Cordeliers, Sorbonne Université and INSERM, and at the ophthalmology service of Cochin Hospital; Martinsons, corresponding author, at the health, environment and mobility directorate of the Centre Scientifique et Technique du Bâtiment. Two of the four are already cited in this comment by name. Martinsons is the lead author of the 2024 intergovernmental review at Appendix D.1 and Part V.C.2.f. Behar-Cohen was an external expert of the 2012 Opinion at Appendix D.1 and Part V.K.9. Part V.A.1 draws the general point about the size of the field; this entry is a documented instance of it, requiring no inference.

Design. Cross-sectional sampling and laboratory testing, with a paired method comparison on a subsample. Between 2021 and 2023, inspectors of the French consumer protection and market surveillance directorate anonymously purchased fifty toys, containing one hundred and three light-emitting diodes, from toy retailers. The toys were intended for children under fourteen. Accredited laboratories tested each diode against the eye safety requirements of IEC 62115, the standard for the safety of electric toys, in both its 2003 and 2017 editions. The emitters included blue, green, amber, red, phosphor-converted white and red-green-blue white diodes, and one infrared diode.

The sample limitation, stated by the authors. The toys were selected by inspectors during store visits rather than by a statistical sampling design, and the authors state that the

sample is therefore not statistically representative. The sample is small and confined to the French market, although the authors note the toys were not manufactured in France and carried multilingual packaging. Variability between manufacturers and between testing laboratories was not evaluated. The method comparison was confined to ten toys for reasons of time and budget.

Non-compliance found. Fifteen of the fifty toys, thirty percent, contained at least one non-compliant diode. Fifteen of the one hundred and three diodes tested were non-compliant, about 14.6 percent. Blue diodes were the worst class: eleven of thirty-four failed, about thirty-two percent. The remaining failures were two phosphor-converted white, one red, and one of unidentified color. Approximately eighty-seven percent of the non-compliant diodes failed the blue light hazard limit rather than the retinal thermal limit.

The method comparison, which is the most consequential result in this entry. The two editions of the standard differ in the distance at which the measurement is made: the 2003 method at distances from 14 to 100 millimeters, the 2017 method at 200 millimeters. Across the full sample the 2003 method found fourteen of sixty diodes non-compliant, twenty-three percent, and the 2017 method found two of fifty-four, four percent. In the paired subsample of ten toys and nineteen diodes, tested both ways, eight failed under the 2003 method and one failed under the 2017 method. The authors attribute the difference principally to the longer assessment distance. Part V.C.2.k sets out what the Foundation draws from this and what it does not.

Measurement parameters worth recording. The testing used a 7 millimeter circular aperture, which is the dark-adapted pupil diameter on which the optical relations at Part V.B.2 are built, and a 100 second exposure time for the blue light photochemical dose calculation, which is the duration corresponding to the Risk Group 1 boundary described at Part V.C.2.k. The paper does not report peak wavelengths or irradiance values for the individual diodes, which is the principal gap in it for this comment's purposes.

A discrepancy within the paper, recorded because this appendix records them. The abstract reports ten diodes non-compliant for blue light hazard and five for the thermal hazard. Tables 1 and 2 report eleven blue diodes and thirteen blue-light non-compliant diodes. The counts in the abstract and the counts in the tables do not agree and the paper does not explain the difference. The figures given in this entry follow the tables where the two conflict, and that choice must be checked against the full text.

Funding. Funded by the French Agency for Food, Environmental and Occupational Health and Safety, with additional support from the consumer protection and market surveillance directorate as part of its market surveillance campaigns. Funding number 2022-SA-0193.

Conflicts of interest, recorded in full because one of them is material. Martinsons is employed by the Centre Scientifique et Technique du Bâtiment, a public institute. Enouf has been invited as an expert by the European technical committee for electric toy safety, CLC TC61 WG7, and is contributing to a revised test method for light-emitting diode eye safety in toys. The remaining authors declare no relevant conflicts. The Foundation notes the second disclosure specifically: a co-author of a paper demonstrating that the present test method understates non-compliance is participating in the revision of that method. That cuts both ways and the Foundation does not treat it as disqualifying. It gives him direct knowledge of the method, and it gives him an interest in its revision, and a reader should know both.

What it establishes. Two things. First, that when a national authority tested fifty marketed toys against the eye safety limits applicable to them, thirty percent contained at least one diode exceeding those limits, and the great majority of the failures were failures of the blue light hazard limit, concentrated in blue emitters. Second, and independently of the first, that measured non-compliance under this standard is highly sensitive to the assessment

distance the standard specifies: the same products yielded twenty-three percent non-compliance at 14 to 100 millimeters and four percent at 200 millimeters.

What it does not establish. It does not establish that any child was injured, and it reports no health outcome of any kind. It does not establish a non-compliance rate for the French market, because the authors say the sample was not representative, and it establishes nothing whatever about the United States market, where neither IEC 62115 nor any comparable federal optical emission requirement for toys has been identified by the Foundation. It does not establish that the 2017 revision was made in order to reduce measured non-compliance, and the Foundation asserts nothing about the purpose of the revision.

Bearing on the statutory question. Three uses. First and principally, at Part V.C.2.k, on the proposition that a compliance statement is a statement about a product and a measurement convention together, which bears on § 360kk(a)(2) and on what reference conditions a federal performance standard would have to specify. Second, at Part V.K.5, against the 2018 Opinion's treatment of the European toy standard, for the proposition that the existence of a standard is not evidence of compliance with it. Third, at Part V.A.1, as a documented instance of the overlap between the authors of the expert assessments and the authors of the primary literature. It is not offered for any proposition about harm.

C.60 Jeffery and others (2025) — long wavelengths measured through the human body, and a visual effect with the eyes shielded

Citation. Jeffery G, Fosbury R, Barrett E, Hogg C, Rodriguez Carmona M, Powner MB. Longer wavelengths in sunlight pass through the human body and have a systemic impact which improves vision. Scientific Reports 2025;15:24435. doi:10.1038/s41598-025-09785-3. Received May 26, 2025; accepted June 30, 2025; published July 8, 2025.

Relation to the other entries from this group, which the Foundation states because it bears on independence. This is the third Appendix C entry authored or co-authored by Glen Jeffery, with Appendix C.1 and Appendix C.19. Barrett is a co-author of C.1 and of this study; Powner is a co-author of C.19 and of this study. Part V.B.6 relies on all three, and Part V.A.1 states the general point: a line of argument resting substantially on the output of one laboratory is weaker than the number of papers suggests, and the Foundation would rather say so than have it observed. Independent replication of the head-shielded result by a group unconnected to these investigators is the single thing that would most strengthen Part V.B.6.

Design. Two components. First, field spectrometry of sunlight transmitted through the human thorax, and qualitative transmission imaging of the hand, thorax and layered clothing. Second, a laboratory exposure study with a baseline measurement, a single fifteen-minute exposure or sham, and a retest twenty-four hours later. The paper does not describe randomization or blinding.

Subjects, and the group structure, which is the entry's principal weakness. Forty subjects in total, described in the methods as aged 25 to 63, of both sexes, and all Caucasian. Sunlight transmission, 7 males, mean age 37 ± 17. LED transmission, 8 subjects, mean age 46 ± 15. The 850 nanometer exposure group, 13 subjects, 8 male and 5 female, mean age 48 ± 20. The body-only group with the head shielded, 5 males, mean age 36 ± 9. The sham control, 7 females, mean age 35 ± 8. The sham group is therefore all female with a mean age of 35, against a treated group that is mixed-sex with a mean age of 48. For a psychophysical outcome measured against a control, that is an unmatched comparison on both sex and age, and the Foundation identifies it as the first thing a reviewer will raise.

Light sources and exposure. Sunlight, direct, approximately 11:00 to 13:00, about 17 milliwatts per square centimeter at 850 nanometers at the body surface. For the laboratory

exposure, a 60 by 60 centimeter ceiling panel of 3,024 light-emitting diodes peaking at 850 nanometers, output 9.18 milliwatts per square centimeter at 50 centimeters. Exposure was fifteen minutes at approximately 9 milliwatts per square centimeter to the bare upper back in a dark room.

The transmission result. Sunlight transmitted through the thorax peaked at approximately 800 to 875 nanometers with very little energy below 600 nanometers, and the average transmitted irradiance at 850 nanometers was approximately 5.6 microwatts per square centimeter. The clothing figure caption describes layered garments as roughly a hundred times more transparent at 850 nanometers than in visible light, which the authors present as qualitative.

The exposure result. Color contrast detection thresholds, measured on the Chroma test. After back exposure, protan thresholds fell approximately 9 percent, p = 0.0053, and tritan thresholds fell approximately 16 percent, p = 0.0003. With the head wrapped in foil so that the eyes were shielded, the tritan reduction was approximately 7 percent, p = 0.0351, and the protan change was not significant, p = 0.1856.

The gap between the two components, which the paper does not address. The transmission measurement gives approximately 5.6 microwatts per square centimeter delivered through the thorax by direct sunlight. The exposure experiment produced its effect at approximately 9 milliwatts per square centimeter. The two differ by a factor of roughly 1,600. The study establishes that the band penetrates the body at ambient levels, and separately that it produces an effect at laboratory levels. It does not establish that the ambient level is sufficient to produce the effect, and the Foundation does not use it for that proposition. Part V.B.6 states the limit in the text.

Internal inconsistencies, recorded because this appendix records them. The methods give the half-power band of the source as 830 to 865 nanometers while the results describe it as approximately 35 nanometers wide. The exposure distance is given as 50 centimeters in one place and 1.5 meters in another. The hand imaging subject is described as a 75-year-old male, which falls outside the stated subject age range of 25 to 63. Each must be resolved against the published text before any figure here is filed.

Limitations stated by the authors. Field sunlight measurements were noisy because conditions were not tightly controlled. Clothing transmission was qualitative and is not generalizable quantitatively. Reflected light could reach the eyes, so head shielding did not fully isolate the non-ocular route. The mechanism and the absorbing species are not established and no action spectrum has been defined. The authors note that 670 nanometer light did not transmit across the body in data they do not report, and that comparisons with 670 nanometers were not made under identical conditions. Groups are small and differ in sex and age. All subjects were Caucasian, which for a study of transmission through skin is a limitation of a particular kind, because melanin absorbs in this region and the transmitted irradiance is therefore likely to vary with skin pigmentation. The authors do not draw that implication and the Foundation does not assert its magnitude, but a federal evaluation of this pathway would have to address it. Data are available from the corresponding author on request rather than deposited.

Funding and competing interests. No funding statement appears in the content the Foundation obtained. The authors declare no competing interests. The acknowledgements thank Light, Power Health UK for building the 850 nanometer panel used in the experiments. The Foundation records that because the practice of this appendix is to record such relationships in full: the apparatus for a study reporting benefits of near-infrared exposure was built by an entity in that field. It is not a declared competing interest and the Foundation does not characterize it as one. A reader should know it.

What it establishes. Three things. That sunlight transmitted through the human thorax is confined almost entirely to wavelengths above about 600 nanometers and peaks near 800

to 875 nanometers, at an average of about 5.6 microwatts per square centimeter at 850 nanometers. That fifteen minutes of 850 nanometer light at about 9 milliwatts per square centimeter delivered to the back was followed, twenty-four hours later, by improved color contrast thresholds on both axes. And that one of those improvements survived shielding the eyes, which is human experimental evidence for an extraocular route to a visual outcome.

What it does not establish. That ambient sunlight exposure improves vision, for the reason given above. That any light-emitting diode product causes harm; the study concerns a wavelength band those products omit rather than one they emit, and the argument it supports is about absence. That the effect generalizes beyond the population studied, which was small, unmatched between groups, and entirely Caucasian. And nothing at all about mechanism, which the authors expressly leave open.

Bearing on the statutory question. Two uses. First at Part V.B.6, as the fourth of four studies on the consequences of removing long-wavelength content from the human environment, and specifically for the transmission spectrum, which is the physical premise the other three assume. Second at Part V.C.2.h, for the proposition that optical radiation acts on the body outside the eye and that a framework addressed only to ocular hazard does not reach those routes. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure; the spectral composition of indoor light, including what it omits, is such a condition.

C.61 Kim and others (2024) — a photooxidation route that acts on ordinary proteins at the wavelength of the light-emitting diode peak

The governing limitation, stated first. This study reports no irradiance for its light source. The blue light was the illumination of the single-molecule imaging apparatus rather than a controlled exposure variable, and the paper specifies it only by peak wavelength. Without an irradiance there is no way to relate the exposure to ambient lighting, to sunlight, or to any exposure limit, and this comment does not attempt to. The work is in purified protein and in cultured cells. There is no tissue, no organism and no health outcome of any kind.

Why the entry is nonetheless here. Because of what the mechanism acts on. Every other mechanistic entry in this appendix concerns a specialized light-absorbing molecule in a tissue adapted to light: an opsin, a photoreceptor, a retinal pigment. This one concerns a structural feature of proteins in general. If it operates in people at the levels people receive, which is not established, it is not a mechanism the ocular hazard framework is addressed to. Part V.C.2.h.

Four authors are recorded as having contributed equally.

Affiliations. Department of Chemistry and the X-Dynamic Research Center, Ulsan National Institute of Science and Technology, Ulsan, Republic of Korea, with further Korean institutional affiliations not fully captured by the Foundation. Corresponding authors Seung Kyu Min, Tae-Hyuk Kwon and Duyoung Min.

Design. Mixed experimental and computational, with no single dominant method. Single-molecule magnetic tweezers performing repeated unfolding and refolding of maltose-binding protein, with five to twelve molecules per condition. Mass spectrometry of oxidized residues. All-atom molecular dynamics, three trajectories of one microsecond. Density functional theory calculations. Spectrophotometric and electron paramagnetic resonance assays for reactive oxygen species, three independent samples. Monte Carlo

proximity analysis. Structural survey of the human and Escherichia coli proteomes from AlphaFold and the Protein Data Bank. Whole-cell proteomics of HeLa cells.

How the finding arose, which bears on how it should be read. The authors state that the study was prompted by the unexpected observation of a rapid decline in protein foldability under blue light. They were not investigating light damage. The blue light was the imaging illumination of their instrument, and the damage presented as an artifact which they then pursued. The Foundation records that because it bears in both directions: an incidental observation is less vulnerable to motivated analysis than a result that was sought, and an imaging illuminator is a light source of unknown and possibly high intensity.

Light conditions. Blue light at a peak wavelength of 447 nanometers for all experiments except two control conditions, with the full spectrum given only in supplementary material the Foundation has not obtained. Infrared at a peak wavelength of 860 nanometers as one comparison. Darkness as the other, imposed for an initial six hours. No irradiance, power density or illuminance is reported for any condition.

The principal results. Protein foldability fell to zero over approximately 200 unfolding cycles, with a decay constant of 207 plus or minus 7 minutes under the control condition. Reducing dissolved oxygen slowed the decay, to approximately 456 minutes in vacuum-degassed buffer and 357 minutes with nitrogen bubbling. Raising oxygen accelerated it sharply. Darkness and infrared light both delayed the decay, the latter the authors state even at higher power, which makes the effect specific to the short wavelength rather than to light in general. Mass spectrometry identified eighteen significantly oxidized residues under blue light, of whose side-chain atoms 64 percent lay in the protein core rather than at the surface. Calculations predicted an absorption near 445 nanometers for a tryptophan-oxygen pair, and assays supported production of singlet oxygen and hydroxyl radical from tryptophan under blue light. Oxidized residues lay within about 2 nanometers of the nearest tryptophan, a proximity the authors calculate would arise by chance about 0.2 percent of the time.

The structural survey, which is the part this comment uses. Approximately 92 percent of distinct human and Escherichia coli proteins were found to contain cavities, and approximately 31 percent to contain large cavities containing tryptophan, on the AlphaFold structures; the corresponding figures from the Protein Data Bank were approximately 95 and 42 percent. In HeLa cells the proportion of proteins with large tryptophan-containing cavities rose with the degree of oxidation, to as much as 22 percent, though the authors note that a few protein categories showed the opposite trend, which they attribute to differences in microenvironment.

What the authors say about tissue relevance. They propose that the route could affect many cellular proteins, particularly in tissues exposed to visible light, and they name the skin and the eyes. That is a statement in their discussion rather than a result, and the Foundation presents it as such.

Funding and competing interests. Supported by the National Research Foundation of Korea under several grants, the National Cancer Center, the Korea Basic Science Institute, the Institute for Basic Science and the POSCO TJ Park Foundation. The authors declare no competing interests. Mass spectrometry data are deposited at ProteomeXchange under accession codes PXD056895 and PXD038746, with a transparent peer review file published alongside the article. The Foundation notes the data practice favorably: deposited data and an open review record are better evidence of rigor than most entries in this appendix can show.

What it establishes. That in a purified protein under laboratory illumination at 447 nanometers, oxygen confined within the protein is converted by tryptophan into reactive oxygen species that oxidize residues in the protein interior; that the effect is specific to the short wavelength, being absent in darkness and under infrared; and that the structural

precondition for the mechanism, a large cavity containing tryptophan, is present in roughly a third of human proteins.

What it does not establish. Anything about people. It does not establish that this occurs in human tissue, at what irradiance it would occur, whether ambient or occupational light-emitting diode illumination delivers that irradiance to any tissue, or that any functional or clinical consequence follows if it does. It is a mechanism demonstrated in vitro and supported computationally, and Part V.A sets out what weight this comment gives evidence of that kind.

Bearing on the statutory question. One use, at Part V.C.2.h, for the proposition that mechanisms of optical radiation damage are not all ocular and not all mediated by specialized photoreceptors, so that a framework addressed to retinal hazard does not by its terms reach them. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation; whether a mechanism of this kind operates at the irradiances people receive is a question within those words and the Foundation cannot answer it.

C.62 Abboushi and others (2024) — the position index measured for diode sources, and two findings adverse to this comment

Citation. Abboushi B, Miller NJ, Rodriguez-Feo Bermudez E, Irvin L, Royer M. The position index of overhead LED sources under different spectral power distributions and background luminances. LEUKOS: The Journal of the Illuminating Engineering Society. Published online April 17, 2024. doi:10.1080/15502724.2024.2327863. Volume and pagination not captured and must be completed. The Foundation consulted a copy held on its own server and must cite the published article.

Affiliation, which bears on how the entry is used. All five authors at Building Systems, Pacific Northwest National Laboratory, Portland, Oregon. A national laboratory of the Department of Energy. The journal is that of the Illuminating Engineering Society. This is the lighting profession and the federal research establishment examining their own metric, which is why the Foundation treats its statements of inadequacy as admissions rather than as advocacy.

Design. Human-subjects laboratory experiment in a hemispherical apparatus of 0.96 m radius fitted with tunable diode modules of 22 mm aperture, approximately 0.0004 steradian. Two psychophysical procedures: discomfort-level matching, and adjustment to the borderline between comfort and discomfort. Variables were source position, background luminance at approximately 1 and 35 cd/m^2, spectral power distribution at approximately 4,550 K and 2,500 K, and starting anchor, high and low, averaged. Results reported as geometric means.

Participants. Thirty enrolled, twenty-nine analyzed, one excluded. Two age groups. The methods give these as 21 to 30 and 57 to 70 years while the introduction gives 18 to 30 and 55 and over; the discrepancy must be resolved. Migraine sufferers were excluded, which the Foundation identifies as the most consequential feature of the sample for its purposes, because Part V.E.2 concerns precisely the population excluded and because a glare study that excludes photophobic participants cannot describe the experience of the people whose reports are collected at Part VII.

Positions tested. Reference at 0 degrees azimuth, 20 degrees elevation for the matching procedure. Test sources at 0 and 0, 0 and 20, 0 and 40, 0 and 60, plus and minus 45 at 60, plus and minus 67.5 at 60, and 0 and 80 degrees. Sources at 60 and 80 degrees above the line of sight were found to be detectable and quantifiable, which the authors say supports including sources outside the field of view in discomfort glare metrics.

The principal numerical result. Against an on-axis reference, the geometric mean position index for a source 60 degrees above the line of sight was 53, against 16.9 in Luckiesh and

Guth 1949, with the gap widening as vertical angle increased. Measured on-axis borderline luminance was 8,922 cd/m² against 2,844 in the 1949 work. Against a 20-degree reference, the 80-degree source had index values approximately two to three times those of the 60-degree source. The authors attribute the differences to the smaller source, 0.0004 against 0.0011 steradian, to a wider luminance range, and to anchor bias.

The spectral result, which is adverse. No statistically significant difference in position index or in borderline luminance between the cool and warm sources at either background level, with inconsistent direction: at 0 and 80 degrees under high background the warm source gave a higher index, 31.6 against 23.3, while at 0 and 60 degrees it gave a lower one, 10.5 against 13.6. The authors state that the study calls into question the effect of spectral power distribution on discomfort glare, and hypothesize that adaptation periods of two to five minutes between spectral conditions may have weakened any effect. Background luminance did not significantly affect the index, though borderline luminance was significantly higher at the higher background, $p < 0.01$, which the authors describe as consistent with earlier work.

What the authors recommend. That the position index values from this study, which they say account for range and anchor bias, be incorporated into discomfort glare models; that the present practice of applying one position index irrespective of source size warrants further study; and that sources outside the field of view be included in discomfort glare metrics. They do not conclude that the position index is applicable to diode sources without further testing, and they do not directly test the Unified Glare Rating or reach a judgment on the adequacy of any model.

What it establishes. That a term in continuous use in discomfort glare prediction since 1949 had not been evaluated for light-emitting diode sources until 2024; that its measured values for such sources differ from the 1949 values by a factor of roughly three at 60 degrees and more at greater angles; that the dependence of the index on source size is untested; and that sources well outside the central field of view produce quantifiable discomfort.

What it does not establish, and what it tells against. It does not establish that existing glare models understate discomfort from diode sources. For the term it measured and the geometry it tested, it indicates the opposite: computing a rating with the 1949 values predicts more discomfort from a high off-axis source than these measurements support. Nor does it support the proposition that warmer light produces less discomfort glare, and this comment does not advance that proposition. The study is a single laboratory experiment with twenty-nine participants, one source size, two background levels, uniform rather than patterned sources, fixed horizontal viewing without dynamic gaze or cognitive task, and the exclusion of migraine sufferers.

Bearing on the statutory question. Three uses. At Part V.C.4.c, for the proposition that the terms of the governing discomfort glare metric were derived for other sources and that their dependence on source size is untested on the field's own account. At Part V.C.4.c again, as the correction of a claim this comment does not make about spectral power distribution. And at Part II.H.4 and Part IV.G, for the proposition that the federal capacity to conduct human-subjects research on the visual effects of these products exists and sits in the Department of Energy rather than in this Department. Paragraph 360ii(a)(3) and paragraph (a)(6).

C.63 Françon, Behar-Cohen and Torriglia (2024) — the phototoxicity threshold re-measured, and the weighting function challenged

Why this entry matters more than most in this appendix. It attacks the instrument on which the determination of May 24, 2024 ultimately rests. Every assurance of photobiological safety for a light-emitting diode product traces back to a threshold dose measured in animals and to a weighting function applied to the emitted spectrum. This

study re-measures the first in rats and challenges the second on two independent grounds. It was published in February 2024, three months before the determination.

Citation. Françon A, Behar-Cohen F, Torriglia A. The blue light hazard and its use on the evaluation of photochemical risk for domestic lighting. An in vivo study. Environment International 2024;184:108471. doi:10.1016/j.envint.2024.108471. PMID 38335626. Creative Commons Attribution-NonCommercial-NoDerivatives licence. The Foundation read the author version deposited at inserm.hal.science under identifier inserm-04456445, submitted February 14, 2024, and must verify against the published article.

Authors, and two institutional facts. Behar-Cohen was an external expert of the 2012 Opinion of the European predecessor committee described at Part V.K.9 and is a co-author of the market surveillance study at Appendix C.59. The contribution statement records her role here as writing, review and editing; Torriglia conceived and supervised the work and obtained the funding, and Françon performed the investigation and analysis. The Foundation states that precisely rather than leaning on her name. Second, the light exposure devices were manufactured and designed by the Centre Scientifique et Technique du Bâtiment, the institute of the author of the reference chapter at Appendix D.5 and of the 2024 intergovernmental review at Appendix D.1.

The governing limitation, stated first. Male albino Wistar rats, exposed at six weeks of age, to acute doses under laboratory light sources, in a single laboratory. Rats are nocturnal, which Part V.A.2 sets out as a general caution on rodent light studies. The reported overestimates are of the accepted threshold for rats, not of the human exposure limit; the extension to human limits is the authors' inference from the shared derivation method, and they state it as a suggestion. The animals were young, and the authors themselves note that susceptibility to light increases with age and that evaluation in older animals would be worth performing.

The albino question, and the authors' answer to it. An albino rodent is the classic hypersensitive model for retinal light damage and the Foundation raises the objection before a reader does. The authors address it: they state that the action spectrum curves of van Norren show albino and pigmented rats to have the same sensitivity to light. That answer rests on a secondary source and must be checked against van Norren and Gorgels 2011 directly. If it holds, it substantially blunts the objection; if it does not, this entry must be re-weighted.

Design and exposure. Rats exposed individually from above at 9 a.m. by arrays of ten diodes, with exposure time varied to deliver specified retinal doses, then kept in darkness for 26 hours before sacrifice, that interval being the reported peak of photoreceptor cell death after white light. Sources: phosphor-converted white at 2700 K, blue at 450 nm, green at 507 nm, red at 630 nm, characterized with a spectroradiometer. Retinal dose computed as the product of exposure time and retinal irradiance, the latter derived from corneal irradiance, ocular transmittance, pupil diameter and focal length. Ethics approval Apafis 21910-2019090612065253v6.

The regulatory chain the paper sets out. Limit exposure values for domestic lighting rest on action spectrum curves giving a retinal threshold dose at 445 nanometers of 22 joules per square centimeter for primates and 11 for rodents. The primate values were used to establish the current lighting regulations. Those regulations weight polychromatic light by $B(\lambda)$, a curve peaking at 445 nanometers, and a device is labeled as presenting no risk if after 10,000 seconds the weighted retinal dose is below 2.2 joules per square centimeter. The regulatory limit is therefore one tenth of the measured primate threshold. This comment had not previously stated that chain and now does, at Part V.C.2.f.

Principal results. The phototoxicity threshold currently accepted for rats is overestimated by a factor of 50 for blue light and by a factor of 550 for white light. The excess phototoxicity of white light is attributed to its green content, which promotes an inflammatory response:

the green content of white light produced eight times more macrophage invasion of the retina than the blue content. Red light mitigated damage, inhibiting the nuclear translocation of L-DNase II and reducing TUNEL-positive cells by 33 percent, and the blue light hazard weighting does not evaluate the red content of a source at all.

The authors' conclusions, quoted. That the phototoxicity of a polychromatic source should be assessed across the entire spectrum rather than by its blue content alone; that "As current human phototoxicity thresholds were estimated with the same methods used for rats, our results suggest that they might need to be reconsidered"; and that "the commercial LED that are currently classified as safe for the retina could actually induce retinal damage if used daily at high luminance."

A convergence with Part V.B.6, reached independently. The finding that red light is protective and that the weighting ignores it arrives at the same place as the long-wavelength argument at Part V.B.6, by a different route. That argument rests on a London group working on mitochondrial function and visual performance in humans. This is a Paris group working on retinal cell death in rats, by a mechanism of apoptosis regulation. The two lines do not share endpoints, methods, species or authors.

A second line the paper reports and the Foundation has not read. The authors record that Hunter and others, in work published in 2012 and 2018, identified a potential overestimation by a factor of 20 of the current safety standards in humans. If that holds it is an independent corroboration in a primate or human model and it must be obtained.

An exposure figure the paper reports from a national agency. The paper states that in a 2019 report on new lighting technologies the French agency carried out measurements in real-life conditions and concluded that artificial lighting adds up to 50 percent of the phototoxic dose received from natural lighting, rising to 200 percent where only cool light-emitting diode sources are used, with screens among the largest artificial contributors. Part V.K.6 uses that against the 2018 Opinion's statement that exposure from these products is likely to be insignificant compared with natural light. The Foundation has not obtained the 2019 report and the figure is taken at second hand.

Funding, competing interests and data. Supported by the French agency for food, environmental and occupational health safety under contract 2022/EST/134 to Torriglia. The authors declare no known competing financial interests or personal relationships. Data will be made available on request rather than deposited. The Foundation notes the funding without discounting the work: a national health agency funding research that challenges the adequacy of a lighting safety standard is the kind of research paragraph 360ii(a)(2) directs this Secretary to plan, conduct, coordinate and support.

What it establishes. In this model and these conditions: that retinal damage occurs at doses far below the threshold currently accepted for rats; that the green component of white light contributes more to the inflammatory response than the blue component; and that the red component is protective and is not evaluated by the weighting function on which the regulations depend.

What it does not establish. That any human being has been injured by any light-emitting diode product. That the human exposure limit is wrong by any particular factor; the 50 and 550 are overestimates of a rodent threshold. That commercially available products in the United States exceed any limit. The final quoted sentence is a conditional about daily high-luminance use and the Foundation presents it as the authors' conclusion rather than as a finding about products in commerce.

Bearing on the statutory question. Three uses. At Part V.C.2.f, as the quantified instance of the proposition the 2024 intergovernmental review states without numbers, that damage has been found below the limit. At Part V.C.2.a and Part V.B.3, for the peak of $B(\lambda)$ at 445 nanometers and for the attribution of the limits to the ICNIRP guidelines of 2013. At Part

V.K.6, for the national agency exposure apportionment. Section 360kk(a)(1)(A) directs the Secretary to consider the latest available scientific and medical data in prescribing a standard, and this paper was available three months before the determination.

C.64 Zhang and others (2023) — a documented macular injury in a child from a marketed handheld diode light

What this entry is, and the weight it carries. A single interventional case report. It is the weakest design in this appendix and the Foundation says so at the outset. A case report cannot establish incidence, risk, or that any population is affected. It establishes that an identified injury occurred to an identified person in identified circumstances, documented by imaging. That is what it is offered for and nothing more.

Citation. Zhang L, Lei CY, Zhang ZC, Gu JY, Zhang MX. Accidental macular injury from short-term exposure to a handheld high-intensity LED light. Heliyon 2023;9(8):e18705. doi:10.1016/j.heliyon.2023.e18705. PMID 37554811. PMCID PMC10404656. Published July 26, 2023. Open access under a Creative Commons Attribution-NonCommercial-NoDerivatives licence; full text read.

Affiliations and funding. West China Hospital, Sichuan University, Chengdu, and the Fourth People's Hospital, Zigong, Sichuan Province, China. Corresponding author Zhang Mei-Xia. Supported by Sichuan University, grant ZYJC21025. The Foundation has not located a competing interests declaration and must obtain it.

The patient and the exposure. A thirteen-year-old girl presented with vision loss and scotomas in the right eye. Five days earlier a classmate had directed a handheld light-emitting diode light at that eye several times, at very short distance, in flash mode. The device was bought online and is described as an outdoor lighting product with high-output sources: thirty chip-on-board emitters rated together at 5 watts, 100 lumens per watt at 500 milliamperes. No radiometric measurement of the device was made and none is reported.

Findings and course. At three days after exposure, best corrected visual acuity in the right eye was 6/20. Optical coherence tomography showed a hyperreflective area in the external retinal layers corresponding to disruption of the ellipsoid zone and the photoreceptor outer segments. Treatment was a single retrobulbar injection of 20 mg triamcinolone acetonide at five days. Acuity recovered to 16/20 at nineteen days and 20/20 at thirty-three days. Multifocal electroretinography showed reduced foveal P1 amplitudes in the affected eye at nineteen days and improvement at thirty-three days. Imaging through three months documented restoration of the outer retinal layers. The authors note that the patient was not seen until five days after exposure, so no examination was obtained in the acute phase.

The comparison the authors draw, which is the entry's principal value. They report that the imaging findings were particularly similar to those seen in solar maculopathy, in welding arc maculopathy, and in maculopathy following viewing of a plasma flash produced by a femtosecond laser, and suggest a shared phototoxic cause. Part V.C.1.d sets out what follows for this comment: an injury of the same clinical description is produced by four sources, of which the agency regulates three.

The authors' own statement limiting their case. They write that no evidence of direct adverse health effects from light-emitting diodes has been found in conditions of normal use, and that it is misuse which may cause eye damage, particularly in children. The Foundation adopts that statement. This entry is not evidence that ordinary lighting injures the retina and is not offered as such anywhere in this comment.

Two animal studies the report relies on, recorded as leads. Park and others are reported as finding that a high-power diode source of 25 watts, rated 150 lumens per watt at 700 milliamperes, applied for five seconds at one centimeter from the corneal surface, caused

temporary phototoxicity to visual function in rabbits which recovered within twenty-four hours. Araújo and others are reported as finding, in Wistar rats exposed to high-intensity diode light at 3,200 milliwatts per square centimeter for 144 seconds at 30 centimeters, morphometric alterations in retinal structures, specifically in the nuclear area of the photosensitive cells. Neither has been read by the Foundation. The second supplies an irradiance figure for a whole device, which this comment needs and lacks.

What it establishes. That a marketed handheld light-emitting diode device, obtainable online, produced a macular injury in a thirteen-year-old that was documented by optical coherence tomography and electroretinography, that reduced visual acuity to 6/20, and that resolved over approximately five weeks. The authors state it is the first such case report for a handheld diode lighting device.

What it does not establish. Incidence, prevalence, or risk of any kind. That ordinary lighting is hazardous; the authors say the contrary. That the injury would have occurred at ordinary viewing distances or without the light being deliberately directed into the eye. That any permanent harm resulted; acuity returned to normal. The case also cannot show what the device emitted, because it was never measured, and this entry should not be cited for any emission figure.

Bearing on the statutory question. Two uses. At Part V.C.1, for the regulatory asymmetry: an injury clinically indistinguishable from that caused by three regulated sources, caused by an unregulated one. And at Part V.C.2.k, for the proposition that the aversion response cannot operate as the photobiological framework assumes when a source is directed into the eye without warning and repeated. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation, and a device of this kind in the hands of children is a condition of exposure.

C.65 Ogawa and others (2023) — blue diode light as the standard insult, and the stress pathway it activates

The governing limitation, stated first. The exposure was 36 hours of continuous blue light-emitting diode illumination on a monolayer of cultured cells. No retina receives 36 hours of uninterrupted light. The cells were a murine photoreceptor-derived line in a dish, lacking the retinal pigment epithelium, the choroidal circulation, the repair processes and the tissue architecture of an eye. And the subject of the paper is not the light. It is a plant extract tested for protective effect, for which the light exposure is the assay. This entry is offered for the pathway and for one observation about the literature, not for any proposition about human exposure.

Citation. Ogawa K, Karitani T, Otsu W, Nishiyama K, Kunitake H, Goto Y, Nomiyama S, Hara H, Yamasaki M. Blueberry stem extract suppresses blue light-emitting diode light-induced endoplasmic reticulum stress on retinal photoreceptor cells. BPB Reports 2023;6(3):87–97. Received March 16, 2023; accepted April 20, 2023. The Foundation read the article as supplied and must verify the digital object identifier and the journal's indexing status.

Affiliations, and a commercial interest in the test article. University of Miyazaki, Institute for Tenure Track Promotion and Graduate School of Agriculture; Gifu Pharmaceutical University, Department of Biomedical Research Laboratory and Molecular Pharmacology, Department of Biofunctional Evaluation; and Biolabo Co., Ltd., Kobe. The blueberry stem extract tested was provided by Biolabo Co., Ltd., and one of the authors is affiliated with that company. The Foundation records that because the finding of the paper is that the company's product is protective. It does not bear on the light exposure, which is what this comment uses, but a reader is entitled to know it.

Design and exposure. Cultured 661W cells, a murine photoreceptor-derived line, seeded on well plates and placed on a transparent acrylic plate 300 millimeters above a blue light-emitting diode device of 470 nanometer peak wavelength, inside a carbon dioxide

incubator at 37 degrees Celsius. Illuminance at the cells was 500 lux, measured with a digital light meter. Exposure was continuous for 36 hours, with lysis for protein analysis at 6, 12, 24 and 36 hours and assessment of cell damage at 24 hours. Control cells were shielded from the light with aluminum foil. Cells were pre-treated with the extract or with N-acetyl-L-cysteine as a positive control antioxidant.

What the light did. Blue light triggered the endoplasmic reticulum stress factors BiP, PERK, ATF6, eIF2α, ATF4 and CHOP; these in turn upregulated the cell cycle arrest factors p53 and p21 and the apoptosis-inducing factor caspase-3; and morphological abnormality and cell damage followed. The extract and the antioxidant each suppressed the increases in BiP, ATF4, ATF6, CHOP, p53, p21 and caspase-3, but not in the mitochondrial apoptotic factors Bax and cytochrome c. The authors conclude that the blue light-induced endoplasmic reticulum stress is primarily caused by oxidative stress.

The mechanism the paper describes, which is new to this comment. The introduction states the sequence the Foundation relies on: that blue light can cause aggregation of short-wavelength opsin, a photoreceptor protein, leading to endoplasmic reticulum stress; that the unfolded protein response is regulated by three transmembrane sensors, PERK, IRE1 and ATF6; and that prolonged stress ending in failure of that response leads to apoptosis. It also states that endoplasmic reticulum stress is known to be one of the causes of age-related macular degeneration, and that a positive correlation has been observed in human studies between the onset of that disease and exposure to blue light. Those are statements of the authors' understanding of their field, supported by citations the Foundation has not read, and are not findings of this study.

What it establishes. That continuous blue light-emitting diode illumination at 470 nanometers and 500 lux activates the unfolded protein response in a photoreceptor cell line within hours, and that the activation proceeds to markers of cell cycle arrest and apoptosis; and that both a plant extract and a known antioxidant suppress that sequence, which the authors take as evidence that the pathway is driven by oxidative stress.

What it does not establish. Anything about human retinas, about tissue, or about exposures of the kind described at Part VI. The illuminance figure must not be read as comparable to room lighting: it is a measurement at the surface of a cell monolayer, and the quantity governing exposure of a living retina is the irradiance of the retinal image, which is set by source radiance and treated at Part V.B.2. Nor does the study bear on the extract in any way this comment relies upon; the Foundation takes no position on whether blueberry stem extract protects anything.

Bearing on the statutory question. One use, at Part V.C.1.a, and it is an observation about the literature rather than a finding. Blue light-emitting diode illumination functions in this branch of research as the standard means of producing photoreceptor damage, against which protective compounds are screened. The damaging capacity at laboratory doses is not contested by the researchers who rely on it. The open question is the one § 360ii(a)(4) assigns to the Secretary: at what exposure, under what conditions, and with what margin.

C.66 Chan and others (2023) — a retinal barrier protein cleaved, and an exposure reported only in lux

Citation. Chan YJ, Hsiao G, Wan WN, Yang TM, Tsai CH, Kang JJ, Lee YC, Fang TC, Cheng YW, Li CH. "Blue light exposure collapses the inner blood-retinal barrier by accelerating endothelial CLDN5 degradation through the disturbance of GNAZ and the activation of ADAM17." Fluids and Barriers of the CNS 2023;20(1):31. doi:10.1186/s12987-023-00430-7. PMID 37095509; PMCID PMC10124034. Received December 8, 2022; accepted April 7, 2023. Published open access under a Creative Commons Attribution license. Department of Physiology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan. Chan and Hsiao are stated to have contributed equally.

Exposure conditions, which govern the use made of this study. In the cell experiments, blue light-emitting diodes were mounted at the base of an exposure chamber and illuminance at the culture was set by varying the distance to the emitting plane. Three illuminances were used – 80, 160 and 240 lux – for durations of 6, 12 and 24 hours. All of the barrier measurements on which the paper's conclusions rest were made at 160 lux for 6 to 12 hours. In the animal experiments, C57BL/6 mice aged six weeks were held in a blue or red light exposure chamber for six hours per day, from 10 a.m. to 4 p.m., on three consecutive days, with a battery of fundus photography, fundus fluorescein angiography, optical coherence tomography and electroretinography performed before exposure and repeated on the fifth day. Animal protocol LAC-2020-0482.

What is not reported. The paper reports no irradiance anywhere, and it does not state the peak wavelength of the diodes it used. The only wavelength figures in the paper are the 400 to 500 nanometer band used in the introduction to define blue light generally, and the 318 and 449 nanometer excitation and emission pair of a fluorometric enzyme assay unrelated to the exposure. The exposure is therefore specified in photometric units alone, with the spectrum left undefined.

What it reports. Claudin-5, the endothelial tight junction protein, fell in an illuminance-dependent and time-dependent manner. After six hours at 160 lux it stood at 0.53 plus or minus 0.08 of control in the murine endothelial line and 0.63 plus or minus 0.07 in primary human retinal microvascular endothelial cells. Transmission electron microscopy showed the tight junction ultrastructure of control cells replaced by a gap. Transendothelial electrical resistance and paracellular permeability changed accordingly. The loss was attributed to activation of the metalloprotease ADAM17, and both a pharmacological inhibitor and genetic knockdown prevented it. In the resting state ADAM17 is bound by GNAZ, described by the authors as a circadian-responsive, retina-enriched inhibitory G protein; blue light released it. Knocking down GNAZ produced protease hyperactivation, junction protein loss and permeability in culture, and retinal damage resembling blue light exposure in the animal, with no light exposure involved. In mice, the three-day regimen produced angiographic leakage with attenuation of the electroretinogram b-wave and of the oscillatory potentials. Supplementary figures report that red light left both the junction protein and the phosphorylation state of the protease unchanged, and that two related proteases, ADAM9 and ADAM10, do not participate.

What it establishes. That blue light acting on the retina has a route of action whose target tissue is vascular endothelium, whose mechanism is proteolytic cleavage of a tight junction protein, and whose functional endpoint is barrier integrity and the electrical response of the inner retina – none of which is the outer-retinal photochemical lesion from which the blue-light weighting function and the numerical limits built on it were derived. That this route is wavelength-dependent rather than merely energy-dependent, red light having left it untouched. And that the route can be interrupted at a defined molecular step, which is the strongest form of mechanistic evidence available from a study of this kind: the light produced the effect, blocking the mediator prevented it, and removing the mediator's natural brake reproduced it without light.

What it does not establish, and the reason the Foundation is careful with it. It does not establish that any effect occurs at or below a regulatory limit, and the comment does not cite it for that. The abstract's phrase "even at non-cytotoxic lighting" is stronger than the paper's own results text, which states that at the working condition the cells "were less viable but were still alive" and reports that the lowest illuminance tested, 80 lux, significantly reduced metabolic activity at 24 hours. What was preserved at the working condition was cell density, not viability. Separately, the authors describe their illuminances as common in consumer displays and suitable for a reading distance. Because lux is weighted by a photopic function that is small in the blue, a stated illuminance of near-monochromatic blue light carries a radiometric and blue-light weighted dose one to two

orders of magnitude above the same stated illuminance of white light, so that comparison does not hold as a comparison of blue-light dose and the comment does not repeat it. The opening assertion of a rising incidence of retinopathy attributable to consumer devices is not adopted. The work is in cell culture and in mice; one of the two cell lines is of cerebral rather than retinal origin, although the authors state the principal findings were confirmed in the primary human retinal line. One point in the discussion rests on data the authors describe as unpublished.

A qualification to the preceding field, added after a later study was read. The judgment above that viability rather than only cell density was affected rests on the reported fall in succinate dehydrogenase activity, measured by tetrazolium reduction. Appendix C.69 reports that blue light directly inhibits succinate dehydrogenase, the enzyme of mitochondrial Complex II. If that is so, a tetrazolium assay performed under blue light measures the activity of an enzyme the light is itself inhibiting, and a reduced signal does not establish a reduced number of living cells. That is consistent with what this study reports, since the dye-based measure of cell density was preserved at the working condition while the enzymatic measure fell. The Foundation therefore softens its objection to this extent: the claim of a non-cytotoxic exposure is better supported than the enzymatic data alone suggest. The objection is not withdrawn, because the exposure level remains the governing problem and is unaffected by the assay question. This reasoning is the Foundation's and is advanced by neither set of authors.

Disclosures and data. Funded by the Ministry of Science and Technology of Taiwan (MOST 110-2320-B-038-066, 110-2320-B-038-080 and 111-2320-B-038-024) and the Ministry of Education higher education sprout project (DP2-110-21121-01-N-06-02). The authors declare no competing interests. The source data underlying the figures are published as a supplementary file, which is better practice than most of the studies in this appendix and permits independent checking of the reported effect sizes.

Where it bears. Part V.C.1.g, as the study of a retinal tissue and an injury mode that the weighting function was not measured to describe. Part V.C.2.h, as a further instance of the framework's scope being narrower than the evidence. Part V.B.6 and Appendix C.63, on wavelength specificity and the behavior of the red end. The circadian character of GNAZ bears on Part V.F only as a research gap, not as a finding.

C.67 Antemie, Samoilă and Clichici (2023) — a review of the human clinical evidence, and the most adverse conclusion in this record

Citation. Antemie R-G, Samoilă OC, Clichici SV. "Blue Light—Ocular and Systemic Damaging Effects: A Narrative Review." International Journal of Molecular Sciences 2023;24(6):5998. doi:10.3390/ijms24065998. PMID 36983068; PMCID PMC10052719. Received February 14, 2023; revised March 13, 2023; accepted March 20, 2023; published March 22, 2023. Academic editor Settimio Rossi. Open access under a Creative Commons Attribution license. Departments of Physiology and of Ophthalmology, Faculty of Medicine, Iuliu Haţieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Article type, and why it is the strongest of its kind in this appendix. A narrative review, so secondary throughout and cited in the category described at Part V.A.2 as evidence of the state of expert opinion and not as primary evidence of any effect. It is nonetheless the most disciplined narrative review in Appendix C. The authors state that they followed the SANRA instrument for assessing narrative reviews; they searched PubMed/Medline, Scopus, EMBASE, the Cochrane Database of Systematic Reviews and Clinical Trials for the period 2010 to 2022; they restricted inclusion to clinical studies and randomized controlled trials in English with human participants; and they excluded studies with fewer than ten participants. Two searches were run, one on blue light and the retina and one on the intrinsically photosensitive retinal ganglion cell. The yield is reported as a flow: 333 records after filters, 20 abstracts selected, three excluded on reading for having fewer than

ten participants per study, and 17 studies in the final review. No risk-of-bias instrument was applied and nothing was pooled, so it remains a narrative review and not a systematic one.

Its conclusion, quoted because it is adverse. The authors conclude: "We find it difficult to express with certainty that blue light exerts a harmful effect at the level of the human retina". They further state that there is little evidence that the theoretical protection of blue-blocking filters against retinal degeneration is clinically significant, and that "many findings are theoretical or based on observations in cell culture or animal experiments". This is the most directly adverse peer-reviewed authority in this comment's record. It is confronted on its own terms at Part V.C.1.h and is not characterized as an outlier.

The other half of the same conclusion. The concluding passage does not rest there. The authors state that as more research groups examine the subject, using designs that resemble contemporary conditions and enrolling healthy young participants who use display terminals often, studies are beginning to obtain more consistent results that "all point towards the possible noxious effect of long-term blue light exposure", and that questions remain despite the groundwork having been laid more than two decades ago. The Foundation quotes both halves and relies on neither beyond its terms.

What it establishes, and it is a finding about the record rather than about light. That a search of five databases over thirteen years, restricted to human clinical studies and trials with ten or more participants, yields seventeen studies on blue light and the retina. That the reasons the human literature cannot answer the question are methodological and specific: small samples, inadequate follow-up, predominantly subjective endpoints, and exposure conditions that are not standardized between groups. On the last point the review is concrete, reporting that research groups defined the mesopic setting differently, "ranging from 0.1 lx to 50 lx", and that the wavelength and stimulus duration used for experimental exposure also vary between studies. A literature whose exposure specifications differ by more than two orders of magnitude between groups cannot be synthesized, and that is a condition a federal exposure specification would remedy. These findings are used on the research-needs question and at Part V.K.

What it does not establish. Any effect of any light-emitting diode product on any human retina. Any threshold, dose-response relationship or exposure limit. It is secondary throughout, so every figure in it is reported at one remove and none has been verified by the Foundation against its source. The scope is also narrower than the title suggests: the systemic material is confined principally to photophobia and migraine and to cardiac autonomic function, and the review does not address the wider systemic literature its title invokes. The data availability statement offers datasets on request, which is not meaningful for a review containing no primary data.

Two leads it supplies, recorded as leads and not as findings. First, the review describes work by Gagné and colleagues, its reference 46, as the first to show that short exposures to blue light can affect both cone and rod electroretinogram responses, in the review's characterization even where exposure fell within the standard safety range, with b-wave reduction under both scotopic and photopic conditions, still measurable an hour afterward, and treated by those authors as temporary. Second, work by Yuda and colleagues, reference 50, on cardiac autonomic function under colored organic light-emitting diode illumination: a red arm at 39 lux, a green arm at 71 lux and a blue arm at 10 lux, with high-frequency power falling and the low-to-high frequency ratio rising, the change greater for blue than for red or green, and with only the highest blue illuminance producing significant heart rate and heart rate variability changes, persisting into the darkness following the exposure, under a paced breathing protocol intended to remove the respiratory confound. Neither study has been read by the Foundation. Neither is relied on.

Disclosures. The authors state that the research received no external funding and declare no conflict of interest. Published by MDPI, which bears on the standing question recorded for Appendix C.18 and C.59 and should be resolved once for all three rather than separately.

Where it bears. Part V.C.1.h, as the adverse authority the comment confronts. Part V.A.2, as an application of the evidentiary hierarchy. Part V.K and the research-needs response, for the finding that exposure specifications are not standardized across the literature. Part V.E.5 and Part V.E.1 only by way of the two leads above, which must be obtained before either section relies on them.

C.68 Li, Zhu and Qi (2023) — a fourth injury mechanism reported, on an abstract the Foundation could not go behind

The governing limitation, stated first. The article is closed access. It is not in PubMed Central, no author manuscript or repository copy exists, and an open-access location search returns none. The Foundation has read the abstract only. In accordance with the practice applied at Appendix C.58, this entry is confined to what an abstract reliably establishes – that a mechanism has been reported in the peer-reviewed literature – and is not an appraisal of the study. No exposure conditions are stated in the abstract: no wavelength, no irradiance, no illuminance and no duration. Nothing in this entry may be cited for any proposition about dose, threshold or human effect.

Citation. Li X, Zhu S, Qi F. "Blue light pollution causes retinal damage and degeneration by inducing ferroptosis." Journal of Photochemistry and Photobiology B: Biology 2023;238:112617. doi:10.1016/j.jphotobiol.2022.112617. PMID 36495671. Lanzhou University Second Hospital, Lanzhou, China. Cite the publisher's version.

What the abstract reports. That blue light triggered a burst of reactive oxygen species in retinal cells with a significant increase in intracellular ferrous iron; that deferoxamine, an iron chelator, significantly improved lipid peroxidation and cell death in ARPE-19 cells, a human retinal pigment epithelial line; that ferrostatin-1, an inhibitor of ferroptosis, alleviated retinal oxidative stress and degeneration in rats; and that blue light produced an imbalance in both of the systems by which cells defend against ferroptosis, the glutathione-GPX4 system and the FSP1-coenzyme Q10-NADH system. The authors conclude that ferroptosis may be a crucial pathway for blue-light-induced retinal damage.

What it establishes, on the abstract alone. That a fourth distinct injury mechanism is reported in this literature. Ferroptosis is an iron-dependent form of regulated cell death driven by lipid peroxidation, and it is distinct from the endoplasmic reticulum stress and caspase-dependent route at Appendix C.65, from the proteolytic cleavage of an endothelial junction protein at Appendix C.66, and from the photooxidation of buried protein residues at Appendix C.61. The abstract also reports that the effect was interrupted at a defined molecular step in two independent ways, one in human cells and one in the intact animal, which is the form of evidence that distinguishes a mechanism from a correlation. The Foundation uses the entry for that single proposition, at Part V.C.2.h.

Independent earlier support, added after a later reading. The components of the pathway this abstract names were measured six years earlier by a different group on another continent. Appendix C.76 reports, in rats exposed to monochromatic light at matched irradiance, that total retinal iron rose significantly under all three wavelengths and most under blue; that ferritin, ferroportin and the ferroxidase ceruloplasmin were up-regulated and transferrin and its receptor down-regulated as wavelength decreased; and that lipid peroxidation and glutathione peroxidase activation formed part of the account. Iron overload, lipid peroxidation and glutathione peroxidase are the constituents of ferroptosis. That earlier work did not name the pathway, which had barely been defined when it was performed. The effect is that this entry, which rests on an abstract the Foundation could not go behind, is no longer a solitary report: the phenomenon it names was independently measured before it was named.

What it does not establish, including two statements the Foundation declines to adopt. Nothing about any exposure level, because none is reported. Nothing about any product. Nothing about humans: the work is in a cell line and in rats. Two further statements in the abstract are not adopted. The first is that blue light is "the main culprit of teenage vision problems in the modern environment". The second is the closing statement that the results help explain why blue light pollution causes visual impairment in adolescents. That is a conclusion about human adolescents drawn from a cell line and a rodent, no adolescent having been studied, and the Foundation does not repeat it. The phrase blue light pollution in the title is the authors' characterization and is not used by this comment as a term of art.

Where it bears. Part V.C.2.h, in the enumeration of distinct reported mechanisms, and nowhere else. Part V.J.4, as one of the studies whose reported exposure cannot be placed against a numerical limit.

C.69 Song and others (2022) — the mechanism the 2019 study lacked, and an age dependence

The governing limitation, stated first and in the same terms as Appendix C.50. The subject is the fruit fly. The evolutionary distance, the compound eye, the open circulatory system and above all the size and translucency of the body mean that light reaches internal tissue in this animal by a route that has no counterpart in a human. The exposure was also continuous rather than cyclic: constant blue light for days, a condition no person encounters. Nothing in this entry is offered as evidence of an effect in humans, and the Foundation does not advance it as such.

Published in partnership with the Japanese Society of Anti-Aging Medicine.

Exposure conditions, which are among the best specified in this appendix. Constant blue light with a peak emission of 460 nanometers, produced by a commercial 165 watt dimmable aquarium light-emitting diode fixture, at a photon flux density of 20 to 30 micromoles per square meter per second, corresponding to an irradiance of approximately 0.4 milliwatts per square centimeter, measured at the level of the horizontally placed vials holding the animals, 25 per vial. The control arm is what distinguishes this study: rather than darkness alone, the authors also exposed animals to white light-emitting diodes behind a yellow long-pass filter, giving a peak emission of 584 nanometers at the same irradiance of approximately 0.4 milliwatts per square centimeter. The comparison is therefore matched on irradiance and differs only in spectrum. Lifespan was measured on at least 50 animals per genotype and condition, held in groups of 25, with mortality recorded and fresh diet provided every two to three days.

Design, and the feature that makes it relevant to this comment. Animals were held in constant darkness and then transferred to constant blue light at 2, 20, 40 or 60 days of age. The mechanistic work was conducted entirely in eya2 mutants, which lack compound eyes altogether, the authors stating that their aim was to understand effects on extra-retinal cells. The question the design answers is therefore not whether blue light damages a retina but whether it damages an organism that has none.

Results. Survival under blue light was reduced in proportion to the age at which the animals were transferred to it, in both wild-type and eyeless strains. Young animals of both strains

survived in blue light two to three times longer than old ones. Ten days of blue light followed by return to darkness reduced lifespan by approximately 6 percent in young animals and by a further 15 percent against the dark control in middle-aged animals. Brain vacuolization, the measure of neuronal loss, was minimal in young animals with no significant difference between light conditions, and increased in the aged animals. Light with the blue wavelengths removed, at matched irradiance, produced survival not significantly different from constant darkness.

The mechanism, which is what this study adds to Appendix C.50. Blue light significantly reduced the activity of mitochondrial Complex II and the biochemical activity of succinate dehydrogenase, in both young and old animals, with the reduction more pronounced in isolated heads than in whole animals. Complex IV activity and adenosine triphosphate content were reduced by age rather than by light. Respiration through Complex III was affected by neither. The authors therefore propose that light-induced damage to Complex II compounds an age-related decline in energy metabolism that proceeds even in darkness, which accounts for the age dependence. For the molecular route they offer a hypothesis and label it as one: succinate dehydrogenase requires a flavin adenine dinucleotide cofactor derived from riboflavin, riboflavin is maximally activated at 450 nanometers and can be degraded by blue light into inactive photoproducts, and they speculate that blue light impairs the enzyme by affecting its flavination status. They note that another flavin-dependent dehydrogenase was unaffected, which cuts against the hypothesis, and they say so.

What it establishes. That in an animal with no eyes, constant blue light at 460 nanometers and approximately 0.4 milliwatts per square centimeter shortens life and increases neuronal loss; that light of the same irradiance with the blue removed does not, so the effect follows the spectrum and not the energy; that susceptibility increases markedly with age; and that a specific enzyme of mitochondrial respiration is inhibited. It supplies the candidate mechanism that Appendix C.50 recorded as unidentified, and it is a fifth distinct injury route alongside those at Appendices C.61, C.65, C.66 and C.68.

What it does not establish. Anything about humans, and the Foundation repeats that it does not advance it for any such purpose. Anything about any product: the exposure is near-monochromatic blue at an irradiance well above the blue content of ordinary ambient lighting, delivered continuously, from an aquarium fixture. It sets no threshold and identifies no safe level. The flavination hypothesis is explicitly speculative and the authors report a result against it. The age dependence is an age dependence in an animal whose maximum lifespan is measured in weeks.

Why the Foundation nonetheless relies on it, and for what. For one proposition, at Part V.C.2.h and Part V.C.1.g: that the photobiological framework assesses a photochemical lesion in the outer retina, and that effects of the same waveband on tissues the framework does not address are reported in the peer-reviewed literature and have an identified cellular target. An eyeless animal cannot sustain a retinal lesion. Whatever happened to these animals is outside the scope of every exposure limit described in Part V.C.2, not because the limits are set too high but because they measure something else. The Foundation also relies on the matched-irradiance control, which is the design feature that distinguishes a spectral effect from a thermal or energetic one, and which Part V.J.4 identifies as absent from much of this literature.

Disclosures and data. Partially supported by the National Institute on Aging of the National Institutes of Health under awards R56 AG062621, R01 AG061406 and RF1AG069334. The authors declare no competing interests. All data are stated to be included in the article and its supplementary information, with additional material available from the corresponding author. Three authors – Law, Kretzschmar and Giebultowicz – are shared with Appendix C.50, which bears on the concentration question recorded for Part V.A.1.

C.70 Jun and others (2020) — the spectral distribution as the governing variable, within one technology and across two

Funding, stated first because it bears on the use made of this study. Supported by the Basic Science Research Program (NRF-2019R1F1A1063311) and the Korea Mouse Phenotyping Project (2013M3A9D5072551) of the Ministry of Science and ICT through the National Research Foundation of Korea, and by LG Display Co., Ltd., of Seoul. LG Display manufactures organic light-emitting diode panels, and the organic panel used as a test article in the study was an LG Display product, model LL056RS1-54P1. The authors state that the funding sources had no role in the design or conduct of the study or in the decision to publish, and separately declare no competing interests. The Foundation records the declaration and the funding together and leaves the reader to weigh them. The consequence for this comment is stated below: the study's recommendation is not adopted, and the finding relied on is one that is adverse to the labeling of both technologies rather than favorable to either.

Citation. Jun I, Han SJ, Shin HS, Kim J, Kim EK, Kim TI, Yoon SC, Seo KY. "Comparison of ophthalmic toxicity of light-emitting diode and organic light-emitting diode light sources." Scientific Reports 2020;10(1):11582. doi:10.1038/s41598-020-68565-3. PMID 32665663; PMCID PMC7360575. Received September 6, 2018; accepted June 23, 2020. Open access under the Creative Commons Attribution license; full text read. Department of Ophthalmology, The Institute of Vision Research, Yonsei University College of Medicine, Seoul. The title is reproduced verbatim and contains a word this comment otherwise avoids.

Light sources, which are the point of the study. Three lamps, each identified by manufacturer and model. A white light-emitting diode, RFsemi Technologies PBA-0422-04, at 5,700 kelvin. A warmer light-emitting diode, the same RFsemi part number, at 4,000 kelvin, included by the authors for the stated purpose of matching the correlated color temperature of the organic panel. And an organic light-emitting diode panel, LG Display LL056RS1-54P1, at 4,000 kelvin. Spectral power distributions for all three are given in the paper's Supplementary Figure S5, which the Foundation has not obtained.

Exposure conditions. Cells were exposed to 10,000 lux for 45 minutes at room temperature. Animals were exposed to 1,000 lux of the white light-emitting diode or the organic panel for twelve hours a day for eight weeks, lights on at 8 a.m., which the authors describe as simulating the brightness of typical indoor illumination. A further set of animals was exposed at 2,000 lux to clarify the difference between the two sources. Illuminance was monitored and maintained throughout and ambient temperature held at 24 plus or minus 2 degrees Celsius. Exposures were therefore matched on illuminance, which is a photopically weighted quantity, and not on irradiance or on blue content.

Materials. Four human cell lines: an SV40-immortalized corneal epithelial line, the Chang conjunctival line, ARPE-19 retinal pigment epithelial cells and HLE-B3 lens epithelial cells. Animals: eight-week-old female BALB/c mice, which are albino. Approved by the Committee on Animal Research at Yonsei Medical Center under the institution's guidelines, the AAALAC standards and the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research.

The comparison that identifies the variable, and it is not the comparison in the title. The white lamp at 5,700 kelvin and the warmer lamp at 4,000 kelvin were the same manufacturer's same part number, RFsemi PBA-0422-04, differing in correlated color temperature. In conjunctival epithelial cells, reactive oxygen species rose to approximately eighteen and eleven times the unexposed level respectively, both significant. The emitting technology, the manufacturer and the product line were therefore held constant while the spectral distribution varied, and the response varied with it. That comparison, which the paper's title does not advertise, is the one the Foundation relies on at Part V.B.3, because it

establishes that the governing variable is the spectrum rather than the product type. The comparison across the two technologies at matched correlated color temperature, described in the next field, establishes the complementary half: that the descriptor fails across technologies as well.

The finding the Foundation relies on, and it is a finding about a descriptor. At a matched correlated color temperature of 4,000 kelvin, the light-emitting diode lamp and the organic panel produced different biological responses. In conjunctival epithelial cells, reactive oxygen species rose approximately elevenfold above unexposed levels under the light-emitting diode at 4,000 kelvin, while the organic panel at the same correlated color temperature produced no statistically significant increase. Interleukin-8 expression showed the same pattern: significantly raised by the white light-emitting diode, and not significantly different from unexposed for either the correlated-color-temperature-matched light-emitting diode or the organic panel in conjunctival cells. Reactive oxygen species production was significantly higher under the white light-emitting diode than under the organic panel in all four cell lines. The authors attribute the difference to peak structure: a phosphor-converted light-emitting diode generates white from two spectral peaks and an organic panel from three, so reaching a given correlated color temperature with two peaks requires proportionally more energy in the blue. That explanation is a statement about how the technologies work and is checkable independently of the study's conclusion.

The animal results, and the problem with them. At 1,000 lux, photoreceptor layer thickness was significantly reduced in both light-exposed groups against the dark control, and significantly greater in the organic panel group than in the light-emitting diode group. The electroretinogram was significantly reduced in both light groups against control in the scotopic a-wave, scotopic b-wave and photopic b-wave, but there was no statistically significant difference between the two light sources at this illuminance. The authors then doubled the illuminance to 2,000 lux to obtain a difference, and at that level the photoreceptor layer measured 45.33 plus or minus 2.07 micrometers in controls, 8.40 plus or minus 9.31 under the light-emitting diode and 18.89 plus or minus 4.31 under the organic panel. The Foundation draws attention to the second of those figures. The reported dispersion exceeds the reported mean, which indicates that some animals retained almost no photoreceptor layer at all and that the group was severely and unevenly damaged. A comparison whose more affected arm has a standard error larger than its mean will not bear weight, and the Foundation places none on it. The cautious reading of the animal data is the 1,000 lux result: a structural difference between the two sources without a corresponding functional one.

Two further results worth recording. First, the ocular surface. 4-hydroxynonenal, a marker of lipid peroxidation, was most intense in the light-emitting diode group, less in the organic panel group and barely detectable in controls, while gross morphology and histology of the ocular surface showed no abnormality in either light group. An inflammatory and oxidative response at the ocular surface, below the threshold of anything visible on examination, is a target the hazard framework described at Part V.C.2 does not address for this waveband. Second, an unexpected finding the authors report and cannot explain: the epidermal thickness of the eyelid was greater in both light-exposed groups than in controls. They compare it to the epidermal thickening produced by repeated ultraviolet exposure, note that no such effect has been reported for light-emitting diodes, and call for further investigation.

What it does not establish. Nothing about humans; the animals are albino mice, which lack a macula and have a rod-dominated retina. Nothing about ordinary domestic exposure: 1,000 lux is brighter than a typical home interior, it was delivered for twelve hours a day for eight weeks to caged animals with no means of avoidance, and the cell exposures were at 10,000 lux. No threshold and no safe level. And the Foundation expressly does not

adopt the authors' recommendation that a change from light-emitting diode to organic light-emitting diode lighting may be warranted. That recommendation favors the product of a funder of the study, the Foundation takes no position on any commercial technology, and the proposition it relies on here does not depend on the recommendation being right.

Two matters it sharpens elsewhere in this comment. First, the albino question. These authors state that pigmented animals are more resistant to light damage than albino animals, and give that as a reason their findings may overstate the effect in pigmented animals and in humans. The authors at Appendix C.63 take the contrary position, defending their use of albino animals on the authority of published action spectra reported to show albino and pigmented rodents equally sensitive. Those positions cannot both be right, and both trace to the same body of work. The acquisition of van Norren and Gorgels is already the highest-priority verification item in this comment for the retinal dose figures at Part V.C.2.f; it is now load-bearing for this disagreement as well. Second, the electroretinogram. This is the third independent group in Appendix C to report attenuation of the electroretinogram after blue or blue-enriched light exposure, the others being at Appendix C.66 and the study reported at second hand at Appendix C.67. Three groups converging on one functional endpoint is worth stating at Part V.C.1 once the underlying paper behind the third is obtained.

Where it bears. Part V.B.3, as the biological demonstration that correlated color temperature does not determine blue content, which is the subsection's central proposition and underwrites the request at Part IX.C for spectral power distributions rather than correlated color temperature. Part V.J.4, in the audit of reported exposures. Part V.C.2.h and Part V.C.1.g, for the ocular surface findings, which concern tissues the framework does not address for this waveband.

C.71 Zhao and Shen (2020) — the retinal ganglion cell, the compromised eye, and a quantified concentration of the literature

Article type and version. A review. The authors state that twenty-six related articles were included after a database search, and the body of the paper describes twelve in vitro studies in its Table 1 and sixteen animal studies in its Table 2, which total twenty-eight; the discrepancy is unexplained and is recorded here rather than resolved. No search strategy, date range, keyword list or appraisal instrument is stated, so it is a narrative review and is cited in the category described at Part V.A.2, as evidence of the state of expert opinion and not as primary evidence of any effect. The Foundation read the copy served by PubMed Central. An open-access location search characterizes that deposit as the author's submitted version rather than the version of record, and the lesson of Appendix C.1 is that the two can differ materially, so the published version must be checked before any figure here is relied on.

PMID 32107750; PMCID PMC11448955. Published online February 27, 2020. Department of Ophthalmology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou. Cite the publisher's version.

Why it is new to this comment. Every mechanistic entry in this appendix concerns the photoreceptors, the retinal pigment epithelium or, at Appendix C.66, the retinal vasculature. This review concerns the retinal ganglion cell, whose axons constitute the optic nerve and whose loss is irreversible. It is therefore a fourth retinal target. It also joins two bodies of literature this comment has kept separate, because the melanopsin-containing cells that mediate the non-image-forming responses discussed at Part V.F are themselves retinal ganglion cells.

The three mechanisms it identifies. First, direct action on ganglion cell mitochondria and on DNA, raising reactive oxygen species and producing caspase-dependent or caspase-

independent cell death. Second, mediation through gliotransmitters or the receptors of retinal glial cells; the review reports that astrocytes contain chromophores capable of absorbing components of the visible spectrum, and that Mueller cells and microglia are activated after light exposure. Third, a secondary consequence of photoreceptor and pigment epithelial degeneration with subsequent retinal remodeling. The review places the first two early and the third late. The mitochondrial route connects to Appendix C.69, where inhibition of a specific mitochondrial complex was measured, and the glial route connects to the study reported at second hand at Appendix C.67, whose proposed mechanism for a reduced electroretinogram b-wave was a change in Mueller cell conductance.

The statement the Foundation relies on, and it concerns susceptible populations. The review states that ganglion cell mitochondrial photosensitizers in a homeostatic state can counteract the effect of light, but that where that homeostatic state is compromised – the review names glaucoma, diabetic retinopathy, the aged retina and the genetic defect of Leber's hereditary optic neuropathy – then, in the authors' words, normal or even less than normal intensity of light may become one type of insult to these cells. The Foundation draws attention to the phrase. It is a statement from within the field that for an identified set of conditions the ordinary ambient level is not known to be safe. It corroborates the sensitive-population material at Part V.C.2.c and the observation of the predecessor European committee, recorded at Part V.K.9, that a low risk group classification should not be taken to imply adequate protection of the general population as a whole. The review adds that intraocular lens implantation or aphakia removes the filtering of the aged lens, which bears on the aphakic action spectrum discussed at Part V.C.2.c.

A second statement, on premature infants. The review reports a study in which neonatal mice had one eyelid incised to permit light exposure before the eyelids would naturally open, and in which the ganglion cells of the light-exposed retinas suffered considerable loss. The reviewers draw the inference that a relatively dark environment may be more beneficial for the development of the visual system in premature infants. The Foundation records it as a lead bearing on lighting in neonatal care settings, which Part VI.E addresses, and not as a finding about any human infant.

What it reports about exposure, which bears on Part V.J.4. The review characterizes the exposures of the studies it summarizes in illuminance only. Cell studies used 250 to 4,000 lux for durations from 3.5 minutes to five days, most longer than 24 hours. Animal studies used 500 to 20,000 lux for 1 to 48 hours, most under 12 hours. No irradiance, no radiance and no spectral power distribution appears anywhere in the paper. Two further statements by the reviewers are more useful to this comment than the ranges. The first is that different groups, and the same group in different experiments, used diverse conditions differing in spectrum, intensity and duration – which is the third independent statement of the standardization problem recorded at Part V.J.4, the others being at Appendix C.67 and in the systematic review discussed in that subsection. The second is that the light levels used in animal models are, in the reviewers' assessment, relatively excessive compared with what reaches the retina in everyday situations. That is the Foundation's own criticism of this literature, stated from within it, and the Foundation adopts it as such rather than treating these studies as descriptions of ordinary exposure.

A methodological detail with consequences for every stated illuminance. The review records that in the majority of the studies the animals' pupils were dilated with atropine or tropicamide in order to admit more light. A stated illuminance therefore understates the retinal dose delivered in those experiments by an amount that depends on the pupil area achieved and is not reported. This belongs in the Part V.J.4 treatment of what reported exposures do and do not permit, and it is an additional reason that an illuminance figure from this literature cannot be placed against an exposure limit.

The concentration of the literature, quantified. The review reports that among its sixteen animal studies at least nine come from a single group, and that among its twelve in vitro studies nine are from the team of one investigator. The Foundation has recorded in several entries that the literature in this field is concentrated in a small number of groups; this is the first quantified instance, and it is stated by reviewers with no interest in making the point. Part V.A.1 is the place for it.

What it does not establish, and two findings adverse to the Foundation. It is secondary throughout and establishes nothing about humans, about any product, or about any exposure level. Two statements in it run against the Foundation and are recorded for that reason. The first is the review's own premise, stated twice: that normal daily levels of light are believed to have no harmful effect on eyes in healthy conditions. The Foundation does not dispute it and notes that the entire force of the review lies in the qualification rather than the premise. The second is a reported beneficial effect: the review describes a study in which blue light pulsed at 5 and 20 hertz for one hour enhanced neurite outgrowth in postnatal retinas, acting through ganglion cells including the melanopsin-containing subset, without significantly increasing cell death. That effect was obtained in a preparation expressing an engineered light-sensitive channel, which limits what it shows about ordinary light, but it is a reported benefit of pulsed blue light and the comment should not omit it. The review also notes reported benefits of red light, consistent with Appendix C.63.

Disclosures. Funding is stated as provided by the National Health and Family Planning Commission of China (WKJ-ZJ-1820) and the Department of Science and Technology of Zhejiang Province (2018C03017). The Foundation located no competing-interests declaration in the copy it read, and records that as an absence rather than as a declaration of none. Indexing metadata attributes one of the two grants to a differently named provincial department, and the article text is preferred.

Where it bears. Part V.C.2.c and Part V.K.9, for the susceptible-population statement, which is its principal value. Part V.J.4, for the exposure characterization, the standardization problem and the pupil dilation point. Part V.A.1, for the quantified concentration of the literature. Part V.F, for the ganglion cell as the shared substrate of injury and of the non-image-forming responses. Part VI.E, for the neonatal lead.

C.72 Tao, Zhou and Zhu (2019) — the mitochondrial target named, and a confound in the cell-culture literature

Article type. A review. No search strategy, date range, inclusion criteria or appraisal instrument is stated in the text the Foundation read, so it is a narrative review and is cited in the category described at Part V.A.2, as evidence of the state of expert opinion and for the framework it supplies, not as primary evidence of any effect. Every figure in it is reported at one remove.

Citation. Tao J-X, Zhou W-C, Zhu X-G. "Mitochondria as Potential Targets and Initiators of the Blue Light Hazard to the Retina." Oxidative Medicine and Cellular Longevity 2019;2019:6435364. doi:10.1155/2019/6435364. PMID 31531186; PMCID PMC6721470. Published August 21, 2019. Open access under the Creative Commons Attribution license; full text read. Department of Neurosurgery, The Second Affiliated Hospital of Nanchang University, Nanchang. Tao and Zhou are stated to have contributed equally.

Provenance, disclosed because an agency reader may raise it. The journal was published by Hindawi when this article appeared and is now published by Wiley. Hindawi's portfolio, this journal included, was the subject of large-scale retractions in 2022 and 2023 arising from compromised special issues and organized submission of fabricated manuscripts, an episode widely reported in the research-integrity press. The Foundation records three things against that background. This article carries no retraction, correction or expression of concern. The National Library of Medicine catalog

records the journal as currently indexed for MEDLINE, with no ceased date. And a journal-level integrity episode is not evidence about a particular paper: this review is cited as reference 11 of the study at Appendix C.69, published in a Nature Portfolio journal three years later, which is some indication of its standing in the field. The Foundation raises the point so that the Department does not have to.

The identification the Foundation relies on, which is the principal value of the entry. The review names the mitochondrial chromophore and gives its absorption. Complex IV of the electron transport chain, also called cytochrome oxidase or cytochrome c oxidase, contains heme centers and has an absorption peak at approximately 420 nanometers in the oxidized form and approximately 440 nanometers in the reduced form. That is the same enzyme on which the deep red and near-infrared literature discussed at Part V.B.6 rests, and the coincidence of a blue absorption band and a long-wavelength one in a single enzyme is what connects the two halves of Part V.B. The review further reports that cytochrome oxidase expression in the rat retina was irreversibly inhibited by blue light at 404 nanometers; that a study testing the four respiratory complexes separately concluded at least two of the four are implicated in blue-light injury; that one group attributes adenosine triphosphate depletion to direct action on respiration and oxidative stress to indirect action; and that the injury was attenuated in fibroblasts whose respiratory chain function had been deliberately perturbed, which is the control that most directly implicates the chain itself.

The finding about visible change, which bears on what a limit measures. The review reports that cytochrome oxidase activity was significantly altered in different layers of the rat retina over time while no visible retinal morphological change was observed by ophthalmoscopy or by light microscopy. The Foundation relies on that sentence at Part V.B.6 and Part V.C.1.g. A measurable change in a respiratory enzyme with no lesion detectable on examination is the class of effect that a limit calibrated to threshold lesion formation is not constructed to detect.

The three injury mechanisms, which the comment adopts as a framework. The review states that at least three mechanisms operate between 400 and 1,400 nanometers. Photomechanical damage is produced by very high irradiance, of the order of megawatts to terawatts per square centimeter, over picoseconds to nanoseconds, and is, in the review's words, not determined by the wavelength of light; the energy is absorbed by melanin granules in the pigment epithelium and produces lethal microcavitation bubbles, a mechanism used deliberately in yttrium-aluminum-garnet laser iridotomy and capsulotomy. Photothermal damage is also governed by irradiance thresholds and requires microseconds to a few seconds to reach thermal equilibrium. Photochemical damage is the wavelength-dependent mechanism. Part V.B uses that division, because two of the three turn on delivered irradiance rather than on wavelength, which is the spatial characteristic, and all three turn on duration.

A confound in the cell-culture literature, reported against the Foundation's own evidence. The review warns that culture media themselves contain photosensitizers and that researchers should attend to medium-mediated effects. It reports that neurite outgrowth from retinal explants was inhibited when the medium was irradiated, and that unirradiated mammalian cells died when incubated in medium that had previously been irradiated near 365 nanometers, an effect attributed to riboflavin together with tryptophan or tyrosine present in the medium. The Foundation states the consequence plainly because it runs against several of its own entries. Appendices C.61, C.65, C.66, C.68 and C.70 all report effects in cultured cells in media of this kind. To the extent that irradiated medium generates injurious photoproducts, some part of what those studies attribute to light acting on cells may be light acting on the medium. None of them reports a medium-only irradiated control. That is a real limitation of the in vitro literature, it is identified from within the field, and the comment records it rather than waiting for the agency to.

Two further items. First, the review states that more than 65 percent of blue light at 460 nanometers is transmitted to the retina in children younger than nine, which independently corroborates the figure the comment takes from the 2012 Opinion of the predecessor European committee at Part V.C.2.g and supplies a further route to the underlying measurement through its own reference 43. Second, the review records a subdivision of the waveband into blue-violet light of approximately 400 to 440 nanometers and blue-turquoise light of approximately 440 to 500 nanometers, which is worth noting because the two subranges do not have the same relationship to either the hazard weighting of Part V.C.2.a or the melanopic sensitivity of Part V.F.

What it does not establish, and one statement not adopted. No primary data, no threshold, no exposure limit, and nothing about any product. The Foundation also does not adopt the abstract's characterization of blue light as having strong penetration. The phrase appears once, in the abstract, and is not developed in the body. Short wavelengths penetrate biological tissue less than long ones, and the reason blue light reaches the retina is ocular transmittance rather than penetrating power; the review's own careful treatment of wavelength-resolved absorption by the cornea, aqueous humor and lens makes that clear. The comment uses the transmittance account and not the penetration phrase.

Disclosures. Supported by the National Natural Science Foundation of China (81760446 and 81660420), the Natural Science Foundation of Jiangxi Province (20171ACB20035), the Construction Plan of the Superior Science and Technology Innovation Team of Jiangxi Province (20152BCB24009) and the Foreign Science and Technology Cooperation Plan of Jiangxi Province (20151BDH80009). The authors declare no conflict of interest.

Where it bears. Part V.B.6, as the identification of the mitochondrial chromophore and the bridge between the blue-light and long-wavelength material. Part V.B, for the three injury mechanisms that substantiate the three-characteristic frame. Part V.C.1.g, for the alteration of enzyme activity without visible change. Part V.C.2.g, corroborating the pediatric transmittance figure. Part V.A.2 and Part V.J.4, for the culture-medium confound.

C.73 Zhao, Zhou, Tan and Li (2018) — a 2018 review scored against the record assembled since

Article type and quality of the text. A five-page review with no stated search strategy, inclusion criteria or appraisal instrument, cited in the category described at Part V.A.2 as evidence of the state of expert opinion and not as primary evidence of any effect. The Foundation records a presentational matter because it affects quotation. The English of the published text is unreliable: it uses "Blu-ray" throughout as a term for blue light, which is a disc format and not a waveband; it renders the lipofuscin fluorophore A2E by a garbled chemical name; it refers to the lens as the crystal and to the vitreous as the glass cavity; and in one passage it appears to write skin cells where retinal pigment epithelial cells are meant. Nothing should be quoted from this source without checking the sense against the cited original, and the Foundation has paraphrased rather than quoted it except where noted.

Citation. Zhao Z-C, Zhou Y, Tan G, Li J. "Research progress about the effect and prevention of blue light on eyes." International Journal of Ophthalmology 2018;11(12):1999–2003. doi:10.18240/ijo.2018.12.20. PMID 30588436; PMCID PMC6288536. Published December 18, 2018. Department of Ophthalmology, Xi'an No. 4 Hospital, Xi'an, Shaanxi. The lead author is not the Zhao of Appendix C.71, which is a different investigator at a different institution.

Why the Foundation treats this entry differently from the other reviews. It is cited for its date. The determination the comment examines at Part I.C.7 issued on May 24, 2024. This review appeared in December 2018, five and a half years earlier, in a journal indexed in the National Library of Medicine. It therefore bears on what the ordinary literature

contained before the determination, which is the question line (3) of that subsection raises. Because a 2018 review can be assessed against what followed, the Foundation has scored its claims rather than merely summarizing them, and reports the result in both directions.

Claims borne out by the literature assembled since. Five, in descending order of how specifically they were later confirmed.

The blood-retinal barrier as a target. The review reported blue-light retinal edema in two mouse models on imaging and optical coherence tomography, barrier impairment mediated by inflammatory factors including tumor necrosis factor and interleukin-1, and the speculation that some cell death is caused indirectly by exuded blood components rather than directly by light. Appendix C.66, published in 2023, identified a molecular route to barrier failure: cleavage of the endothelial tight junction protein claudin-5 by the metalloprotease ADAM17. The phenomenon was correctly identified in 2018. The mechanism proposed in 2018 was inflammatory and secondary to photoreceptor death; the mechanism since identified is direct and proteolytic and does not require photoreceptor death first. Right about the target, partly wrong about the route.

Mitochondria as the principal target. The review stated that mitochondria are the main targets of blue-light-associated oxygen free radicals. Appendix C.72 subsequently named the chromophore and its two absorption peaks, Appendix C.69 measured inhibition of a specific respiratory complex in an intact animal, and Appendix C.71 gives direct mitochondrial action as the first of three injury routes to the ganglion cell. Vindicated, and since measured rather than inferred.

The retinal ganglion cell as a distinct target, with mitochondrial injury and programmed necrosis as the mechanism. Appendix C.71, published two years later, is a review devoted to that subject. Vindicated.

The ocular surface. The review attributed reactive oxygen species production, inflammatory signaling and dry eye to blue light acting on corneal and conjunctival epithelium. Appendix C.70 reported reactive oxygen species and interleukin-8 in human corneal and conjunctival epithelial cells and a lipid peroxidation marker on the ocular surface in mice, with no change visible on examination. A different cytokine, the same tissue and the same oxidative mechanism. Vindicated.

The waveband. The review placed the most injurious region between 415 and 455 nanometers. The peak of the weighting function in the governing guidelines is 445 nanometers, inside that range. Right, and more accurate than an earlier draft of this comment, which gave the peak as 435 to 440 nanometers before the error was corrected.

Claims not borne out. Two, and the Foundation states them because a scoring exercise that reported only the hits would be worthless. The review asserted that blue light can accelerate the occurrence and development of age-related macular degeneration, and that oxidative stress in lens epithelial cells may lead to cataract. Neither proposition has been established in humans. The 2023 review of the human clinical literature at Appendix C.67 concludes that it is difficult to state with certainty that blue light exerts a harmful effect on the human retina at all, and the comment does not advance either the macular degeneration claim or the cataract claim. The review's chain from blue light through sleep disruption to raised corticosteroids, reduced androgens, meibomian gland dysfunction and evaporative dry eye is the weakest reasoning in the paper, every link being at one remove, and the Foundation does not adopt it.

One body of claims pointing the other way, and unresolved. The review devotes a section to refractive development and reports the opposite valence from the rest of the paper: that short-wave light inhibits axial elongation, that monochromatic blue light produced relative hyperopia in guinea pigs, that myopia could be reversed toward hyperopia after blue light exposure, and that the richness of daylight in short wavelengths

may be why outdoor activity protects against myopia. If those findings hold, blue light is protective for one of the most prevalent ocular conditions in the world. The Foundation records this as unresolved rather than scoring it, because the comment contains no myopia material and the state of that literature in 2026 has not been established by the Foundation. It is recorded because an agency reader may know it, and because a comment that cited this review while omitting its refractive section would be selectively quoting a source it had read in full.

The sentence the Foundation relies on. Writing in 2018, the authors observed that research indicating minimal risk from ordinary digital displays, with most displays falling within the applicable standard, was a conclusion about short-term exposure only, and that measures addressed to long-term exposure remained necessary. That is the gap identified at Part V.C.2.c, where the framework ceases to accumulate dose at ten thousand seconds, and at Part V.K, where the limits are shown to have been calculated for a maximum of one eight-hour day. Practising ophthalmologists stated it in an indexed journal in 2018. The Foundation uses it at Part I.C.7 for that reason and for no other.

A caution the review states that the Foundation endorses. The review states that it is unscientific to treat all blue light as directly injurious, and sets against the injury material the benefits of blue light for circadian regulation and, on its account, for refractive development. That caution, offered in 2018 against the prevailing direction of concern, is the most creditable judgment in the paper and is consistent with the position the Foundation takes at Part V.C.2.e. It also anticipates the wavelength-specific findings at Appendix C.63, where green content drove white-light injury and red content mitigated it.

Disclosures. Supported by the National Natural Science Foundation of China (81400424), the Science and Technology Research and Development Project of Shaanxi Province (2014K11-03-07-04), the Innovative Talents Promotion Project of Shaanxi Province (2017KJXX-87) and the Hunan Province Education Department Outstanding Youth Science Foundation (15B210). Conflicts of interest are declared individually for each of the four authors, each as none, which is a more explicit form of declaration than most entries in this appendix carry.

Where it bears. Part I.C.7, for what the indexed literature contained before the determination of May 24, 2024, which is its principal use. Part V.C.2.c and Part V.K, for the short-term-only observation. Nowhere as evidence of any effect.

C.74 Nakamura and others (2018) — eleven times the illuminance from a fluorescent source did less damage

What the Foundation has read. The article is closed access and the publisher does not serve it to automated retrieval. The Foundation has read the abstract together with the introduction, the conclusion, the opening of the discussion and the section extracts the publisher exposes, supplied by Mr. Baker. That text contains the exposure levels and the principal results. It does not contain the complete methods. The specific omissions are recorded in the note at the end of this entry and the entry must be completed when the full text is obtained.

Citation. Nakamura M, Yako T, Kuse Y, Inoue Y, Nishinaka A, Nakamura S, Shimazawa M, Hara H. “Exposure to excessive blue LED light damages retinal pigment epithelium and photoreceptors of pigmented mice.” Experimental Eye Research 2018;177:1–11. doi:10.1016/j.exer.2018.07.022. PMID 30040948. Published online July 21, 2018. Molecular Pharmacology, Department of Biofunctional Evaluation, Gifu Pharmaceutical University, Gifu, Japan. Cite the publisher’s version.

Exposure conditions, which are the reason for the entry. Blue light-emitting diode illumination at 1,100 lux, for one day or for three days. The comparison arm was white fluorescent illumination at 12,000 lux for a comparable duration. Animals were male

C57BL/6J mice, eight weeks of age, obtained from Japan SLC, housed on a twelve-hour light and twelve-hour dark schedule. C57BL/6J is a pigmented strain. Approved by the Institutional Animal Care and Use Committee of Gifu Pharmaceutical University under the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. The peak wavelength of the diode source is not stated in the text available to the Foundation, nor is the source distance, nor whether the stated illuminance was continuous or delivered within the light phase of the housing cycle.

The finding the Foundation relies on. Blue diode light at 1,100 lux damaged the retinal pigment epithelium and the photoreceptors of pigmented mice. White fluorescent light at 12,000 lux did not produce severe retinal damage in the same strain. A source delivering approximately one eleventh of the photometric quantity produced the injury that the brighter source did not. The paper sets this against three earlier results in pigmented animals under fluorescent light, which the Foundation reproduces at Part V.B.3: no retinal damage at 1,200 to 1,600 lux for 24 hours in pigmented mice; no severe damage at 10,000 lux on a twelve-hour cycle for six consecutive days in pigmented rats; and the paper's own negative result at 12,000 lux. The authors state that no light-induced retinal damage model for pigmented mice had previously been established, and that their own earlier work in albino animals had already found blue diode light damaging at a lower intensity than fluorescent light.

Results in detail. Outer nuclear layer thickness was significantly reduced six days after exposure to blue diode light for either one or three days, with changes more severe and longer lasting after three days. Fundus appearance and optical coherence tomography were altered on days one, three and six; by day six the fundus showed white spots, and on days three and six the retinal layers were significantly thinner on tomography. Histology showed material accumulated at the junction of the inner and outer segments of the photoreceptors, staining for the macrophage marker Iba-1 and positive on periodic acid-Schiff staining. The area of the retinal pigment epithelium was enlarged immediately after exposure, particularly around the optic nerve, and photoreceptor degeneration followed as a secondary event. The authors describe the accumulated material as pseudodrusen-like and the changes as resembling those in eyes with non-exudative age-related macular degeneration.

A criticism of the field made by these authors, which the Foundation adopts. Reviewing the earlier literature, the authors describe a 2013 study that exposed mice to 7,000 lux of white fluorescent light for fifty hours and state that the exposure time may have been too long and the intensity too high for meaningful interpretation. That is the fourth independent statement in this appendix, from within the field, that the exposures used in this literature are too severe to support inference about ordinary conditions; the others are at Appendices C.63, C.67 and C.71. The Foundation notes that the criticism applies with some force to this study as well, whose own title describes its exposure as excessive.

What it does not establish, and the Foundation is emphatic about this one. It does not establish that light-emitting diode products cause age-related macular degeneration in humans, and the Foundation does not advance it for that purpose. Material described as pseudodrusen-like in a mouse is evidence that an exposure can produce a morphology resembling a human disease in an animal, and the authors' stated conclusion is that the model is useful for studying mechanisms, which is a statement about a research tool. The comment scores the contrary claim as unvindicated at Appendix C.73 and records at Appendix C.67 that the human clinical literature does not support it. Nothing here changes either assessment. Nor does the study establish a threshold: 1,100 lux of near-monochromatic blue light sustained for a day or more is far above the blue content of ordinary domestic illumination, and the comparison establishes a relationship between two sources rather than a safe level for either.

The narrower uses the Foundation makes of it. Four. First and principally, at Part V.B.3: that the photometric quantity in which lighting is specified and procured did not predict the outcome of this comparison and predicted it backwards, which is a demonstration of the defect that subsection identifies. Second, that the injury occurred in a pigmented animal, which answers the objection that this literature is an artifact of albino susceptibility and bears on the unresolved disagreement between Appendices C.63 and C.70. Third, that the retinal pigment epithelium was the primary target and photoreceptor loss secondary, consistent with the third injury route at Appendix C.71. Fourth, at Part V.C.1.a, that blue diode light is used by investigators as a method for producing retinal degeneration, this being the clearest instance because the phenotype resembles a named human condition.

Shared authorship, recorded for Part V.A.1. The last author and the departmental affiliation are shared with Appendix C.65: Molecular Pharmacology, Department of Biofunctional Evaluation at Gifu Pharmaceutical University appears in both, and Hara is an author of both. The two entries are not independent observations from separate groups. This is the third instance of author concentration identified in this appendix, with the laboratory shared between Appendices C.50 and C.69 and the figures reported within Appendix C.71.

Where it bears. Part V.B.3, as the second and stronger biological demonstration that illuminance does not determine the hazard. Part V.B, in the spectral leg of the three-characteristic frame. Part V.C.1.a, as a damage model. Part V.C.2.f, Appendix C.63 and Appendix C.70, on pigmented and albino animals. Part V.J.4, in the column of studies whose exposure cannot be placed against a numerical limit, the wavelength being unreported, with the qualification that the internal comparison between the two arms remains valid because both were measured in the same unit. Part V.A.1, for the shared authorship.

C.75 Jaadane and others (2017) — damage below the threshold the exposure limit was derived from, in the unit the limit is written in

Citation. Jaadane I, Villalpando Rodriguez GE, Boulenguez P, Chahory S, Carré S, Savoldelli M, Jonet L, Behar-Cohen F, Martinsons C, Torriglia A. "Effects of white light-emitting diode (LED) exposure on retinal pigment epithelium in vivo." Journal of Cellular and Molecular Medicine 2017;21(12):3453–3466. doi:10.1111/jcmm.13255. PMID 28661040; PMCID PMC5706508. Published online June 29, 2017. Open access; full text read. A correction was added on July 12, 2017 after first online publication, the author affiliations having been labeled incorrectly. Centre de Recherche des Cordeliers and Inserm; Ecole Nationale Vétérinaire d'Alfort; and the lighting and electromagnetism division of the Centre Scientifique et Technique du Bâtiment.

Why this entry matters more than most. Three reasons. The exposure was a commercially available warm white lamp of a named retail model, which the authors describe as widely used in residential lighting, rather than a monochromatic laboratory source. The exposure is reported as a retinal radiant exposure dose in joules per square centimeter, which is the unit in which the blue light hazard exposure limit is expressed, so the study can be placed directly against the limit; so far as the Foundation has found, no other entry in this appendix can. And the doses were, by the authors' express design, fixed below the damage threshold from which the exposure limit values were calculated.

Exposure conditions. A device built and characterized by the Centre Scientifique et Technique du Bâtiment containing ten Xanlite Evolution 5 watt white light-emitting diode lamps, fitted with a diffuser to improve uniformity and to suppress point-source effects. Resulting luminance 2,680 candelas per square meter and radiance 8.33 watts per square meter per steradian. Retinal radiant exposure dose computed with software developed by that laboratory, accounting for the cage, following the methods of Sliney and of van Norren and

taking the spectral transmittance of the rat ocular media into account. Posture coefficient 0.5, pupil diameter 5 millimeters, focal length 5.25 millimeters. Animals were male Wistar rats, albino, purchased at six weeks and described in the figure legend as seven weeks at exposure, four per condition, exposed to constant light for 4.75, 6, 12, 18 and 24 hours, giving computed retinal doses of 4.14, 5.23, 10.5, 15.7 and 20.9 joules per square centimeter. Pupils were neither dilated nor dark-adapted, the authors stating that this was to avoid introducing procedures that sensitize to photodamage. A fluorescent comparison arm used the same age and strain at 2,000 lux for 6 hours 25 minutes from bulbs 20 centimeters above the cages, which the authors compute as the same retinal dose of 4.14 joules per square centimeter.

The regulatory figures it reports, which corroborate Part V.C.2.f. The authors state that exposure limit values were calculated on the basis of a factor of ten to one hundred fold below the values that induce macroscopically observable retinal lesions; that for the retinal blue light hazard the limits were derived from a basic restriction of 2.2 joules per square centimeter of retinal exposure dose; and that this represents one fifth of the calculated damaging dose evaluated at 11 joules per square centimeter. Those are the same 2.2 and 11 figures the comment states at Part V.C.2.f from a different source, independently corroborated here. The Foundation notes one tension the authors do not address: the general margin they describe is a factor of ten to one hundred, while the specific blue light figures they give stand in a ratio of five.

Results. At 4.14 joules per square centimeter, after 4.75 hours, the actin cytoskeleton of the pigment epithelium was disorganized and protein kinase C zeta had translocated to the plasma membrane. At 5.23, after 6 hours, tight junctions were disrupted with changes in cell morphology and the appearance of stress fibers. At 10.5, after 12 hours, syncytia appeared. At 15.7, after 18 hours, actin became sparse with cytoplasmic aggregates, some cells losing the cytoskeleton almost entirely and showing vacuoles, and protein kinase C zeta had translocated to the nucleus following cleavage, which the authors treat as a death signal. Serum albumin leaked into the interphotoreceptor space and the leakage increased with exposure time, which is the direct evidence of outer blood-retinal barrier failure. Oxidative stress was inferred from cellular responses rather than measured directly, the authors stating that labeling oxidation of proteins and lipids in the pigment epithelium proved difficult. Basal autophagy was disturbed. Cell death was necrotic: staining for apoptosis was negative. The authors also report early formation of polynucleated cells and increased cell size, both features they associate with ageing of the pigment epithelium. An intravitreal protein kinase C zeta inhibitor was used as an interruption experiment.

The sub-limit figure, and the three qualifications the Foundation attaches to it. In the discussion the authors take the lowest damaging dose, 4.14 joules per square centimeter in total, observe that the blue part of the spectrum accounts for 14 percent of it, and give the blue retinal dose as 0.58 joules per square centimeter, which they describe as far below the 2.2 figure presumed completely safe. That is roughly one quarter of the limit. The Foundation relies on it subject to three qualifications, set out at Part V.C.2.f and summarized here: the 0.58 figure is a flat band fraction rather than a dose weighted by the hazard function the limit uses; the computed retinal dose rests on an assumed pupil diameter of 5 millimeters where the authors' own cited sources give values between 0.4 and 1.2 millimeters, an assumption that could overstate the delivered dose by a factor of seventeen to one hundred, erring in the direction that favors the finding but leaving the absolute values uncertain; and the dose was delivered over 17,100 seconds at the shortest, against a limit constructed for no more than 10,000 seconds.

An internal inconsistency, recorded. The discussion states that the dose of 4.14 joules per square centimeter was delivered not in 10,000 seconds but in 64,800 seconds. Sixty-four thousand eight hundred seconds is eighteen hours, which the figure legend assigns to a dose of 15.7 joules per square centimeter; 4.14 is assigned to 4.75 hours, or 17,100 seconds,

and the fluorescent arm delivering the same dose ran 6 hours 25 minutes, or 23,100 seconds. The pairing in that sentence therefore does not match the rest of the paper. The point the sentence makes survives the error, because every exposure in the study exceeded 10,000 seconds, by factors between 1.7 and 8.6. But the specific number should not be quoted until it is resolved.

What it does not establish. Nothing about humans. The animals were albino rats, and the comment records at Appendix C.63 and C.70 that whether albino rodents are more susceptible than pigmented ones is disputed. Four animals per condition. Nothing about age-related macular degeneration in people, notwithstanding that the pigment epithelial changes reported resemble features of that disease; the comment's position on that is at Appendix C.67, C.73 and C.74. And the exposures, though below the lesion threshold, were continuous illumination for between five and twenty-four hours, which is not a domestic exposure pattern.

Author overlap, which is substantial and belongs at Part V.A.1. This study shares Behar-Cohen, Martinsons and Torriglia with Appendix C.63, the 2024 threshold re-measurement. Behar-Cohen sat on the working group of the 2012 Opinion of the predecessor European committee recorded at Appendix D.1 and is an author of Appendix C.59. Martinsons is the author of the chapter at Appendix D.5, is an author of Appendix C.59, and his laboratory built the exposure apparatus both for this study and for the 2024 study. Torriglia held the French agency contract behind the 2024 study. The Foundation states this as a fact about the size of the field and not as a criticism of anyone: the same small group has produced the measurements, built the measuring apparatus and contributed to the expert assessments. That is a reason to weight the two studies as one sustained line of investigation rather than as independent confirmations, and it is also a reason the Department should fund work by groups outside it, which is a request Part IX.C can carry.

Funding and disclosures. Supported by Inserm, the Ecole Nationale Vétérinaire d'Alfort, the Centre Scientifique et Technique du Bâtiment, and a grant from the French environment and energy agency ADEME under the RETINALED and UV-LED projects; the first author held an ADEME fellowship. The Foundation records that the building science laboratory was both a funder of the study and the employer of the three authors who, by the stated contributions, designed, measured and mounted the lighting devices. The authors declare no conflict of interest, in a sentence whose wording is garbled in the published text.

Where it bears. Part V.C.2.f, as the identified instance behind the 2024 intergovernmental review's statement that independent teams have found retinal damage well below the exposure limit, and as the only entry whose exposure is reported in the unit of the limit. Part V.C.2.c, on the ten thousand second ceiling. Part V.C.1.g and Part V.C.2.h, as the outer blood-retinal barrier counterpart to the inner barrier study at Appendix C.66. Part V.J.4, in the audit of reported exposures. Part V.A.1, for the author overlap.

C.76 Shang, Wang, Sliney, Yang and Lee (2017) — three wavelengths at matched irradiance, and an author of the exposure limits among the authors

Citation. Shang Y-M, Wang G-S, Sliney DH, Yang C-H, Lee L-L. "Light-emitting-diode induced retinal damage and its wavelength dependency in vivo." International Journal of Ophthalmology 2017;10(2):191–202. doi:10.18240/ijo.2017.02.03. PMID 28251076; PMCID PMC5313540. Published February 18, 2017. Full text read. Institute of Environmental Health, National Taiwan University, Taipei. The journal is the same as that of Appendix C.73.

Why this entry carries unusual weight: the authorship. The third author is David H. Sliney, who is listed by the International Commission on Non-Ionizing Radiation Protection as a member of its Scientific Expert Group. The methods by which retinal radiant exposure dose is computed in Appendix C.75 are attributed in that paper to Sliney

and to van Norren. His stated contribution to this study is that he revised the study design and the manuscript and provided scientific collaboration, which is substantive involvement rather than courtesy authorship. The Foundation records this as a fact and draws from it only what follows: a study reporting wavelength-dependent retinal injury from light-emitting diode exposure in a mammal was designed with the participation of a person who contributed to the international framework by which such exposures are assessed. It is not an admission by anyone, and the Foundation makes no suggestion that it is. It does mean that this finding cannot be characterized as the work of investigators unfamiliar with the exposure limits.

Exposure conditions, which are the best characterized in this appendix. Three monochromatic light-emitting diode sources: blue peaking at 460 nanometers at 102.3 microwatts per square centimeter, green at 530 nanometers at 102.8, and red at 620 nanometers at 102.7. The arms were therefore matched on radiometric irradiance to within one percent, and wavelength was the only variable. Irradiance was measured at the level of the cornea, at 20 centimeters from each source, with the sources mounted at the top of shelves in a rack of six layers, each shelf curtained in black to separate the light conditions. The white light-emitting diode used for the spectral characterization is described as a yellow phosphor-converted source at a correlated color temperature of 6,500 kelvin, with a first peak at 460 nanometers at 0.028 watts per nanometer and a second broad yellow peak, and the paper plots the blue light hazard weighting function alongside it. Controls remained at 15.57 microwatts per square centimeter under cyclic compact fluorescent light at the same correlated color temperature. One author is credited specifically with coordinating the light source photometry and radiometry.

Design, and four features that distinguish it. In total 202 adult male eight-week-old Sprague-Dawley rats: 40 controls and 162 exposed. Ten days of environmental adaptation at the control light level, exposure beginning at 6 p.m. on day 11, and total exposure durations of 3, 9 or 28 days on a twelve-hour light and twelve-hour dark cycle. Temperature 22 to 23 degrees Celsius, humidity 50 to 70 percent, food and water without restriction. Four features are worth stating because they are uncommon in this literature: the comparison is matched on radiometric irradiance rather than on illuminance, so it isolates wavelength; the exposure is cyclic rather than continuous, which no other animal entry in this appendix can say except Appendix C.74; the investigators state that they were blinded to group allocation during the experiment and in assessing the outcome; and the sample is an order of magnitude larger than the four to eight animals typical elsewhere in this appendix, at 54 animals per exposure group for the electrophysiology.

Results. Electroretinography: the blue arm significantly weakened responses after three days, and after nine days the b-wave amplitude was significantly reduced in all three arms against control, with the blue arm showing the greatest loss. Histology after 28 days showed uneven alteration including absent photoreceptors and inner nuclear layer degeneration, with outer nuclear layer thickness significantly reduced in all exposure groups and most reduced under blue. Apoptosis and necrosis of photoreceptors and pigment epithelium were both found. Superoxide anion counts reached about 60,000 after three days of blue exposure against mostly under 20,000 for green and red. Hydrogen peroxide reached 0.13 nanomoles per retina under blue against 0.089 and 0.083 under green and red. Total retinal iron rose significantly under all three wavelengths, to about 2 nanomoles per retina under blue. Iron-handling proteins moved coherently as wavelength decreased: ceruloplasmin, ferritin and ferroportin up, transferrin and the transferrin receptor down, which the authors read as the cells detecting an increase in intracellular iron. Antioxidant defenses including heme oxygenase-1, superoxide dismutase 2 and glutathione peroxidase 1 were activated, the authors noting that heme oxygenase-1 can itself generate ferrous iron and carbon monoxide and so potentially worsen oxidative stress.

A result that runs against the simple account, stated for that reason. After nine days the b-wave was significantly reduced not only by blue but also by green and by red, and outer nuclear layer thinning after 28 days was significant in all three arms. At matched irradiance, red light at 620 nanometers produced a measurable functional and structural deficit. That is in tension with the long-wavelength material at Part V.B.6 and with the mitigating effect of red light reported at Appendix C.63, and the Foundation does not attempt to reconcile them here. The honest statement is that this study found a wavelength gradient with blue worst, not that it found blue harmful and the other wavelengths harmless. The gradient is the finding; the absence of a safe wavelength within the visible range, at this irradiance and duration, is also a finding and it is not one that favors the Foundation's emphasis on the short-wavelength peak alone.

A second tension, with Appendix C.63. The 2024 study at Appendix C.63 reports that within white light the green content drove phototoxicity, producing some eight times more macrophage invasion than blue, and that red mitigated injury. This study reports blue as the most injurious of three monochromatic arms. The designs differ: this comparison is monochromatic at matched irradiance assessed by electrophysiology and histology, while that one concerns the contribution of spectral components within a white source at high luminance assessed in part by macrophage invasion. They are not strictly contradictory. But the headline directions differ and the comment should not cite both as if they agreed.

What it does not establish. Nothing about humans, and the authors say so: they state that interpretation from the animal study to human applications should be carefully considered from a risk assessment perspective. The animals are albino, rod-dominant and without a macula. And although the irradiance of 102 microwatts per square centimeter is modest by the standards of this appendix, the paper does not convert it to a retinal dose and does not compare it against any exposure limit. The words ICNIRP, ACGIH and exposure limit do not appear in the paper. The Foundation notes that absence without drawing an inference from it, and does not attempt the conversion itself: corneal irradiance becomes a retinal dose only through the optical geometry of the eye, and Appendix C.75 shows how sensitive that computation is to the assumed pupil.

Disclosures. Supported by a grant of the Taiwan Ministry of Science and Technology, NSC 103-2314-B-002-076-MY3. Conflicts of interest are declared individually for each of the five authors, each as none.

Where it bears. Part V.B.3 and Part V.B, in the spectral leg of the three-characteristic frame, as the wavelength-resolved comparison at matched radiometric irradiance. Part V.J.4, at the head of the audit of reported exposures. Appendix C.68, which it independently supports. Part V.C.1 and Part V.C.2.f, on the authorship point. Part V.A.1, on the composition of the field.

C.77 Shang, Wang, Sliney, Yang and Lee (2014) — retinal injury at domestic levels, in this Department's own journal, a decade before the determination

Citation. Shang Y-M, Wang G-S, Sliney D, Yang C-H, Lee L-L. "White light-emitting diodes (LEDs) at domestic lighting levels and retinal injury in a rat model." Environmental Health Perspectives 2014;122(3):269–276. doi:10.1289/ehp.1307294. PMID 24362357; PMCID PMC3948037. Received June 30, 2013; accepted December 19, 2013; published online December 20, 2013; issue date March 2014. Institute of Environmental Health, National Taiwan University, Taipei. Full text read.

The publisher, which is why this entry is placed first among the pre-2024 material. Environmental Health Perspectives is published by the National Institute of Environmental Health Sciences, a component of the Department to which this comment is addressed. The journal states that publication in it lies in the public domain and is without copyright, and that its text may be reprinted freely with acknowledgment. The Foundation is therefore not constrained in the length of what it quotes, and has quoted the operative

sentences in full at Part I.C.7 rather than paraphrasing them. Part II.E.6 relies on a different article in the same journal, so the standing of the publication is already established in this comment.

Exposure conditions. Four light sources, each measured at 20 centimeters to deliver 750 lux at the animals, which the authors describe as the common domestic level. Single-wavelength blue diodes at 460 plus or minus 10 nanometers and phosphor-converted white diodes at a correlated color temperature of 6,500 kelvin, both custom made for the study; a white compact fluorescent lamp also at 6,500 kelvin; and a yellow compact fluorescent lamp at 3,000 kelvin. The white diode and the white fluorescent lamp were therefore matched both in illuminance and in correlated color temperature. Spectral power distributions and total intensities for every source were measured by the Industrial Technology Research Institute, a certification body testing laboratory, with each source programmed for forty measurements in an integrating sphere. The Foundation notes that this is independent accredited characterization of the exposure, which no other entry in this appendix reports.

Design. One hundred twenty adult male eight-week-old Sprague-Dawley rats. All held in darkness for fourteen days first, to clear the effect of prior lighting. Unexposed controls remained in darkness, three per time point; the remaining 108 were divided among the four sources, eight per source per time point. Exposure began at 1800 hours on day fifteen, for total durations of 3, 9 or 28 days on a twelve-hour light and twelve-hour dark cycle. A further thirty-two animals, eight from each exposure group, were exposed for 28 days and then returned to darkness for fourteen days of recovery, to allow for possible clearance of necrotic photoreceptor debris. Electroretinography before and after exposure with eighteen hours of dark adaptation before each measurement, then hematoxylin and eosin staining, terminal deoxynucleotidyl transferase labeling, immunohistochemistry, transmission electron microscopy and measurement of free radical production.

Results. Histology and electron microscopy showed apoptosis and necrosis of photoreceptors, which the authors read as photochemical injury. Free radical production in the retina was increased in the diode-exposed groups. Immunohistochemistry associated oxidative stress with the injury. The comparative finding is the one the Foundation relies on: the authors report serious retinal light injury in the diode groups and moderate to mild injury in the compact fluorescent groups.

The conclusion, quoted because it is a recommendation and because the text is in the public domain. The authors conclude that their results raise questions about adverse effects on the retina from chronic exposure to light-emitting diode light compared with other light sources having less blue light, and then: “we suggest a precautionary approach with regard to the use of blue-rich “white” LEDs for general lighting.” Earlier, in the introduction, they state that from an environmental health perspective retinal light injury and the potential risks of chronic exposure from using light-emitting diodes as a domestic light source require assessment before further development of the technology.

A finding about the product rather than the retina, which the comment now uses at Part V.B.1. The introduction records that a phosphor-converted diode progressively emits more short-wavelength light as lumen depreciation proceeds through phosphor degradation, and that light quality deteriorates past the 70 percent lumen maintenance level, for which the authors cite a 2009 publication of the United States Department of Energy. The Foundation had not previously identified this point and it has a consequence for a performance standard rather than for a person: the spectral distribution of the product drifts over its service life, in the direction of more blue, so a classification or a measurement performed on a new lamp is not a statement about the same lamp in service. Part V.B.1 develops it. The cited Department of Energy publication must be obtained and identified before the point is filed.

What it does not establish, including a limitation the authors state themselves. Nothing about humans. The authors say so: because albino rats were used, the exact risks for the pigmented human retina require further investigation. The exposure, though characterized as domestic in illuminance, was delivered for twelve hours a day for up to 28 days to caged animals that could not look away, which is not how a person encounters domestic lighting. Illuminance at 750 lux is a photometric quantity and the paper does not convert it to a retinal dose; as at Appendix C.76, the words ICNIRP, ACGIH and exposure limit do not appear, so the study makes no comparison with any limit and the Foundation does not attempt one. The injury descriptions are qualitative as between serious and moderate to mild rather than expressed as a measured ratio.

Disclosures. Supported by National Taiwan University Hospital grant UN101-036 and Taiwan National Science Council grant NSC 101-2314-B-002-073-MY2. The authors declare no actual or potential competing financial interests. Indexed as research support, non-United States government.

Relation to Appendix C.76. That 2017 study is this group's successor, with the same five authors. This one compares a diode source with the fluorescent source it displaced at matched illuminance and correlated color temperature; that one compares three monochromatic wavelengths at matched radiometric irradiance. Read together they are a single line of investigation and should be weighted as such, which Part V.A.1 must record. Where they differ in emphasis the later and better-characterized study should be preferred on exposure, and this one on the comparison with the displaced technology.

Where it bears. Part I.C.7, as the strongest item in the foreseeability argument, and the reason that argument is stated separately from the specialty-journal material. Part IX.B.4, which asks whether this study was considered. Part V.B.1, for the spectral drift with phosphor degradation. Part V.B.3, for the matched-correlated-color-temperature comparison against a fluorescent source, alongside Appendix C.70 and C.74. Part II.E.6, as the second article from this journal on which the comment relies. Part V.A.1, for the author overlap with Appendix C.76.

C.78 Jaadane and others (2015) — the regulatory endpoint negative, the injury extensive, and what the limits were built on

Citation. Jaadane I, Boulenguez P, Chahory S, Carré S, Savoldelli M, Jonet L, Behar-Cohen F, Martinsons C, Torriglia A. "Retinal damage induced by commercial light emitting diodes (LEDs)." Free Radical Biology and Medicine 2015;84:373–384. doi:10.1016/j.freeradbiomed.2015.03.034. PMID 25863264. The published article is closed access and the publisher does not serve it to automated retrieval; the Foundation read the author manuscript deposited in the French national open archive HAL under identifier hal-04674687, submitted August 21, 2024. Page citations must be taken from the published version. Cite the publisher's version.

Why this is the most important entry in the appendix for Part V.C.2.c. It states, in the authors' own words, the experimental basis of the exposure limit values: that they rest on fundus examination following a single eight-hour exposure, and that they define light as injurious when there is bleaching of the retina. The Foundation had previously inferred the first two of those three elements from the arithmetic of the standard and had taken the third at second hand. Here they are stated together by a group that includes the author of the handbook chapter at Appendix D.5 and the investigators of Appendices C.63 and C.75. Part V.C.2.c quotes the passage in full.

The result that follows from applying that endpoint. Dilated fundus examination was carried out immediately after exposure by a veterinary ophthalmologist with two assistants. No bleaching of the retina was detected in any animal, across exposures from twelve hours to three days and across all five sources used. The regulatory endpoint was therefore negative throughout. In the same animals the authors report interphotoreceptor

edema on semi-thin sections; activation of microglia and infiltration of macrophages on CD11b and Iba-1 staining after one and two days, which they read as retinal inflammation; oxidation of DNA and RNA by 8-hydroxyguanosine staining, most marked in the inner nuclear layer, and of proteins by nitrotyrosine staining; loss of photoreceptors; and the activation of caspase-independent apoptosis, necroptosis and necrosis. They also report marked chemosis, an edema of the ocular tissues, in almost all animals during the first twenty-four hours of exposure, resolving thereafter.

Sources and exposure. Commercially available white light-emitting diodes and four blue sources at 507, 473, 467 and 449 nanometers, on Wistar rats, which are albino. Exposures ran from twelve hours to three days. The authors report a corneal irradiance dose of approximately 0.0026 joules per square centimeter and state that this is about one thousandth of the flux used in the earlier experimental work they cite. The Foundation records, and Part V.C.2.c repeats, that this is a corneal quantity and must not be compared with the 2.2 joules per square centimeter retinal figure at Part V.C.2.f; the two differ by the optical gain of the eye. The luminance and radiance figures that Appendix C.75 attributes to its own apparatus, 2,680 candelas per square meter and 8.33 watts per square meter per steradian, are cited in that paper to this one and should be confirmed here. A wavelength dependence was observed, and the authors report that a named commercial royal blue diode produced a higher degree of protein oxidation than the other blue sources.

A detail that bears on the disagreement recorded at Appendix C.76. One of the four sources this paper calls blue has a peak at 507 nanometers. In the 2024 study at Appendix C.63, by three of the same authors and with apparatus from the same laboratory, a source at 507 nanometers is the green arm, and it is the arm that drove phototoxicity in white light. The same wavelength therefore appears in this group's 2015 work within a set described as blue and in its 2024 work as green. That is a matter of nomenclature rather than of measurement, but it bears on the apparent conflict between Appendix C.63 and Appendix C.76, where the green arm was at 530 nanometers. Part of the disagreement about whether blue or green drives injury may be a disagreement about where the boundary between them is drawn.

What it does not establish. Nothing about humans. The authors state the limitation themselves, writing that the pertinence of the albino rat model and the translation of the results to human beings is a matter of discussion, and that the model is useful for forming an idea of the kind of lesions these devices produce. No threshold and no safe level. The absence of bleaching does not establish that the exposures were below any limit, because the paper does not compute a retinal dose and makes no comparison with the numerical limit; what it establishes is that the endpoint on which the limit is defined was not reached while other injury was present.

Prior work it identifies, which the Foundation had not. Three leads. Dawson, 2001, reporting that a blue diode at 460 nanometers and an argon laser at 458 nanometers produced the same retinal lesions at a corneal irradiance of 10 joules per square centimeter. Ueda and colleagues, reporting retinal damage at the macula from blue diodes at 465 nanometers. And Mukai and colleagues, reporting that the retinas of monkeys exposed to light-emitting diode light for eight hours showed intracellular vacuoles in the photoreceptor outer segments together with reduced rod and cone responses on electroretinography, a mechanism these authors note was not analyzed there. The third is the most important: a primate study, at eight hours, with a functional deficit. The exposure limits were derived from primate thresholds, as Part V.C.2.f records, so a primate result bears on them more directly than any rodent study in this appendix.

Funding and disclosures. Indexing records the funders as Inserm, the Ecole Nationale Vétérinaire d'Alfort and the Centre Scientifique et Technique du Bâtiment, together with the French environment and energy agency ADEME and its RETINALED project, which are the same funders as Appendix C.75. The funding and competing-interest statements

must be confirmed from the published version; the Foundation has not located them in the deposited manuscript. The observation at Appendix C.75 applies here too: the building science laboratory was both a funder and the employer of authors who built the exposure apparatus.

Where it bears. Part V.C.2.c, as the primary statement of what the exposure limits were constructed to detect, which is the central proposition of that subsection. Part V.C.1.g and Part V.C.2.f, on injury without a visible lesion. Part V.B.3, on wavelength dependence. Appendix C.63, C.75 and D.5, as the earliest member of one line of investigation. Part V.A.1, on the concentration of that line in one group.

C.79 Kuse and others (2014) — the same radiant power at three wavelengths, and the same illuminance at three wavelengths

Citation. Kuse Y, Ogawa K, Tsuruma K, Shimazawa M, Hara H. "Damage of photoreceptor-derived cells in culture induced by light emitting diode-derived blue light." Scientific Reports 2014;4:5223. doi:10.1038/srep05223. Received January 24, 2014; accepted May 21, 2014; published June 9, 2014. Licensed under a Creative Commons Attribution-NonCommercial-ShareAlike 4.0 International License; full text read. Molecular Pharmacology, Department of Biofunctional Evaluation, Gifu Pharmaceutical University, Gifu, Japan.

The design, which is why the entry is here. Cone photoreceptor-derived 661W cells were exposed from below the plate for twenty-four hours under two separate schemes. In the first, all three sources delivered the same radiometric irradiance of 0.38 milliwatts per square centimeter: blue at a peak of 464 nanometers, white with peaks at 456 and 553 nanometers, and green at 522 nanometers. In the second, all three delivered the same illuminance of 2,500 lux. The study therefore holds radiant power constant in one scheme and the photometric quantity constant in the other, which is the comparison this comment has been making by argument. Radiant power was measured with a handheld optical power meter, which the paper identifies by model. Control cells were incubated in the dark and drawn from the same stock, which the authors state was to eliminate pre-existing bias in light and temperature exposure, following a published protocol.

The figures the Foundation relies on, which are incidental to the paper and central to this comment. The authors record the illuminance equivalent of their single matched irradiance for each source: 0.38 milliwatts per square centimeter corresponds to 450 lux for the blue source, 1,600 lux for the white source and 2,500 lux for the green source. Three sources delivering identical radiant power to the same preparation therefore differed in measured illuminance by a factor of about five and a half, for the reason given at Part V.J.1. That is published confirmation, from a measurement rather than from the Foundation's arithmetic, that photometric and radiometric quantities are not interchangeable across spectra. Part V.B.3 relies on it.

Results. Blue light increased reactive oxygen species production, altered protein expression, and induced aggregation of short-wavelength opsin, with severe cell damage. In primary retinal cells the damage was photoreceptor specific. N-acetylcysteine, an antioxidant, protected against it. The conclusion the Foundation quotes is that the damage was, in the authors' words, wavelength- but not energy-dependent, and that blue light-emitting diode light may cause more severe photoreceptor damage than the other sources tested.

The mechanism, and its place in a lineage already in this appendix. The authors identify aggregation of short-wavelength opsin as the route. Their reasoning is that medium-wavelength opsin is readily degraded by the proteasome while short-wavelength opsin is not, so that the short-wavelength pigment accumulates in aggregates and causes rapid cone degeneration. They cite their own earlier work for the proposition that excessive light exposure aggregates short-wavelength opsin and leads to endoplasmic reticulum stress in this same cell line. That is the pathway developed nine years later at

Appendix C.65, by overlapping authors in the same department and in the same cell line. The two entries are one line of work.

What it does not establish. Anything about a retina, a human or a product. This is a monolayer of a transformed murine cell line in a ninety-six-well plate, illuminated from below continuously for twenty-four hours, with no retinal pigment epithelium, no choroidal circulation, no tissue architecture and no repair processes. The governing limitation recorded at Appendix C.65 applies with equal force here. It sets no threshold and makes no comparison with any exposure limit. The culture-medium confound identified at Appendix C.72 applies: no irradiated medium-only control is reported.

Shared authorship, now a pattern rather than an instance. This is the third entry in this appendix from Molecular Pharmacology, Department of Biofunctional Evaluation at Gifu Pharmaceutical University, with Hara an author of all three and Shimazawa of two. The others are Appendix C.65, which develops this paper's endoplasmic reticulum stress pathway in the same cell line, and Appendix C.74, the pigmented mouse study. The three are not independent observations.

Disclosures. The authors declare no competing financial interests. The Foundation has not located a funding statement in the article as read, and records that as an absence rather than as a declaration of no funding.

Where it bears. Part V.B.3, as the third and cleanest of the three biological demonstrations that the hazard follows the spectrum rather than the photometric quantity. Part V.J.1 and Part V.J.4, for the measured illuminance equivalents at constant radiant power. Part V.B, in the spectral leg of the three-characteristic frame. Appendix C.65, as its predecessor in mechanism. Part V.A.1, for the authorship pattern.

C.80 Youssef, Sheibani and Albert (2010) — the three-mechanism framework, from an American department, and the age of the question

Citation. Youssef PN, Sheibani N, Albert DM. "Retinal light toxicity." Eye (London) 2011;25(1):1–14. doi:10.1038/eye.2010.149. PMID 21178995; PMCID PMC3144654. Published online October 29, 2010. Department of Ophthalmology and Visual Sciences, University of Wisconsin School of Medicine and Public Health, Madison. Full text read. The journal is published for the Royal College of Ophthalmologists.

Article type and why the Foundation prefers it for the framework. A review, cited in the category described at Part V.A.2 as evidence of the state of expert opinion. Its value to this comment is that it is the framework source the comment needs and it comes from an American academic ophthalmology department in a journal of the Royal College of Ophthalmologists. Part V.B had rested its three-mechanism division on Appendix C.72 alone, a review whose journal was subject to the retraction episode recorded in that entry. This review states the same division independently, six years earlier, from a different continent, and the comment now relies on it in preference.

The three mechanisms as this review states them. Photothermal damage: radiant energy transferred to tissue where, at the longer visible and near-infrared wavelengths, vibrational and rotational states predominate over electronic excitation, so that mean kinetic energy and therefore temperature rise. The review notes that the capacity to raise kinetic energy is inversely proportional to wavelength, and that in a closed system thermal effect is proportional to exposure time while in an open system more energy is required for a given thermal effect as exposure lengthens. Photomechanical damage: compressive and tensile forces from the rapid introduction of energy into the melanosomes of the pigment epithelium, at irradiances of the order of megawatts to terawatts per square centimeter over nanoseconds to picoseconds, producing microcavitation bubbles lethal to those cells and sonic transients that can damage photoreceptors; the clinical application is the neodymium-doped yttrium aluminum garnet laser used for iridotomy and posterior

capsulotomy. Photochemical damage: the wavelength-dependent mechanism, which the review associates with both long exposure durations and shorter wavelengths, mediated by chromophores and the free radicals their excitation generates.

The chromophore list, which corrects a framing in this comment. The review gives the chromophores of the retina and pigment epithelium as including the photoreceptors, flavoproteins, heme proteins, melanosomes and lipofuscin. Part V.C.2.h had presented a convergence of four chromophore findings as a pattern the Foundation had noticed. Three of the four are members of classes on this list, published in 2010 before any of those four studies. The convergence is therefore the standard account rather than a discovery, and Part V.C.2.h has been amended to say so. The amendment strengthens the proposition and removes a claim to novelty that was not the Foundation's to make.

The age of the question, which bears on Part I.C.7. The review opens with a chronology the Foundation records because the determination it examines rests on a history. Socrates is quoted from Plato's Phaedo warning that people may injure the eye by gazing at an eclipse. Galileo lost vision studying sunspots. Newton described a scotoma and an afterimage persisting for days after observing the sun through a telescope. Solar retinal damage was first studied clinically in 1916. And in 1966 Noell and colleagues suggested that damage to the retina was possible with low-intensity light. That last citation is sixty years old and it is the origin of the proposition this comment is concerned with. The capacity of light to injure a retina has never been the open question. The open question has always been the level, which is what Part I.C.7 and Part IX.B.4 ask the Department to determine.

A body of human clinical evidence the Foundation had not identified. The review cites retinal phototoxicity from the operating microscope during cataract surgery, with nine references, and from endoillumination during vitreoretinal surgery, with four. It also cites histological study by Green and Robertson of human eyes exposed to various light levels before enucleation for choroidal melanoma. That is human evidence of retinal injury from artificial light sources, documented clinically over decades. It says nothing about domestic lighting levels and the Foundation does not offer it for that. It does establish that light-induced retinal injury in humans is an established clinical entity rather than an inference from animals, which is the premise Appendix C.64 supports with a single case and which this literature supports with a surgical subspecialty's accumulated experience.

Protective mechanisms, and what they are not. The review describes the eye's adaptations: photostasis, by which rhodopsin concentration is regulated so that relative photon absorption remains steady independent of ambient intensity; endogenous antioxidant generation, with rats raised in lighted environments producing protective enzymes; greater susceptibility in mice carrying a superoxide dismutase mutation; and the macular pigment formed by the dietary carotenoids zeaxanthin, meso-zeaxanthin and lutein, which neutralize singlet oxygen and free radicals. The Foundation notes what this material does not contain, because it had hoped otherwise.B.8 calls for literature on the aversion response, the blink reflex and glare to support or soften an inference made there. This review does not supply it: its protective mechanisms are biochemical and adaptive, not behavioral. That note remains outstanding.

What it does not establish. It is a review and contains no primary data. It is not about light-emitting diodes, which it mentions twice in fourteen pages; it predates the general lighting transition and should not be cited as addressing it. It sets no threshold and, notably for a review of retinal light injury by an academic ophthalmology department, it does not discuss exposure limits at all: the terms used by the standards bodies do not appear in it. The Foundation records that absence without inference, beyond observing that the clinical literature on retinal phototoxicity and the standards literature on optical radiation limits appear to have been written largely in isolation from one another.

Disclosures. The Foundation did not locate a funding statement or a competing-interests declaration in the text as read, and records that as an absence rather than as a declaration of none. Both must be checked against the published version.

Where it bears. Part V.B, as the preferred source for the three-mechanism framework that substantiates the three-characteristic division. Part V.C.2.h, for the chromophore list and the correction it requires. Part I.C.7, for the age of the question and the 1966 low-intensity citation. Part V.C.1, for the surgical phototoxicity literature, alongside Appendix C.64.

C.81 Jordan and Vanderheiden (2024) — flash thresholds that exist, in a domain that is not this one

The governing limitation, stated first. This article concerns flashing content presented on displays. It is not about light sources. The words display or screen appear in it more than two hundred times; lighting, luminaire, streetlight and lamp together fewer than ten; light-emitting diode twice; and vehicle, emergency and police not at all. Nothing in this entry is evidence that any lamp, luminaire, beacon or vehicle light triggers seizures, and the comment does not cite it for that. It is cited for the thresholds that exist in the display domain, for the epidemiology of the condition, and for the regulatory asymmetry those thresholds reveal.

Citation. Jordan JB, Vanderheiden GC. "International Guidelines for Photosensitive Epilepsy: Gap Analysis and Recommendations." ACM Transactions on Accessible Computing 2024;17(3):1–35. doi:10.1145/3694790. PMID 40026540; PMCID PMC11872230. Open access under a Creative Commons Attribution license; full text read. University of Maryland, College Park. The Foundation read the author manuscript served by PubMed Central; page citations must be taken from the published version.

Funding, which bears on Part I.C.7. Supported by the National Institute on Disability, Independent Living, and Rehabilitation Research under grants 90REGE0008 and 90REGE0024, by the Administration for Community Living of the Department of Health and Human Services, and by a gift from Meta. The first two are components of the Department to which this comment is addressed. The Foundation records, without drawing a conclusion about anyone's state of knowledge, that in the same year as the determination examined at Part I.C.7 this Department funded a thirty-five page analysis finding that the guidelines governing a known light-triggered neurological condition are not harmonized, that technology has outrun them, and that their thresholds should be revised. The gift from Meta is disclosed because that company has an interest in display content standards.

What it establishes. That flash thresholds for photosensitive epilepsy exist, are numerical, and are applied. A general flash in which the two states differ by more than 20 candelas per square meter is treated as potentially hazardous where the darker state is below 160 candelas per square meter; the more conservative of the two Web Content Accessibility Guidelines criteria prohibits any flashing more than three times per second; and the 20 candela figure was chosen because an estimated 7 percent of those who would respond to maximal black-to-white flashing may still respond at that level. Diagnostic photic stimulators, by comparison, flash at 400 to 10,000 candelas per square meter or more. It further establishes the epidemiology relied on at Part V.E.1, and the existence of automated compliance tools, including the commercial Harding Flash and Pattern Analyzer available since 2001 and the Photosensitive Epilepsy Analysis Tool of the Trace Research and Development Center, which is free for web content. The Foundation notes the tools because the existence of automated conformance testing answers the objection that a flash limit would be impractical to enforce.

The proposition the comment takes from it, which is regulatory rather than clinical. That the Web Content Accessibility Guidelines, including the photosensitive epilepsy success criteria, have been applied through Section 508 of the Rehabilitation Act to digital

documents and software purchased, procured or created by government, and in the European Union through EN 301 549. If that is right, a quantified federal flash limit for this condition exists in the United States for procured digital content and exists nowhere for physical light sources. Part V.E.1 develops the consequence. The proposition is load-bearing and is taken here from a secondary characterization.

Findings that complicate the comment's position. Two, recorded because they run the other way. The authors identify reduction of risk attributable to display technology as one of the risk factors that has changed: the inherent flicker of cathode ray tube screens, which contributed to the hazard historically, is absent from modern displays. And on ambient conditions they describe counteracting effects, bright surroundings reducing effective display contrast and constricting the pupil while prompting users to raise screen luminance, concluding that the exact relationship between these factors and photosensitive epilepsy is not fully understood. The Foundation does not assert that screens have become more hazardous over time, and this entry does not support that.

What it does not establish. Nothing about light sources, as stated above. Nothing about the light-emitting diode as a technology. It is an analysis of guidelines rather than an experimental study, so the thresholds it reports are reported at one remove from the work that established them. The comment does not presently cite that underlying work, and this entry is not a substitute for it. The authors propose working values for revised thresholds; those proposals are not adopted by this comment, which relies only on the thresholds presently in force.

Where it bears. Part V.E.1, which is built on it, and principally for the Section 508 asymmetry. Part V.D.3, where it partly answers the question whether the United States regulates temporal light modulation at all. Part V.B, as the first entry in this appendix addressed to the temporal characteristic. Part I.C.7, for the funding. Appendix D.2, which catalogues the five instruments it analyzes.

C.82 Soker-Elimaliah and others (2022) — the pupillary light reflex, measured in people who do not have the condition

The governing limitation, stated first. This study included no autistic participants. Its samples were described by its authors as non-autistic, and autistic traits were measured dimensionally with a trait questionnaire administered within those samples. It is a study of what its title calls the broader autism phenotype, meaning trait variation in a population without the diagnosis. The comment does not cite it for any proposition about autistic people, and Part V.E.3 states that expressly.

Citation. Soker-Elimaliah S, Lehrfield A, Scarano SR, Wagner JB. "Associations between the pupil light reflex and the broader autism phenotype in children and adults." Frontiers in Human Neuroscience 2022;16:1052604. doi:10.3389/fnhum.2022.1052604. PMID 36895201; PMCID PMC9990758. Open access under a Creative Commons Attribution license. Brief Research Report. Department of Psychology, College of Staten Island and the Graduate Center, City University of New York, with one author at the University of Southern California and one at the Albert Einstein College of Medicine.

Funding. National Institute of Mental Health, grant R15 MH112090, and the Professional Staff Congress of the City University of New York, awards 69677-00-47 and 64484-00-52. The authors declare no commercial or financial conflict of interest. The National Institute of Mental Health is a component of the Department to which this comment is addressed, which bears on Part I.C.7 in the same way as the funding recorded at Appendix C.81.

Participants. Fifty-nine children after exclusions, mean age 6.36 years, standard deviation 2.72, range 2 to 12; and sixty-six adults after exclusions, mean age 19.64 years, standard deviation 2.04, range 18 to 28, who were students in an introductory psychology course receiving course credit. Participants with fewer than four valid trials were excluded. No

participants aged 12 to 18 were included, which the authors identify as a limitation preventing analysis of age as a continuous variable.

Exposure conditions, which are not recoverable. The stimulus is described as a white flash of 120 milliseconds presented during a fixation animation on a black screen, viewed at 65 centimeters on a 22-inch monitor, with eye position sampled at 120 hertz. Nine trials per session, with inter-trial videos of 10 seconds for children and 15 seconds for adults included to encourage saccades and prevent retinal saturation. Wavelength is not stated. Luminance is not stated. The background adaptation level is not stated. Nothing in the report permits the retinal exposure to be reconstructed, and the entry is classified as not recoverable for the purposes of the audit at Part V.J.4.

What it establishes, and in which group. In the adult sample, and after correction for multiple comparisons at an alpha of 0.0125, two associations held. Higher scores on the restricted and repetitive behavior subscale were associated with smaller relative pupil constriction amplitude, r(64) = minus 0.36, p = 0.003; and with longer median constriction latency, r(64) = 0.32, p = 0.008. The authors state the finding as being that increased levels of restricted and repetitive behavior are associated with smaller relative pupil constriction and longer latency to respond to light. Relative constriction amplitude was defined as the fractional reduction in pupil area.

What it does not establish, including against the comment's interest. The total score on the trait questionnaire did not survive correction, at p = 0.024 against an alpha of 0.0125; only the one subscale did. In the child sample no association survived correction. Absolute constriction amplitude showed no group difference. The reported correlation of minus 0.36 corresponds to approximately thirteen percent of variance. Constriction latency is nowhere reported in milliseconds and pupil diameters are nowhere reported in millimeters, so no absolute quantity can be taken from this paper. Peak constriction velocity was used only as an inclusion criterion and not reported as an outcome. Redilation was not measured. The design is correlational and cross-sectional, and the adult sample was a single cohort of undergraduates.

The proposition the comment takes from it, which concerns the construction of a limit rather than autism. That pupillary response varies systematically with a measurable characteristic of a population. The relation at Part V.B.2 expresses retinal irradiance with pupil diameter as a term, and Part V.C.2.f sets out why the retinal dose computed at Appendix C.75 depends on an assumed pupil diameter of 5 millimeters where the sources cited for that assumption give smaller figures. Retinal irradiance scales with pupil area. It follows that an exposure limit computed from a single assumed pupil diameter does not describe the exposure of a person whose pupillary response departs from the assumption, and that the direction of the departure determines whether the limit is conservative or permissive for that person. This paper does not quantify any such departure and the comment does not claim that it does. It establishes that the parameter is not a constant of the population, which is enough to make its value a question a standard would have to answer.

Relation to Appendix C.83. The two entries are complements and should be read together. This study measures the response to light and lacks the population. Appendix C.83 has the population and measures nothing. Neither characterizes the light. Part V.E.3 is built on that relation rather than on either entry alone.

Where it bears. Part V.E.3, with Appendix C.83. Part V.B.2 and Part V.C.2.f, for the pupil term. Part V.J.4, as a study of the response to light which does not report the light. Part IX.C.6, for the research request. Part I.C.7, for the funding.

C.83 Nair and others (2022) — the population, and no measurement of the light

The governing limitation, stated first. This is a questionnaire survey. Its instrument is forty questions put to autistic children and their parents at a single autism center, answered on a suitability ranking. It contains no measurement of any light source, no controlled exposure, no comparison group, and no physiological or observed behavioral outcome. The Foundation cites it for the population it reached and for what its absence of measurement demonstrates about the state of this literature, and for nothing else.

Citation. Nair AS, Priya RS, Rajagopal P, Pradeepa C, Senthil R, Dhanalakshmi S, Lai KW, Wu X, Zuo X. "A case study on the effect of light and colors in the built environment on autistic children's behavior." Frontiers in Psychiatry 2022;13:1042641. doi:10.3389/fpsyt.2022.1042641. PMID 36532166; PMCID PMC9748440. Open access under a Creative Commons Attribution license; full text read. School of Architecture and Interior Design and three engineering departments of the SRM Institute of Science and Technology, Chennai, with co-authors at Universiti Malaya and at Xuzhou Medical University. Funded by the Xuzhou Science and Technology Program.

Participants, which are the reason for the entry. Eighty-seven autistic children aged between 6 and 16, 45 male and 42 female, mean age 8.7 years, standard deviation 2.3, identified by diagnosis. The survey was conducted at an autism center, and the paper states that it was administered among the children and their parents. This is the only study in this appendix whose participants are a diagnosed population identified by a sensory characteristic.

Exposure conditions. There are none reported, and the Foundation states how it established that. The Foundation searched the full text, of approximately 163,000 characters, for each of the following terms: lux, lumen, candela, candelas per square meter, illuminance, luminance, kelvin, correlated color temperature, spectral, nanometer and wavelength. None appears. The Foundation further searched for the common lamp technologies, and the paper does not identify whether the lighting it concerns was light-emitting diode, fluorescent or incandescent. A paper whose title is the effect of light on the behavior of autistic children therefore reports no photometric quantity, no radiometric quantity, no color temperature, no wavelength, no spectral power distribution, and no lamp type. For the audit at Part V.J.4 this is the limiting case in this appendix: not an exposure reported in the wrong units, but no exposure reported at all.

What the authors report. That the children expressed varying color preferences and responded differently to different shades; that neutral tones and mellow shades were found to be preferred, with a calming effect described; that bright, bold and intense colors were found stimulating; and, in the abstract, that "The stimulus of bright-lighting causes behavioral changes in autistic children prone to light sensitivity." The conclusions are addressed to designers and clinicians for the design of interior spaces.

Why the Foundation does not rely on the sentence just quoted. Because the method cannot support it, and because this comment holds other parties to that standard and must hold itself to it. A ranking of preferences collected from children and their parents can establish what was reported. It cannot establish that a stimulus causes a behavioral change, and the word causes is not available from this design. The Foundation records the same objection to the abstract's statement that certain shades were proven to be autistic-friendly; a preference ranking does not prove that either. The paper also describes itself as a case study while reporting a survey of eighty-seven respondents with a stated margin of error, and its limitations section consists of a single sentence calling for more participants, without reference to the absence of measurement, the absence of a comparison group, or the limits of self and proxy report. The Foundation makes these observations rather than omitting the paper, for the reason it gave in declining to rely on the consultancy report described at Part VI.E.3: a comment that cited only what suited it, without saying what each source can and cannot bear, would deserve to be discounted.

What it nonetheless establishes. Two things, and the second is the more important. First, that the question has occurred to investigators and that a diagnosed population can be reached and surveyed about lighting, so the obstacle to a proper study is not access to participants. Second, that in 2022 a paper could be published in an indexed journal on the effect of light on this population without stating a single physical property of the light. That is evidence about the state of the field rather than about the children, and it is the form in which this entry is used at Part V.E.3 and at Part V.J.4.

Relation to Appendix C.82. The two entries are complements and should be read together. This study has the population and no measurement. Appendix C.82 has the measurement and no autistic participants. Neither characterizes the light. Part V.E.3 draws the conclusion from the pair, which is that the deficiency in this literature is one of design rather than of volume, so that a further study of either kind would not remedy it.

Where it bears. Part V.E.3, with Appendix C.82. Part V.J.4, as the limiting case of unreported exposure. Part IX.C.6, for the research request.

C.84 Zhong and others (2023) — outdoor light at night and childhood leukemia, and what the authors say their exposure metric cannot do

Citation. Zhong C, Wang R, Morimoto LM, Longcore T, Franklin M, Rogne T, Metayer C, Wiemels JL, Ma X. "Outdoor artificial light at night, air pollution, and risk of childhood acute lymphoblastic leukemia in the California Linkage Study of Early-Onset Cancers." Scientific Reports 2023;13:583. doi:10.1038/s41598-022-23682-z. PMID 36631468; PMCID PMC9834257. Open access under a Creative Commons Attribution license; full text read. Keck School of Medicine of the University of Southern California, Yale School of Public Health, the School of Public Health of the University of California, Berkeley, and the Institute of the Environment and Sustainability of the University of California, Los Angeles. The digital object identifier carries 2022 and the article appeared in the 2023 volume; cite the volume and year as given.

Funding, which bears on Part I.C.7. National Cancer Institute of the National Institutes of Health, under contracts HHSN261201800032C and 32I, HHSN261201800015C and 15I, and HHSN261201800009C and 09I; the National Center for Chronic Disease Prevention and Health Promotion of the Centers for Disease Control and Prevention, under NU58DP006344; and the National Institute of Environmental Health Sciences, under T32 ES013678 and P30 ES007048. Three components of the Department to which this comment is addressed. The Foundation records the funding without inference, as it does at Appendix C.11 and Appendix C.81.

Design and population. Population-based case-control study using the California Linkage Study of Early-Onset Cancers, which links diagnoses in the California Cancer Registry, a Surveillance, Epidemiology and End Results program registry, to birth records. Two thousand seven hundred and eighty-two cases of acute lymphoblastic leukemia and one hundred thirty-nine thousand one hundred controls, identified during 2000 to 2015, with fifty controls per case matched on year of birth. No case or control was contacted, which the authors identify as minimizing selection bias.

Exposure, as assigned, and the limits of the assignment. Outdoor light at night was assigned from the New World Atlas of Artificial Night Sky Brightness, which supplies, on a 750-meter grid, a modeled estimate of luminance at the zenith expressed in millicandela per square meter. The Atlas was constructed from National Oceanic and Atmospheric Administration Visible Infrared Imaging Radiometer Suite observations taken between May and December 2014, together with handheld sky-meter measurements. Median assigned value 3.27 millicandela per square meter, interquartile range 1.83 to 5.92. Fine particulate matter was assigned from an ensemble-based prediction model. Both exposures were assigned to the maternal residential address recorded at delivery. The Foundation asks the Department to hold three features of that assignment in view: the

quantity is the brightness of the sky overhead and not the light reaching any person; a single six-month average from 2014 is assigned to births spanning 2000 to 2015; and no residential history was available for controls.

Results, stated in full rather than as the abstract states them. The association reported in the abstract is confined to one stratum: in Hispanic children, the highest tertile of light at night against the lowest gave an adjusted odds ratio of 1.15, 95 percent confidence interval 1.01 to 1.32. The lower bound excludes unity by 0.01. For fine particulate matter the unadjusted association with leukemia, odds ratio 1.11 (1.01 to 1.22), did not survive adjustment, falling to 1.08 (0.96 to 1.20); the borderline figure of 1.24 (0.98 to 1.56) reported in the abstract for non-Hispanic White children does not exclude unity. In age-stratified analysis the light association rose from 1.00 (0.84 to 1.19) in the 0 to 2 year group to 1.22 (0.88 to 1.69) in the oldest group, and was not significant in any stratum. The model adjusted for census block group poverty in tertiles, sex, race and ethnicity, birthweight, mode of delivery, maternal age, maternal education, mother's place of birth, and complications during pregnancy.

The finding the comment principally relies on, which is a statement by the investigators about their own method. In the limitations of the published paper the authors write: "Another limitation is that the measure of outdoor ALAN that we used was based on observations from 2014 and consisted of an estimate of luminance at the zenith. It did not characterize light at various wavelengths, which may be an important distinction. Animal studies show that shorter, blue spectrum wavelength light (450–500 nm) was more detrimental to sleep, which could be an issue as cities are moving away from amber lights towards more shorter wavelength LED (light emitting diode) streetlights." They add that their work "can inspire investigators of future studies to expand the scope of exposure assessment to include all types of ALAN."

Why that passage matters more to this comment than the odds ratio does. Because it is the argument of Part V.J, stated by investigators funded by three components of this Department, about the method they themselves employed. The exposure metric on which this literature rests is spectrally blind. It records how much light is in the sky and not what kind. The transition this comment is about is a change in the kind. The authors identify that limitation, identify the conversion to shorter-wavelength light-emitting diode street lighting as the reason it matters, and state that their metric cannot address it. The Foundation does not need the odds ratio to make the point that follows: a body of epidemiology that cannot distinguish amber from blue-rich light cannot answer the question whether the conversion to light-emitting diode sources has changed the risk, in either direction. That is a reason for the measurement program requested at Part IX.C.1, not a reason to discount the epidemiology.

What it does not establish. Causation, which the design cannot deliver. Any dose-response relation, since the only significant estimate is a single tertile contrast within one stratum and the age-stratified estimates are not significant. Anything about light-emitting diode products specifically, since the exposure metric does not identify source technology and the authors say so. And anything about indoor exposure, bedroom light, or light reaching the eye, none of which was measured. The Foundation notes additionally, against its own interest, that Hispanic ethnicity was independently associated with higher leukemia risk in this study (adjusted odds ratio 1.29, 1.16 to 1.43), so the single stratum in which the light association appears is also the stratum with the higher baseline risk, which leaves residual confounding as a live explanation that the paper does not exclude.

Relation to Appendix C.11, which is not an independent replication. Appendix C.11 is a study of pediatric papillary thyroid cancer by substantially the same investigators, using the same California birth-record linkage, the same two exposures, and the same New World Atlas product. Six authors are common to both: Wang, Zhong, Wiemels, Morimoto, Metayer and Ma. The two entries should therefore not be read as two independent findings

about light at night. They are two outcomes examined by one group using one exposure assignment, and any defect in that assignment is inherited by both. The Foundation records one substantive difference between them: the thyroid study reported no significant differences by race or ethnicity, while the light association here appears only within one ethnic stratum. A subgroup pattern that differs between two outcomes examined with the same exposure product is more readily explained by chance or by residual confounding than by a consistent biological effect, and the Foundation states that rather than presenting the two as mutually supporting.

Bearing on the statutory question. Part V.J.1 and Part IX.C.1, for which this entry is now the clearest illustration in the appendix of a spectrally blind exposure metric identified as such by its own users. Part V.F, with Appendix C.11, for the light-at-night literature. Part I.C.7 and Part II.E.6, for the funding and for the position of this research relative to the determination of May 24, 2024. Part VII, for the affected population, these being children. As evidence of risk from light-emitting diode products the Foundation relies on it for nothing.

C.85 Hering and others (2024) — off-axis light-emitting diode exposure, measured loss of central visual field sensitivity in humans, and an exposure that neither radiometry nor photometry alone predicts

Citation. Hering D, Jakobs FM, Ritt G, Henrichsen M, Hohberger B. "Impact and visualization of scotomatic glare in central visual field perception." Vision Research 2024;222:108457. doi:10.1016/j.visres.2024.108457. PMID 39029384. Published online 18 July 2024. Open access under a Creative Commons Attribution license; full text read. Designed in collaboration between the Fraunhofer Institute of Optronics, System Technologies and Image Exploitation at Ettlingen and the Department of Ophthalmology of the German Air Force Centre of Aerospace Medicine at Cologne and Fuerstenfeldbruck. Ethical approval by the Bavarian State Medical Association, Munich, reference 19032, 5 November 2019. The work was performed in fulfillment of the requirements for the first author's doctorate in medicine.

Funding, which is unusual in this appendix. The authors state that the perimeter was provided on temporary loan by Fraunhofer and that "this research has not been funded by any scientific, industrial, or governmental institution." They declare no competing financial interests or personal relationships. Of the entries in this appendix bearing on glare, this is the only one with no funder at all.

Design and participants. Prospective, with exposure sequences randomized and blinded as to level. Forty-eight volunteers recruited, thirty-one completed, sixteen female and fifteen male, mean age 32.2 years, median 31, range 18 to 58, in three age strata of 18 to 29 (n=13), 30 to 40 (n=13) and over 50 (n=5). All ophthalmologically healthy: best corrected acuity 20/20 or better, intraocular pressure below 22 millimeters of mercury, clear media, intact visual field, with glaucoma, disc drusen, opacities and high refractive error excluded. Right eyes only, the fellow eye occluded. Four hundred thirty-four completed visual fields and 32,984 data points.

Apparatus and exposure geometry. An Octopus 900 automated perimeter modified by mounting an interchangeable light-emitting diode on an adjustable carrier along the inner horopter, driven by a four-channel Thorlabs DC4100 driver at bounded intervals of 25, 50, 75 and 100 percent of nominal output. Incoherent diodes were used in place of coherent laser light for safety. The source was placed 15 degrees inferior and 10 degrees left of center, deliberately avoiding direct irradiation of the fovea. Standard 30-2 white-on-white perimetry on a 6-degree grid, 76 points per field. The perimeter's background illumination was switched off, giving a background luminance of 0.255 candelas per square meter, which the authors describe as comparable with mesopic conditions and which is a fortieth of the 10 candelas per square meter at which photopic perimetry is conventionally run.

Device ceiling 40 decibels; threshold defined as the stimulus luminance seen with 50 percent probability.

Exposure, measured and reported in both systems of units. This is the best-characterized human exposure in this appendix, and the Foundation reproduces the authors' table because the comparison between its two halves is the reason the entry matters. Irradiance was measured at eye level; illuminance was computed from the radiometric measurements following the published photometric principles of the International Bureau of Weights and Measures; retinal illuminance was calculated from source luminance and mean pupil area.

Quantity and wavelength	25%	50%	75%	100%
Irradiance at eye, 470 nm (µW/cm²)	4.91	9.21	13.12	16.68
Irradiance at eye, 530 nm	5.74	9.73	13.01	15.83
Irradiance at eye, 625 nm	6.84	13.24	19.19	24.52
Illuminance at eye, 470 nm (lux)	1.62	2.92	4.31	5.34
Illuminance at eye, 530 nm	26.80	44.60	57.33	68.03
Illuminance at eye, 625 nm	12.35	24.02	34.30	41.57

Results on disability glare. Unexposed fields gave mean sensitivities of 34.1 to 39.7 decibels, mean 37.8 with standard deviation 1.5. Under glare, mean sensitivity fell as intensity rose, at every wavelength, with the inferonasal quadrant significantly worse than the others (p less than 0.001) where unexposed subjects showed no inter-quadrant difference at all. Loss was greatest at 530 nanometers, then 470, least at 625, at every intensity (p at most 0.001). Reconstructed fields placed the deepest scotomas around 15 degrees in the lower left quadrant and 10 to 15 degrees off center. The inferonasal quadrant carried 71 absolute scotomas, comparable with the 70 found in the blind spot itself, and 15 absolute scotomas appeared out at the 30-degree limit of measurement. Adjusted coefficients of determination for the intensity model were 0.125 at 625 nanometers, 0.224 at 470 and 0.252 at 530.

The finding the comment relies on, which is about units. The ordering of functional impairment was 530, then 470, then 625 nanometers, at every intensity. The ordering of irradiance was 625 highest at every intensity. The ordering of illuminance was 530, then 625, then 470 at every intensity. The impairment ordering therefore matches neither. At full power the red source delivered about 1.5 times the irradiance of the blue and about 7.8 times its illuminance, and produced the least impairment of the three; the green source delivered slightly less irradiance than the blue and about 12.7 times its illuminance, and produced the most. The authors state the puzzle themselves, that the result "was unexpected" given illuminances about eight times higher at 625 nanometers and up to fifteen times higher at 530 than at 470, and they resolve it by the adaptation state: the mesopic background shifted the spectral luminous efficiency function toward the blue, so that neither the photopic weighting nor the unweighted radiometric total described what the eye did.

Why that is the most useful thing in this entry. Because it is a measured demonstration of the proposition Part V.J.1 asks the Department to adopt. A single number did not predict the effect, and this is true of both single numbers. Photometric reporting failed because it weights by a photopic observer who was not present. Radiometric reporting failed on its own because an unweighted total discards the spectral distribution. What predicted the response was the spectral composition read against the adaptation state of the eye. That is why Part V.J.1 requests spectral power distribution with photometric quantities given in

addition rather than instead, and why Part V.B treats the spectral characteristic as independent of the others. The Foundation knows of no cleaner instance in the literature it has examined.

Results on discomfort glare, and the dissociation from disability. Discomfort was rated on the de Boer scale, which the authors describe as still the most common perception scale in automotive and public lighting and which runs unbearable (1), disturbing (3), just admissible (5), satisfactory (7), unnoticeable (9). Ratings worsened stepwise with intensity at every wavelength, from about just admissible at 25 percent to nearly disturbing at 100 percent, significant at full power against lower levels for all three wavelengths except red at 100 against 75 percent. But the two measures came apart. Perceived discomfort was highest at 470 nanometers while measured field loss was greatest at 530, so that blue was the most annoying and green the most disabling. Relative to baseline, measured field defects moved 1 to 25 percent while subjective ratings moved up to 60 percent, and the coefficients of determination for discomfort were very low, 0.066 at 625 nanometers, 0.094 at 470 and 0.007 at 530. The Foundation draws the conclusion that bears on Part V.C.4: what a person reports about glare and what glare does to that person's vision are different quantities, and neither substitutes for the other.

Age. No difference by sex in measured sensitivity at any wavelength or intensity. Participants aged 50 and over were significantly more affected than the rest (p less than 0.001), with no difference between the 18 to 29 and 30 to 49 groups. Including age raised the explained variance substantially, to 0.385 at 625 nanometers, 0.433 at 470 and 0.561 at 530. The authors attribute it to the known increase of straylight with age-related opacity of the refractive media. The comment should read that alongside the age-resolved transmittance figures at Part V.C.2.g, which run the other way for children, and should not merge the two: one concerns short-wavelength transmittance in the young, the other scatter in the old, and both describe departures from the single assumed observer on which limits are built. Discomfort ratings showed no age or sex effect.

What it establishes for Part V.C.1. That measurable functional impairment occurs at exposures the authors describe as subthreshold. Their conclusion opens: "our results indicate that LED dazzling with subthreshold amounts of monochromatic light tends to affect the complete central visual field of exposed individuals with relative and absolute scotomas scattered around the source of glare, even when exposure is decentered and the light is not precisely focused by physiological accommodation." Their introduction states the consequence for the products this comment concerns: that because the remote risk of retinal injury from distant illumination is considered generally low, "glare-induced visual impairment has to be regarded the main hazard for mobility-related tasks i.e., road and air traffic." A framework that asks only whether a source produces a lesion does not reach that hazard.

Mechanism, as the authors describe it. They distinguish veiling glare, the generalized flooding of the eye by forward scatter, from what they call scotomatic glare, in which the loss is spatially tied to the retinal location corresponding to the external source. They attribute their result mainly to the latter and suggest photoreceptor saturation rather than inter-reflection as the key mechanism for a point source. They report a paradoxical central sparing and offer two explanations, the high cone density at the center and a Stiles-Crawford-like directional effect arising because the eccentric source did not enter through the center of the pupil. They state the mechanism is probably multifactorial and unresolved.

Limitations, including two that run against the comment and one that runs for it. Against: light-emitting diodes were substituted for lasers, so the study does not describe laser exposure, and the authors judge that it probably understates what a laser pointer would do; the source was moved off axis to protect the fovea, which the authors say introduced additional variables and biometric confounding; the exposures were

monochromatic where the products this comment concerns are broadband; the subjects were thirty-one healthy volunteers in a clinical setting, not drivers or pedestrians; and the framing throughout is deliberate dazzling and its misuse, not illumination. For: the three wavelengths were not isoluminant, and the blue channel in particular "had to be technically lowered on behalf of the ethics comittee" to avoid excess dose. The blue source was therefore run at the lowest illuminance of the three by a wide margin, and still produced more impairment than the red. The authors recommend isoluminant sources in future work.

The authors on the de Boer scale, which bears on Part V.C.4. They conclude that de Boer's scale, "although representing the most widely used rating scale for glare environments, might be less useful in small-study populations and real-life applications," and call for larger samples and more detailed rating scales. The Foundation records that the Federal Highway Administration study described at Part V.D.4 used a three-category scale of its own devising and named no established scale at all. The most widely used instrument for discomfort glare is criticized by its users as unsuitable for real-life application, and the federal research on the subject did not use it.

The inference the Foundation draws, and whose it is. Part V.D.4 records that the research arm of the Federal Highway Administration hypothesized in 2015 that a driver who looks away from an unbearable glare source "might miss the identification of conflicts or hazards located near the glare source," and did not test it. This study supplies the step that hypothesis needs, that impairment does not require the observer to be looking at the source, and its authors reach the adjacent conclusion that "glare-induced visual field reduction might be a stronger predictor of driver or pilot incapacitation than visual impairment only." Joining those to the devices at Part VI.C is the Foundation's inference and is advanced by neither set of authors.

Where it bears. Part V.C.3, which should be written on it. Part V.C.1, for functional impairment below the injury threshold. Part V.C.4, for the two findings on rating scales. Part V.J.1 and Part V.J.4, for the units. Part V.B, for the spectral characteristic in humans. Part V.D.4 and Part VI.C, for the roadway inference. Part IX.C.1, for the measurement request.

C.86 Khan (2019) — closed-form derivation of the near-field intensity distribution of a finite flat light-emitting diode, and why Lambert's law supplies the shape of the emission and not its magnitude

Citation. Khan MN. "Derivation and Experimental Verification of the Near-field 2D and 3D Optical Intensities From a Finite-size Light Emitting Diode (LED)." IEEE Photonics Journal 2019;11(6), article 8201219, pages 1 to 19. doi:10.1109/JPHOT.2019.2948816. Received 20 September 2019, accepted 18 October 2019, published online 22 October 2019. Open access under a Creative Commons Attribution 4.0 license; full text read. Sole author, affiliated to IEM LED Lighting Technologies, Red Bank, New Jersey, and the author of a monograph on light-emitting diode illumination published by CRC Press in 2013 which the paper cites. The near-field goniometric measurements reproduced in the paper were supplied by TechnoTeam Bildverarbeitung GmbH and are acknowledged as such.

What kind of paper this is. A theoretical derivation with partial experimental verification, published in a peer-reviewed journal of the Institute of Electrical and Electronics Engineers. It is not a health or safety study and makes no claim about either. The Foundation relies on it for the physics of how light leaves a light-emitting diode, which is a question the comment must answer before any exposure quantity can be stated, and for four explicit statements by the author which bear on the adequacy of the quantities in which the product is presently described.

The author on the quantity at issue. The paper opens on the question Part V.B.2 and Part V.B.8 address. "These applications require high-quality color properties of light that

depend on the brightness of the light source, which is technically known as luminance. Luminance is equal to luminous intensity per square area, and for LEDs and lasers, it depends on the viewing angle rather significantly." The conclusions identify the derived surface distribution in the same terms: "This surface distribution, known as luminance in the lighting and display industry, is a paraboloid, which resembles a Gaussian over a substantial part of the transverse domains where the transient effects only play a small role."

The derivation, in outline. For an infinitesimal flat element the author integrates the generalized solid angle in spherical coordinates and recovers Lambert's Cosine Law, I = I(max) cos φ. She then sums the elements over a finite emitting rectangle of dimensions X(L) by Y(L) containing m by n radiative electron-hole pairs, each contributing an inherent luminance L(avg), and obtains a luminous intensity distribution of the same Lambertian form whose constant of proportionality scales with the product of the emitting area, the number of pairs and L(avg). Projecting that three-dimensional distribution onto the emitting surface yields the surface intensity profile, which is a paraboloid of the form $z = C(max) - r^2$. The author notes that the Lambertian result is widely used and its condition widely forgotten: "it appears that many overlook as to why it is only valid for a 'differential-area' source, i.e., an infinitesimally small, flat source."

First finding relied on: the law gives the shape and not the peak. The author states the limitation of the Lambertian description expressly. "Although Lambert's Law holds for a differential area element in both near and far fields, it is only useful for a far-field luminous intensity pattern generated by a flat source that can be treated as an infinitesimal, flat source from very far away. From this law, one cannot calculate or predict I max in near or far field. In order to use Lambert's law, I max must be measured and then I can be calculated for any φ, provided the flat source is a square." The consequence for this comment is direct. The Lambertian assumption that runs through lighting design and photometric reporting fixes how intensity falls away from the axis. It is silent on how large the on-axis value is. That value must be measured, and Part V.J records that for the products at issue it is not.

Second finding relied on: what the peak scales with. The author states the scaling of the peak in terms, and the Foundation quotes it rather than paraphrasing because the word is hers. "the peak of the parabola shown in Fig. 11 would become enormous when L avg for the LED is very high due to very high inherent quantum efficiency, high light extraction efficiency form the LED chip, and driven by a large current. The peak of the parabola would also become very large when the size of the LED chip is very large." The word form in that passage appears in the original. Four quantities therefore govern the peak: the area of the emitting surface, the number of radiative pairs within it, the inherent luminance of each, and the drive current. None of the four is reported on a component data sheet, required by any standard examined in this comment, or recoverable from the lumen rating by which the product is sold. The author describes the practical use of the result as design control: "Our derived formula for surface intensity distribution provides a unique way to calculate the peak intensity generated by an LED which occurs in the middle of the diode surface."

Third finding relied on: directivity follows from the flat geometry. The author contrasts the emission of a finite flat diode with that of a point source. "Fig. 17 also shows the directivity of the beam generated by a finite, flat LED and such a behavior is never observed from a point radiant source that generates intensity distribution omni-directionally over the full solid angle range spanning from 0 to 4π steradians." She further reports that the transverse confinement depends on the shape of the emitting surface: it is circular on planes perpendicular to the optical axis where X(L) and Y(L) are equal, and where $X(L) \neq Y(L)$ the confinement is elliptical. This is the mechanism underlying the difference between a square and a round emitter recorded at Appendix D.3. The

significance for the comment is that the beam is a consequence of the shape of the emitter, present before any lens or reflector is fitted, and not a property conferred by the optic.

Fourth finding relied on: the comparison with a fluorescent lamp. The author photographed a G12 corn lamp carrying seventy surface-mount light-emitting diode modules, operating at 10 watts on 100 to 240 volts alternating current and producing 1,080 lumens, and observed the weighted Lambertian pattern from each flat face. She then states the comparison: "such patterns are never observed for fluorescent G12 lamp counterparts because their emitting surfaces are not flat." A lamp of the same fitting and comparable output does not produce the pattern, and the difference is attributed to one property of the newer source, namely that its emitting surface is flat.

The array measurement, which bears on Part V.J.3. Near-field goniometric measurement was performed on a task lamp carrying twenty-one discrete light-emitting diode modules mounted on flat surfaces, using a RiGO-801 near-field goniometer and plotted in candelas per kilolumen. The measured distribution was not that of a single emitter enlarged. The author reports a weighted Lambertian, attributes the departure to the number of elements, their coarser spacing and the greater size of the emitting plane, concludes that "the Lambertian LIDs are indeed weighted according to the x and y dimensions of the flat LED sources", and notes that the data would show more asymmetry at higher angular resolution.

What was verified experimentally, and what was not. The angular shape was verified against measured goniometric data. The magnitudes were not, and the author says so: "The magnitudes of the measured LIDs are not associated with our analytic solution in this study because one would have to measure the 'L avg' equivalent luminance values for the individual LED modules in the experimental samples. These will be included in our future studies." The surface-profile comparison was made against Philips LXHL data distributed for ray-tracing software rather than against a direct measurement of surface luminance, and the author records the limitation: the simulated plot "does not strictly represent the source surface intensity, i.e., exactly at z = 0. Instead, it is approximated via simulation at the detector plane." She identifies four sources of error in that comparison. The predicted dependence of the peak on emitter size is likewise stated as future work: "Our future work will also include measurements and calculations of LEDs of various sizes and shapes for the light emitting surface showing the increase of peak intensities as the surface size increases while keeping the drive current constant." No part of this comment may state that this paper measured a peak luminance for any product.

A statement in this paper that runs against the comment. The author states that "LEDs in general have random polarization and they are incoherent light sources because of the spontaneous emission process; therefore, random polarization, birefringence, and random phase all get averaged in the intensity that is generated by the surface normal LED." That is the opposite of the proposition for which Part V.C.2 relies on the measured spatial coherence lengths reported in the optics literature. The two statements concern different quantities, as Part V.C.2 now records, and neither author addresses the other. The Foundation does not cite this paper in support of the coherence argument and has placed the conflict in the body text rather than leaving it to be found.

A technical reservation, and its consequence for how the paper is used. Equation 5 of the paper carries the cube of the viewing-distance magnitude, so that luminous intensity appears to scale with distance, while the discussion later states correctly that luminous intensity in a given direction "is unchanged regardless of the distance of the viewer or detector by definition." The author reconciles the two by treating the distance term as absorbed into a constant evaluated at a chosen viewing distance. The cosine dependence, which is the result the Foundation relies on, is unaffected. The comment accordingly cites the proportionalities and the Lambertian result and does not reproduce the paper's equations as quantitative formulas.

Two further matters of quality, recorded rather than concealed. The paper cites an encyclopedia article accessible on the public internet as its authority for Lambert's Cosine Law, which is a textbook result available in the standard references the paper cites elsewhere; the comment does not rely on this paper for the statement of that law. The published text carries several uncorrected typographic errors. Twenty-eight days elapsed between submission and acceptance for a paper of nineteen pages. None of this bears on the four findings above, each of which is either direct quotation or an immediate consequence of the author's algebra, but it is the reason the comment cites the paper for its derivation and its express statements rather than treating it as settled authority.

Where it bears. Part V.B.8, which is written on it, for the geometry that produces the emission pattern and for the scaling of the peak. Part V.B.2, for the identification of luminance as the governing quantity and for the fourth consequence now recorded at subsection e. Part V.J.3, for the array measurement. Part V.C.2, for the contrary statement on coherence. Appendix D.3, whose square and round emitter figures this paper explains.

C.87 Williamson and McLin (2018) — quantitative exposure limits for visual impairment without injury, derived for coherent sources and proposed for international safety standards

Citation. Williamson CA, McLin LN. "Determination of a laser eye dazzle safety framework." Journal of Laser Applications 2018;30(3):032010. doi:10.2351/1.5029384. Published 18 July 2018 by the Laser Institute of America; designated an Editor's Pick. Open access under a Creative Commons Attribution 4.0 license; full text read. The acknowledgment thanks colleagues across the United Kingdom Ministry of Defence and the United States Department of Defense.

Why this entry is in an appendix otherwise concerned with light-emitting diodes. It is not about light-emitting diodes and the Foundation does not present it as evidence about them. It is in this appendix because it is a worked instance, in the peer-reviewed literature and with United States federal authorship, of the thing this comment says has never been done for incoherent sources: the derivation of quantitative exposure limits for impairment of vision that produces no injury. What it supplies is a method and a demonstration of feasibility, not a number that may be carried across.

The gap the authors identify, in their own words. The introduction states the asymmetry this comment makes for a different emitting technology. "Cases of permanent eye damage caused by lasers are still relatively rare, with the risks of eye damage from laser systems being well understood and comprehensively documented in international laser safety standards. However, despite the significantly greater frequency of laser eye dazzle events, there is an absence of equivalent guidance for laser eye dazzle effects in these standards." The standards referred to are ANSI Z136.1-2014 and EN 60825-1:2014. The authors characterize the need as urgent and the paper as the scientific background to a framework proposed for adoption, the full text of which is an annex to the paper.

The quantity defined, and the limit it is built against. Dazzle is defined at the opening as "the temporary impairment of human performance caused by visible wavelength laser light." The limit is the Maximum Dazzle Exposure: "The MDE is the laser irradiance at the eye above which an object cannot be visually detected through this dazzle field." The authors then state the structural point this comment takes from the paper: "MDE is analogous to the established concept of Maximum Permissible Exposure (MPE) which sets the laser irradiance limit above which there is a risk of permanent eye damage." The field therefore has two limits in the same units for the same radiation, one for injury and one for

functional impairment, and the second was constructed because the first did not describe what was actually happening to people.

How the limit is resolved, which is the part that matters for method. Three variables, each of which the Foundation argues at Part V.J must enter any adequate specification. Extent of impairment, through a defined dazzle level: very low is a 2-degree full-angle obscured field centered on the source, low is 10 degrees, medium 20 degrees and high 40 degrees. State of adaptation, through three ambient luminances approximating night at 0.1, dusk or dawn at 10, and day at 1,000 candelas per square meter, with the authors noting that dazzle is "more readily achieved as the ambient light level decreases from day to night." And wavelength, by dividing every tabulated value by the photopic luminous efficiency V(λ) at the wavelength concerned, the authors giving V(450) = 0.0647, V(550) = 0.9890 and V(650) = 0.1193.

The proposed limits. Table VI of the paper, offered by the authors as "the proposed table of MDE values to be used in laser safety standards." Values are irradiance at the eye in microwatts per square centimeter, each to be divided by V(λ).

Acceptable dazzle level	Night (0.1 cd/m²)	Dusk or dawn (10 cd/m²)	Day (1,000 cd/m²)
Very low – 2° obscured	0.001	0.6	40
Low – 10° obscured	0.04	30	2,000
Medium – 20° obscured	0.16	120	8,000
High – 40° obscured	0.6	450	30,000

What was measured and what was modeled, which the entry separates because the authors do. The experimental basis is a human-subject letter-orientation task reported in the authors' earlier work: a tumbling-E character of 0.4 degrees with a 0.08-degree bar width at 60 percent contrast, viewed monocularly in negative contrast, across up to eight laser wavelengths. The table above is not that measurement. It is modeled output, computed for binocular viewing after the model had been validated against the monocular experimental data, then rounded. Three qualifications follow and all are the authors'. Night values for the standard object were not measured at all, because the target "was too near threshold and could not be reliably discriminated by many of the subjects"; measured night values exist only for a larger and higher-contrast target. Many of the daylight values were extrapolated beyond the irradiances actually used, the experiment having never exceeded 1,000 microwatts per square centimeter. And the model assumes a single observer profile, age 40 with dark eye pigmentation. The authors state the status of the result plainly: "The final MDE table should be taken only as an approximate guide to the laser irradiances required to cause the stated dazzle levels at the given ambient light levels."

The first finding the comment takes from the table, and the arithmetic is the Foundation's. The paper states that the Maximum Permissible Exposure for a 10-second visible exposure is 1,000 microwatts per square centimeter, and that for a quarter-second exposure it is 2,546. Set the injury limit against the impairment limits above. At night, the irradiance that obscures 40 degrees of the visual field is 0.6 microwatts per square centimeter, which is about one thousand seven hundred times below the injury limit for a 10-second exposure. The irradiance producing the least dazzle the framework recognizes is 0.001, about one millionth of it. Even at 450 nanometers, where the division by V(λ) raises the limit by a factor of about fifteen, a high dazzle level at night arrives at roughly 9 microwatts per square centimeter, still about one hundred times below the injury limit. The Foundation states the consequence and no more: for this radiation, in darkness, compliance with the injury limit leaves between two and six orders of magnitude of headroom above the exposure that destroys the usability of the visual field. The ratios

are the Foundation's arithmetic on the authors' published values; the authors do not state them in that form.

The second finding, likewise the Foundation's arithmetic. The same table quantifies the dependence on adaptation that Part V.B.2 and Part V.C.3 argue for. Holding the dazzle level constant, the irradiance required in daylight exceeds that required at night by a factor of 40,000 at the very low level and 50,000 at each of the other three. From night to dusk the factor is 600 at the very low level and 750 at the others. The authors note the direction of the effect; the factors are the Foundation's computation from the tabulated values.

The daylight collision between the two limits, which the authors do state. In daylight the relationship inverts, and the authors say so: "During the day, a Very Low DL can be achieved with around 40 μW cm−2, but greater levels of dazzle require irradiances that exceed the visible wavelength MPE–i.e., the observer would be at risk of eye damage if exposed to these levels of dazzle." Three of the four daylight values in the table carry a footnote recording that they exceed the injury limit. So the injury limit binds first in daylight and is almost irrelevant at night. A limit addressed to injury is therefore not a conservative proxy for impairment; whether it protects against impairment at all depends entirely on the ambient condition, and in the condition where these products are most used it does not.

The object the limit is defined against, which bears on Part VI.C. A limit of this kind requires a defined visual task, and the authors chose one: an object of 0.08 degrees at 60 percent contrast. They give the everyday equivalents, and the second is the one this comment should notice. Detecting an object of that size is "approximately equivalent to detecting a 5 m long car at a range of 3.5 km or a 0.5 m human torso at 350 m." The limits above are therefore limits on the irradiance at which a human torso at 350 meters ceases to be detectable. Part V.D.4 records the research arm of the Federal Highway Administration measuring pedestrian detection distances averaging 116 feet at night, and hypothesizing without measuring that a driver who looks away from an unbearable glare source might miss a hazard near it. The laser safety literature has built the quantity that hypothesis requires, for its own emitting technology.

A tension with Appendix C.85 that the Foundation records rather than resolves. The framework scales by photopic luminous efficiency, so it predicts that equal dazzle follows equal photopic illuminance regardless of wavelength. The study at Appendix C.85, which applied dazzle methodology to light-emitting diodes at a mesopic background of 0.255 candelas per square meter, reports a result that does not follow that rule. At full intensity its three sources delivered 5.34, 68.03 and 41.57 lux at 470, 530 and 625 nanometers. Photopic scaling predicts impairment ordered 530, then 625, then 470. The measured impairment was ordered 530, then 470, then 625: the blue source impaired vision more than the red while delivering about one eighth of its photopic illuminance. The Foundation does not call this a refutation and the comparison is its own arithmetic across two papers. The endpoints differ, one being detection of a defined object through a dazzle field and the other perimetric sensitivity across the central field, and the sources differ in coherence. What it indicates is that a photopic weighting is the element of this framework least likely to transfer to incoherent sources, and that it would err in the direction of understating the short wavelengths, which are the wavelengths at issue in this comment.

The practice of the field, offered as a comparison. The authors published the complete data and analysis for both this paper and the underlying experiment as citable datasets, together with a spreadsheet calculator for computing limits, protection requirements and the Nominal Ocular Dazzle Distance, which they define as the distance beyond which a source delivers less than the Maximum Dazzle Exposure and which stands to the dazzle limit as the Nominal Ocular Hazard Distance stands to the injury limit. Their stated purpose was "to encourage independent verification of the methodology." The Foundation records this because Part V.J reports the opposite condition for the products at issue,

where neither the emission characteristics nor the measurement protocols are published in a form permitting verification.

What it establishes. That exposure limits for impairment of vision without injury can be derived from human subject data; that they can be resolved by severity of impairment, by state of adaptation and by wavelength; that a limit so derived can be expressed in the same irradiance units as the injury limit and used in the same safety calculations; that the derivation was carried out with the participation of a United States federal research organization and published in the peer-reviewed literature; and that the field undertaking it regarded the absence of such guidance from its safety standards as urgent.

What it does not establish. Nothing about light-emitting diode products. The values depend on a monochromatic collimated beam producing a particular retinal irradiance distribution, and the comment's position at Part II.C.3, that diodes and lasers differ in coherence and collimation and that the difference is real, is unchanged. No value in this entry may be applied to an incoherent or extended source. The table is modeled rather than measured, is extrapolated at the upper end, assumes one observer profile, and is offered by its authors as an approximate guide. The framework is proposed for adoption into standards; this entry does not establish that it has been adopted.

Where it bears. Part V.C.3, which is written on it and whose outstanding request for Williamson it answers. Part V.K.3, for the margin between the injury limit and the impairment threshold, which bears directly on a safety conclusion conditioned on compliance with an injury limit. Part V.C.1, for the distinction between lesion and impairment. Part II.E, for the asymmetry between the agency's treatment of coherent and incoherent optical radiation, which this paper extends from standards recognition to the hazard science itself. Part V.J.1 and Part V.J.4, for the units. Part VI.C, for the object standard.

C.88 Babadi and others (2017) — why a street lighting luminaire needs a secondary optic, the threshold at which an emitter stops behaving as a point, and the dependence of the designed distribution on the source

Citation. Babadi S, Ramirez-Iniguez R, Boutaleb T, Mallick T. "Performance Comparison of a Freeform Lens and a CDTIRO When Combined With an LED." IEEE Photonics Journal 2017;9(5), article 6501008, pages 1 to 8. doi:10.1109/JPHOT.2017.2728701. Received 21 March 2017, revised 13 July 2017, accepted 14 July 2017, published online 18 July 2017. Open access; full text read. Marked an invited paper. The first three authors are at the School of Engineering and Built Environment, Glasgow Caledonian University; the fourth at the Environment and Sustainability Institute, University of Exeter. Supported in part by the Energy Technology Partnership of Scotland, by Optical Antenna Solution, and by Glasgow Caledonian University.

How the Foundation came to this paper, which bears on how it is cited. The work was first presented as a conference paper, Analysis of uniformity of illumination of a freeform lens when combined with different optical sources, SPIE Proceedings volume 9744, article 974417, 2016. A conference paper is not an article in a peer-reviewed scholarly journal and is therefore outside the criterion stated in the preamble to this appendix. The present entry is of the journal paper, which reports the same program of work and cites the conference paper as its own authority for the threshold described below. The same four authors published two further journal papers on this work, in Applied Optics in 2018 and in Optical Engineering in 2020, neither of which has been read.

What the paper is. An optical engineering study comparing two secondary optics, a single refractive freeform lens and a circular dielectric totally internally reflecting optic of the authors' own design, each combined with the same light-emitting diode and each intended to convert its output into uniform illumination of a defined area. Both were designed by energy mapping, fabricated in polymethyl methacrylate by computer numerical control to

a precision of 5 to 30 micrometers, simulated by ray tracing in Zemax, and then measured. It is not a health study and reports no biological endpoint. The Foundation relies on it for four propositions about the emission of these sources and about what an optic can and cannot do with it.

Apparatus and dimensions. The emitter was a Cree XLamp 1507 with an active area 0.89 centimeters in diameter. The freeform lens was 2.5 centimeters high and 4 centimeters wide and was designed to illuminate a circle of 50 centimeters radius at a distance of 1 meter. The alternative optic had an entrance aperture 1.7 centimeters high and 0.9 centimeters in radius and was designed for a circle of 35 centimeters radius at the same distance. Uniformity is defined by the authors as "the ratio of the minimal illuminance over the area weighted average illuminace", the misspelling being theirs, and both optics achieved over 95 percent on that measure in both simulation and measurement.

First proposition: these sources cannot be used for street lighting as they emit. The authors state the reason a secondary optic is required at all, and the Foundation quotes it because it is the application-side counterpart of the derivation at Appendix C.86. "In spite of the advantages of LEDs, it is impractical in many cases to use them in street light luminaires directly without a suitable secondary optic due to their lambertian radiation pattern. Normally, the LED produces high light intensity at the centre and low light intensity at the edge of its circular illumination footprint." The spelling centre is the authors'. Two things follow that this comment uses. The distribution is Lambertian, which is what Khan derives from the geometry of a flat emitter and what the manufacturer at Appendix D.3 states it designs for. And the intensity is concentrated at the center of the footprint, which is the peak the whole of Part V.B.2 concerns.

Second proposition: the threshold at which an emitter stops behaving as a point. The design method assumes a point source. The authors state where that assumption fails: "A point light source (small LED) has been assumed in Fig. 1. However, high power LEDs (extended light sources) are required in application such as street lighting. Using an extended light source reduces uniformity on the target plane. To keep uniformity the size of the light source and the optic have to be taken into account. An extended light source acts as an approximate point light source when the size of the optic is five times larger than the light source." That is a stated numerical threshold for the failure of the point-source approximation, and it is the third independent statement of such a threshold the Foundation has collected: Khan derives at Appendix C.86 why a finite flat emitter is not a point, the metrology reference work described at Appendix D.5 gives a photometric distance of five to fifteen times the source extent, and these authors give five times the source size as the condition on the optic. The authors attribute the threshold to their own earlier conference paper.

Third proposition, and the one with the most consequence: the designed distribution depends on the source. The finding stated in the abstract is that the two optics differ in robustness rather than in peak performance. "Both optics can produce over 95% uniformity within an illuminated area. However, the uniformity produced by the freeform lens reduces abruptly compared with the CDTIRO when some parameters such as size and the position of the light source are changed." In the comparison section the authors put it as a property of their own design: because its footprint is the sum of two illuminations, the alternative optic "reduces the effects of changing the light source or the size of the optic in the uniformity of illumination." The consequence the Foundation draws is that the illumination a luminaire actually produces is a property of the source and the optic together and not of the optic's design, and that it is not robust to a change in the size or position of the emitter.

Fourth proposition: optics in an array interfere. On the freeform lens in a multiple-element installation: "it is necessary to provide a gap between them in order to keep uniformity of illumination. Otherwise the lenses act like obstacles and uniformity

deteriorates." The emission of an array is therefore not the sum of the emissions of its elements on the optical side either, which is the proposition Part V.J.3 advances on other grounds.

What it does not establish, and a limit the Foundation states against itself. It establishes nothing about health, exposure or injury and the Foundation does not offer it for any such purpose. On its own central finding it is qualitative: the degradation of uniformity is described as abrupt and is nowhere quantified, no figure is given for how much uniformity is lost for a given change in source size or position, and no part of this comment may imply a magnitude. The work concerns illumination of a target plane and not exposure of an eye. And the uniformity measured is uniformity of the illuminated surface, which is a different quantity from the uniformity of the emitting surface discussed at Part V.B.2.

An attempted inference the Foundation abandoned, recorded because the abandonment is informative. The Foundation attempted to explain the difference in robustness by the authors' own five-times threshold and could not. The freeform lens is 4 centimeters across against an emitter of 0.89 centimeters, a ratio of about 4.5 and so just below the stated threshold, which would account for its fragility. But the alternative optic has an entrance aperture about 1.8 centimeters across, a ratio of about 2 and so further from the threshold, and it is the more robust of the two. Either the threshold does not govern robustness or the relevant dimension is not the one used here. The authors attribute the robustness to the summing of two illumination components and not to size. The arithmetic is the Foundation's, it does not support the inference, and no part of this comment advances it.

Considerations bearing on confidence. In favor: both optics were fabricated and measured rather than only simulated; the simulation and the experiment used the same optic size, source size, refractive index and source radiation pattern, which the authors state expressly; the emitter is a named commercial component and the manufacturer's own simulation data were used; and the central finding runs against the authors' interest in neither direction, since both optics are reported to reach the same peak uniformity. Against: the paper is an invited paper accepted one day after revision; the study compares the authors' own novel optic favorably with an established alternative, which is an interest; the measurement of uniformity is described only as taken with a light sensor at marked intervals, with no instrument named and no uncertainty stated; and the scholarly apparatus is careless in several respects. The Foundation accordingly cites this paper for the authors' own measurements and their own stated design rules and not as authority for anything they attribute to others.

Where it bears. Part V.B.8, for the Lambertian and center-peaked emission and for the point-source threshold. Part V.J.1, for the dependence of the delivered distribution on the source. Part V.J.3, for the interference between optics in an array. Part VI.D, Roadway, Area and Parking Lighting, which is presently unwritten and for which this is one of the sources.

C.89 Moreno and Sun (2008) — the radiation pattern of real light-emitting diodes, why the chip and the package differ, and a published recommendation that manufacturers disclose what the half angle does not

Citation. Moreno I, Sun C-C. "Modeling the radiation pattern of LEDs." Optics Express 2008;16(3):1808 to 1819. doi:10.1364/OE.16.001808. Published by the Optical Society of America, now Optica Publishing Group. Open access under the publisher's version-of-record open access license; full text read. The first author is at the Universidad Autónoma de Zacatecas, Mexico, and the second at National Central University, Taiwan. Supported by the Ministry of Economic Affairs of the Republic of China under contract 94-EC-17-A-

07-S1-043. The publisher records 297 citing works, which makes it the most cited item in this appendix so far as the Foundation is aware.

Article type. A modeling paper in a peer-reviewed optics journal. It proposes an analytic representation of the angular intensity distribution of a light-emitting diode, fits it to the published distributions of named commercial devices from several manufacturers, and reports the accuracy of the fit. It is not a health study and reports no biological endpoint. It is in this appendix because the appendix admits peer-reviewed articles whatever their subject matter, and because four propositions in it bear on Part V.B.

First proposition: the chip is Lambertian and the finished device is not. The authors locate the Lambertian form precisely, and the location is the emitting region rather than the product. "In LEDs, light is produced by spontaneous emission from the light-emitting region of chip. Therefore, the generated light is incoherent and its superposition is a linear combination in intensity terms. From the radiometric point of view, the emitting region is a Lambertian light source." And of the chip faces: "The radiation pattern emitted by every chip face will generally be Lambertian, although in some LEDs, this pattern is modified by special microstructures on the chip and by wave guide effects inside the chip." The emitted pattern of the finished device is then the sum of three contributions, from the chip, from the reflecting cup and from the encapsulating lens, and the authors identify the three structural factors that modify it: the roughness of the chip faces, the geometry and roughness of the reflective cup, and the geometry of the encapsulant lens.

Second proposition: the lens is what narrows the beam. The authors state the direction of the effect: "In most cases, the lens angularly narrows the radiation pattern (due to the chip and the mirror), though sometimes it enlarges the pattern." That supplies the mechanism for the measurement at Part V.B.8 in which four packaged devices were found to depart from the Lambertian form in the narrowing direction, and it is the explanation the Foundation preferred there over coherence. The authors also supply the term the literature uses for that departure, calling a cosine-power distribution with an exponent above unity an imperfect Lambertian.

Third proposition: the point-source approximation fails further out for these devices than the standard rule predicts. The authors set out the conventional rule and then correct it for this technology. The rule is that a source may be treated as a point beyond about five times its largest dimension. Of that rule they write: "this rule of thumb is not so easily applied to LEDs because of the radiance complexity and wave effects", and they record that a separate concept, the mid field, had to be proposed for these sources. Then the figure: "Using the radiometric definition, a high-power LED with a 1mm2 chip should have a 5-mm near field, but in practice up to 20-mm mid fields are found." Their own laboratory measurements place the onset of the far field at about 20 millimeters from the tip for some power devices and "a little longer in multi-chip LEDs." The rule therefore under-predicts, for this technology, by up to a factor of four.

Fourth proposition, and the one the comment principally relies on: a published recommendation that the data sheet disclose more. The authors state what manufacturers publish and why it is not enough, and then make a recommendation. "Most manufacturers use $\theta 1/2$ (the view angle when radiant intensity is half of the value at 0°) to characterize the angular distribution of LEDs with a single intensity peak." They note a second published attribute, the total included angle within which ninety percent of the flux is radiated, and then: "However, additional parameters are needed to render the shape of the radiation pattern. Therefore, we propose that the manufacturer should include a simple formula (like those reported here) with its coefficients in their technical data sheets." That is a recommendation, published in a peer-reviewed optics journal in 2008 and since cited several hundred times, that the information this comment asks for at Part IX.F be disclosed on the data sheet.

What was modeled, and against what. The model is a sum of at most two or three Gaussian or cosine-power terms, the number corresponding to the three optical elements. It was fitted to the published distributions of named devices from Nichia, Cree, Lumileds Philips, Edison, Osram and Seoul Semiconductor, including the Nichia NSPW345CS, the Cree XLamp XR-E, the Lumileds Luxeon Rebel, K2, Side Emitter and Batwing, the Edison EdiPower 3-RD-01-H0001, the Osram Firefly Hyper-Bright LB-V19G and the Seoul Semiconductor Z-Power Side Emitter. The authors set their own acceptance criteria at a root mean square error below 5 percent and a normalized cross correlation above 99 percent, and report that both were satisfied in every case.

Three incidental findings the Foundation records, because each bears on the reliability of a published figure. That not even the device best described as Lambertian is well described by a simple cosine: of the Edison part the authors write that it "fits well as a perfect Lambertian emitter, and a first order analysis can be performed by using a simple cosine function, but with a 5.1% RMS error", which exceeds their own five percent threshold. That the published pattern of a device is an envelope rather than a curve: several manufacturers publish an upper and a lower bound, and the authors attribute the difference between them to "manufacturing errors related to the emission, reflection and transmission of the optical flux." And that a published pattern may be misaligned: to fit one manufacturer's data the authors had to displace the entire distribution by 2.55 degrees, which they attribute to "a misalignment of the optical axis of the LEDs tested by the manufacturer."

What it establishes. That the angular distribution of a finished light-emitting diode is the product of a Lambertian emitting region modified by a reflector and a lens, and is not itself Lambertian; that the lens generally narrows it; that for this technology the distance beyond which the device may be treated as a point is up to four times the conventional rule; that the half angle published on a data sheet is insufficient to render the shape of the distribution; and that the specialists who established this proposed in 2008 that manufacturers publish the coefficients that would render it.

What it does not establish. Nothing about health, exposure, injury or any biological endpoint, and the paper addresses none of those. It models intensity and irradiance and no other quantity. The devices modeled are those of 2008 and the fits are to manufacturers' published distributions rather than to the authors' own measurements of the parts, a distinction the entry preserves. The authors' statement that the generated light is incoherent is an assertion in passing and not a measurement, and Part V.C.2 treats the coherence question on the sources that measured it.

Where it bears. Part V.B.8, which is written on it. Part V.J.1, for what a single published figure does not determine. Part IX.F, for which it supplies a peer-reviewed precedent dating from 2008. Part V.C.2, for the incoherence assertion, recorded there as an assertion.

C.90 Miller, Irvin, Royer and Strachan (2024) — the phantom array effect remains visible to 7,000 hertz, is seen and resented more by people with a history of migraine, and is not described by the function in the governing international document

Citation. Miller N. J., Irvin L., Royer M., Strachan C. "Visibility and annoyance of the phantom array effect varies with age and history of migraine." Lighting Research and Technology 2024. doi:10.1177/14771535241288783. Received 16 July 2024, revised and accepted 16 September 2024. Published by SAGE for the Chartered Institution of Building Services Engineers. The copy read carries the article-in-press pagination 1 to 31 and no volume number. The first, second and fourth authors are at Pacific Northwest National Laboratory, Portland, Oregon; the third is also at the School of Civil and Construction Engineering, Oregon State University.

Funding, which is the first thing the Foundation asks the Department to notice. The funding statement reads that the work "was supported by the U.S. Department of Energy's Lighting R&D Program, part of the Building Technologies Office within the Office of Energy Efficiency and Renewable Energy (EERE)." The authors declared no conflicts of interest. This is accordingly federally funded research, performed at a national laboratory, finding that an artifact of light-emitting diode modulation is more visible and more resented by an identifiable group of people. It is not the work of an affected party and the Department need not weigh it as such.

Design. A within-subjects psychophysical experiment. Fifty-five participants, 25 with migraine and 30 without, 27 under 40 years and 28 aged 40 or over, median age 39 and mean age 45 in both groups, evaluated 85 unique temporal light modulation waveforms for visibility of the phantom array, and a subset of 51 for annoyance. Migraine history was established by a pre-participation questionnaire reviewed by a medical professional, and the paper states that no person in the migraine group was excluded on account of symptoms. Sessions ran about 90 minutes. An exit questionnaire was administered at the end of the session and a follow-up questionnaire one to three days later.

The effect studied, in the authors' definition. The phantom array effect is "a series of repeated images that may be perceived when a person moves their eyes in large saccades across a light source (or a specular reflection of that light source) that is modulating in output over time." It is therefore distinct from the stroboscopic effect, which concerns a moving object under a modulating source, and from directly visible flicker.

Apparatus and stimulus, with two figures that bear on Part V.B. The source was a ThorLabs MWWHLP1 blue-pump phosphor-coated light-emitting diode of 2871 kelvin, emitter 3.5 millimeters in diameter by 1.6 millimeters high, driven through an arbitrary waveform generator. The participant sat about 3.0 meters away at an eye height of 1.2 meters, with fixation targets 22.5 degrees to each side and the wall around the source draped in matte black cloth. Saccades were paced by a metronome at 126 beats per minute, giving an average saccade velocity of 95 degrees per second and a peak near 500. Vertical illuminance at the eye was about 8.8 lux from the ambient lighting and 1.9 plus or minus 0.2 lux from the source. The overhead luminaires were driven at a nominal 32 kilohertz, so the ambient lighting was not itself a source of low-frequency modulation. Two figures are recorded for use elsewhere in this comment. The source subtended a visual angle of 0.06 degrees across the scan dimension, which is about 1.05 milliradians and therefore below the 1.5 milliradian minimum angular subtense of the instrument described at Appendix D.1. And the target luminance was 52,400 candelas per square meter, which is about 5.2 times the luminance above which that instrument states a hazard assessment is normally required. The conversion and the ratio are the Foundation's arithmetic.

The waveforms. Fifty sinusoidal conditions at 120, 400, 800, 1,200, 2,400 and 4,800 hertz with seven or eight modulation depths each from 100 percent down to 5 percent, plus single conditions at 7,000 hertz and 100 percent and at 10,000 hertz at 55 and 100 percent. Twenty-eight rectangular conditions across seven frequencies from 120 to 10,000 hertz, each at two modulation depths of 100 and 55 percent crossed with two duty cycles of 10 and 50 percent. Six complex waveforms measured from commercial lighting products. One nominally direct-current condition, which served as the control against which visibility was tested. Measured luminous output was within 10 percent of the mean for all waveforms.

First finding: the frequency extent. Peak sensitivity fell between 400 and 800 hertz, with the individual peak having a median and mode of 800 hertz and a mean of 831, which the authors qualify by noting that the frequency resolution was not designed to locate the true average peak. Stimuli up to 7,000 hertz were statistically more visible than the direct-current control across all participants. Sine waves at 100 percent modulation were "still problematic – and more visible than DC at 7000 Hz." At 10,000 hertz the effect was not

statistically more visible than the control on sample averages, although five reliable participants reported visibility above threshold there. The control figures are given and the Foundation reproduces them because they establish that the 10,000 hertz result is a true null rather than a weak signal: for the rectangular waveform at 100 percent modulation and 10 percent duty cycle, detection at 4,800 hertz was accurate for 84 percent of reliable observers and 73 percent of all observers, while at 10,000 hertz it was 13 percent of reliable observers and 16 percent of all observers against a false-positive rate of 15 percent of all observers on the direct-current waveforms.

Second finding: history of migraine. The authors state that this question had not been examined before: "no research has investigated if or how PAE sensitivity varies between people with and without migraine. Likewise, there has been no research on physiological symptoms following exposure to the PAE – for either migraine or non-migraine groups." In the mixed-effects binary logistic model of visibility, migraine status gave an odds ratio of 3.31 with a 95 percent confidence interval of 1.22 to 8.94 at p equal to 0.019, and the interaction of migraine status with frequency was significant at p below 0.001, the migraine group being relatively more sensitive at the higher frequencies. Rectangular waveforms were more visible than sinusoidal ones at an odds ratio of 1.41.

Third finding: age. Younger participants found more stimuli visible, at p below 0.001 and an odds ratio of 0.94 for each year of age. The Foundation states the effect size with the qualification the authors give it. Excluding the least sensitive participants, the decline in the proportion of visible stimuli was about 2.8 percent per ten years of age, and "a linear regression between age and number of stimuli visible above threshold had R2 = 0.08." The direction of the age effect is therefore well established and its magnitude is not. Unlike migraine status, the interaction of age with frequency was not statistically significant.

Fourth finding: the questionnaires, and what the annoyance data do and do not show. The Foundation separates these because the paper reports two different kinds of annoyance result and a comment that merged them would overstate. On the questionnaires, the migraine group reported being bothered by the effect more than rarely at 72 percent against 40 percent, physical symptoms attributed to it at 84 against 47 percent, headache at 64 against 10 percent, eye fatigue or strain at 60 against 17 percent, distraction or disorientation at 64 against 34 percent, and having changed a behavior such as leaving a restaurant at 60 against 17 percent. In the four hours after the session, 64 percent of the migraine group against 19 percent reported discomfort or an adverse reaction, and 41 against 8 percent a headache. Younger participants reported more headache and more visual fatigue, each 36 against 9 percent. Whether participants see the effect in everyday life at all did not differ significantly, at 84 against 73 percent and p equal to 0.328. In the model of annoyance ratings recorded during the experiment, by contrast, migraine status was not significant as a main effect, at p equal to 0.062, while its interaction with frequency was, at p equal to 0.001; age was not significant as a main effect at p equal to 0.182 although its interactions were. The accurate statement is therefore that the migraine group reported substantially more annoyance and more symptoms outside the experiment, and that within the experiment their greater annoyance was concentrated at the higher frequencies rather than present across the board.

Fifth finding: the range of individual sensitivity. Six participants saw fewer than 10 percent of stimuli above threshold, three of them saw none and two never saw the effect at all, while seven saw at least 75 percent of the unique stimuli. "A small number of reliable observers were able to detect the PAE above threshold even at only 5% modulation." Of the predictive measure the authors write that "it cannot predict any individual's ability to see the phantom array, as there is extreme variation in sensitivity to the PAE."

Sixth finding, and the one that bears on standards: the function in the international document is not supported. The provisional phantom-array function of CIE 249:2022 was based principally on a study using a 0.02 degree target at 250 or 500 lux and

frequencies of 100, 600 and 1,200 hertz only. The authors state the resulting limitation of both available functions: "The CIE 249 function was developed using data up to 1200 Hz, and the PAVM threshold function was developed using data up to 2000 Hz." Against measurement, "CIE 249 suggests threshold visibility at 76% modulation for 2400 Hz sine waves, but threshold visibility was 49% in this experiment." Saturation at full modulation would occur at 2,700 hertz on the Commission model and 5,100 hertz on the phantom array visibility measure, against approximately 6,000 hertz on this experiment's own model. The authors conclude: "This experiment does not support the use of the PAE threshold modulation function published in CIE 249." They endorse the alternative: the phantom array visibility measure and the performance levels of IES TM-39 "were effective at differentiating stimuli" at the two ends of the range.

The qualification that runs the other way, which the Foundation states because the paper does. The failure of the Commission function is a failure about the shape of the frequency dependence and not a uniform permissiveness. The authors write: "Aside from relative differences, both the CIE 249 function and PAVM function predict lower absolute threshold modulation." In absolute terms, that is, both functions predict visibility at lower modulation than this experiment measured, and the authors note that another recent experiment found lower thresholds still at the peak. They also list the application and individual factors on which absolute thresholds depend: background and contrast, ambient illumination, stimulus size and shape, the size of the scanning angle, saccade speed and personal sensitivity. A comment that presented this paper as showing the standards to be generally too permissive would misdescribe it. What it shows is that the Commission function understates sensitivity at the frequencies above its evidence base.

The authors' own statements of consequence. Three, quoted because they are the authors' and not the Foundation's. On the weight of the evidence: "this is strong evidence that TLM is a major problem in lighting and should be remedied, even if it requires trade-offs with other performance attributes." On the choice of population against which any metric is normalized: "if a general population is used to model threshold visibility, and individuals with migraine and other sensitive individuals were excluded as subjects, then the average values may not be protective for some at the more sensitive end of the normal distribution. In that case, more strict performance criteria can be set to account for more sensitive observers." And on what should happen: "We advocate for rapid uptake of metrics and specifications to mitigate the PAE – and other responses to TLM – such as those proposed in IES TM-39."

The frequency recommendation, and the conditions the authors attach to it. The recommendation and its limits are in one sentence and the Foundation quotes the whole of it, because the exclusions are what make it relevant to Part VI: at 10,000 hertz the pulse-width-modulation waveform "was not statistically more visible or more annoying than DC, making this a reasonable target minimum frequency if PWM is utilized in lighted environments similar to those in the experiment space (i.e. not areas with larger eye movements, darker finishes or very low ambient light conditions)." The excluded conditions are those of the nighttime outdoor environment. The authors record what is known about them: "Others have examined higher frequencies using luminous targets in very dark surrounds, in which case some observers can reliably see the PAE above 10 000 Hz."

What it establishes. That the phantom array effect is visible well above the frequencies at which modulation is commonly assumed to become imperceptible, to 7,000 hertz on these averages and reliably above 10,000 hertz in dark surrounds on the literature the authors cite; that pulse-width modulation at full depth is the most visible and most annoying waveform class tested; that sensitivity varies with history of migraine and with age; that the range of individual sensitivity is wide enough that some observers detect the effect at 5 percent modulation; that the provisional function in CIE 249:2022 does not describe

measured sensitivity at frequencies above its evidence base; and that the authors, funded by the Department of Energy, consider the evidence strong enough to call for remediation accepting trade-offs.

What it does not establish. That the phantom array effect causes the symptoms reported. The authors are explicit, and the Foundation adopts their statement rather than softening it: because the task was visually demanding, requiring an hour or more of repeated saccades, "the negative outcomes (for the migraine group in particular) cannot be explicitly linked to the TLM itself." Nor does it establish the prevalence of anything in the general population, the sample being 55 volunteers recruited in one city. Nor does it establish effects of ordinary duration: exposure to each stimulus was momentary, and the authors note that "Longer durations of exposure may increase the annoyance level or the prevalence of adverse physiological responses." A specific caution attaches to the symptom figures, which the authors raise themselves: all participants were told during recruitment that symptoms were possible and the migraine group received an additional history questionnaire, so "It is possible the migraine group inferred a higher likelihood of headaches afterward, which could have increased the number of post-experiment headaches reported." The study was also not designed to identify which stimuli produce adverse reactions, and whether visibility is necessary for symptoms at all is left open as a question for future work.

Where it bears. Part V.D.2, which is written on it. Part V.D.1, for the standing of pulse-width modulation at full depth. Part V.D.3, for the relation between this material and IEEE Std 1789-2015, which addresses frequencies far below those at issue here. Part V.D.4 and Part VI, for the nighttime and high-contrast conditions the authors expressly exclude from their frequency recommendation. Part V.E, for the migraine findings, which belong with the neurological material rather than with the photochemical. Part VII, for the population-normalization passage. Part V.B.8, for the two incidental figures recorded above.

C.91 Martinsons and others (2024) — the authors of the governing recommended practice state that no measurement method exists for the phantom array effect, that the model in the international report has never been validated, and that there is insufficient data to set safe levels for sensitive people

Citation. Martinsons C., Gaines J., Vollers J., Nachtrieb R., Wolfman H., Zissis G. "A Review of Contemporary Issues with Temporal Light Modulation of Lighting Systems." IEEE Transactions on Industry Applications, early access 12 July 2024. doi:10.1109/TIA.2024.3425821. Print ISSN 0093-9994, online ISSN 1939-9367. The copy read is the early-access version and carries no volume, issue or page numbers. An author copy is deposited in the open archive HAL as hal-04659609. The paper states that it is an augmented and updated version of a paper presented at the eleventh International Conference on Energy Efficiency in Domestic Appliances and Lighting and seventeenth International Symposium on the Science and Technology of Lighting, Toulouse, 1 to 3 June 2022.

The authors, which the Foundation sets out in full because the authorship is the reason this paper carries the weight it does. Christophe Martinsons, Centre Scientifique et Technique du Bâtiment, a French public research institute. James Gaines, Standards and Regulations, Signify, Burlington, Massachusetts. Jonathan Vollers, Director of Engineering Services, Cree Lighting, Ideal Industries, Racine, Wisconsin. Robert Nachtrieb, Lead Scientist, Lutron Electronics, Coopersburg, Pennsylvania. Howard Wolfman, University of Illinois at Chicago and Lumispec Consulting, Northbrook, Illinois. Georges Zissis, LAPLACE, Université Toulouse 3, France. Four of the six are of the lighting industry, including the standards and regulations function of one of the largest lighting manufacturers in the world and the engineering services director of a second manufacturer whose products are described at Part VI.

Their standing, which they state themselves. The paper records that the joint working group of the IEEE Industrial Applications Society and the Illuminating Engineering Society was created to review the existing knowledge on temporal light modulation, that the group's survey was incorporated into the IEEE 3001.9 and IES RP-48-2023 Recommended Practice published in May 2023, and then: "This paper is authored by members of the joint IES / IEEE working group." The acknowledgment thanks the chair and the secretary of that working group by name. The statements recorded below are therefore the statements of the people who wrote the American recommended practice on the design of power systems supplying lighting, and of the manufacturers whose products that practice governs. They are not the statements of a critic of the industry.

Article type. A review. It presents no new experiment and reports no biological endpoint of its own. It surveys the origins of temporal light modulation in lighting products, the visual, neurophysiological, health and psychological effects, the metrics, the measurement methods, and the standards and regulations, and closes with an application of modulation as an optical signature for remote sensing. It is in this appendix because the publication is peer reviewed.

First matter: what the paper says is not known about sensitive people. This is the proposition for which the Foundation principally relies on the paper. Introducing the health material the authors write that "The case of sensitive people is worth considering because a significant fraction of the general population is known to suffer from symptoms associated with the exposure to TLM." Their section on sensitive populations then states: "An unknown fraction of the general population is particularly sensitive to temporal light modulation. This population is not well understood but includes migraineurs and people suffering from headaches induced by flickering lights, those suffering from pre-existing conditions such as photosensitive epilepsy, and some people who have suffered head injuries such as traumatic brain injuries." And then the sentence on which Part V.D.1 rests: "Safe TLM levels were defined for photosensitive epilepsy, but there is insufficient data to define safe levels for other categories of sensitive people." In the conclusions the same point is made as a recommendation: the symptoms "seem to occur more frequently and more intensely for a fraction of the general population which is yet to be rigorously identified. For these well-known effects, more research should be done to provide dose-response relationships to be able to improve health and safety requirements for sensitive people." The conclusions add that "Other conditions, such as traumatic brain injuries, require specific protective measures against exposure to modulated light sources."

Second matter: the health effects are described as confirmed. The paper states that "The known health effects of TLM are eyestrain (asthenopia), headaches, migraine, and photosensitive epilepsy", and in the conclusions that "Headaches, migraines, and eyestrain have been commonly reported, studied, and confirmed in the scientific literature." It also supplies the reason such effects are difficult to attribute, which bears on Part VIII: "Eyestrain, headaches, and migraine happen during, or after, prolonged exposures to TLM, typically of one or several hours. The delay in the onset of these effects makes it difficult to identify TLM as a critical factor of lighting systems." On neurophysiological effects it reports that modulation at 100 or 120 hertz "can disrupt eye movements and reduce visual performance compared to higher modulation frequencies, or to constant light", and that work using electroencephalography and pupillometry found that tasks performed under modulation near 100 hertz lead to "greater physiological arousal" and "a general increase in brain activity, particularly in the right hemisphere", in each case by comparison with higher modulation frequencies or with constant light.

Third matter: that exposure has changed and the response to it is unknown. The paper states that the standard on which the American framework rests was built on the literature of its time, and that the circumstances have since changed: "the ubiquity of solid-state lighting and solid-state display technologies profoundly changed the characteristics

of human exposure to TLM. Longer exposures to an increasing number of modulated light sources are becoming the norm. The human response to these repeated stimuli is still unclear but some recently published results are now available." That bears directly on the limitation the authors of the experiment at Appendix C.90 placed on their own work, which examined momentary exposure only.

Fourth matter: the frequency range, stated by the standards writers. The conclusions give the ranges within which the three common artifacts may appear: "from about 1 Hz to about 60 Hz for flicker (maximum visibility at about 8 Hz), 60 Hz to about 2 kHz for the stroboscopic effect associated with hand motion (maximum visibility at 80 Hz), and from about 100 Hz to about 10 kHz for the phantom array effect (maximum visibility at 600 Hz)." The consequence the authors draw is addressed to design: "The electrical design of power supplies, drivers and dimmers should minimize the occurrence of undesired effects of temporal light modulation in this wide frequency range." The paper's summary table of effects against modulation frequency runs from 1 hertz to 10 kilohertz and marks the upper extent of both the neurophysiological and the health effects as an "Unknown boundary."

Fifth matter: that the model in the international report has never been experimentally validated. Of the phantom array effect the paper states flatly that "There is currently no metric to quantify the visibility threshold or the sensitivity function to the phantom array effect." Of the governing international report it states that CIE 249:2022 "informs that the phantom array effect is more visible with small light sources in high contrast with their background (dark environments) at modulation frequencies from about 100 Hz to 10 kHz" and that "This report contains a tentative visibility model which has not been experimentally validated yet." The Foundation asks the Department to read that beside Appendix C.90, where a federally funded experiment tested that model against measurement and concluded that its threshold function is not supported. An industry and standards review and a Department of Energy experiment, published in the same year and by different people, say respectively that the model was never validated and that it fails when tested.

Sixth matter: the thresholds reported for the effect, which are very low. The paper reports, from experimental studies of 2023 which it cites and the Foundation has not obtained, that the phantom array was most visible at 600 hertz "with a visibility threshold, expressed in terms of modulation depth for a pure sine wave, of 7% for a white-light stimulus observed in dark conditions. For a red-light stimulus under dark conditions, the visibility threshold was about 3% at 600 Hz." Further: "The visibility of the phantom array was found to be significant at modulation frequencies as low as 80 Hz. At such frequencies, the phantom array was visible at a threshold of 10% for red light, but only at a threshold of 35% for white lights." The paper also records a dependence of the effect on the color of the modulated source, including at the upper frequency limit of visibility.

Seventh matter: where the authors say the effect is encountered. "In real-life application, the phantom array is best seen in indoor and outdoor luminaires (and displays) using PWM dimming at low illuminance levels. It is also noticeable in automotive headlights and rear lights." And on waveform, corroborating Appendix C.90: "The effect is more visible under rectangular versus sinusoidal TLM and when duty cycles are low (typically 10% or 30%, versus 50%)".

Eighth matter: the metrics, their stated domains, and the limits. Of flicker: "The PstLM value of 1 is now consensually accepted as a limit value below which flicker is acceptable. It is specified in most standards and regulations as the upper limit for flicker, throughout the world." But the response function underlying it "was originally derived using a small size luminous stimulus with sharp edges, seen in central vision in well-lit conditions. However, PstLM can be assessed, and is now used, outside its original range of lighting conditions, included in dim environments (mesopic conditions)." Of the stroboscopic measure: its "upper frequency limit is 2000 Hz"; it applies where motion is of the order of human

motion and illuminance exceeds 100 lux; "It is not applicable in dark environments, nor with outdoor lighting"; and "SVM is not adapted to assess the stroboscopic effects observed on high-speed rotating or reciprocating machinery under modulated light, where motion may be considerably faster than 4 m/s." On its limit value: "Unlike the flicker metric PstLM, there is currently no consensus on an acceptable upper limit for SVM. The European eco-design regulation EU 2019/2020 defined the limit at 0.4, following an interim two-year period during which the accepted limit had first been set at 0.9. The NEMA specifies a maximum SVM of 1.6, which is considerably higher than the EU limit." On displays: "There is currently no standard metric associated with TLAs observed on electronic devices."

Ninth matter: the measurement methods, and the range they cover. The joint American national standard for laboratory measurement of the luminous waveform, ANSI and IES LM-90-20 of 2020, is described as "covering modulation frequencies 1 Hz and 3 kHz". The Foundation observes, and the observation is its own, that the paper's own stated range for the phantom array effect extends to 10 kilohertz, so the laboratory measurement standard covers less than a third of the frequency range in which the authors say the effect occurs. For field measurement: "Portable instruments are now available to perform on site TLM waveform measurements and return TLM and TLA metrics. However, there is no standard covering the field measurement of these parameters." And the conditions the paper specifies for valid measurement exclude the ordinary environment: "Temporal light modulation parameters should be measured without daylight, without any unwanted light from another lighting/display installation nearby and without any moving objects or people in the field of view of the measurement device." The paper's summary table records the measurement method as nonexistent for the phantom array effect, for stroboscopic effects with machines and tools, and for eyestrain, migraine, headache and other neurophysiological effects.

The statement that runs against the Foundation's position, recorded because the paper makes it. "The temporal light modulation in a real-world application, consisting of multiple light sources is generally lower than the TLM performance of a single light source due to the averaging out of the light modulation from the different light sources." In an interior lit by many luminaires, therefore, measured modulation is expected to be lower than any one product's rating. The Foundation accepts that and states the limit of it: the averaging requires multiple independent sources in the field of view, and it does not apply to a single dominant source viewed against a dark field, which is the case of the headlamp, the warning beacon, the message sign and the single luminaire overhead at night. The paper also notes that combination of waveforms "could, in principle, lead to beat frequencies if the frequencies slightly differ between luminaires".

What the paper says about the adequacy of existing requirements. The authors characterize the present position with three qualifiers, and the Foundation reproduces the sentence whole rather than paraphrasing it: "International standards and regional regulations now include requirements providing a certain degree of protection against undesired visual effects of temporal light modulation that may occur at high levels." A certain degree of protection; against visual effects; at high levels. The paper nowhere states that existing requirements are sufficient, and on health effects and sensitive people it states the opposite.

What it does not establish. It is a review and establishes no new fact of its own. The thresholds at the sixth matter and the neurophysiological findings at the second are reported at second hand from studies the Foundation has not obtained, and are attributed to this paper accordingly. The paper reports no exposure of any person, no dose-response relationship, and no measurement of any named product. Its treatment of health is brief, occupying a small part of a paper whose main subject is metrology and whose final section concerns an application of modulation to remote sensing. The Foundation does not

suggest that the authors call for regulation of these products; they call for research, for improved design, and for improved requirements.

Where it bears. Part V.D.1, which is written on it. Part V.D.2, for the corroboration of the frequency range and for the non-validation of the international model. Part V.D.3, for what IEEE Std 1789-2015 was built on and what has changed since. Part V.D.4 and Part VI, for automotive headlights and rear lights and for the inapplicability of the stroboscopic measure to outdoor lighting. Part V.E, for the sensitive populations and the traumatic brain injury statement. Part VII, for the absence of safe levels for sensitive people. Part VIII.D, for the divergence between the European limit and the American recommendation. Part IX, for the measurement gaps.

C.92 Wald, Erwin, Annon-Eberharter and Werther (2023) — light from an examination lamp drove a pulse oximeter to report 85 percent saturation, the manufacturers could not explain it, and medical lamps are excluded from the regulation that would have prohibited the flicker

Citation. Wald M., Erwin P., Annon-Eberharter N., Werther T. "LED light can falsify pulse oximetry readings via the stroboscopic effect." Physical and Engineering Sciences in Medicine 2023;46(4):1667 to 1675. doi:10.1007/s13246-023-01328-2. Published 19 September 2023 by Springer. PubMed Central PMC10703953; PubMed 37725312. Open access, funding for open access provided by Paracelsus Medical University. Full text read from the PubMed Central deposit. The published article gives the authors' affiliations by superscript and the Foundation has not recorded them in full.

Independence. The declarations state that the study "was not supported by any grants. None of the companies mentioned in the study were involved in the study", and that "None of the authors made financial disclosures or had a conflict of interest." The companies named in the article are the manufacturers of the monitor, the oximetry module, the closed-loop oxygen controller and the examination lamp.

Design, and what is observation as against what is model. The Foundation separates these at the outset because the paper does two different things and their evidentiary weight differs. The first is a clinical observation in a neonatal intensive care unit, reported as a single event with an informal reproduction. The second is a mathematical model, built in MATLAB, of a pulse oximeter and its light-cancellation algorithm, used to show that the observed behavior follows from the stroboscopic interaction between the lamp's modulation and the instrument's sampling. The model is the paper's contribution; the event is the reason it was built. No measurement of a pulse oximeter under controlled light was performed, and the paper does not claim one. The ethical statement records that "No animals or humans were involved in the experiments, and no ethical review was required."

The clinical event. An infant, after intubation and with ventilation well established, did not according to the monitor achieve saturation above 90 percent despite increasing the fraction of inspired oxygen through a closed-loop controller. The devices are named in the paper: a Philips IntelliVue X3 monitor with Nellcor pulse oximetry and OxiMax technology of Medtronic, a closed-loop oxygen controller of Fritz Stephan GmbH, and an examination lamp, the Dräger Variolux. Then: "Surprisingly, an abrupt increase in the recorded saturation occurred when the examination LED (light-emitting diode) lamp … was switched off. Within seconds, the monitor indicated 100% saturation, and the FiO_2 was reduced to ambient air. Each time the lamp illuminated the infant, a similar drop in oxygen saturation (SpO_2) could be observed." The paper adds that "The saturation sensor was never in the central light cone but was only illuminated by the scattered light of the lamp."

That the interference was optical and not electromagnetic, which the authors established and stated. The event was reproduced by placing another person's finger, with the sensor attached, in the lamp's stray light. "The effect disappeared when an opaque

shield was placed over the sensor. This indicated that the interference was caused by light and not electromagnetic interference." The Foundation records this sentence with particular care. The paper identifies visible light as the interfering agent and expressly excludes electromagnetic interference, by the simplest available test, which is to block the light.

That the manufacturers could not explain it. "For clarification, the occurrence was brought to the attention of all manufacturers involved. Neither the manufacturers, nor a review of scientific literature could provide an explanation for this phenomenon."

What was measured in the lamp. The lamp was characterized by the compact flicker degree method. It operates by pulse-width modulation at 207 hertz. The compact flicker degree was 63.9 percent undimmed and 80.1 percent fully dimmed, and the paper states that this "resulted in light emission only 37% of the time in the non-dimmed mode and 13% of the time in the fully dimmed mode." The Foundation notes the direction of the dimming effect, which is the opposite of what a reader might assume: dimming the lamp increased its flicker and reduced its duty cycle to about one part in eight.

The mechanism the model demonstrates. A pulse oximeter emits red and infrared light in turn and measures in a dark phase between each, subtracting the dark measurement to cancel ambient light. The paper states the assumption on which that works and why modulated light defeats it: "Assuming the ambient light to be constant at least during the measurement cycle, this will eliminate the disturbance of the ambient light in the measurements of the red (infrared) signal. Ambient LED light, on the other hand, is not constant and therefore will not be eliminated by subtraction of the dark measurements, and can subsequently induce a stroboscopic effect." The instrument's red-dark-infrared-dark cycle repeats 311.25 times per second. The authors observe that this "is almost exactly 1.5 times the frequency of the PWM signals output by the LED, and this may be significant."

The magnitude of the error the model produces. With a distortion factor of one tenth of the constant component of the signal, the computed ratio gave a saturation of 85 percent, which then remained at that value as distortion increased further. The computed pulse rate plateaued at 108 beats per minute against a true rate of 140. The paper also shows that the error depends on the frequency relationship rather than on the light alone: at a sampling rate of 300 hertz instead of 311.25, the same distortion gave 96 percent rather than 85, and the resulting waveform was irregular enough that "a medical doctor would suspect an artefact". The authors report more regular output at 414 hertz, twice the lamp frequency, and at 500 hertz.

The finding the Foundation regards as the most important in the paper. That the false reading does not announce itself. Of the erroneous pulse rate the authors write that it "corresponds to a plausible heart rate for neonatal patients. This pulse curve can be interpreted by the pulse oximeter as a valid measurement, particularly when the interference already existed at the beginning of each measurement. The incorrect pulse frequency therefore does not represent a warning signal for an incorrect measurement." A saturation of 85 percent and a pulse of 108 are both physiologically plausible in a newborn. There is no artifact flag, and in the originating event the value was being acted upon automatically by a closed-loop controller.

The consequence the authors identify. From the abstract: "The stroboscopic effect leads to low saturation values, which can lead to the risk of blindness in premature infants due to excessive oxygenation." And from the conclusion: "Erroneously low saturation levels can lead to unnecessary increases in oxygen administration, which increases the risk of retinopathy in preterm infants." The recommendations are two: "To minimize inaccuracies in pulse oximeter readings, flicker-free LED lamps should be used in medical settings. On

the other hand, manufacturers should be quite capable of producing pulse oximeters that can detect artifacts caused by PWM LEDs."

The regulatory finding, which is why this paper bears beyond its own subject. "There are EU regulations in place for the use of indoor lighting, which prohibit strong flickering light at the frequency of the lamps we tested. However, medical lamps, with their specific requirements such as spot brightness and color fidelity as essential diagnostic features, are excluded from these regulations. This should be fundamentally questioned, as the technical effort to produce flicker-free LED lamps seems manageable." The regulation cited for that proposition is Commission Regulation (EU) 2019/2020, which is the same instrument the review at Appendix C.91 identifies as setting the European limit on the stroboscopic visibility measure. So the lamp in a neonatal intensive care unit flickers at a degree that the European instrument would prohibit in an office, because medical lamps are carved out of it.

What the authors say about flicker frequency and perception, recorded as reported rather than as established. The discussion states that seizures from flickering light occur "usually … only at low frequencies around 15 Hz", that "Frequencies above 80 Hz cause stress", and that "Above a frequency of 200 Hz, the phantom array effect occurs." Of their own lamp: it "flickers at 207 Hz, which corresponds to a frequency that can not only cause stress but also multiple perceptions." The authority cited for the phantom array proposition is the preliminary Opinion of the Scientific Committee on Health, Environmental and Emerging Risks, which this comment holds at Appendix D.1. The Foundation does not adopt the bare statement that frequencies above 80 hertz cause stress; it is asserted in a discussion section without a figure or a citation to a study, and Part V.D.2 rests on the measurement literature instead. The authors also state that "It is not yet known how flicker affects the immature brains of premature babies."

What runs against the Foundation's position, stated because the authors state it. The paper does not claim the effect is peculiar to light-emitting diodes. "In theory, LED light does not necessarily cause the interference described here. The phenomenon of a saturation measurement displaying on the monitor, although the pulse oximeter is not attached to a patient, occurs even when no LED light source is present. It can therefore be assumed that such phantom signals can be caused by any flickering light source. Both incandescent bulbs and fluorescent tubes flicker during standard operation with alternating current. Consequently, these light sources can also cause the interference signal we have shown." The Foundation accordingly does not advance this paper for the proposition that the interference is unique to this technology, and Part V.D.5 says so. What the paper does establish about this technology is specific and sufficient: the lamp that produced the observed event is a light-emitting diode lamp operating by pulse-width modulation at 207 hertz with emission for 37 percent of the time, and the authors attribute the interference to that modulation.

Stated limitations. The authors identify three. The model is simplified, and they did not test different versions of the red-dark-infrared-dark cycle. They did not use the calibration curve of the instrument in question, which was not accessible to them, but constructed one from a published curve for a different manufacturer's oximeter, "although the measurement is based on a Nellcor algorithm." And the underlying pulse waveform was not a measurement of the patient but a publicly available arterial pressure signal, compressed and inverted to represent a premature infant. To these the Foundation adds the obvious ones: one lamp, one oximeter model, one clinical event, and a reproduction on one adult.

What it establishes. That a light-emitting diode examination lamp in clinical use was measured to operate by pulse-width modulation at 207 hertz with a compact flicker degree of 63.9 percent undimmed and 80.1 percent dimmed; that illumination of a pulse oximeter sensor by that lamp's scattered light was repeatedly associated with depressed saturation

readings and that the readings recovered within seconds when the lamp was switched off or the sensor shielded; that the interfering agent was light and not electromagnetic interference; that the manufacturers of the devices involved could not explain the effect; that a model of the instrument reproduces an error of the observed magnitude by the stroboscopic interaction of the lamp's modulation with the instrument's sampling; that the resulting values are physiologically plausible and carry no artifact warning; and that medical lamps are excluded from the European regulation that would otherwise prohibit the measured flicker.

What it does not establish. That any infant was harmed; the paper reports none, and the Foundation asserts none. That the effect occurs with other lamps, other oximeters or other frequency combinations; the paper shows the error depends on the frequency relationship and expressly leaves those cases to further research. That the effect is peculiar to this technology; the authors say it is not. And nothing about prevalence: the paper gives no indication how often this combination of lamp and instrument occurs in clinical use anywhere.

Where it bears. Part V.D.5, which is written on it. Part V.D.1, for the measured modulation depth and duty cycle of a lamp in service and for the finding that dimming increased the flicker. Part V.D.2, for the frequency at which the authors place the phantom array effect. Part VIII.D, for the fact that the manufacturers could not explain an effect reported to them. Part IX, for the exclusion of a product class from a flicker limit on the ground of its clinical function.

C.93 Bartossek, Kemmerer and Schmidt (2021) — flashing light at 3 and 10 hertz measurably alters visual perception in screened healthy adults, and the protocol required to expose them discloses what such exposure is understood to warrant

Citation. Bartossek M. T., Kemmerer J., Schmidt T. T. "Altered states phenomena induced by visual flicker light stimulation". PLoS ONE 2021;16(7):e0253779. doi:10.1371/journal.pone.0253779. Published 1 July 2021. PubMed Central PMC8248711; PubMed 34197510. Open access. Full text read from the PubMed Central deposit. Work conducted at the Center for Cognitive Neuroscience Berlin at the Free University of Berlin; approved by the ethics committee of Charité Berlin.

Why the Foundation records the mismatch before anything else. This study used flicker at 3 and 10 hertz. The modulation addressed at Part V.D is that produced by the drive electronics of light-emitting diode products, which the sources there place between about 100 hertz and 10 kilohertz. These are different phenomena at different frequencies, and the comment does not cite this paper for any proposition about the modulation of lighting products. The exposure conditions are likewise not comparable to encountering a lamp: participants sat in a reclined chair at about 50 centimeters from a purpose-built stroboscope, with the room lights off, wearing earplugs, with their eyes closed, for twenty minutes. The Foundation states all of this at the head of the entry so that no reader of the comment mistakes its reliance for a wider one. The paper is cited for two things only: the frequencies at which flashing light is known to alter perception, and what was required before a university would permit the exposure.

Design. A within-subjects study of 24 volunteers, mean age 24.0 plus or minus 6.4, 19 female and 5 male, German native speakers without a history of neurological or psychiatric disorder, recruited through social media and student mailing lists. Each attended three sessions of twenty minutes: constant halogen light, then 3 hertz and 10 hertz flicker in randomized order, at least four days apart. Outcomes were measured by the Altered States of Consciousness Rating Scale in its five-dimension and eleven-factor forms, the Phenomenology of Consciousness Inventory, the Positive and Negative Affect Schedule, time-estimation ratings, and an alternative-uses task for divergent thinking, with

personality assessed by the NEO Five-Factor Inventory-2 and the Tellegen Absorption Scale. None of the participants had prior experience of flicker light stimulation.

The stimulus. The device was the Lucia N°03 stroboscope of Light Attendance GmbH, Innsbruck, which the paper describes as having been "developed to evoke hypnagogic visual impressions by intermittent light stimulation" and as "used in various recreational contexts". It carries one halogen lamp for constant light and eight light-emitting diodes for the flicker, each at 700 lumens and a light color of 6300 kelvin. The flicker conditions were 3 and 10 hertz at a 50 percent on-off duty cycle.

What the screening required, which is the Foundation's principal reason for citing the paper. Before any participant was exposed, the protocol required the following. "To minimize the risk of any aversive effects of FLS, all participants underwent a semi-structured video interview with a psychologist previous to the experiment to ensure that they were not affected by an acute mental or neurological disorder, were not currently or regularly taking any psychotropic medication or drugs and were not pregnant". Then an instrumented screen: the initial assessment included "a screening for indications of photosensitive epilepsy based on electroencephalography (EEG)", comprising a resting record, four-second flicker episodes at 1, 3, 10, 20, 30 and 40 hertz each presented twice, and about two minutes of hyperventilation, the whole reviewed by a trained expert. Participants were informed of the risks and gave written consent, and a familiarization session with constant light preceded the flicker sessions. Notwithstanding all of that, "One participant dropped out of the study due to self-reported migraine symptoms after the first experimental session with FLS of 10 Hz". That participant was replaced.

What was found, stated as the Results state it rather than as the abstract states it. On the eleven-factor scale, Elementary Imagery, which records basic visual impressions such as colors and patterns, scored 48.44 plus or minus 27.59 at 3 hertz and 63.05 plus or minus 27.90 at 10 hertz on a scale of 0 to 100. Vigilance Reduction, reflecting drowsiness and clouded consciousness, was the highest of the five dimensions at about 32 in both conditions. The global altered-state score was 12.04 and 14.20. The Foundation then records the qualification the figure caption supplies, because the abstract does not: "None of the differences between the dimension scores of 3 Hz and 10 Hz conditions were significant after Bonferroni-correction of the α-threshold for multiple comparisons". The abstract's statement that effects were "strongest in the 10 Hz condition" therefore describes a trend and not a significant difference, and the comment should not report it as a frequency-dependence result.

The comparison that gives the paper its public profile, and its status. The abstract states that the technique is "capable of inducing visual effects with an intensity rated to be similar in strength to effects induced by psychedelic substances". The basis is a descriptive comparison of this study's ratings against published values for other agents, not a within-study test. On Elementary Imagery the 10 hertz figure of 63.05 is set beside 64.01 plus or minus 32.03 reported for 100 micrograms of lysergic acid diethylamide, and about 61.1 expected for psilocybin at 300 micrograms per kilogram; Vigilance Reduction is set beside 28.93 for low-dose ketamine. The authors immediately confine the claim: "the visual effects appear limited to elementary imagery (i.e., colorful, dynamically changing fractal structures), while complex, hallucination-like visions of meaningful objects were rarely reported in the study at hand". The resemblance is to the colors-and-patterns component only.

The frequency range the wider literature identifies, which is the second reason for citing the paper. The discussion collects the frequencies at which flashing light has been found to alter visual perception. One study reported "most radial illusory percepts at ~10 Hz and spiral percepts to be most pronounced at the slightly higher frequency of ~15Hz". Another found visual phenomena "most strongly pronounced between 10–25 Hz". Two further reports indicate "the strongest illusory percepts in the range of 15 to 30 Hz". Taken

with the present study, the band in which the effect is established runs from about 3 to about 30 hertz. The authors also record what has not been done: "With respect to future research, it will be informative to assess the effects of higher flicker frequencies with standardized questionnaire tools, as well".

Personality, reported precisely because the abstract compresses it. The trait of Absorption correlated with the global altered-state score in both conditions, at r equal to 0.61 and p equal to 0.002 at 3 hertz and r equal to 0.68 and p below 0.001 at 10 hertz. It did not correlate with Elementary Imagery in either condition, and its correlation with Complex Imagery did not survive correction. The abstract's statement that Absorption "highly correlated with the experienced alterations in consciousness" is accurate of the global score and not of the imagery subscales.

What it establishes. That twenty minutes of flashing light at 3 or 10 hertz, delivered to the closed eyes of screened healthy adults in a dark room, produced measurable alterations of visual perception and of vigilance on standardized instruments; that on the colors-and-patterns dimension the ratings fall in the range published for substantial doses of psychedelic drugs; that the effect is established across the literature in a band from about 3 to about 30 hertz; and that a university ethics committee required psychological interview, exclusion of pregnancy and psychotropic medication, and electroencephalographic screening for photosensitive epilepsy before such exposure was permitted.

What it does not establish. Nothing about light-emitting diode lighting products or their drive modulation, which operate at frequencies an order of magnitude and more above those used here. Nothing about exposure with the eyes open, which is the only exposure at issue in this comment, and the difference is not a detail: the closed eyelid both attenuates and diffuses the stimulus and the paper does not address what an open-eyed observer would experience. Nothing about brief exposure, the sessions being twenty minutes. Nothing about frequency dependence, the two conditions not differing significantly. Nothing about vigilance specifically, because there was no condition without light and the authors say so: "the study at hand did not include a control condition without light stimulation", so twenty minutes seated with the eyes closed in a dark room is not excluded as the cause of the drowsiness scores. And nothing about the general population, the sample being 24 young adults, mostly women, recruited from a university and screened to exclude the people most likely to be affected.

Where it bears. Part V.E.6, which is written on it. Part V.D.4, for the frequency band in which the beacon counted there operates. Part V.E.1, for the frequencies at which the screening in this protocol was conducted. Part VII, for the asymmetry between what is required before a volunteer may be exposed and what is required before a member of the public is.

C.94 Inger, Bennie, Davies and Gaston (2014) — the largest collation of critical fusion frequencies finds species able to resolve flicker far above the frequencies of mains-driven lamps, and states candidly that the evidence of actual effect is thin

Citation. Inger R., Bennie J., Davies T. W., Gaston K. J. "Potential Biological and Ecological Effects of Flickering Artificial Light". PLoS ONE 2014;9(5):e98631. doi:10.1371/journal.pone.0098631. Published 29 May 2014. PubMed Central PMC4038456; PubMed 24874801. Open access. Full text read from the PubMed Central deposit. The authors were at the University of Exeter.

Design. A systematic collation with statistical analysis. The authors searched Web of Science, Google Scholar and Google in September 2012 for reported critical fusion frequencies in non-human animals, took the mean photopic value where a range of intensities was reported, extracted values from figures where only figures were given, and admitted only peer-reviewed papers containing a full description of method. They then fitted linear mixed-effects models with taxonomic class, natural light exposure, light source type and measurement method as fixed factors and species as a random factor. The critical fusion

frequency is defined as the threshold at which an animal ceases to perceive a flickering source as a series of flashes and perceives it instead as a continuous stream.

The collation, which is the paper's own work and the part the comment relies on. Fifty-six studies yielding 93 measurements, 19 behavioral and 74 by electroretinography, for 81 species in 66 genera and 9 classes. The range found was wide: the lowest value was 6.7 hertz for the cane toad and the highest 400 hertz for a fire beetle. The proportion exceeding the doubled mains frequency is given four ways: "In a considerable number of cases (16.1% of measurements, 13.5% of species, 16.6% of genera and 44.4% of classes), CFFmean values were above the flicker frequency of fluorescent lamps on a 50 Hz electrical supply; i.e. 100 Hz". The authors add the point that matters for a comment addressed to a United States agency: "It should be noted that a number of countries utilise a 60 Hz electrical supply and hence the flicker frequency with be higher at 120 Hz".

The two taxa the authors treat as most exposed, with their figures. Of insects, values have been characterized for only nine diurnal and three nocturnal species, "producing a wide range of values (42.5–400 Hz)", and the authors state that "Given the vital role insects play in ecosystem functioning (e.g. pollination, decomposition), and as nutrition for other organisms, this depauperate knowledge base should give cause for concern". Of birds, values exist for five species only, ranging from 40 to 143 hertz, with direct measurement for just two diurnal species. One is the domestic chicken. The other is the pigeon, which the authors describe as "a very common urban bird that is likely to encounter high levels of artificial light" and which has "the highest CFF values recorded (143 Hz) of any vertebrate species and will easily be able to perceive flicker from artificial lights". Values above 100 hertz have been inferred for starlings. The authors reason from this that "it is likely that other birds capable of rapid flight have high CFFs, and are able to detect flickering artificial light".

What the paper says about the technology. "Light emitting diode (LED) technology is also increasing in popularity particularly for street lighting and these lamps also have a high flicker index. Indeed the perceived brightness of many LED lamps is controlled by regulating the flicker frequency". The Foundation records that the last clause is imprecise, and says so rather than quoting it approvingly: pulse-width modulation controls output by varying the duty cycle at a fixed frequency, as Part V.D.1 establishes from the sources there, not by regulating the frequency. The error does not affect the paper's analysis, which turns on frequency of flicker rather than on how dimming is achieved.

The concession the Foundation places at the center of its use of this paper. The authors state the weight of their own evidence, and the comment would be worth less if the Department had to find the sentence itself. "The evidence presented here suggests that impacts from the perception of the flicker of artificial light may be rather limited for most species studied thus far. There remains, however, a scarcity of data on CFFs for many taxa that are most likely to be affected, hence we suggest that the potential ecological effects should not be wholly dismissed". The title of the paper says potential, and the authors mean it.

The limits the authors place on perceptibility, which are substantial. Three. First, taxonomic: "all animals able to detect artificial flicker are naturally diurnal hence only species for which artificial light serves effectively to increase day length, or which are facultatively nocturnal, are likely to be affected". Second, intensity, because "CFF decreases with light intensity, which itself decays with distance from the light source". Third, and as a consequence, distance: tsetse flies retain high values at low intensity and "will still be able to perceive flickering street lamps at 3 lux, which is approximately the lowest intensity light found at ground level between neighbouring metal halide lamps", whereas for honeybees and domestic chickens "a subject would need to be closer than three metres to the light source in order to perceive the flicker". Of chickens the authors go further: they "will only be able to perceive flicker at light intensities exceeding the range likely to be

produced by artificial lamps". The figure in which this is plotted identifies the perceptible region for 50 hertz supply lamps as lying within 0 to 40 lux.

What the authors say about evidence of actual effect. "Explicit studies of the biological effects of light flicker on animals remain scarce, and have focused on the efficacy of trapping devices for insects and on welfare issues for captive vertebrates". The paper's table of documented effects lists sixteen entries across eleven species, predominantly insects and the European starling, with effects classified as behavioral, physiological, physiological stress or visual, and the authors note that such effects "can be produced by flicker that may or may not be perceivable by the animal". The groups the authors flag for further work are nocturnal animals that move fast in dark conditions, naming hawkmoths, certain nocturnal flying birds and bats, and observing that some bats "often utilise artificially lit areas as they act to concentrate their food resources".

Their conclusion. "Given the precautionary principle and that it is likely that in the future an increasing level of artificial light will come from lamps with a high flicker index, as incandescent bulbs are phased out, and replaced with fluorescent (including compact fluorescent bulbs, generally referred to as 'low energy bulbs') and LED lamps, we suggest the impacts of flickering light on natural systems are given urgent attention".

The paper's table of human effects, which the Foundation examined and does not rely on. The paper opens with a table of fifteen documented effects of flickering light on humans, with frequencies and references, four rows of which are labeled unperceived. The table is attractive to this comment and the Foundation traced three of its rows to their sources before deciding not to use it. The row reading unperceived neurological effects, light-emitting diode, up to 200 hertz is referenced to Burns, Elsner and Kreitz, Analysis of nonlinearities in the flicker ERG, Optometry and Vision Science 1992;69:95 to 105. That is a 1992 methodological study of retinal electrophysiology in which light-emitting diodes were the laboratory stimulator, and an electroretinographic response is evidence that the retina responds to a stimulus rather than evidence of a neurological effect in any ordinary sense. The row materially overstates its source. Two other rows are better founded: unperceived retinal effects at 76 to 162 hertz is referenced to Berman, Greenhouse, Bailey, Clear and Raasch, Human electroretinogram responses to video displays, fluorescent lighting and other high frequency sources, Optometry and Vision Science 1991;68:645 to 662, which is directly about that question; and unperceived neurological effects from a computer monitor at 42.5 to 75 hertz is referenced to Lu, Cai, Shen, Zhou and Han, Alerting and orienting of attention without visual awareness, Consciousness and Cognition 2012;21:928 to 938, whose title states the proposition. The Foundation therefore treats this table as a bibliography rather than as authority, cites nothing to it.

What it establishes. That across 81 species in 9 classes the measured temporal resolution of vision ranges from about 7 to 400 hertz; that 16.1 percent of measurements and 44.4 percent of classes exceed 100 hertz, with the relevant comparison in a 60 hertz country being 120 hertz; that the pigeon, a common urban bird, has the highest recorded vertebrate value at 143 hertz; that insect values span 42.5 to 400 hertz on a base of twelve species; that flicker has been overlooked relative to the intensity, duration and spectrum of artificial light; and that the authors, on the precautionary principle, call for urgent attention to the question.

What it does not establish. That any animal is harmed by the flicker of any lamp. The paper is a collation of temporal resolution and not a study of effect, its own authors state that the impacts may be rather limited for the species studied so far, and the explicit effect studies it tabulates are about insect traps and captive animal welfare. It does not establish that resolving a flicker is adverse: perceiving a light as flashing rather than steady is a perceptual fact, not an injury. Its perceptibility findings are heavily conditioned on intensity and therefore on distance, to the point that two of the three species modeled would need to be within three meters of the lamp. The collation mixes electroretinographic

and behavioral determinations, which the authors expected to differ and included as a factor, although they report finding no effect of method. And it reports no measurement of any lamp: the frequencies it compares against are the nominal doubled mains frequencies, not measured product output.

Where it bears. Part V.I, which is written on it. Part V.D.1, for the proposition that perceptibility of modulation falls with illuminance, which is the same relation the instrument maker at Appendix D.3 states from the measurement side. Part VI.D, for street lighting.

C.95 Oliveira, Ferreira and Martinez-Perez (2024) — a survey of festival attendees finds self-reported sensitivity to stage lighting differing by refractive condition, and measures no light

Citation. Oliveira A. P., Ferreira G. and Martinez-Perez C. "Effects of Stage Lighting on Visual Comfort at Summer Festivals: A Study in Portugal". Healthcare (Basel) 2024;12(23):2441. doi:10.3390/healthcare12232441. Published 4 December 2024. Open access; full text read. The authors are of the Instituto Superior de Educacao e Ciencias de Lisboa and are optometrists rather than neurologists or lighting engineers, which bears on what the paper is evidence of.

Design. A cross-sectional self-report survey. An instrument of eighteen questions in five sections was built in Google Forms and distributed through Facebook, Instagram and Twitter, through festival-related groups and pages, through targeted paid advertisements, through the authors' personal networks and their institution's databases, and by some festival organizers at summer 2024 events. It was open from June to September 2024. Participants were not compensated and there were no inclusion or exclusion criteria. Ethics approval was given by the institution's ethics committee under code CE/2024/09/01 on 22 May 2024. The authors declare no conflicts of interest. Analysis in IBM SPSS v.27.

Sample. Two hundred and six participants.

What was measured, stated first because it governs everything else. Nothing was measured. No luminance, illuminance, spectral content, flash rate, modulation depth or duty cycle of any light source at any festival is reported, and no instrument is described. No clinical examination was performed and no biological endpoint was recorded. The paper is a record of what two hundred and six people said about their experience of lighting at events they attended.

The findings the comment relies on. Sensitivity to stage lighting: 14.3 percent of participants reported high sensitivity and 23.4 percent moderate sensitivity. Women reported significantly higher sensitivity to stage lighting than men (3.29 ± 1.28 against 2.68 ± 1.31; p = 0.0070; Cohen's D = 0.47). Sensitivity varied significantly by age (p = 0.0472), highest in the 66 to 75 group at 4.00 and lowest in the 19 to 25 group at 3.08 ± 1.28. Sensitivity to light varied significantly by refractive condition (p = 0.0375): astigmatism 3.51 ± 1.42, hyperopia 3.62 ± 1.19 and presbyopia 3.88 ± 0.99, against emmetropes at 2.75 ± 1.28 and myopes at 3.08 ± 1.36. The conclusion reports that 33.1 percent of festivalgoers with refractive errors experienced heightened sensitivity to artificial and stage lighting.

What the participants asked for, which is the part that bears on Part IX. Asked what would improve visual comfort, 44.81 percent favored high-quality light-emitting diode systems, 37.66 percent designated low-light areas for visual rest, 37.01 percent more shaded areas, and 31.82 percent minimizing the use of intermittent lighting. Of the aesthetic perception of the stage lights, 43.51 percent found them pleasing, 36.36 percent were indifferent and 20.13 percent found them uncomfortable.

What the paper is NOT evidence of, and the Foundation states it plainly because the paper is easily misread. It is not evidence that strobe lights provoke seizures. The paper contains a sentence in its introduction to the effect that strobe lights are known to trigger disorientation or discomfort and that for individuals predisposed to photosensitive epilepsy they can trigger seizures. That sentence is background narrative and not a finding. It carries three citations, to Harding and Harding, Applied Ergonomics 2010;41:504 to 508; to Silva and Leal, Seizure 2017;50:209 to 218; and to Fisher R. S., Acharya J. N., Baumer F. M., French J. A., Parisi P., Solodar J. H., Szaflarski J. P., Thio L. L., Tolchin B., Wilkins A. J. and Kasteleijn-Nolst Trenite D., Visually sensitive seizures: an updated review by the Epilepsy Foundation, Epilepsia 2022;63(4):739 to 768, doi:10.1111/epi.17175. The study itself did not examine seizures, photosensitivity, flash frequency or any person with epilepsy. The comment cites the source of the proposition and not this paper, and no part of this comment relies on this paper for any neurological claim.

Limitations the authors state, reproduced because they are unusually candid. Four. That the sample of 206, while sufficient for exploratory analysis with an estimated margin of error of 6.8 percent, does not achieve the 5 percent margin typically desired for population-wide estimates, which the authors address by "focusing on identifying trends and relationships rather than drawing generalized conclusions". That the study relies on self-reported data and may carry recall and social desirability bias. That the cross-sectional design limits the ability "to infer causal relationships between stage lighting and reported symptoms". And that the geographic scope, Portugal only, may affect generalizability.

Two internal inconsistencies the Foundation found and does not reproduce. The abstract states that cooler stage lighting was associated with a higher incidence of glare "with male participants reporting greater discomfort than females", while the results report women as significantly more sensitive to stage lighting than men. These are different measures, and any use of either must say which. More seriously, the abstract states that "participants aged 19–25 experienced more frequent tearing under stage lighting" and presents it as notable, while the conclusion states of the same comparison that "these differences were not statistically significant". The comment does not use the tearing finding.

Where it bears. Part V.C.5, for the differential by refractive condition. Part VI.K, for entertainment and event lighting as a product class. Part IX.F, for what the surveyed population asked for. It does not bear on Part V.D or Part V.E and is not cited there.

C.96 Mankowska, Grzywinska, Winklewski and Marcinkowska (2022) — a neurophysiological review finds that whether modulation is seen depends on eight variables, and that colored flashes carry their greatest seizure risk at fifteen hertz

Citation. Mankowska N. D., Grzywinska M., Winklewski P. J. and Marcinkowska A. B. "Neuropsychological and Neurophysiological Mechanisms behind Flickering Light Stimulus Processing". Biology (Basel) 2022;11(12):1720. doi:10.3390/biology11121720. Published 28 November 2022. Open access; full text read.

Design, and the limits that follow from it. A narrative review. It states no search strategy, no database query, no date range and no inclusion or exclusion criteria, and it does not describe itself as systematic. It should be read as a subject-matter summary by its authors rather than as a reproducible synthesis, and the Foundation cites it accordingly.

What it is about, which is not what this comment is about. Its subject is flickering light as a research and diagnostic stimulus: the flicker test, critical flicker fusion, steady-state visual evoked potentials, electroencephalography and functional magnetic resonance imaging, and their possible clinical uses. It is not a review of environmental exposure to light-emitting diode products, and it states of its own field that the clinical applications of

flickering light "are still not well understood". The comment uses it for specific statements of fact within it and not as an assessment of the subject of this comment.

The eight determinants, which is the principal reason it is cited. The review states that distinguishing flickering from steady light depends on the frequency of modulation, the amplitude of modulation, the average illumination intensity, the position on the retina at which the stimulus occurs, the wavelength or color of the light-emitting diode, the intensity of ambient light, the viewing distance, and the size of the stimulus. The measurement standards and the recommended practice treated at Appendix D.2 address the first two. Relied on at Part V.D.1 and Part V.J.

Color and flash rate in the induction of photoparoxysmal responses. The review reports that white light requires frequencies above 20 hertz to induce seizures while for colored stimuli such as blue and red the risk is greatest around 15 hertz; gives a summary table in which color exceeds white at 10 to 15 hertz, the 15 hertz entry is red-blue alternating stimulation, and color and white are equivalent at 20 to 30 hertz; and reports that blue with green elicited the fewest epileptiform responses. It attributes the identification to a documented broadcast incident in which children had seizures while watching a sequence it describes as an intense blue-red light flashing at 15 hertz. Its abstract states that because flicker testing carries a risk of inducing seizures, every effort must be made to avoid high-risk combinations including red-blue light flashing at 15 hertz. Relied on at Part VI.C.1 and Part II.H.6.

Three further statements the comment uses, each with the review's own qualification attached. That the critical fusion threshold in humans is estimated at 50 to 90 hertz, with a report of discrimination at 500 hertz attributed to saccadic eye movement, and with the review recording that the studies are not consistent with one another. That reports exist of a stroboscopic effect above 1000 hertz where objects elsewhere in the visual field are moving. And that there is limited evidence of a visual cortical response to modulation perceived as steady, which the review bases on a functional imaging study it describes as having few participants. The Foundation has read none of the underlying studies and cites each as reported by this review.

A caution the review supplies against a measure this comment uses elsewhere. It reports a conclusion that critical flicker fusion has limited value as a clinical measurement because the threshold depends on both the gain of the visual system and its processing speed without separating them. Carried to Part V.D.2 and applicable at Part V.I.

What it does not establish. That any light-emitting diode product in commerce harms anyone. It reports no exposure to any commercial product, measures no lamp, and contains no photometry. Every stimulus it discusses is a laboratory or clinical stimulus, and its orientation throughout is toward the diagnostic and therapeutic use of flicker rather than toward its avoidance.

C.97 Hall and Madsen (2022) — a roadside safety message designed to capture attention increased crashes, and the authors conclude that an intervention can be too salient

Citation. Hall J. D. and Madsen J. M. "Can behavioral interventions be too salient? Evidence from traffic safety messages". Science 2022;376(6591), article abm3427. doi:10.1126/science.abm3427. Published 22 April 2022.

What the Foundation read, stated first. The structured abstract, the abstract and the editor's summary as published. The full text was not read. The publisher's site was not accessible to the Foundation, and the Foundation declined to rely on a copy of the article hosted by a third party. Every figure and every quotation used in this comment is from the structured abstract. This is a limitation on the use of the source and it is recorded wherever the source is used.

Design. A natural experiment with difference-in-differences and instrumental variable estimation. The Texas Department of Transportation displayed the year-to-date statewide count of road fatalities on its dynamic message signs for one week each month, the week before its monthly board meeting, from August 2012. The authors used data on 880 signs and all crashes in Texas from 1 January 2010 to 31 December 2017, holding fixed road segment, year, month, day of week and time of day. Placebo tests used weeks before the campaign began and road upstream of the signs. The authors state that they consider seven alternative hypotheses and give evidence inconsistent with each.

Results as the authors state them. A 1.52 percent increase in crashes within 5 kilometers of a sign during campaign weeks, diminishing to 1.35 percent over the 10 kilometers after a sign; an instrumental-variable estimate of a 4.5 percent increase over 10 kilometers for the effect of displaying a message; statewide on-highway crashes higher during campaign weeks; the effect comparable to raising the speed limit by 3 to 5 miles per hour or reducing highway troopers by 6 to 14 percent; and, on a calculation the authors themselves describe as back-of-the-envelope, an additional 2,600 crashes and 16 fatalities a year in Texas with a social cost of $377 million a year.

The mechanism the authors propose, and the pattern supporting it. That negatively framed messages seize too much attention and interfere with drivers' ability to respond to changes in traffic conditions. In support: a higher displayed count causes more crashes than a lower one; the effect is larger on more complex road segments; the effect is largest near the sign and falls with distance; and the messages increase multi-vehicle but not single-vehicle crashes.

Scope of the practice studied. The authors state that the campaign has been implemented in 28 United States. It is therefore a national practice on devices governed by the Manual on Uniform Traffic Control Devices and not a single State's experiment.

What it does not establish, and the Foundation puts this in its own field because the paper is easily misdescribed. It does not establish that the emission of an electronic sign causes crashes. The signs were previously installed and operating in both conditions. Luminance, spectral content, modulation and physical presence were identical during campaign and non-campaign weeks; only the displayed message differed. The study holds emission fixed and varies content, and nothing in it bears on the optical quantities this comment is concerned with. No part of this comment cites it for any proposition about emission.

What it is used for. For the proposition that the premise underlying every conspicuity device in Part VI, that greater attention capture is better, is an empirical claim capable of being tested; that it has been tested once, rigorously, on real crash data; and that it failed. Also for two findings that answer standing objections: that individuals did not habituate to the stimulus over five years, and that the effect did not persist after the practice stopped. And for the authors' conclusion that it is important to measure an intervention's effect because good intentions do not necessarily imply good outcomes.

Where it bears. Part VI.J.7, which is written on it. Part VI.C.1, for the premise beneath warning lamps. Part II.H.6, for what it shows about evaluation of devices governed by the Manual on Uniform Traffic Control Devices. Part IX.C, for the research request.

C.98 Fisher and others (2022) — the Epilepsy Foundation's updated review states the four conditions under which a flash is a hazard, says that the effect of light-emitting diodes on people with epilepsy is unstudied, and says that flashing police lights only rarely provoke seizures

Citation. Fisher R. S., Acharya J. N., Baumer F. M., French J. A., Parisi P., Solodar J. H., Szaflarski J. P., Thio L. L., Tolchin B., Wilkins A. J. and Kasteleijn-Nolst Trenite D.

"Visually sensitive seizures: An updated review by the Epilepsy Foundation". Epilepsia 2022;63(4):739 to 768. doi:10.1111/epi.17175. Full text read.

What it is, and the limit its authors place on it. A review by a working group of the Epilepsy Foundation, updating the same body's 2005 review. It is expressly not systematic: the authors state that the literature summary derives from a nonsystematic review via PubMed using the terms photosensitive and epilepsy, that the prior reviews were not systematic and neither is this one, and that a paucity of controlled studies in the field would make a systematic review difficult. The Foundation cites it as the considered statement of the leading expert body and not as a systematic synthesis.

The four criteria, which are the reason the comment needed this document rather than the sources that quote it. Section 9.2: a flash is a potential hazard if it is brighter than 20 candelas per square meter, occupies at least 10 percent of the visual field, flashes or changes color at a frequency between 3 and 60 hertz, and endures for at least half a second. The conditions are conjunctive. Avoidance of these characteristics is estimated by the review to be protective for at least two-thirds of people with epilepsy. A pattern criterion is stated separately: at least five clearly discernible oscillating stripes, eight if drifting smoothly, brighter than 50 candelas per square meter and enduring for over one-half second.

A discrepancy between the abstract and the body, recorded because the comment quotes the body. The abstract renders the spatial condition as occupying "at least 10 to 25% of the visual field". Section 9.2 gives it as at least 10 percent of the visual field, and section 9.3 explains that more than 10 percent of the visual field is "typically about one-fourth of the screen area at typical viewing distances". These are one quantity in two expressions rather than a range, and the comment uses the body text.

What it says about this comment's product classes, stated in its own field because it is adverse. Section 3.1: "Flashing police car lights only rarely provoke seizures, perhaps because the image rarely occupies a large part of the visual field." The sentence carries one citation, is qualified by the word perhaps, and appears in a passage on syndromes imitating photosensitivity rather than in the review's treatment of stimulus characteristics. It is quoted in full and answered at Part VI.C.1 and referred to at Part VI.I. No part of this comment cites this review while omitting it.

Section 8.6, on light-emitting diodes, which is the most directly relevant passage in the document. It states that modern light-emitting diodes have significantly increased luminance; that photostimulators in electroencephalography laboratories now use them to generate bright lights, so that it is clear flashes from them can provoke photoparoxysmal responses; and that what is not known is whether they have provocative properties distinct from the known responses to bright flashes. It records a dated literature search: PubMed, 25 January 2021, terms light emitting diode and seizures, five results, none indicating provocation and two animal studies showing suppression. It states that frequencies up to 11 kilohertz generate a visible pattern on the retina when a saccade is made across a flickering diode, more visible to individuals who complain of eye strain. And it concludes that the effect of these devices on people with epilepsy is a subject that would benefit from additional research.

Regulatory content. Section 9.1 states that prevention "can take place at the level of government regulation, industry, families, and individual patients". Section 9.3 lists eight commercial or academic tools for detecting provocative flashing, including the Harding Flash and Pattern Analyzer and the Photosensitive Epilepsy Analysis Tool, which supports the abstract's statement that equipment to assay for these characteristics is probably underutilized. It names the United Kingdom, Japan, Russia and Italy as having implemented regulations for broadcast material, and the United States is not among them. It records that British guidelines prohibit flashes greater than 3 hertz, brightness above 20

candelas per square meter, or red flashes occupying more than 25 percent of the screen; and, separately from broadcast, that "In the UK, devices that flash in public are limited to frequencies no higher than 4 Hz, and they should not be visible from stairways". It states that "Frequency, brightness, binocularity, and large area are all key factors in contributing to seizure provocation".

Prevalence and population. Light, pattern or color stimuli can provoke seizures in up to 1 in 4,000 persons, with the review noting that prevalence may be higher because of selection bias. A photoparoxysmal response is reported in 0.3 to 8 percent of the normal population and 0.6 to 30 percent of people with epilepsy. Females are approximately twice as likely as males. About half of individuals with electroencephalographic photosensitivity are unaware of the trait, and most children affected in the broadcast incident of 1997 were unaware of it. That last figure bears on Part VIII and Part IX.F: a person who does not know they are susceptible cannot avoid a stimulus that is not disclosed.

The sentence the comment relies on at Part IX. The abstract concludes that visually-induced seizures remain significant public health hazards so they warrant ongoing scientific and regulatory efforts and public education. That is the expert body of the field calling for regulatory effort, in a peer-reviewed review, and the Foundation asks the Department to weigh it as such.

What it does not establish. That any light-emitting diode product in commerce has provoked a seizure in anyone. Its section 8.6 says the opposite: that the literature is close to empty and the question unstudied. It measures no product, reports no exposure to any commercial lamp, and its criteria were developed for broadcast and display content rather than for luminaires.

Where it bears. Part VI.C.1, for the criteria, the adverse sentence and the British four-hertz rule. Part VI.I, for the criteria applied to a measured lamp. Part V.D.1 and Part V.D.2, for section 8.6. Part V.B.8, for increased luminance. Part V.J, for the measurement tools. Part V.L and Part IX.C, for the research gap. Part VIII and Part IX.F, for unawareness of susceptibility. Part IX, for the call for regulatory effort. It supersedes the secondhand renderings at Appendix C.95, Appendix C.96 and Appendix D.2 wherever those quote it.

C.99 Salet, Visser, Stam and Smulders (2018) — a cohort of 400,343 people finds the seizure rate at stroboscopically lit events more than three times higher when the event takes place in darkness

Citation. Salet N., Visser M., Stam C. and Smulders Y. M. "Stroboscopic light effects during electronic dance music festivals and photosensitive epilepsy: a cohort study and case report". BMJ Open 2018. doi:10.1136/bmjopen-2018-023442. Open access under Creative Commons Attribution Non Commercial 4.0. Not commissioned; externally peer reviewed. No specific grant declared and no competing interests declared. Full text read.

Design. A retrospective cohort study reported in accordance with the Strengthening the Reporting of Observational Studies in Epidemiology statement, together with a case report. The domain was visitors to electronic dance music festivals in the Netherlands between 1 January and 31 December 2015. All such festivals use stroboscopic lighting and those without it were excluded; the presence of the effects was verified from publicly available video. The cohort was divided by whether the event took place in darkness, indoors or at night, or in daylight. Data came from the source files of a company providing medical assistance to more than 90 percent of such events in the Netherlands. Approved by the hospital's medical ethics committee. Power to detect a twofold difference exceeded 90 percent.

Cohort. Twenty-eight festivals and 400,343 visitors, representing 4,556,556 person hours. Exposed: 241,543 people and 2,222,196 person hours. Unexposed: 158,800 people and

2,334,360 person hours. Medical assistance was provided 2,776 times, and its incidence density was equally divided between the two groups.

Result. Thirty-nine seizures identified as epileptic, thirty in the exposed group and nine in the unexposed. Incidence density ratio 3.5, 95 percent confidence interval 1.7 to 7.8, p less than 0.0005. The authors conclude that stroboscopic light effects at events occurring in darkness probably more than triple the risk of epileptic seizures.

The accompanying case. A twenty-year-old man collapsed at an indoor festival with features of a tonic-clonic seizure witnessed by bystanders, having reported an urge to turn his eyes away from the stroboscopic effects beforehand. He denied drugs and alcohol and had no seizure history. At later examination after overnight sleep deprivation his electroencephalogram was normal at baseline, while stroboscopic stimulation throughout the 14 to 25 hertz range elicited generalized epileptiform discharges; the same discharges and sensations occurred when he was shown cell-phone video of the concert he had attended, recorded by one of the authors who was present.

Why the comment relies on it, which is not for the reason a reader might assume. Not for anything about intensity. The exposure variable is darkness. The same kind of event, with the same kind of lighting and a similar audience, produced three and a half times the seizure incidence when held against a dark background rather than in daylight. It is the only population evidence the Foundation has that the state of adaptation of the viewer, which the measurement literature treats as a condition under which instruments perform poorly, is a variable capable of moving a clinical outcome. Relied on at Part VI.K and Part V.D.1, and bearing on Part V.C.3.

What it does not contain. Any photometry. No luminance, no measured flash rate, no modulation depth, no spectral content, and no measurement of any fixture at any venue. No part of this comment cites it for a proposition about any of those quantities.

Limitations, as the authors state them. That the individual epileptogenic components could not be fully disentangled, the authors writing that stroboscopic light effects are prime suspects but probably not solely responsible, with sleep deprivation, physical exertion and stimulant use also present and more likely at night-time events. That the database is anonymous and aggregate, so unique persons could not be identified and ecstasy use could not be formally adjusted for, though the proportion of seizure cases involving ecstasy was similar in the two groups at 27 and 33 percent. That seizures were identified by on-site medical staff from witness reports and physical findings rather than by confirmed diagnosis, permitting both under and over diagnosis, with the authors judging their figures an underestimate. That people with known photosensitivity may have taken precautions or avoided medical staff. And that the results "may be less applicable to other types of concerts or festivals, which use less stroboscopic lights and attract a different audience". The data were not shared.

What the authors recommend. That organizers and audiences warn of the risk and promote precautionary measures, the authors noting that organizers do not routinely warn visitors. That bears on Part IX.F.

C.100 Minamisawa, Funayama, Matsumoto, Matsuki and Ikegaya (2017) — a brief flash evokes cortical activity outlasting it by seconds, and repeated pairing suppresses perception for hours in mice

Citation. Minamisawa G., Funayama K., Matsumoto N., Matsuki N. and Ikegaya Y. "Flashing Lights Induce Prolonged Distortions in Visual Cortical Responses and Visual Perception". eNeuro, 2017. PMCID PMC5429040; PMID 28508035. Graduate School of Pharmaceutical Sciences, University of Tokyo. Open access; full text read.

What kind of study it is, stated first. Basic neuroscience in mice, and methodological in purpose. The authors describe their object as a new method for the noninvasive induction

of long-term plasticity in the mature brain, and propose flashing light as an experimental tool. It is not a study of exposure to any commercial product and makes no claim about one.

Preparation and subjects. Male C57BL/6J mice, postnatal days 68 to 75 for the adult experiments and 28 to 35 for juvenile preparations. Head-plate implantation under ketamine and xylazine, habituation to head fixation, then craniotomy and durotomy over the left hemisphere. Recordings in awake animals, one acute recording per animal, each limited to under an hour. Whole-cell and cell-attached patch clamp of layer 2/3 neurons, local field potentials, and two-photon calcium imaging with Fura-2. Behavior assessed by a virtual optomotor test on freely moving animals. Approved by the Animal Experiment Ethics Committee of the University of Tokyo.

The stimulus. A white screen at 240 candelas per square meter, about 65 lux at the eye, presented for 100 milliseconds every 10 seconds against a continuous gray screen at 60 candelas per square meter. A 17-inch monitor at 30 centimeters covering 38.8 degrees of the horizontal and 29.6 degrees of the vertical visual field. For the pairing protocol a sinusoidal drifting grating was presented 400 milliseconds after each flash, at the onset of the flash-evoked late response, and the pairing was repeated 30 to 50 times.

Findings. That a flash evokes a fast transient response followed by a long-delayed response persisting for seconds, the authors stating in their significance statement that this occurs in mice, rats and humans. That pairing the late response with a drifting grating produced a suppression of the cortical response to that direction and a fall in the animals' ability to detect motion in it. That both the neurophysiological and the behavioral change persisted for at least several hours. And that both were prevented by local application of the N-methyl-D-aspartate receptor antagonist AP5 to the visual cortex, identifying a receptor mechanism.

The limitation the authors state, which governs every use of this paper in the comment. In their discussion: "Although the intensity of the flashing stimulus employed here (Δluminance = ~60 lx) is comparable to that experienced in our daily lives, such as that of a camera strobe, we rarely encounter such repeated, specific exposures to visual stimuli." The intensity is therefore ordinary and far below anything described in Part VI, and the exposure is a conditioning protocol rather than an environmental one. The comment relies on this paper for mechanism and for the existence of an unexamined question, and nowhere asserts that the demonstrated perceptual deficit occurs in people exposed to any product.

Two further qualifications. The suppression was specific to the paired direction and not a general loss of vision. And the direction of the plastic change was not uniform: the authors report that cells in which the flash increased the response to the paired grating later showed facilitation, while those in which it decreased the response showed suppression, with the mean modulation index near zero. The headline result is the mean effect across cells and not a uniform one.

Where it bears. Part V.E.7, which is written on it. Part V.D.2, for the observation that no measurement criterion contemplates a response outlasting the stimulus. Part V.L and Part IX.C, for the research gap.

C.101 Voyzey, Mazzae and Andrella (2023) — a federal measurement of how accurately new vehicle headlamps are aimed, and a statement that no federal requirement governs it

Citation. Voyzey N., Mazzae E. N. and Andrella A. "Assessment of Headlamp Aim for New Vehicles." Report No. DOT HS 813 481. National Highway Traffic Safety Administration, October 2023. 28 pages. Performed at the agency's Vehicle Research and Test Center, East

Liberty, Ohio; performing organization code NVS-120. Two of the three authors are of Transportation Research Center Inc.; the second is of the agency.

What kind of document it is, stated first. A government technical report of original measurements, not a peer-reviewed paper and not a rulemaking document. It carries the agency's standard disclaimer that it is distributed in the interest of information exchange and that no conclusions about safety performance or compliance should be drawn from it. It is placed in Appendix C rather than Appendix D because it reports measurements the authors made, which is the criterion this appendix applies.

What was measured, and how. The vertical aim angle of the lower beam headlamps of fifteen light vehicles of model years 2022 and 2023, measured soon after delivery and before any other testing. Method per SAE J599: the beam was shone on a white matte screen twenty-five feet from the vehicle in a darkened laboratory and the vertical position of the beam cutoff was located relative to the headlamp optical center height, marked by a self-leveling laser. Each vehicle was measured unloaded and again with a 165-pound load in the driver seat. All fifteen were measured visually from digital photographs; five were additionally measured with a Radiant Vision Systems ProMetric Y imaging photometer, the aim being taken as the location of maximum gradient along a vertical line two degrees from the headlamp center. Fourteen of the fifteen vehicles had light-emitting diode headlamps and one a halogen projector.

The finding the comment principally relies on, which is not a measurement. That "There are currently no requirements in Federal Motor Vehicle Safety Standard (FMVSS) No. 108, Lamps, reflective devices, and associated equipment (49 CFR § 571.108, 2011), for aiming headlamps on a vehicle", stated twice, and that "SAE J599 is not an incorporated reference standard to FMVSS No. 108".

The measurements. Against the voluntary SAE criteria most lamps passed. Against the aim targets of the vehicles' own manufacturers, which the report states were in every case as strict as or stricter than the SAE criteria, fewer did: with a driver load, nine of ten driver-side and five of ten passenger-side lamps were within tolerance on visual measurement, and four of five and one of five respectively on photometric measurement of the subset. Driver-side lamps were better aimed than passenger-side lamps in all four test combinations. The two measurement methods differed by an average magnitude of 0.12 degrees, with extremes of plus 0.23 and minus 0.26 degrees.

The direction of deviation, which is the Foundation's tally and not the report's. Of the ten vehicles for which manufacturer targets were available, in the unloaded condition six of ten driver-side and six of ten passenger-side lamps were aimed above the manufacturer's target, the largest upward deviation being 0.50 degrees. The report tabulates the signed deviations and defines a positive value as aimed above the headlamp height; it does not itself count them by direction.

A disclosure about what can be known. For five of the fifteen vehicles the manufacturer's aim target and tolerance are recorded as Confidential Business Information, the report stating that some manufacturers "do not publicly disclose their aim target and tolerance information".

What it does not establish. Anything about glare, which the report mentions twice in a single repeated sentence of rationale and never measures. Anything about vision, injury, or any other biological endpoint; there was no human subject and no illuminance was measured at any eye. Anything about the fleet; fifteen vehicles bought for unrelated research are not a sample. And nothing about dynamic conditions: every measurement is static, on a level laboratory floor, and the report does not address pitch, load change, road profile or any in-use condition. Its reference list contains two items and no scientific literature.

Where it bears. Part VI.B.1, which is written on it. Part II.H.5, for the chronology of the agency's statements and for the second instance of the liaison point, the agency having acquired an imaging photometer in the course of this work. Part V.B.8, for the distinction between the

lamp's coordinate frame and the road's. Appendix D.6, where the European submission makes the dynamic-geometry claim this report's static method cannot reach.

C.102 Hsieh, Tsai, Hung, Lin and Li (2023) — a headlamp designed to the federal standard, in which no biological quantity appears

Citation. Hsieh C.-C., Tsai C.-L., Hung C.-C., Lin H.-H. and Li T.-C. "Design of Multi-module LED Headlamp of Vehicle Under Federal Motor Vehicle Safety Standard." Sensors and Materials, volume 35, number 7 (2023), pages 2433–2448. Article S&M 3333. doi:10.18494/SAM4448. Received 7 April 2023; accepted 3 July 2023. Authors at the National Kaohsiung University of Science and Technology, the National Pingtung University of Science and Technology and Asia University, Taiwan.

What kind of study it is. Optical engineering design, simulated and then prototyped. Not a health study, not a study of any population, and not a measurement of an existing production lamp. Its object is to design a light-emitting diode low beam headlamp that satisfies Federal Motor Vehicle Safety Standard No. 108 using fewer watts than the halogen lamp it would replace.

Why it is in the comment. Because it is a complete, published and checkable record of what the federal standard requires a headlamp designer to achieve. The comment uses it at Part VI.B.1 for two things: the structure of the photometric requirement, and the exhaustive list of what the designers were required to optimize.

The requirement as the authors reproduce it. Eighteen numbered test points, each with an angular position relative to the lamp axis expressed in degrees up, down, left or right, a required luminous intensity in candelas, and the derived illuminance in lux. Stipulated measurement distance sixty feet, given as 18.3 meters; test voltage 12.8 volts ± 20 millivolts. Eleven points specify a minimum only, five a maximum only, and two a range. Of the eight points below the horizontal, six specify a minimum and no maximum, including the two highest requirements in the table: at least 10,000 candelas at 0.6 degrees down and 1.3 degrees right, and at least 15,000 candelas at 1.5 degrees down and 2 degrees right.

The design, in outline. Two commercial light-emitting diodes, a Visera 6363 rated at 5 watts and 340 lumens and a Nichia NVSW119A rated at 3 watts and 190 lumens. The conventional shade of a projector headlamp was replaced by an asymmetric floorboard, raising simulated luminous flux from 228.9 to 334.6 lumens, with an ellipsoidal reflector designed by the simultaneous multiple-surface method, an aspheric lens and a cylindrical condenser. The final system superposes one asymmetric-floorboard module and three horizontal-floorboard modules and draws 16 watts, reported as 70 percent less energy than a 55 watt halogen low beam, with a stated 30 percent reduction in energy loss attributed to the floorboard.

The finding the comment relies on, which is an absence. That no biological quantity appears anywhere in the design. In sixteen pages the words eye, vision, visual, retina, comfort, human and health do not occur. Neither do luminance, wavelength, spectral, blue or color temperature. The word safety occurs four times, three within the name of the standard and one within a cited conference title. The word glare occurs twice, once describing earlier work by others and once in the authors' report that after a condenser recovered light scattered above the cutoff, "drivers of approaching vehicles on the opposite lane do not suffer from any glare caused by scattered light from headlamps". That is the only appearance of a human being in the paper, and it records a consequence of an efficiency change rather than a criterion the design was required to meet.

What it does not establish. Anything about health, injury, exposure or any biological endpoint, none of which it addresses. Anything about industry practice generally; it is one design by one group. Anything about a production lamp; the prototype measured 700 lux peak illuminance at four meters against 1,071 lux in simulation, which the authors attribute to assembly and rotation tolerances and to the reflectivity of polished aluminum. And it is not the

regulation: its table is the authors' reproduction of requirements they attribute to the Electronic Code of Federal Regulations as accessed in June 2023.

Where it bears. Part VI.B.1, which is written on it. Part II.H.5, as independent confirmation of the agency's statement of 13 February 2024 that Standard No. 108 does not directly regulate peak luminance or spectral power distribution. Part V.B.8, for the lamp-axis coordinate frame in which the requirement is expressed. Appendix C.101, with which it pairs: the one shows the requirement is written in the lamp's frame, the other that no federal requirement fixes that frame to the road.

C.103 Sefer, Ayaz, Ajder and Nakir (2023) — at equal illuminance, the source that transmitted best through fog was not the source under which people saw best

Citation. Sefer T., Ayaz R., Ajder A. and Nakir I. "Performance investigation of different headlights used in vehicles under foggy conditions." Scientific Reports 13, article 4698 (2023). doi:10.1038/s41598-023-31883-3. Department of Electrical Engineering, Yildiz Technical University, Istanbul. Open access under Creative Commons Attribution 4.0. Ethical approval of the Yildiz Technical University Ethical Committee (2022.09); informed consent recorded; no competing interests declared.

What kind of study it is, stated first. A bench experiment with human observers. Not a road study, not a driving study, and not a study of any health endpoint. Its subject is target detection under a scattering medium with the quantity of light held constant and the spectrum varied.

Design. Three production headlamps: a 55 watt Philips HIR2 halogen measured at 3031 kelvin, an 8 watt light-emitting diode unit at 5122 kelvin, and a 25 watt Philips D5S xenon unit at 5098 kelvin, spectra measured on an Everfine HAAS-2000 array spectroradiometer. Targets were five-centimeter yellow and red cubes in a matte black box of one meter by eighty centimeters by one meter, fogged by an Antari Z800II machine. Illuminance at the target was equalized across lamps to within five lux. Twelve participants, six female and six male, aged 21 to 36, screened for color blindness, pressed a counter on detecting a cube. Observer angle 20 degrees, target viewing angle 1 degree.

What it reports. That transmittance through the fog was highest for xenon, by about 2 to 3 percent over halogen and the diode lamp, and that relative target luminance was likewise highest for xenon. That detection times by human observers ran in the opposite order: shortest under halogen, then xenon, then the diode lamp. That transmittance was about 20 percent at thirty seconds for all three, rising to 53 to 54 percent at fifteen minutes. The authors attribute the reversal to the white wall effect in the eye of the observer rather than to differential transmission, and recommend diode sources of lower correlated color temperature.

The finding the comment relies on. The divergence itself, and the authors' statement of its methodological consequence: that transmittance is insufficient alone to evaluate headlamp performance under fog, that a luminance camera in fog measures the luminance of the fog rather than of the target, and that user-based tests are therefore required.

A finding in this paper that the Foundation does not rely on, and why. Its abstract reports that female participants detected targets between 1.72 and 3.65 times more slowly than male participants. The Foundation does not use that finding, does not reason from it, and records here that it declines it on methodological grounds. The comparison is between groups of six. Within a single condition the detection times of the twelve participants span a factor of more than eight, from 11.75 seconds to 100.55 seconds. No analysis in the paper separates a group effect from variation of that magnitude, and the single supporting citation offered is to a reaction-time study of first-year medical students. The Foundation states this expressly so that its reliance on the paper is not mistaken for reliance on the whole of it.

Other limitations. Twelve participants. An optical path of about one meter. Fog very much denser than any road condition: the reported transmittances imply, on an assumed one-meter

path, meteorological visibilities of a few meters against the thousand meters by which the paper's own introduction defines fog. No vehicle, no distance, no driving task, no moving target and no roadway. Detection times running to nearly three minutes. One lamp tested at each technology, so nothing in the paper supports extrapolation across color temperature. And no biological endpoint of any kind: the study measures what people could see, not what the light did to them.

Where it bears. Part VI.B.1, in the passage on the condition the certification test does not include. Part V.B.8 and Part V.C.2, as a measured instance of a photometric quantity and a human outcome diverging. Part V.F, for correlated color temperature as a determinant of a visual outcome, with the caution stated above that one lamp at 5122 kelvin supports no inference about higher values.

C.104 American Automobile Association (2019) — the only American evaluation of adaptive driving beam, and the five people who rated it

Citation. American Automobile Association. "Comparison of European and U.S. Specification Automotive Headlamp Performance." April 2019. 58 pages. Published at the association's newsroom.

What kind of document it is. A closed-course engineering evaluation published by a motoring membership organization. Not peer reviewed, and not a health study. It is the American counterpart, in sponsorship though not in method or scale, of the European consumer study at Appendix D.6.

What was tested. Four vehicles from two manufacturers, each manufacturer supplying one United States specification vehicle with light-emitting diode headlamps and automatic high beam switching, and one European specification vehicle of the same model with adaptive driving beam. Static roadway illumination was measured on twelve-inch non-reflective black targets along an unlit asphalt course about 1,300 feet long, at least ninety minutes after sunset. Glare was evaluated dynamically, the test vehicle passing a stationary observation vehicle at thirty-five miles an hour.

What it reports on illumination. That United States specification lower beams delivered 1.9 percent more illumination on the targets, that European upper beams delivered 12.5 percent more, and that the adaptive systems held upper beam operation everywhere except the shaded region while the United States systems were obliged to drop to lower beam, a difference the association puts at as much as 86 percent more roadway lighting. It records the permitted upper beam maxima as 430,000 candelas in Europe against 150,000 in the United States.

What it reports on glare, which does not assist the Foundation. That all four vehicles rated in the low perceived glare band, between Satisfactory and Just Acceptable on the de Boer scale; that one manufacturer's adaptive vehicle rated better than its United States counterpart and the other's rated worse; and that on cresting hills, the scenario the association identifies as the worst case for every headlamp system then available, glare occurred less frequently with the adaptive systems than with the United States automatic systems. The Foundation records these findings in the body of Part VI.B.2 and does not argue against them.

The limitation that governs every use of this report. The glare evaluation rested on five raters. They were the association's own researchers rather than naive participants, all five were men, and they had conducted the illumination testing beforehand and so knew which vehicle was which. Each gave a single retrospective rating on a nine-point subjective scale after one pass, having been instructed to look down the lane rather than at the beam. The report is candid about all of this; the Foundation records it because a reader meeting the phrase low perceived glare should know what produced it.

What it does not establish. Anything about health, injury or any biological endpoint, none of which it addresses. Anything about distraction, which the agency's definition of the technology names and which this evaluation did not measure. Anything about disability glare,

contrast threshold or recovery time. Anything about exposure of any duration. And anything about any person outside a vehicle: the observation point was a parked car with its lower beams lit, which is the object these systems are built to detect, so what was measured is how well the shading works on the one road user it recognizes.

Where it bears. Part VI.B.2, which is largely written on it, including the passages that run against the Foundation. Part VI.B.1, for the permitted upper beam maxima and for the comparison of scale with the European consumer study. Part II.H.5, for the quoted definition of adaptive driving beam and the three criteria in it.

C.105 Stone, Santoni de Sio and Vermaas (2019) — a vehicle that navigates by sensors does not need the light, and the feasibility question that follows

Citation. Stone T., Santoni de Sio F. and Vermaas P. E. "Driving in the Dark: Designing Autonomous Vehicles for Reducing Light Pollution." Science and Engineering Ethics (2019). doi:10.1007/s11948-019-00101-7. Received 28 January 2018; accepted 18 March 2019. Delft University of Technology, Departments of Industrial Design and of Ethics and Philosophy of Technology. Open access under Creative Commons Attribution 4.0.

What kind of document it is, stated first because it governs every use of it. A work of philosophy in an engineering ethics journal. It reports no experiment, no measurement and no original data of any kind. It is classified in Appendix C rather than Appendix D only because it is a peer-reviewed article; it is unlike every other entry in this appendix in reporting nothing empirical.

What it argues. That autonomous vehicles are still a technology in development whose shape is not settled; that engineering ethics should build values into a technology during that phase; that nighttime lighting is a supporting infrastructure which should be a prima facie design consideration for such vehicles; and that two scenarios, parking lots and highways, show how vehicles might be designed to operate with greatly reduced lighting or none.

The proposition the comment relies on. That a vehicle navigating by light detection and ranging, coupled with maps and satellite positioning, does not require visible illumination to move safely, so that the visible emission of its forward lighting is severable from the function of the vehicle. The authors describe systems requiring little or no lighting to navigate at night, state that this can potentially allow such systems to drive in total darkness, and set as their object designing vehicles to function without both streetlights and headlights.

What that proposition rests on in the paper, which is thin. A single secondary reference to press reports of an early Ford test. The authors present it as a design goal to be pursued rather than a demonstrated capability, and describe their own proposals as initial considerations to be assessed through future technical research. The comment states the claim as theirs.B.6 records that a technical source is required.

What the comment does not take from it, recorded expressly. The aesthetic and cultural case for darkness, which occupies most of the paper. Of the eight values the authors tabulate, the comment does not advance stellar visibility, wonder and beauty, connection to nature, or heritage and tradition, and Part VI.B.6 names them in order to disclaim them. The Foundation also takes no health proposition from this paper. It contains no health data; the words glare, headlamp, retina, eye, blue light, circadian and melatonin do not occur in it; and its three mentions of human health are passing citations to secondary literature.

Where it bears. Part VI.B.6, which is written on it, for the severability of the emission from the function and for the consequence under section 360kk(a)(2). Part I.C.7, for the proposition that the moment to ask a design question is before the design is settled. Part II.H.3, which supplies the statutory reading of unnecessary radiation that the subsection applies.

C.106 Fullerton and Peli (2009) — the apparatus built to put a calibrated headlamp in front of a person, and what its authors say about the test the Department uses

Citation. Fullerton M. and Peli E. "Development of a System to Study the Impact of Headlight Glare in a Driving Simulator." In Proceedings of the Fifth International Driving Symposium on Human Factors in Driver Assessment, Training and Vehicle Design, 22–25 June 2009, Big Sky, Montana. Iowa City: Public Policy Center, University of Iowa, 2009, pages 412–418. doi:10.17077/drivingassessment.1351. The second author is of the Schepens Eye Research Institute, Harvard Medical School; the first was then also at the University of York and the Technical University of Munich.

What kind of paper it is, stated first. A conference paper reporting the construction of a prototype instrument. It presents no experiment on human subjects and no result about any population. The only statement in it about people is that drivers testify to being unable to see the area around the headlamps. Nothing in the comment rests on it as a finding.

What was built. A dynamic simulation of oncoming headlamp glare for a driving simulator. A separate diode array is combined with the simulator screen through a fifty-fifty beam splitter, its lit position synchronized in real time to the simulated oncoming vehicle, its intensity set from an interpolated lookup table and calibrated against illuminance measured at the driver's head position. The diode was selected for high intensity and, because of evidence that higher color temperatures cause more discomfort, presorted for the lowest available color temperature. The simulator carries combined head and eye tracking to better than one degree.

Why the instrument had to take that form. Because no display could produce the light. The authors computed required display luminances running from several hundred to several thousand candelas per square meter, against 50 to 100 for a cathode ray tube, 200 to 600 for the liquid crystal displays of the period, and 10,000 only for experimental high dynamic range displays. They concluded that current display technology could not achieve the luminance needed to create realistic headlight glare on a screen.

The two sentences for which the comment principally cites it. First, that the standard test used in a number of Food and Drug Administration studies, the Night Driving Simulator of Vision Sciences Research Corporation, does not accurately simulate glare in terms of light intensity because the headlights appear only as part of a filmed scene. Second, that manufacturers of ophthalmic devices are required to satisfy the Administration's safety concerns and wish to verify that their products are not worsening night driving. Together those place a Departmental glare test on the record, and place the obligation it supports on the maker of the lens rather than the maker of the lamp.

Two further propositions the comment takes from the authors' review. That changes in the ocular media from age, eye surgery, cataract, contact lenses, intraocular lenses and spectacles all worsen the veiling luminance responsible for disability glare, which corroborates Part V.C.5. And that drivers' subjective impression of a glare source does not relate well to their on-road performance, reported from Theeuwes and others in 2002, which bears on the subjective ratings relied on in the evaluation at Appendix C.104.

What it does not establish. Any effect of headlamp glare on anyone. No subject was tested and no outcome measured. The quantities tabulated are computed from the CIE general equation for disability glare for a thirty-year-old with blue eyes, using fiftieth-percentile beam data from a 2001 technical report, and are therefore modeled throughout. The display comparison describes the technology of 2009 and is now dated. And the paper reports a prototype whose limitations the authors state, including diode spacing coarse enough to make the simulated headlamp motion less smooth than they wished.

Where it bears. Part VI.B.1, in the closing movement on measurement, which is written on it. Part II.H.3, for the proposition that developing measurement methods referred to the point of human exposure is directed work and not a detail. Part V.C.5, for the ocular media

corroboration. Part VI.B.2, as the reason the subjective ratings there cannot carry a conclusion about performance.

C.107 Bullough, Skinner, Pysar, Radetsky, Smith and Rea (2008) — the congressionally directed federal glare study, conducted on a fleet that no longer exists

Citation. Bullough J. D., Skinner N. P., Pysar R. M., Radetsky L. C., Smith A. M. and Rea M. S. "Nighttime Glare and Driving Performance: Research Findings." Report No. DOT HS 811 043. National Highway Traffic Safety Administration, September 2008. 118 pages. Prepared by the Lighting Research Center, Rensselaer Polytechnic Institute, under contract DTNH22-05-D-01002. Contracting officer's technical representatives Stephanie Binder and Michael Perel.

Why it exists. Section 2015 of the Safe, Accountable, Flexible, Efficient Transportation Equity Act of 2005 directed the Department of Transportation to study the risks of glare to oncoming drivers, with particular attention to two-lane highways, to drivers over the age of 50, and to the overall effects of glare on driver performance, and to make recommendations. The agency had opened a public docket on headlamp glare in 2001 and records that most responses received were complaints.

What it comprises. Seven studies: a state-of-knowledge report; a pilot study using naturalistic methods on glare, driving behavior and crash risk; analyses comparing headlamp characteristics for visibility and glare; assessments of headlamp illumination and aim on real vehicles; a review of visual needs and metrics; a field experiment on glare recovery in older drivers; and development and demonstration of a prototype safety-based adaptive forward-lighting system.

The countermeasure ratings, which are the report's answer to Congress. Mounting height low; aim high; optical design low; low beam distribution low; adaptive beam distributions high; color medium; cleaning and maintenance medium. The aim rating records that some new and many in-use vehicles have mis-aimed headlamps. The color rating states that bluer sources such as high-intensity discharge headlamps do increase discomfort, so that restricting short-wavelength output could reduce discomfort, though with little effect on visibility.

The fact for which the comment principally cites it. That it is silent on the technology that has since taken the fleet. In 118 pages light-emitting diodes are mentioned twice, both times as a speculative future means of building the adaptive prototype, and no diode headlamp, spectrum or exposure was measured. The report records that during its field work discharge headlamps were very rare and almost all oncoming headlamps were halogen.

Four further findings the comment uses. That glare reduces visibility more for drivers over 50 because of increased scatter in the ocular media. That drivers' perceptions of glare often differ from disability glare and glare recovery, bluer discharge sources eliciting greater discomfort without diminishing visibility more at the same luminous intensity. That present low beam patterns do not appear to give sufficient visibility at many of the speeds at which they are used, even with no oncoming vehicle. And that despite clear evidence relating glare to reduced visibility there is little direct evidence linking glare to increased crash risk.

The instrument it used. A head-worn illuminance meter developed by the Lighting Research Center, the Daysimeter, carrying both a photopic detector and a short-wavelength detector, which together allowed differentiation among sources of differing spectral composition. Light at the eye of a driver on a public road was therefore measured, in both photopic and short-wavelength terms, under federal contract in 2008.

What it does not establish. Anything about health, injury, tissue or any biological endpoint; its outcomes are visibility, discomfort ratings, recovery times and driving behavior. Anything about diode sources. And its pilot study on crash risk is expressly described by its authors as

insufficient to draw firm conclusions, with findings that would need replication at larger sample size.

Where it bears. Part VI.B.1, in the movement on what the agency was told in 2008. Part V.B.3 and Part V.F, for the 2008 recommendation that restricting short-wavelength output be considered. Part V.C.5, for the finding on drivers over 50. Part VI.B.2, for the divergence between discomfort ratings and visual performance. Appendix C.101, with which it forms a fifteen-year chronology on headlamp aim. Part II.H.5, for the liaison point about the Daysimeter.

C.108 Mainster and Timberlake (2002) — the ophthalmological account, which attributes the problem to brightness rather than blueness

Citation. Mainster M. A. and Timberlake G. T. "Why HID headlights bother older drivers." British Journal of Ophthalmology, 2002. PMCID PMC1771460; PMID 12488274. Supported in part by the Kansas Lions Sight Foundation.

What kind of article it is. A perspective, not a report of original research. It reports no experiment, measures no lamp and studies no population. Its contribution is to assemble the optics of headlamps, the physics of intraocular scattering and the clinical literature on glare and photostress into an explanation of why complaints about discharge headlamps came from older drivers.

The finding that corrects the Foundation, recorded first. That brightness rather than blueness is the primary cause of the visual problems these headlamps produce. Intraocular scatter from the cornea and lens falls with increasing wavelength while scatter from fundus reflectance rises with it, so that stray light reaching the fovea has little wavelength dependence and a blue-white source should produce no more disability glare than a white one of the same luminance. No part of the comment asserts the contrary.

What the same authors attribute to spectral content. Discomfort glare. Discharge headlamps are reported to cause more of it than halogen headlamps at the same photopic or scotopic illuminance, with the effect larger in drivers aged 61 to 77 than in those aged 20 to 31. Discomfort glare is described as not impairing vision but as startling or distracting and as causing blinking, squinting, ocular aversion and fatigue, with physiological and psychophysical origins that remain uncertain.

The category the comment had not previously named. Scotomatic glare, or photostress: a brilliant source decreases visual sensitivity, which recovers only as dark adaptation is restored, producing afterimages that interfere with vision. It is attributed primarily to bleaching and slower regeneration of photoreceptor photopigments. Recovery time increases with source luminance and with age.

Three further propositions the comment uses. That light scattering increases in people over 50 and that older individuals have increased intraocular stray light, glare sensitivity and photostress recovery time, with disability glare increased by cataract, intraocular lens implantation and posterior capsule opacification. That transient glare of the kind a headlight encounter produces is worse than static glare from a source of the same luminance, the effect increasing with age and media opacity, and that conventional clinical glare tests accordingly understate disability glare from moving sources. And that scattering by large particles such as fog droplets is not wavelength dependent, which is why fog does not change the apparent color of headlights.

What it does not establish. Anything about light-emitting diode headlamps, which it predates and does not mention. Anything about injury: its subject is scattering and photopigment bleaching, both reversible processes of normal vision, and it makes no claim about damage to tissue. And nothing original: every quantitative claim in it is drawn from the literature it reviews.

Where it bears. Part VI.B.1, in the closing movement on the ophthalmological account. Part V.C.5, as the third source for the age gradient in intraocular scatter. Part V.E.7, as the clinically established human instance of a light effect outlasting its exposure. Part V.D, for discomfort glare as aversion and fatigue rather than annoyance. And throughout Parts V and VI as the authority for keeping disability glare, which follows luminance, separate from the spectral questions, which do not.

C.109 Olson and Aoki (1989) — the adaptation level an oncoming headlamp puts a driver into, and how long it takes to come back

Citation. Olson P. L. and Aoki T. "The Measurement of Dark Adaptation Level in the Presence of Glare." Report No. UMTRI-89-34. University of Michigan Transportation Research Institute, Ann Arbor, November 1989. 14 pages. Performing organization code 302753; government accession number PB90 155987/AS.

Sponsorship, stated first. The University of Michigan Industry Affiliation Program for Human Factors in Transportation Safety. The report lists the members as of 1 November 1989 as GE Lighting, GTE Products Corporation, Ichikoh Industries, the Inland and Fisher Guide Divisions of General Motors, Koito Manufacturing, Stanley Electric and Valeo Automotive. This is industry-funded research and the comment says so wherever it relies on it.

What was measured, and how. Driver dark adaptation level in the presence of headlamp glare, obtained indirectly. The time from extinguishing the glare until a target light source could be detected was recorded, and that readaptation time was read against a laboratory calibration in which subjects were adapted to surfaces of known luminance and the same recovery timed. The field condition was facing standard United States low and high beams at about 150 feet.

What it found. Mean readaptation times of 3.63 seconds after low beam glare, standard deviation 0.59, from fifteen subjects, and 5.14 seconds after high beam glare, standard deviation 0.94, from fourteen. Against the calibration those correspond to adaptation levels of about 5 and 20 foot-lamberts respectively, both of which the authors note fall in the photopic zone.

The comparison figures, which come from the authors' earlier work. At the same site, a pedestrian without illumination is at about 0.005 foot-lamberts, a driver using low beams at about 0.3, and a driver using high beams at about 1.7. Meeting an oncoming low beam therefore places the driver three log units above the pedestrian, and an oncoming high beam four times higher again.

What the authors conclude about a road with traffic. That recovery from high beam glare takes a little over five seconds, in which a vehicle at 65 miles an hour travels almost 500 feet, and from low beam glare about 350 feet; and that when meeting a steady flow of oncoming traffic a driver's vision is seldom as good as it could be in the absence of that traffic, through the combination of disability glare and upward adjustment of dark adaptation.

The observation about the pedestrian. That a pedestrian without illumination can see some things better than a driver can with headlamps, because of the difference in adaptation level, and that this may contribute to pedestrians overestimating their own visibility at night.

What it does not establish. Anything about diode headlamps, which it predates by two decades. Anything about health or injury; its endpoint is visual performance. And its adaptation levels are inferred from readaptation times through a calibration rather than measured directly. Fifteen and fourteen subjects, with no age breakdown reported in the pages read.

Where it bears. Part VI.B.1, in the closing movement on measurement. Part V.C.3, for adaptation state as the mechanism by which a glare source reduces visibility. Part V.E.7 and the photostress material at Appendix C.108, as the quantified instance of a visual effect outlasting its exposure. Part VI.B.2, for the adaptation gap between a driver and a pedestrian, which is the person the adaptive driving beam evaluation did not test.

C.110 Fotios and Gibbons (2018) — a review finding little if any credible empirical support for the light levels recommended on roads

Citation. Fotios S. and Gibbons R. "Road lighting research for drivers and pedestrians: The basis of luminance and illuminance recommendations." Lighting Research and Technology, volume 50, number 1 (2018). doi:10.1177/1477153517739055. The first author is at the University of Sheffield and the second at the Virginia Polytechnic Institute and State University. A correction to the article has been published.

What kind of article it is. A review of the evidentiary basis of quantitative road lighting recommendations. It reports no original experiment. Its subject is where the numbers in the standards came from.

Its conclusion. That recommendations for the amount of light do not appear to be well-founded in robust empirical evidence, or at least do not tend to reveal the nature of any evidence; and, in its closing section, that there appears to be little, if any, credible empirical support for the light levels recommended in much current road lighting guidance.

What it reports about the American recommendations. That the recommendations of the Illuminating Engineering Society, implemented in 1972 and still the basis of current North American standards, derive from Box (1971) on 203 miles of freeway; that Box found the lower range of illuminances associated with a lower night to day crash ratio than the higher ranges, a result the reviewers describe as counter to intuition and attribute to additional glare and to the effect on the driver's adaptation level; that the six-lane road data show no relationship between light level and crash rate, the linear fit returning a coefficient of determination of 0.02; and that the levels for road categories other than freeways had no empirical backing, the 0.5 foot-candle figure having been carried through the standards and translated into a luminance criterion.

What it reports about the other recommendations. That the minimum illuminances of the 1927 British standard had no theoretical basis; that for the modern pedestrian classes the empirical evidence, if any, is unknown and there is no published explanation of the basis for the values; that the facial recognition criteria rest on ratios for which there are no known reasons and which appear to be arbitrary; and that the agreement between the international and European documents reflects overlapping committee membership rather than independent groups reaching similar conclusions.

What it says about the trend. That recommended maxima and measured average illuminances have risen over time, and that light levels may have increased because there was an ability to do so rather than because there was evidence of benefit.

The prescription the comment relies on. That future standards may need to include maximum light levels, limitations for spectral power distribution and spatial distribution, and exposure doses. And, reporting Lucas and colleagues, that the management of light resembles administering a drug, with a need to control the dosage so as to maximize benefit while minimizing side effects.

A further finding used at Part V.B.3. That road lighting is specified in photopic quantities although the conditions of use are mesopic, so that the recommended values ignore the contribution of the rods and the short-wavelength sensitive cones, a limitation the authors say has become more important since the widespread introduction of diode sources.

What it does not establish. Anything about health. It reports no biological endpoint and names the side effects of road lighting as energy consumption, sky glow, light trespass and impact on the natural environment. It is a review and contains no original data. And its account of the American standard is an account; the underlying study has not been read by the Foundation.

Disclosure. The authors declare no conflicts of interest. The second author discloses that much of the research referred to was supported by government agencies including the Federal Highway Administration, by local agencies, by lighting companies and by other interested

parties. The first author's contribution was supported by the Engineering and Physical Sciences Research Council.

Where it bears. Part VI.D, which is written on it. Part V.B.3, for the photopic specification of a mesopic task. Part VI.B.1 and Appendix C.109, for glare and adaptation level as the explanation offered for the Box anomaly. Part VI.B.6, for the observation that automated vehicles reduce the need for roadway lighting. Part II.H.3, for the proposition that maximum levels, spectral limits and exposure doses are the quantities a standard would have to address.

C.111 Krumina, Volberga, Ikaunieks and Naumovs (2021) — a road authority and an optometry department apply the American billboard criterion and report that it cannot be used

Citation. Krumina G., Volberga L., Ikaunieks G. and Naumovs L. "The Development of Brigthness Evaluation Method for Digital Billboards." IOP Conference Series: Materials Science and Engineering, volume 1202 (2021), article 012035. doi:10.1088/1757-899X/1202/1/012035. Presented at the 30th International Baltic Road Conference. Open access under a Creative Commons Attribution licence. The title is reproduced as published, including its misspelling of brightness.

Who the authors are, and who funded it. The first three authors are of the Department of Optometry and Vision Science, Faculty of Physics, Mathematics and Optometry, University of Latvia; the fourth is of the Department of Road Equipment and System of the Latvian State Roads. The work was supported by a grant from that road authority and by university grants. It is not industry funded, which distinguishes it from the report at Appendix D.4 whose method it assesses.

What the authors set out to do. To develop a method by which a supervising authority could assess the brightness of a digital billboard while it is operating, using an inexpensive instrument, namely a lux meter.

What they report about the American method. That the method of the Outdoor Advertising Association of America and the International Sign Association, which they describe as a simplification of the recommendation of a former board member of the Illuminating Engineering Society of North America, cannot be applied to billboards above about 25 square meters, because the measurement distance the method computes from the screen dimensions is so great that the illuminance to be measured falls below the sensitivity of the prescribed instrument. They report further that the permitted luminance the method yields does not vary with the area of the display, and that a larger display dazzles more at the same luminance.

The figures the comment relies on. From their Table 2, the maximum billboard luminance implied by the American method across four ambient zones: 322, 423, 524 and 827 candelas per square meter. From their Table 6, for a real 52 square meter billboard near Riga, the permitted luminances and the De Boer discomfort ratings they imply under the American method at 30 and 100 meters across the same four zones, of which seven of eight ratings fall below the value the authors identify as the threshold of comfort.

The scale definition the comment adopts. That the De Boer scale runs from 1 for unbearable glare through 3 for disturbing, 5 for just acceptable and 7 for satisfactory to 9 for unnoticeable glare, and that ratings are considered comfortable at 5 and above, with 4.7 to 4.9 described as the borderline. This definition is used at Part VI.B.2 as well, where the American evaluation of adaptive driving beam headlamps reported ratings on the same scale.

What it does not establish. Anything about health, injury or any biological endpoint, none of which it addresses. Its De Boer values are predicted from an illuminance-based model rather than obtained from observers, the authors reporting a Pearson correlation of 0.87 between predicted and measured values in the study from which they take the model. Its measurements were made in Latvia, and its assessment of an American instrument is made from a different regulatory and lighting context. It is a conference paper.

Where it bears. Part VI.J.6, which is written on it, as the only independent assessment of the American criterion the Foundation has found, and as a check on the Foundation's own derivation of the luminance that criterion implies. Part VI.B.2, for the definition of the De Boer scale. Part V.E.1, for the 16 hertz finding it reports at second hand.

C.112 He, Zhang, Quan, Mi, Cui, Xu and Tian (2021) — field luminances of typical outdoor display screens, and a reaction time penalty for blue

Citation. He Y., Zhang X., Quan L., Mi R., Cui Y., Xu J. and Tian Z. "Influence of coloured light projected from night-time excessive luminance outdoor LED display screens on vehicle driving safety along urban roads." Building and Environment (2021). doi:10.1016/j.buildenv.2020.107448. Authors principally of Chongqing University. Supported by the National Natural Science Foundation of China and by Chongqing research foundations. The authors declare no competing interest.

What the Foundation has read, stated first. The abstract, the highlights, the introduction and the truncated section summaries displayed on the publisher's preview page. The article is behind a paywall. The methods, the full results and the complete conclusions have not been read, and one sentence relied on is cut off mid-clause in the preview. Every use of this paper in the comment is subject to that limitation.

Design, so far as it can be established. A laboratory simulation. Twenty-four subjects viewed fourteen simulated night road scenes, built by integrating photographs with software simulation, on a television at a viewing distance of 920 millimeters in a darkened room, and responded to small targets. Three screen luminance conditions were used, described as excessive luminance values of typical outdoor display screens at night and given as 1,000, 3,000 and 5,100 candelas per square meter. Five thousand and forty reaction time measurements were obtained. A trial was recorded as a missing dot where the reaction time exceeded two thousand milliseconds or no response was made.

The figures the comment principally relies on. The three screen luminances above, and the authors' statement that the average luminance of an urban road surface at night is usually 1.0 to 2.0 candelas per square meter. The comparison between the two is the Foundation's arithmetic and is set out at Part VI.J.6.

What it reports. That colored light from these screens can improve a driver's ability to recognize small targets and reduce reaction times at low screen luminance, but causes more missing dots; and that blue light is the exception, the conclusions stating that it can increase reaction times and worsen driving safety. The introduction states that the luminance of many advertising signs at night greatly exceeds the control values in the applicable specifications and guidelines, and that the United States, Europe, Australia, China and other countries have issued such guidelines.

A finding the comment expressly declines. That the night recognition ability of female subjects under this exposure exceeded that of male subjects. Twenty-four subjects, with the division not disclosed in the material read. The comment declines a sex-difference finding running in the opposite direction at Appendix C.103 and treats this one the same way.

What it does not establish. Anything about health or injury; its endpoints are reaction time and target detection. Anything about an actual road: the exposure was a television at 920 millimeters in a conference room, not a display beside a carriageway. And nothing that the Foundation can presently verify beyond an abstract.

Where it bears. Part VI.J.6, which is where it is used, for the measured luminance of typical screens against the road surface beside them and against the implied criterion. Part V.B.3 and Part V.F, for the reaction time penalty reported for blue. Part VI.D, for the road surface luminance figure.

C.113 Wachtel (2016) — a review of twenty-one studies on distraction from commercial electronic variable message signs

Citation. Wachtel J. "Compendium of Recent Research Studies on Distraction from Commercial Electronic Variable Message Signs (CEVMS)." The Veridian Group, Inc., Berkeley, California, February 2016. The second in a series of updates to the same author's 2009 report for the American Association of State Highway and Transportation Officials under National Cooperative Highway Research Program Project 20-7/256.

What this document is, stated first because it governs its weight. A review of other people's work. Nothing in it was measured by its author. It summarizes twenty-one studies published between 2008 and 2016 in five countries, each in a table giving date, location, authors, forum, whether peer reviewed, sponsor and funding source, type of study, type of signs studied, method, findings, strengths, weaknesses and availability. The tabulation of sponsorship for every entry is the feature that makes the document useful. It is a consultancy publication rather than a product of the sponsoring association, and it is now ten years old.

What the comment uses it for. Three things and no more. First, the correction at Part VI.J.6 of the eight second dwell time figure the Foundation had reported from a trade article, against the conclusion of the on-road study at the end of this review. Second, the description of attention capture by these displays as an involuntary physiological process driven by changes in luminance. Third, the account of the Israeli natural experiment, expressly at third hand.

The principal studies relied on, with their own citations. Belyusar D., Reimer B., Mehler B. and Coughlin J.F., A field study on the effects of digital billboards on glance behavior during highway driving, Accident Analysis and Prevention 88 (2016) 88–96; one hundred and twenty-three subjects, instrumented vehicle, sixty-five mile per hour highway, sponsored by the United States Department of Transportation Region 1, the University Transportation Center at the Massachusetts Institute of Technology and the Toyota Class Action Settlement Safety Research and Education Program. Roberts P., Boddington K. and Rodwell L., Impact of Roadside Advertising on Road Safety, Austroads Research Report AP-R420-13 (2013). Gitelman V., Zaidel D. and Doveh E. (2012) and Gitelman V., Zaidel D., Doveh E. and Zilberstein R. (2014), both for the Israel National Roads Authority.

What it does not establish. Any health, visual or biological endpoint. Not one of the twenty-one studies measures one. The endpoints throughout are glance duration and frequency, lane position, reaction time, mental workload and crash rates. It establishes nothing of its own in any event, being a review.

What runs against the Foundation, recorded here as in the body. The Federal Highway Administration study of 2012 found digital billboards not associated with unacceptably long glances away from the road. Two industry-sponsored studies found no crash increase and no significant headway difference respectively. The review disputes the first at length and the Foundation does not adopt the dispute, the review's author being the author of the critique on which it relies.

A matter the Foundation expressly does not adopt. The review makes an allegation about the conduct of an industry-sponsored study. No evidence for it is given in the document, the Foundation cannot test it, and the comment does not repeat or rely on it.

Where it bears. Part VI.J.6, which is the only place the comment uses it. Part VI.J.8, for the dwell time criterion. Part V.E.1, for the proposition that a change in luminance captures attention involuntarily.

C.114 Wachtel (2014) — measured luminance of American roadside signs, and the origin of the American brightness criterion

Citation. Wachtel J. "Report on Digital Sign Brightness." Prepared for the Nevada State Department of Transportation, Washoe County, City of Reno and City of Sparks. The Veridian Group, Inc., Berkeley, California, November 2014.

Provenance, stated first because it governs weight. The report states that the work was performed at the request of Scenic Nevada, an advocacy organization, which it records as having had no role beyond supplying maps of sign locations. It is a consultant's report prepared for four public bodies; nothing in it indicates that any of them adopted it, and the comment does not describe it as a Nevada standard. Its author is the author of Appendix C.113, and the comment does not treat the two as independent.

What was measured, and with what. Nighttime luminance of identified signs in Reno, Sparks and unincorporated Washoe County, Nevada, on 22 September and 18 October 2014, with daytime readings on 19 October, using a Minolta LS-100 calibrated photometer with a one degree acceptance angle. Appendix 1 of the report tabulates each sign by number, location, jurisdiction, on-premise or off-premise status, the message displayed, the number of meter readings, and the average and range of readings.

The principal figures. Traditional billboards averaged 59.8 candelas per square meter on 22 September, across sixteen signs, range 2.2 to 291; and 51.1 on 18 October across eleven signs, range 2.1 to 240. LED billboards averaged 1,291 on 22 September across seven signs, range 107 to 5,390; and 1,318.2 on 18 October across eight signs, range 44 to 4,440. The report states that digital signs averaged more than twenty-two times the traditional billboards measured in the same county on the same nights, and twelve to thirteen times the level recommended by the experts it cites. The highest nighttime average for a single sign was 3,850. One digital billboard averaging 1,961.9 carries the tabular footnote that its messages were often too bright to be readable.

The recommended values it collects. Thirty candelas per square meter, from a Federal Highway Administration study reported at second hand, as sufficient to read the message at six hundred and fifty feet at night. Thirty to seventy-five, from the United States Sign Council's own commissioned consultants. About forty as an appearance limit, from Luginbuhl and others reasoning from adaptation. Forty-five to one hundred and eleven, from the Illuminating Engineering Society standard written for this product class. One hundred, from Freyssinier, Narendran and Bullough. One hundred and fifty at night, from Carhart. The report's own recommendation is one hundred rural and one hundred and fifty in brightly lit urban areas, with a daytime ceiling of three thousand.

The finding on the origin of the American criterion. That the methodology underlying the criterion, and its resultant recommendations, are based on a standard for light trespass rather than a standard relevant to roadways and driving, the source being an Illuminating Engineering Society technical memorandum on light trespass; that the same society already had a standard written for advertising signs recommending levels consistent with luminances of forty-five to one hundred and eleven candelas per square meter; and that following the trespass memorandum instead yields three hundred to three hundred and fifty, which the report describes as three to six times higher than necessary or desirable.

A finding quoted in it from 1966. Allen, Smith, Janson and Dyer, Sign Brightness in Relation to Legibility, Michigan State Highway Commission, in cooperation with the United States Department of Commerce, Bureau of Public Roads (1966), quoted at page thirty-three as finding that high-luminance signs can change the adaptation level of the eye or the pupil size or both, and that the driver's vision would consequently be impaired for other tasks requiring dark adaptation. The Foundation has not read that study and relies on it only.

What it does not establish. Any health endpoint measured by its author. The measurements are photometric. The visual and biological propositions in it are quoted from other sources, the

1966 study among them. The readings are of whatever message was displayed at the time rather than of a standardized white field or of the sign's maximum capability, and the report's own note records two readings of one sign differing substantially between dates.

Where it bears. Part VI.J.6, which is written on it. Part VI.J.8, for the ask on measurement quantity. Part V.E.1, for the flash-producing malfunction mode and the absence of any American fail-safe requirement. Part VI.B.1 and Part V, for the adaptation finding, which is the same quantity the comment takes from the headlamp literature at Appendix C.108.

C.115 Herrstedt, Greibe and Andersson (2013) — eye tracking on Danish rural roads, and the safety buffer

Citation. Herrstedt L., Greibe P. and Andersson P.K. "Driver attention is captured by roadside advertising signs." 16th Road Safety on Four Continents Conference, Beijing, China, 15–17 May 2013. Trafitec, Scion-DTU, Diplomvej 376, DK-2800, Denmark.

What the Foundation has read. The full text, obtained as published. This is one of the few sources in Part VI that the comment does not rely on at second hand, and the figures below are from the paper.

The limitation that governs its use, stated before the findings. The empirical part measured conventional static advertising signs — painted and printed boards — and no digital or light-emitting display. It reports no optical quantity of any kind: no luminance, no illuminance, no spectral content, no modulation. Nothing in it bears on the emission of an LED product. Its literature review summarizes digital-sign findings, but those are at second hand and the comment does not use them from here.

Design. Thirty-two drivers aged twenty-three to seventy, men and women, not told the purpose of the drive, on four rural main road routes in three regions of Denmark, by day and outside peak hours. Instrumented car with a three-camera eye-tracking system at sixty hertz, a scene camera, satellite positioning for speed, and an Ibeo Lux laser scanner measuring distance to vehicles ahead across approximately fifty degrees either side at eighty to one hundred and twenty meters. One hundred and nine drive pasts of sixteen signs; two hundred and thirty-three glances recorded. Four year study period beginning 2009.

The attention findings. Sixty-nine percent of drive pasts produced at least one glance at the sign; almost half produced two or more at the same sign. Fifty-six percent of glances lasted under half a second, but eighteen percent lasted one second or more. For more than twenty-two percent of drive pasts the total duration of successive glances reached two seconds or more, and for ten percent three seconds or more. Glance angles reached forty-five degrees; forty-eight of the two hundred and thirty-three glances, twenty-one percent, fell outside the authors' defined normal range by the combination of angle and duration.

The safety buffer. Defined as the time gap to the vehicle ahead minus the glance duration, being the time left to perceive, interpret and respond to a sudden incident after the eyes return to the road. A vehicle was present ahead within three seconds in sixty-five of the two hundred and thirty-three glances. In fifty-nine of those the buffer was under two seconds; for twenty percent of all glances it was under 1.5 seconds; and in two cases it was negative, the glance exceeding the entire gap to the car in front. That fifty-nine of sixty-five is about ninety-one percent of the estimable cases is the Foundation's arithmetic and is not stated by the authors, who express the same figure as twenty-five percent of all tracked glances.

The threshold it is measured against. The two second criterion comes from Klauer, Dingus, Neale, Sudweeks and Ramsey, DOT HS 810 594, the hundred-car naturalistic driving study of the Virginia Tech Transportation Institute and the National Highway Traffic Safety Administration, in which eyes away from the road at driving-irrelevant stimuli for at least two seconds within six almost doubles crash and near-crash risk. The Foundation has not read that report and it is on the acquisition list.

Visual distraction. Seventeen of one hundred and nine drive pasts met that criterion, being more than one in six, spread across eleven of the thirty-two drivers and eight of the sixteen signs. The authors conclude the effect "seems to apply to a substantial part of all road users and is not concentrated on a single – or few – persons".

What it does not establish. Anything about light. Anything about digital or LED displays, from its own measurements. Any health or biological endpoint. And, because the signs it measured emit nothing, it establishes that attention capture is not peculiar to light-emitting products — a reading adverse to a careless version of this comment's argument, which the comment states expressly at Part VI.J.7.

Where it bears. Part VI.J.7, which is where it is used, for the safety buffer and for the measured cost of attention capture. Part VI.C.1, for the premise beneath devices designed to be noticed. Part II.H.6, for the division of responsibility between emission and behavior.

C.116 Dukic, Ahlström, Patten, Kettwich and Kircher (2013) — electronic billboards on a Stockholm motorway, measured by the road authority

Citation. Dukic T., Ahlström C., Patten C., Kettwich C. and Kircher K. "Effects of electronic billboards on driver distraction." Traffic Injury Prevention, volume 14 (2013), pages 469–476. Swedish National Road and Transport Research Institute, Linköping, and the Light Technology Institute, Karlsruhe Institute of Technology. Funded by the Swedish Transport Administration.

What the Foundation has read. The author accepted manuscript, manuscript number GCPI-2012-0104.R1, submitted 8 July 2012, with revision marks visible. The published version of record has not been read.

Design. Field study on a four-lane motorway through central Stockholm, autumn 2010. Forty-one drivers, mean age forty-two, twenty driving in daylight and twenty-one at night, in an instrumented vehicle with a head-mounted eye tracker at fifty hertz. Four electronic billboards against seven conventional signs and one large static paper billboard on the same stretches. Message cycle seven seconds. Participants not told the purpose until afterward. Approved by the local ethics committee.

The regulatory setting. Sweden had not permitted roadside electronic billboards. In 2009 the administration gave temporary permission for twelve, of which eight were installed, subject to a road traffic safety evaluation in which driver distraction was of particular interest.

Findings adverse to this comment, recorded first. The authors conclude that whether the billboards are a traffic safety hazard "cannot be answered conclusively based on the present data". No consistent significant changes were found in speed, lateral placement or headway. No difference was found between day and night on any visual measure, from which the authors infer that the brightness was not high enough to cause considerable glare. The accompanying crash analysis of the larger Swedish investigation found no significant differences attributable to the billboards. And a substantial number of drivers did not look at the billboards at all, which the authors treat as indicating that they can be ignored.

The limitation that qualifies the glare inference. The authors state that they did not have the opportunity to measure the luminance of the billboards. The inference about brightness is therefore drawn from the absence of a behavioral difference and not from photometry.

Findings supporting this comment. Significantly more participants looked at the billboards than at the conventional signs, and when they did, dwell times were longer, fixations more numerous and maximum fixation duration longer, each significant. Six fixations exceeding two seconds, ranging from 2.1 to 3.5 seconds, occurred across the four billboards, against one in total across the seven conventional signs; six of the seven such glances in the study were at the billboards, and every case exceeding the authors' visual time sharing threshold belonged to the billboard group. The authors describe their sample as a best case scenario because novice and older drivers are more affected, older drivers being more prone to glare.

The mechanism. The authors apply the framework of Trick and Enns and state that for electronic billboards the governing mechanism is reflexive, automatic and bottom-up, that reflexive responses cannot be disengaged, and that the negative effects can at best be minimized by intentional inhibition.

The temporal findings. The seven second cycle is described as a compromise between traffic safety demands and the requests of the billboard owners, set by the road administration by trial and error and refined after public complaints. One refinement is recorded: the displays originally blanked between messages, which was found to cause distraction because drivers could not help waiting for the next message, and the transition was altered so that advertisements followed directly on one another.

The outcome. The authors record that on the results reported together with results from other studies, the Swedish authorities decided not to extend the test period and to remove the billboards under investigation. One of those other studies was an unpublished questionnaire, reported as showing that glare and visual clutter were seen as a problem, which the Foundation has not seen and does not rely on.

What it does not establish. Any health or biological endpoint; its endpoints are gaze and driving performance. Any optical quantity, the luminance having gone unmeasured. And, on its authors' own statement, whether these products are a traffic safety hazard.

Where it bears. Part VI.J.7, which is where it is used. Part VI.J.6, for the provenance of temporal criteria and for the qualification of the involuntary-capture proposition. Part V.E, for the effect of blanking between messages.

C.117 Luginbuhl, Israel, Scowen and Polakis (2010) — the adaptation argument, and what the American criterion was built on

Citation. Luginbuhl C.B., Israel H., Scowen P., Polakis J. and Polakis T. "Digital LED Billboard Luminance Recommendations: How Bright Is Bright Enough?" 9 November 2010. Marked DRAFT on its face.

Status and interest, stated first. A draft. The Foundation has found no final version. The first author is identified on the document as of the United States Naval Observatory Flagstaff Station and the third as of Arizona State University, but the document is not a publication of the Observatory or of any agency and must not be represented as one. The authors write from a concern with the darkness of the night sky.

What it measured. Fifty-five floodlit billboards in the Phoenix metropolitan area, August and November 2009, and three in the Chicago area, November 2010, measured on white surfaces with a Minolta LS-100 luminance meter and tabulated individually. Average fifty-four candelas per square meter; fifty-two of fifty-eight at or below one hundred; fifty-six of fifty-eight below one hundred and fifty. Separately, five hundred and ten billboard faces in the Tucson metropolitan area, for which no direct luminance measurements were made: the values were deduced from lamp lumens and sign areas on assumed light loss factor, coefficient of utilization and reflectance, giving an estimated average of fifty-nine.

The adaptation chain. Roadway design luminances of about one candela per square meter; an asymmetry in adaptation taken from the IESNA Lighting Handbook at page 3-9, by which the eye adapts upward faster than downward; and adjacent-area ratio limits of ten to one in RP-33-99, fifteen to twenty to one in RP-20-98 and twenty to one in RP-2-01, each given with the stated reason that exceeding them may hazard motorists. From twenty to one and a one candela roadway the authors obtain twenty candelas per square meter as the maximum for a sign visible to drivers, and recommend a ceiling of one hundred in an urban environment while stating that this may be too high.

The contradiction it identifies. That the same handbook, at page 17-26, recommends luminous background sign luminances of two hundred and fifty to one thousand four hundred

candelas per square meter, which would impose ratios of 250 to 1400 to one; that this is unsupportable on the handbook's own adjacent-area recommendations; and that nowhere in the discussion of advertising sign brightnesses is transient adaptation or the vision of drivers mentioned.

What it says the American criterion was built on. That the industry method rests on light trespass as developed in IESNA TM-11-00; that it effectively limits signage to three hundred to three hundred and fifty candelas per square meter; that the underlying study asked observers only to rate how objectionable illuminated panels of two thousand to seven thousand five hundred candelas per square meter appeared, with no evaluation of visual performance attempted; that objectionability and the ability to see are essentially unrelated; and that the industry report itself states that digital billboards are not the form of lighting TM-11-00 was developed to limit, yet limits them by it. The last of these is a quotation within a quotation and must be verified at source.

What it does not establish. Any health or biological endpoint measured by its authors. Its endpoints are luminance and, by argument, transient adaptation and visibility. It measured conventional floodlit billboards, not digital displays, and its recommendation for digital displays is reasoning rather than measurement. Fifty-eight signs were measured.

Where it bears. Part VI.J.6, which is where it is used, and which previously carried two of its findings at second hand through Appendix C.114. Part VI.J.8, for the ask on measurement quantity. Part VI.B.1 and Part VI.D, for transient adaptation as the common endpoint. Appendix D.4, which it criticizes directly.

C.118 Marchant and Norman (2025) — the relighting of a whole city, measured against a pre-registered plan

Citation. Marchant P.R. and Norman P.D. "To Determine if Changing to White Light Street Lamps Reduces Crime: A Multilevel Longitudinal Analysis of Crime Occurrence during the Relighting of Leeds, a UK City." Applied Spatial Analysis and Policy, volume 18, article 77 (2025). doi:10.1007/s12061-025-09675-1. Open access under a Creative Commons Attribution licence. Received 14 August 2024, accepted 1 June 2025, published 20 June 2025, supplementary materials corrected 8 August 2025.

Funding and declared interests, stated first. No funding was sought or obtained. The first author declares that he has concerns about light pollution affecting astronomical observations and biodiversity, that he has been motivated by them to examine claims of benefit for increased public lighting, and that he has previously published work critical of such claims. The second declares a concern that public money may be wasted on schemes with no proof of achieving their purpose. The comment discloses these as it discloses the interests recorded at Appendices C.114 and C.117.

Procedural discipline. A confirmatory study following a plan fixed in advance. The protocol was sent to three named independent custodians before analysis and is published with the paper. The modeled data are published with it and the analysis is reproducible. Written with attention to the reporting guideline for cohort studies.

Design. Multilevel longitudinal analysis of weekly police recorded crime in all 107 middle-layer super output areas of Leeds across 456 consecutive weeks, from 3 January 2005 to 29 September 2013, against the cumulative number of replacement white lamps operating in each area in each week. 78,189 lamps were installed over the period, replacing predominantly orange ones. Areas were relit at different times, rates and extents, so each serves as a comparison for the others. The underlying time trend was fitted by a polynomial with area-specific random coefficients, with terms for month and for weeks containing a public holiday, and overdispersion was modeled directly. Installation order was determined by contractor convenience rather than by crime levels, which the authors give as the reason regression towards the mean does not arise.

Data. 679,452 recorded crimes in the period, of which 471,374 could be assigned to darkness or daylight: 221,644 in darkness and 249,730 in daylight. Crimes were assigned by computing sunrise and sunset for Leeds and treating darkness as 30 minutes after sunset to 30 minutes before sunrise.

Results. Daylight-adjusted darkness crime, the principal measure, rose 2 percent from start to finish of the relighting, 95 percent confidence interval minus 3 to plus 7 percent. Unadjusted darkness crime rose 3 percent, interval minus 1 to plus 8 percent. Round-the-clock crime rose 3 percent, interval 0 to plus 6 percent. The authors report consistent null results across many checks, including negative binomial models, autoregressive models, models excluding the city center and models using lamp counts rather than fraction completed.

What had been claimed. The city's 2004 outline business case for public funding assumed a 20 percent reduction in night-time crime, put the net present value from crime benefits alone at £109,049,000 and gave a benefit to cost ratio of 3.75. Those figures are quoted by these authors from the business case, which the Foundation has not seen.

What it does not establish. Any health, biological, visual or physiological endpoint; the outcome is recorded crime throughout. Anything specific to light-emitting diodes: the lamps are described as white and broad-spectrum and the conversion ran from 2005 to 2013. And it does not establish that white light increases crime; the point estimates are slightly positive and none is distinguishable from zero.

Where it bears. Part V.M, which is written on it. Part VI.D, for roadway and area lighting, subject to the qualification that this is not a study of diode sources. Part IX, for the proposition that a countervailing safety benefit should not be assumed when the spectral question is weighed.

C.119 Lee, Leitner and Paulus (2024) — nighttime light and recorded crime in Vienna, a contradictory result

Citation. Lee J., Leitner M. and Paulus G. "Spatiotemporal Analysis of Nighttime Crimes in Vienna, Austria." ISPRS International Journal of Geo-Information, volume 13, number 7 (2024), article 247. doi:10.3390/ijgi13070247. Open access. Department of Geography and Anthropology, Louisiana State University, and Department of Engineering and Information Technology, Carinthia University of Applied Sciences. Supported by the Austrian Marshall Plan Foundation. No conflicts of interest declared.

Design, which governs what it can show. Cross-sectional spatial analysis, not a before-and-after study of any change. 522,880 reported crimes in Vienna from 2014 to 2019, of which 128,322 nighttime incidents in four types were analyzed. Night defined as civil dusk to civil dawn, computed daily. Light measured two ways: streetlight density from an open government dataset, and median radiance from the day-night band of the Visible Infrared Imaging Radiometer Suite on 3,106 grid cells of five hundred meters. Ordinary least squares and geographically weighted regression, univariate and multivariate.

The regression finding. Positive associations throughout. The authors state that the analysis shows a mostly positive relationship between streetlight density or satellite radiance and nighttime crimes, and that brighter areas show a statistically significant increase in nighttime crimes. Burglary showed the strongest relationship; geographically weighted models outperformed ordinary least squares throughout.

The descriptive finding, which runs the other way. The paper reports that Vienna replaced older hanging lamps with light-emitting diodes in 2017 and that the largest single-year fall in nighttime crime in the series followed: theft down about 26.6 percent, robbery about 27.0, burglary about 18.9 and assault about 9.4 between 2016 and 2017. The authors write that the change may have contributed to that decrease.

That the two findings are unreconciled. The authors describe the descriptive and regression results as seeming to contradict one another and do not resolve the contradiction. They identify the underlying tension as one between lighting that reveals opportunities to offend and lighting that raises the risk of detection, and call it an avenue for future research.

What it cannot establish. Causation in either direction. The design is cross-sectional, so a positive association between light and recorded crime is consistent with bright places simply being busy places. The authors identify the confounding themselves, noting that brighter areas have a higher chance of crimes being observed and reported, which is an effect on recording rather than on offending. Indoor and outdoor crimes were analyzed together because the dataset did not distinguish them, which the authors state may have biased the lighting results.

Where it bears. Part V.M, which is where it is used, and only for the proposition that the relationship between outdoor lighting and crime is unresolved. The comment does not rely on its correlations as evidence that light increases crime, and does not rely on its before-and-after comparison as evidence that light reduces crime.

C.120 Marchant and Norman (2022) — road collisions through the relighting of a whole city, and what the city's evidence actually said

Citation. Marchant P.R. and Norman P.D. "To determine if changing to white light street lamps improves road safety: A multilevel longitudinal analysis of road traffic collisions during the relighting of Leeds, a UK city." Applied Spatial Analysis and Policy, volume 15 (2022), pages 1583–1608. doi:10.1007/s12061-022-09468-w. Open access under a Creative Commons Attribution licence. Received 10 August 2021, accepted 15 June 2022, published 5 July 2022.

Procedural discipline, and the disclosed departures from it. A confirmatory study. The protocol was lodged with three named independent custodians on 5 August 2016 and is published, and the analysis dataset is in a public repository at doi 10.17605/OSF.IO/KFG64. Written with attention to the reporting guideline for cohort studies. The authors disclose two departures: the focus on the daylight adjusted darkness rate is a variation from the protocol outcomes, which are nonetheless also reported; and an analysis at a smaller spatial scale contemplated by the protocol was not carried out, for want of time.

Declared interests. As at Appendix C.118 and Appendix D.7.

Design and data. Multilevel longitudinal analysis of weekly personal injury collisions reported to police, from the national STATS19 dataset, in all 107 middle-layer super output areas of Leeds across 456 weeks from 3 January 2005 to 29 September 2013, against the cumulative number of replacement white lamps operating in each area in each week. 78,189 lamps installed. 13,977 daylight collisions and 5,302 darkness collisions. An anomalous pattern in the official data for 2012 and 2013 led the authors to repeat the analysis on a series truncated at the end of 2011, with 11,953 daylight and 4,078 darkness collisions and 76,288 lamps.

Results. Daylight adjusted darkness collision rate ratio of 0.990, 95 percent confidence interval 0.971 to 1.010, per hundred lamps; 0.993, interval 0.971 to 1.015, on the truncated series. For a typical area of about seven hundred lamps, 0.934, interval 0.816 to 1.070, being an 18 percent reduction to a 7 percent increase; and on the truncated series 0.950, interval 0.816 to 1.107. Modeled on the fraction of relighting completed, full relighting gives 0.920, interval 0.776 to 1.09. Combined with Birmingham for a typical area: 0.952, interval 0.838 to 1.082 on the full series; 0.971, interval 0.842 to 1.119 on the truncated series. Every interval includes no change. The authors summarize the plausible range as between a 20 percent reduction and a 10 percent increase.

What it establishes about the basis for the scheme. That the city's bid claimed national evidence that good street lighting can reduce night-time road accidents by between 15 and 35 percent, citing the Institution of Lighting Engineers and two transport research reports; that the first of those reports showed no statistically significant effect for roads with speed limits of 30, 40 and 50 miles per hour, which the authors say form the bulk of roads in Leeds; and that the

second was excluded from the Cochrane systematic review of this question because of its poor methodological design. The authors conclude that the evidential basis for the claim was weak.

What the systematic review found. That of 145 potentially relevant studies, seventeen met the inclusion criteria; that none was a randomized controlled trial; that all were controlled before-and-after studies with collision counts mostly under one hundred and none at city scale; and that the methodological quality of the included studies was generally poor. The present authors separately criticize the review's own conclusion for publication bias and regression towards the mean. The Foundation has not read the review.

A finding that runs in an uncomfortable direction. That across the period daylight collisions in the city fell markedly while collisions in darkness stayed roughly constant, so that the darkness to daylight ratio rose throughout independently of lighting change. The authors offer increased night-time road use or risky behavior as possible causes and do not resolve it. Nothing in the paper attributes the rise to lighting or shows that more or whiter lighting would have arrested it.

What it does not establish. Any health or biological endpoint; the outcome is recorded personal injury collisions. Anything specific to light-emitting diodes; the lamps are described as white and broad-spectrum. And it does not establish that white lighting increases collisions.

Where it bears. Part V.M, which is where it is used. Part VI.D, for roadway lighting. Part IX, for the proposition that a countervailing safety benefit should not be assumed.

C.121 Tompson, Steinbach, Johnson, Teh, Perkins, Edwards and Armstrong (2023) — switching street lights off, measured street by street

Citation. Tompson L., Steinbach R., Johnson S.D., Teh C.S., Perkins C., Edwards P. and Armstrong B. "Absence of Street Lighting May Prevent Vehicle Crime, but Spatial and Temporal Displacement Remains a Concern." Journal of Quantitative Criminology, volume 39 (2023), pages 603–623. doi:10.1007/s10940-022-09539-8. Open access. Accepted 3 January 2022, published 30 March 2022. Funded by the National Institute for Health Research, grant 11/3004/02. No conflict of interest declared.

Design. Controlled interrupted time series using conditional Poisson regression, with the street segment as the unit of analysis. Thames Valley police force area, April 2004 to September 2013. 283,275 recorded offenses across five categories. 33,804 street segments, of which 815 had lights switched off between midnight and six, 1,315 were dimmed and 958 were converted from orange sodium to white light. Streets adjoining each treated street were modeled separately to detect displacement. Crimes classified to night or day by civil twilight; where the hour was unknown the midpoint of the possible range was used, and a sensitivity analysis removing those cases did not change the findings.

Principal results for switching lights off. On treated streets, night-time crime adjusted for daytime: all crime 0.74 (0.63–0.87), theft from vehicles 0.56 (0.41–0.78). All times of day on treated streets: total crime 0.81 (0.75–0.88), burglary 0.75 (0.65–0.85), violence 0.83 (0.71–0.97). All times of day on adjoining streets: total crime 0.83 (0.76–0.89), violence 0.75 (0.64–0.89). Net across treated and adjoining streets combined: total crime 0.83 (0.79–0.88), burglary 0.85 (0.78–0.92), theft from vehicles 0.90 (0.81–1.00), violence 0.79 (0.70–0.88).

The displacement finding. Night-time theft from vehicles rose on streets adjoining those switched off, 1.55 (1.14–2.11), and night-time crime overall on those streets rose 1.18 (1.02–1.38). The authors report that the reduction on treated streets and the increase on adjoining streets were equal in magnitude. For dimming, the net effect on theft from vehicles across treated and adjoining streets was an increase, 1.16 (1.04–1.29), which the authors read as temporal rather than spatial displacement.

Results for white light. No evidence of any association with night-time crime of any type examined. On adjoining streets at night, total crime 0.87 (0.77–0.99) and violence 0.74 (0.61–

0.91). Across all times of day on treated streets, total crime 0.91 (0.83–0.99) and burglary 0.72 (0.62–0.83); net burglary across treated and adjoining streets 0.84 (0.77–0.92). The authors attribute the all-day effect to a community cohesion mechanism rather than to visibility, having predicted in advance that a visibility mechanism would appear at night and a cohesion mechanism equally by day and night.

The mechanism stated by the authors. That the visibility mechanism by which lighting is said to reduce crime can also increase it, because an offender requires light to identify targets of value, assess security and work on a vehicle; and that environmental features make some crimes more likely while making others less likely.

Limitations the comment records. The streets selected for switch-off were chosen under exemption criteria that excluded major junctions, town centers with surveillance or night-time activity, locations where lighting was needed for road safety, and locations where crime might increase; so the treated streets were by design those least likely to suffer from the change. The authors also acknowledge that switch-off may have reduced pedestrian and parking activity on those streets, reducing targets, and that they could not test this. One of forty-three police force areas, and the authors state the findings may not be generalizable.

What it does not establish. Any health or biological endpoint. Anything about light-emitting diodes as such. And it does not establish that darkness prevents crime generally: the effects are specific to offense type, and one offense was displaced to neighboring streets.

Where it bears. Part V.M, which is where it is used. Part VI.D, for the proposition that the white light benefit observed did not appear where an optical mechanism would have placed it. Part IX.

C.122 Svechkina, Trop and Portnov (2020) — how much light people need to feel safe, with instrumental measurement

Citation. Svechkina A., Trop T. and Portnov B.A. "How Much Lighting is Required to Feel Safe When Walking Through the Streets at Night?" Sustainability, volume 12, number 8 (2020), article 3133. doi:10.3390/su12083133. Open access. Department of Natural Resources and Environmental Management, University of Haifa. Funded by the Israel Science Foundation, grant 400/18. No conflict of interest declared.

Design. Field study in ten residential neighborhoods across three Israeli cities. 106 observers walked designated routes after dark and reported feeling of safety on a four-point forced scale at 257 marked points, through a purpose-built mobile application that verified position by satellite and would not operate outside the window from thirty minutes after sunset to midnight; 7,255 assessments. Illuminance was measured instrumentally at the same points with a Konica-Minolta CL-200A chroma-meter following the measurement methodology of the International Commission on Illumination: horizontal at ground level, vertical directional at 1.5 meters, and vertical panoramic across about 120 degrees. Analysis by ordinary least squares with city, vegetation density and traffic intensity as controls.

The principal finding. Feeling of safety rose significantly with illuminance, but non-linearly. Logarithmic transformation of illuminance raised the model R-squared from 0.13 to 0.32, which the authors take as showing diminishing returns. Their conclusion states that reasonably high assessments of safety may occur at relatively low illumination levels of 5 to 10 lux and that increasing illumination beyond that threshold produces only minor further rise. They describe the proposition that brighter is better as a common misconception.

Measured levels and variation between places. Mean measured illuminance was 18.52 lux horizontal, 11.92 panoramic and 11.37 directional, close to the 15 lux recommended by the Commission. The illuminance needed to reach the sample average feeling of safety differed by city, about 5.67 lux in Haifa against about 24.46 lux in Be'er Sheba, which the authors attribute to socio-economic position, recorded crime and accustomed daylight. They describe a one-size-fits-all approach as another misconception. Response curves leveled off in all three cities.

What it does not establish, including as to spectrum. It measures a reported feeling and not safety; it is not evidence about crime. And it says nothing about the color of light. Sites were selected on a design crossing high and low illumination with predominantly short-wavelength and predominantly long-wavelength sources, so both are in the sample, but only illuminance and feeling of safety were analyzed. The authors state that light temperature, glare and uniformity are left to follow-up studies and that the analysis solely focuses on illuminance. The comment therefore does not rely on this study for any proposition about amber or long-wavelength light and perceived safety.

A statement in it about spectrum and health. In the introduction, on the authority of other work rather than their own data, the authors state that evidence of adverse effects of short-wavelength outdoor lighting on circadian rhythm and melatonin secretion in humans and wildlife cannot be ignored, and that the health and ecological impacts of long-wavelength light appear to be less severe.

Where it bears. Part V.M, which is where it is used, for the quantity of light the subjective justification requires. Possibly Part V.G. Part IX, for the research the Foundation asks to be put in hand on the spectral question the authors leave open.

C.123 Chalfin, Kaplan and LaForest — three hundred thousand street light outages in Chicago

Citation, with a caveat. Chalfin A., Kaplan J. and LaForest M. "Street Light Outages, Public Safety and Crime Displacement: Evidence from Chicago." Manuscript posted by the Department of Criminology, University of Pennsylvania. The copy read carries no journal, volume or date on its face. A paper by the same authors appears to have been published in the Journal of Quantitative Criminology in 2021 under the title Street Light Outages, Public Safety and Crime Attraction.

Why the comment reports it. Because its lead author is the author of the randomized experiment that found a crime reduction from adding light, which this comment records twice as the principal evidence against its position, and because this study is the largest examination of the converse question that the Foundation has found.

Design and scale. Nearly 300,000 street light outages in Chicago over an eight-year period, affecting nearly 50,000 street segments, giving about 140 million observations. Because the onset of an outage is known only when reported but the repair date is recorded precisely, the authors compare crime shortly before a repair with crime shortly after, approximating a regression discontinuity in time. Major outages, being more than two lamps on a segment, are analyzed separately from minor ones. Crime on segments within 500 feet is analyzed separately. Placebo tests on daytime crimes and on indoor night-time crimes are reported, and neither responds.

Results on the affected street. Index crimes rose 2 percent, violent crimes 1 percent and property crimes 1 percent, none statistically significant, with a confidence interval for index crimes of minus 3 to plus 6 percent. The authors state that the most reasonable interpretation is that outages do not appreciably impact crime in the short term on affected segments. For outages of only one or two lamps there was no evidence of any effect, the coefficients being uniformly small and of mixed sign, from which the authors conclude that ambient lighting has a non-linear effect on crime. Motor vehicle theft is the exception, rising about 9 percent on the affected segment, marginally short of significance.

Results on surrounding streets. Index crimes rose about 3 percent, violent crimes 2 percent and property crimes 3 percent on segments within 500 feet, significant at the conventional level given the size of the data. Robberies rose about 7 percent, confidence interval 0.6 to 13.4 percent. Motor vehicle theft rose about 6 percent. The authors conclude that outages compromise public safety with effects that reverberate through a community, and compare the magnitude to reducing a police force by 5 to 15 percent.

The mechanism the authors propose. Movement of potential victims rather than offenders alone. A robbery requires a victim present, so when a street goes dark people avoid it and robberies move to adjacent streets; a vehicle theft requires no victim and a parked car cannot move, so vehicle theft rises where the darkness is. The authors state the general principle that the effects of place-based measures can be shaped to a considerable degree by the behavior of potential victims.

A finding about unequal maintenance. That higher-crime areas of Chicago suffer more outages and wait longer for repair, which the authors describe as municipal neglect contributing to unequal crime rates between neighborhoods.

What it does not establish. Any health or biological endpoint. Anything about the spectrum of lighting. And nothing about a planned, uniform change in lighting across a jurisdiction: the intervention studied is an unplanned local failure against an otherwise lit background, which is a gradient rather than a level.

Where it bears. Part V.M, which is where it is used. Part IX, for the distinction between a local differential and a uniform standard. Part VIII, if the equity finding is taken up there.

C.124 Perkins, Steinbach, Tompson, Green, Johnson, Grundy, Wilkinson and Edwards (2015) — the LANTERNS study: street lighting reduced across sixty-two authorities, commissioned by a health department

Citation. Perkins C., Steinbach R., Tompson L., Green J., Johnson S., Grundy C., Wilkinson P. and Edwards P. "What is the effect of reduced street lighting on crime and road traffic injuries at night? A mixed-methods study." Public Health Research, volume 3, issue 11 (September 2015), pages v–107. doi:10.3310/phr03110. Published by the National Institute for Health Research Journals Library, Southampton. Crown copyright; the report states that it may be freely reproduced for the purposes of private research and study with suitable acknowledgement.

Funding and interests. Funded by the National Institute for Health Research Public Health Research programme, project number 11/3004/02. The authors declared no competing interests. The copyright notice records that the work was produced "under the terms of a commissioning contract issued by the Secretary of State for Health". Ethical approval for the qualitative component was given by the London School of Hygiene and Tropical Medicine Ethics Committee, reference 6341.

What the Foundation read. Chapter 3 in full, being the controlled interrupted time series, from a text rendering of that chapter as published on the National Library of Medicine Bookshelf. The abstract, the scientific summary, the table of contents, and the methods and survey results of Chapter 2, from the full report as published by the funder. Not read: Chapter 1; Chapter 4, the cost-benefit analysis of part-night lighting; Chapter 5, the discussion; the appendices; and the qualitative findings of Chapter 2 beyond the point at which the retrieved text ends.

Article type. A report of commissioned primary research, published in the funder's own peer-reviewed journal series. Mixed methods: a rapid appraisal in eight case study areas with 59 residents or workers and 16 stakeholders interviewed formally, 63 informal intercept interviews and 112 documents (Chapter 2); a controlled interrupted time series (Chapter 3); and a cost-benefit analysis (Chapter 4). The quantitative chapter follows the STROBE reporting guidelines for observational studies.

Design of the quantitative component. Panel analysis with fixed effects, so that time-invariant characteristics of a street or area contribute no information and cannot confound. Conditional Poisson regression. Collisions modeled at road segment level by region, with night-time counts adjusted by the change in daytime counts on the same segments. Crime modeled at middle layer super output area level by police force, the explanatory variable being the proportion of road kilometers in the area carrying the intervention. All four interventions entered in one model. Indicator variables for calendar month and year. Overdispersion

accommodated by a scale factor, averaging 1.69 for crime, with none detected for collisions. Zero inflation tested for and not found. Sensitivity analyses under negative binomial and zero-inflated specifications did not alter the interpretation. Night was defined as one hour after sunset to one hour before sunrise, and for part-night lighting as midnight to six in the morning.

Coverage. 174 local authorities in England and Wales approached; contact achieved with 140; usable data from 62. More than thirty thousand kilometers of road affected by lighting change. By December 2013: white light on 15,833 kilometers, part-night lighting on 12,101, dimming on 10,519, permanent switch-off on 946. Collisions 2000–2013: 859,935 in total, 161,049 at night. Crime December 2010–December 2013: 581,837 burglaries, 475,657 vehicle thefts, 67,470 robberies, 730,280 offenses of violence. Anti-social behavior (2,882,758) and criminal damage (486,367) were excluded from analysis for incomplete reporting by some forces.

Collision results. Night-time rate ratios adjusted for daytime change: switch-off 0.97 (0.82–1.15); part-night lighting 0.95 (0.84–1.07); dimming 1.00 (0.91–1.10); white light 1.01 (0.93–1.09). Unchanged and less precise when restricted to killed or seriously injured casualties. No association in any deprivation stratum. One regional exception: white light in London 1.30 (1.03–1.65), described by the authors as weak evidence.

Crime results. Aggregate count, expressed for full coverage of an area: part-night lighting 0.96 (0.86–1.06); switch-off 0.11 (0.01–2.75), uninformative; dimming 0.84 (0.70–1.02); white light 0.89 (0.77–1.03). The authors characterize the last two as weak evidence for a reduction and note that all point estimates for both interventions pointed toward less crime. Individual offenses: part-night lighting with robbery 1.48 (0.99–2.21); dimming with violence 0.78 (0.60–1.01). Strong heterogeneity across the thirty-one police forces, with strong evidence of decreases in some and strong evidence of increases in others, for part-night lighting, dimming and white light alike.

Household survey (Chapter 2). One Shropshire area; five hundred households sampled in part-night lighting streets and five hundred in unaffected streets; 483 responses, 250 and 233. The only significant difference was in perceived safety: 15.6 percent in part-night streets felt very safe walking alone after dark against 26.2 percent in unaffected streets, odds ratio 0.52 (0.32–0.84). No significant difference in walking alone after dark, perceived safety when driving, worry about vehicle crime, trust in the council, whether there was enough lighting to see clearly, carrying a torch, or seeing the stars. Half the residents of part-night streets, 50.4 percent, reported that their street's lighting had been reduced, against 24.0 percent in the unaffected streets.

The sleep item, and why the Foundation draws nothing from it. The survey asked whether street lights keep the respondent awake at night. Strong disagreement was recorded by 74.4 percent in part-night streets and 69.5 percent in unaffected streets, odds ratio 1.27 (0.84–1.94). Switching the lights off for part of the night was therefore not followed by a measurable improvement in self-reported sleep. The Foundation records that and uses it in neither direction, for four reasons. Only half the residents of the treated streets noticed that their lighting had changed at all, which bounds what any self-report could detect. The item asks about being kept awake, which is an awareness of light and not the endpoint at issue at Part V.F, where the question is melatonin suppression and phase shift. Part-night lighting switches off around midnight and leaves the evening exposure window, which is the biologically consequential one, unchanged. And the sample is 483 respondents in a single locality. A null on this item is not evidence that street lighting does not affect sleep, and the Foundation does not report it as though a positive result would have been evidence that it does.

What the report says about the prior literature. Of the systematic review of increased street lighting and crime: a reduction was found in studies examining the entire day, but in the four studies examining night-time crime alone there was "no evidence of an impact of changes to street lighting on crime"; and a major limitation was inadequate control areas, only two studies using multiple controls and some using a control adjoining the treated area. Of the systematic

review of street lighting and road traffic injury: a rate ratio of 0.78 (0.63–0.97) across seventeen controlled before-and-after studies, and 0.68 (0.61–0.77) in the ten that used daytime data as the control, but with the methodological quality of the included studies considered "to be poor, with a high risk of bias". The authors state that they identified no previous research into the effects of reduced street lighting on either outcome.

Limitations the authors state. No measure of exposure, so a reduction in casualties could reflect fewer road users rather than unchanged risk, and an increased hazard to those remaining could be masked; they could not test this. No measure of risk compensation. No measure of fear of crime, which they say might be expected to have increased where lighting was reduced. Other crime prevention and road safety measures could not be accounted for, and they state that such confounding is likely to account for part of the crime associations observed. Crime locations in the public data are deliberately obfuscated to protect victims, which confined the crime analysis to area rather than street level; a companion reliability study established the smallest area at which the public data agree with force records. Switch-off coverage was too small for a precise estimate. Regression to the mean was planned for but not assessed, because no increase was found to assess.

Internal inconsistency recorded. Chapter 3 reports under deprivation analysis that the stratum-specific estimates "were not materially different from the overall estimates, and each was imprecise", and that there were insufficient data for switch-off. The generalizability discussion then reports that the stratified analyses suggest switch-off was associated with increased burglary and vehicle crime in more deprived areas and in city and town centers, and part-night lighting with decreases in less deprived areas. The Foundation relies on neither passage.

The use the comment makes of it. Three. First, as the largest and best-designed test of whether reducing or whitening street lighting is followed by more collisions, which it was not. Second, for the distinction between night-only and all-day findings in the prior literature, which the comment treats as the analytical key to this field and which converges with the independent finding of the Thames Valley study at Appendix C.121. Third and principally, for the published conclusion of a study commissioned by a Secretary of State for Health that "the public were also concerned about other health outcomes" and that "Research is needed also on other public health impacts of light at night". No chapter of the report measured any visual, physiological or biological endpoint of light exposure.

Not relied on for. The state of the health science. The report characterizes the evidence that light at night affects health as weak and describes links to anxiety, depression and cancer incidence as theoretical. That characterization dates from 2015, the report does not claim to have reviewed that literature, and Parts V.C through V.G of this comment set out the evidence as it now stands.

Authorship overlap. Five of the eight authors — Tompson, Steinbach, Johnson, Perkins and Edwards — are co-authors of the Thames Valley study at Appendix C.121, in which Tompson is first author. The two studies are not independent in authorship, and the comment does not present them as independent corroboration of each other's crime findings. The convergence the comment does rely on is between this report's account of the prior review, published in 2015, and the Thames Valley authors' mechanistic interpretation, published in 2023.

C.125 Fyie, Meuti, Sivakoff, Fiorta and Gardiner (2026) — residential lighting prevents overwintering dormancy in the principal West Nile virus vector

Citation. Fyie L.R., Meuti M.E., Sivakoff F., Fiorta M.A., Gardiner M.M. "Artificial light at night (ALAN) is a stronger inhibitor of overwintering dormancy than urban warming in mosquitoes." Journal of Applied Ecology, first published 18 May 2026. doi:10.1111/1365-2664.70407. Handling editor Mariana Mayer-Pinto. Read in full from the publisher.

Funding and interests. Supported by a SEEDS grant from the Ohio Agricultural Research and Development Center of the College of Food, Agricultural and Environmental Sciences at The Ohio State University; by National Science Foundation grant IOS 1944324 and National Institutes of Health grant R01AI188567, both to the second author; and by funding from the MITRE Corporation to the last author. The authors declare no conflict of interest. Data deposited at Figshare, doi 10.6084/m9.figshare.29906006. The National Institutes of Health grant is the fact of institutional significance and is used at Part V.I and cross-referred to Part II.E. The MITRE funding is recorded because that corporation operates federally funded research and development centers, and the comment states provenance of this kind wherever it appears.

Design. Semi-field experiment. Larvae of Culex pipiens f. pipiens were reared to adulthood in enclosures sited in the yards of private properties, schools and churches across Columbus, Ohio and Franklin County, in the autumns of 2022 and 2023. Eight sites in 2022 and seventeen in 2023. Each site carried two enclosures: one beneath an artificial light source the property owner had already installed, being porch, garage, pathway or security lighting, and one in a dark microhabitat on the same property. Mosquitoes came from the Buckeye laboratory colony, established in 2013 from above-ground egg rafts in Columbus with field material added in 2021.

Instrumentation. An Onset HOBO MX2202 logger in each enclosure recorded temperature and light at thirty-minute intervals. Additional single-night readings were taken with an Extech LT300 photometer for illuminance and an International Light Technologies ILT350 chroma meter for correlated color temperature and peak wavelength. Illuminance was measured at the center of the empty enclosure; color and wavelength were measured outside the enclosure near the fixture.

The exposure, as measured. Mean illuminance 4.93 lux with a standard error of 0.97 across all months and years, a maximum of 19.07 lux and a minimum of 0.87 lux. Most sources were warm white at approximately 2,700 to 3,000 kelvin, with a few cooler and more blue-rich. Exposure was entered in the models as the first principal component of all nighttime brightness variables, which accounted for 92.8 percent of their variance.

Outcome measures. Diapause status from mean egg follicle length, a female being classed as in diapause below 75 micrometers; blood-feeding proclivity on an artificial membrane system with chicken blood; and fecundity, being egg rafts laid and rafts hatching, among females that blood-fed. Linear and generalized linear mixed models with site, or enclosure nested in site, as a random effect.

Principal results. Across both Octobers, 100 percent of mosquitoes reared in dark enclosures entered diapause, against 41 percent with a standard deviation of 26 among those reared beneath a light source. In October no female in a dark enclosure took a blood meal, while 29 percent with a standard deviation of 25, being 25 of 117 females, did so beneath the lights; that difference was not statistically significant at p equals 0.09. Of the October light-exposed females that blood-fed, 72 percent produced egg rafts and 55 percent produced living larvae. In September 2023, 70 of 99 light-exposed females took a blood meal against 27 of 73 in the dark. Exposure to light and temperature interacted significantly for egg follicle length and for diapause incidence in both months. Temperature predicted these outcomes in the dark enclosures and did not predict them under light, which is the basis for the conclusion in the title.

The finding the comment treats as most important, and it is adverse to a Foundation position. That warm white light at illuminances below one lux prevented diapause. The authors' policy implication is that "changes in brightness or light colour may not be sufficient to mitigate ecological impacts". The comment adopts this against its own earlier framing, with two qualifications the authors supply. Light color was deliberately excluded as a factor from every analysis, because the only color-brightness relationship detected was driven by one unusually bright site; the study therefore does not test spectrum and shows only that warm white sufficed. And the authors distinguish broad-spectrum warm white from narrow-

band emission, suggesting that phosphor-converted amber or monochromatic sources may mitigate the effect and noting that moths and spider mites exposed to pure red light did enter diapause.

What it does not establish. Any human health effect. The outcome is mosquito reproductive physiology. No human case, no infection and no measure of vector competence. The step to disease incidence is an inference the authors mark as potential, and the further proposition that light-exposed females may be more susceptible to infection is assembled from three findings of other groups, one obtained in males of a different ecotype. It establishes nothing about light-emitting diodes as a class: the fixtures were whatever the property owners had installed and are not separately characterized by technology. And it is one species, one ecotype, one city.

Considerations bearing on confidence. In favor: the comparison is within site, between two enclosures on the same property, which controls the local environment better than any design in this appendix outside the street-level work at Part V.M; exposure was instrument-logged rather than modeled; the fixtures were real installations rather than laboratory lamps; two autumns; the result is consistent with laboratory work on the same species and with field work on other insects; and the data are deposited. Against: small and uneven numbers, with diapause assessed across five to sixteen sites and blood-feeding and fecundity across five to seven; only two dark-treatment cages yielded blood-fed females in September, forcing a chi-square in place of the model; the enclosure design changed between years from plastic containers to mesh cages, expressly to limit a greenhouse effect, while the October analysis pools both years; year was itself a significant predictor of blood-feeding, 38 percent in 2023 against 3 percent in 2022; enclosures were excluded or relocated for light malfunction, animal interference and logger failure; an outlier site was removed from the September analyses; the October 2023 cohort was brought indoors early because of forecast freezing temperatures and finished development in a chamber; and the colony is a laboratory strain.

Two internal inconsistencies, recorded for verification. First, the results section reports that 41 percent of light-exposed mosquitoes entered diapause in October, which implies that 59 percent averted it, while the discussion states that 37 percent averted diapause. Those cannot both be right as stated and the comment uses the results figure. Second, in the September panel of the model summary table the interaction term for egg follicle size is given as an estimate of minus 12.03 with a standard error of 3.67 and a t statistic of minus 13.08; that estimate divided by that standard error is approximately minus 3.28, which is the value reported in the same table for a different term. The reported t statistic is therefore inconsistent with its own estimate and standard error. Separately, the text gives the September interaction for egg follicle length as F equals 7.66 at p equals 0.02 while the table gives p equals 0.006 for the same term; those are different tests and may both be correct, but the pair should be checked. None of these touches the central October contrast of 100 percent against 41 percent, which is reported as a simple proportion.

A distributional finding recorded. The authors state, on the authority of four other studies, that lower-income neighborhoods are more exposed to light pollution and to higher urban heat island magnitudes. The comment records this and draws no lighting recommendation from it, consistently with the position stated at Part V.M.

Bearing on the statutory question. Narrow and expressly not through human health. Paragraph 360ii(a)(2) directs the Secretary to minimize the emissions of, and the exposure of people to, unnecessary electronic product radiation, and Part II.D.4 establishes that the two objects are coordinate and that the first does not require a human receptor. This study is evidence about an emission, measured in a biological endpoint, and the mitigations its authors recommend are shielding against light trespass and limiting duration, light trespass being one of the four categories Part II.D.3 identifies as instances of the statutory term. Separately and independently, the research was funded in part by this Department, and its published recommendation is addressed to public health departments. Part V.I, which is where it is used; Part II.D.3 and Part II.D.4 for the statutory construction; Part II.E for the grant.

C.126 Vardi-Naim, Janovsky, Kronfeld-Schor and Wine (2026) — immune rhythms and survival in a diurnal and a nocturnal mammal under characterized light at night

Citation. Vardi-Naim H., Janovsky G., Kronfeld-Schor N., Wine Y. "Artificial light at night disrupts immune rhythms in wild rodents under semi-natural conditions." Environmental Pollution. doi:10.1016/j.envpol.2026.127774. Read in full from the publisher. The volume, issue and article number are not recorded above and must be supplied from the published version.

Funding and interests. Israel Science Foundation grants 866/17 and 1603/25 to the third author and 666/22 to the fourth; a Dr. Alexander Lester and Eva Lester doctoral fellowship to the first author. The authors declare no competing financial interests or personal relationships. No industry funding. Ethical approval from the Tel Aviv University Institutional Animal Care and Use Committee, protocol 04-21-061. Data are not deposited; the statement is that data will be made available on request.

Why this entry matters to the structure of the comment. Part V.A.3 sets out three grounds, taken from rodent investigators, on which rodent evidence is indirect for a human, the first being that most laboratory rodents are nocturnal so that light at night falls in their active phase rather than their rest phase. That Part formerly recorded that no entry in this appendix used a diurnal model. This entry closes that gap: a diurnal mammal and its nocturnal congener were exposed to the same light in the same enclosures at the same time, and the principal finding was indexed to the rest phase in both. Part V.A.3 has been amended accordingly.

Subjects and design. Semi-natural enclosure experiment. 160 animals: 80 Acomys dimidiatus, nocturnal, and 80 Acomys russatus, diurnal, from a breeding colony at the Zoological Research Garden, Tel Aviv University. Sixteen outdoor enclosures of 1.5 by 3 meters, ten animals of one species per enclosure at an even sex ratio, permitting free movement, social interaction and reproduction. Eight enclosures exposed, eight control. Eight-week acclimation; experiment approximately eight months, December 2021 to August 2022. Animals tagged by radio-frequency identification; biweekly live-trap monitoring; offspring removed at weaning to hold density constant. Physiological sampling was cross-sectional, each animal sampled once; survival was followed longitudinally.

The exposure, as characterized. Low-intensity white light-emitting diode, correlated color temperature approximately 6,000 kelvin, illuminance 10 to 15 lux, a Eurolux G334W. Intensity and spectral composition were measured at the entrances of nesting shelters, the primary resting microhabitat; levels inside shelters were lower, so illumination across an enclosure was spatially heterogeneous. This is the entry in which the emission is best characterized of any animal study in the appendix, and the reason the comment can use it. Contrast Appendix C.125, where the exposure was warm white at 2,700 to 3,000 kelvin and 0.87 to 19.07 lux.

Endpoints. Antibody response to keyhole limpet hemocyanin, administered subcutaneously in two injections fourteen days apart during the species-specific rest or active phase, with complete then incomplete Freund's adjuvant, measured by a species-specific enzyme-linked immunosorbent assay developed for the study; circulating lymphocyte frequency by flow cytometry; fecal cortisol by commercial assay; and survival. Rhythmicity assessed by linear mixed-effects cosinor models against null models by likelihood-ratio test.

Antibody result, which is the cleanest and holds in both species. Under natural light, the ratio of the secondary response at day 28 to the primary response at day 14 was significantly higher in animals immunized during their rest phase than during their active phase, in both species, at p below 0.05 by t-test. Under artificial light at night that time-dependence was absent in both species. In the diurnal species the control secondary response was significantly higher for rest-phase immunization and showed no difference under light; in the nocturnal species the active-period primary response was marginally higher at p equals 0.054 in controls, and the trend was diminished under light. The effect was indexed to activity phase and not to temporal niche, which is the finding the comment relies on.

Rhythm results, all four combinations. Lymphocyte frequency, diurnal species: 24-hour rhythm in controls at p below 0.05, none detectable under light. Lymphocyte frequency, nocturnal species: rhythm in both groups, and formal comparison of treatment-specific models found no difference between them. Fecal cortisol, nocturnal species: 24-hour rhythms in both groups at p below 0.001, with a significant treatment-by-rhythm interaction, chi-square 6.34 on 2 degrees of freedom at p equals 0.042, reflecting reduced amplitude and a small phase shift. Fecal cortisol, diurnal species: no significant daily rhythm in either group, which the authors note is contrary to earlier evidence of daily glucocorticoid variation in this species. Two disruptions, one null, one undetected underlying rhythm.

A dissociation the authors raise against their own mechanism. In both species lymphocyte frequency peaked during the daytime, which is the rest phase for only one of them, while the antibody advantage followed the rest phase in both. The authors conclude that lymphocyte trafficking cannot alone explain the antibody result, and hypothesize that lymphocytes may be more permissive to activation during the rest phase, citing work on circadian gating of CD8 T-cell responses. The comment reports this as the hypothesis the authors label it.

Survival. Kaplan-Meier log-rank p equals 0.035. Cox proportional hazards: hazard ratio 2.35 with an interval of 1.03 to 5.38 at p equals 0.042, concordance 0.615, on 80 animals with 24 events, with treatment and sex as fixed factors and no difference observed between species or sexes.

Qualifications on the survival figure, which are substantial. The lower bound of the interval is 1.03, so the result barely excludes no effect. Cause of death could not be determined and the authors state the result should be read as a fitness-related association rather than evidence of a pathological mechanism; in their earlier work in the same system a subset was examined and no clear pathological cause was found. Shared frailty models including enclosure as a random effect failed to converge for want of events within enclosures, so fixed-effects results are reported and 80 animals housed ten to an enclosure are treated as independent, which overstates precision. A priori power calculation was not feasible; the authors' retrospective sensitivity analysis gives approximately 72 percent power to detect a hazard ratio of 2.35. The survival analysis was restricted after the fact to animals with a complete set of immune measurements, excluding those that died in acclimation and offspring added later. And the finding is described by the authors as consistent with their own previous work in the same enclosures with the same species, so it is a replication by the same group and not independent corroboration.

What it does not establish. Any human effect; every endpoint is a rodent's. Any melatonin-mediated mechanism: melatonin was not measured and the authors state that direct inference about melatonin-dependent mechanisms is therefore limited, which matters because that is the mediator Part V.F treats. Any immunophenotype: lymphocytes were gated on light-scatter morphology alone, species-specific reagents being unavailable, and the authors note the gate may overlap other leukocyte populations. Any within-animal rhythm: physiological sampling was cross-sectional, so daily curves are assembled across animals. And nothing about free-ranging conditions: the authors state that semi-natural enclosures limit pathogen diversity, predation pressure and resource unpredictability, and call the approach a deliberate compromise.

An analytical choice recorded. Outliers were defined as values outside the group mean plus or minus two standard deviations and excluded from subsequent analyses. That is an aggressive rule applied group by group, and at these sample sizes it can affect which comparisons reach significance. The authors disclosed it. The comment records it because a reader weighing these findings is entitled to know it, and imputes nothing.

Bearing on the statutory question. Two grounds. First, the emissions limb of paragraph 360ii(a)(2), as Part II.D.4 construes it: a characterized emission, a blue-rich white diode at a

stated illuminance, producing measurable biological effect, with no human receptor required. Second and more important, mechanism. The pathway proposed — retinal photoreception, the suprachiasmatic nucleus, melatonin and glucocorticoid output, peripheral clocks in immune tissue — is the pathway Part V.F describes in humans, and the authors selected these species expressly as a model for diurnal mammals including humans. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate conditions of exposure; this is a study of a condition of exposure in a mammal, at an exposure a person commonly receives. Part V.I, where it is used; Part V.A.3, whose diurnal-model gap it closes; Part V.F for the mechanism; Part II.D.4 for the construction.

C.127 Ajduković, Drobnjaković, Šošić-Jurjević, Vučić, Petrović and Prokić (2026) — thyroid gland histology in a newt under characterized light at night

Citation. Ajduković M., Drobnjaković M., Šošić-Jurjević B., Vučić T., Petrović T., Prokić M. "Influence of Artificial Light at Night on Thyroid Gland Histology in Triturus Newts (Urodela, Salamandridae)." Animals. 2026;16(3):483. doi:10.3390/ani16030483. Published 4 February 2026. Read in full from the publisher. Open access.

Funding and interests. Science Fund of the Republic of Serbia, grant 11120, styled ENLIGHT; Ministry of Science, Technological Development and Innovation of the Republic of Serbia, contracts 451-03-136/2025-03/200007 and 451-03-136/2025-03/200178. The authors declare no conflicts of interest. No industry funding. Collection of adults approved by the Serbian Ministry of Environmental Protection, permit 353-01-1506/2022-04; procedures approved by the ethical committee of the Institute for Biological Research Siniša Stanković, decision 323-07-07481/2023-05, under European Directive 2010/63/EU. Data are not deposited; the statement is that they will be made available by the authors on request.

Why the comment includes a weak study, stated first. Because of the organ. Appendix C.44 is a prospective cohort of 464,371 American adults in which the highest quintile of light at night carried a 55 percent higher incidence of thyroid cancer, and that entry records that its exposure measurement is spectrally blind and that its melatonin mechanism was hypothesized rather than measured. This entry is the converse: a stated spectrum and illuminance, a measurement in the tissue of the gland, and six animals. The comment uses the pair to describe a research gap and for nothing else. It does not present this study as support for the human finding, and the overdiagnosis objection set out at C.44 is unaffected by it.

Subjects. Metamorphosed juveniles of Triturus ivanbureschi, the crested newt, bred in the laboratory from eggs laid by nine gravid females collected from a natural population at Brebevnica, Serbia. Larvae were reared under a natural day and night regime; the treatment began after metamorphosis, identified by complete gill resorption. Animals were housed individually in two-liter boxes in a dedicated dark room with partitions between light regimes, at 18 degrees Celsius, fed Tubifex without restriction. Six animals per group for the stereological analysis; four per group for the immunohistochemical analysis. The authors state that six is the minimum required for histological analysis and that the species is strictly protected in Serbia, so the smallest possible number was used.

The exposure, as characterized. Night: a white light-emitting diode at 30 lux and a correlated color temperature of 6,000 kelvin for the treatment group, against below 0.1 lux for the control. Day, for both groups: approximately 450 lux of the same 6,000 kelvin diode light. Sixty days. Day length controlled by timer and adjusted weekly to follow the natural photoperiod, from thirteen hours light and eleven dark to eleven and thirteen, corresponding to early September and late October in Serbia. Intensities were measured repeatedly during the experiment. The authors give their reasons for the two settings: 30 lux as corresponding to the intensity perceived in public gardens and emitted by street lights, and 6,000 kelvin as the temperature mostly used outdoors.

Methods. Hematoxylin and eosin and periodic-acid-Schiff staining; immunohistochemistry for thyroglobulin with a horseradish-peroxidase conjugated secondary antiserum. Stereology by Cavalieri's principle in the newCAST package at 20 times objective magnification on a six by six

test grid, with a point area of 12,385.99 square micrometers and a block advance of 25 micrometers, estimating absolute thyroid volume and the volumes of follicular epithelium, colloid and interstitium. Immunostaining quantified semi-quantitatively in ImageJ Fiji with the IHC Profiler plugin by color deconvolution, ten images per animal at 40 times objective, optical density computed as the logarithm of maximum over mean intensity. Shapiro-Wilk for normality; data not normally distributed; Mann-Whitney U throughout.

Results, nulls first. No significant difference between groups in the absolute volume of the thyroid gland, p equals 0.873; nor in the volume of the follicular epithelium, p equals 0.689; nor of the colloid, p equals 0.749; nor of the interstitium, p equals 0.936. One difference: the optical density of thyroglobulin immunopositivity was higher in the light-treatment group, p equals 0.030, which the authors interpret as accumulation of thyroglobulin at the apical surface of the follicular cells and a reduced release into circulation, indicating a hypofunctional gland. Reported without quantification, from representative micrographs: macrofollicles filled with colloid, flattened follicular epithelium and absence of the resorption vacuoles present in controls.

The unresolved question about the one positive result. Ten images were analyzed for each of the eight animals in the immunohistochemical comparison, and the methods do not state whether the Mann-Whitney test was computed across the eight animals or across the eighty images. Images from one animal are not independent observations of a treatment applied to animals, so a test computed over images would return a probability the design does not support. The two readings are both consistent with the figure printed: computed over four animals against four, the smallest two-sided probability a Mann-Whitney test can return is approximately 0.029, so 0.030 would indicate complete separation of the groups, which would be a stronger fact than it appears; computed over images, it would be an artifact of pseudoreplication. The comment reports the result and relies on no part of it until the question is answered.

What the authors state against their own finding. That no circulating thyroid hormone was measured, because a juvenile newt is too small to yield enough blood for reliable quantification without pooled samples or a species-specific validated assay; thyroxine, triiodothyronine, thyroid-stimulating hormone and melatonin are therefore all unmeasured and the hypofunctional state is inferred from histology. That the mechanisms proposed, melatonin suppression acting on the hypothalamic-pituitary-thyroid axis and corticosterone acting through the hypothalamic-pituitary-interrenal axis, require confirmation at hormonal and molecular levels. That in amphibians the effect of light at night on circadian regulators remains poorly understood, one cited study finding only slight effects on the melatonin signaling pathway in two anuran species. And that the changes observed are relatively subtle compared with those produced in the same species by thiourea, a recognized endocrine disruptor studied by the same laboratory.

What it does not establish. Anything about human thyroid function or disease. Any hormone concentration in any animal. That artificial light at night is an endocrine disruptor: the authors use the term as the category of their inquiry, not as a conclusion. And nothing on its own quantified measures, all four of which were null. It is one species, one laboratory, one spectrum, one intensity, sixty days, six animals.

Bearing on the statutory question. Narrow. It is a third characterized emission in this subsection, after C.125 and C.126, and the three together establish that researchers in this field now routinely state the spectrum and illuminance of what they apply, which is what paragraph 360ii(a)(4) directs the Secretary to do for the emissions and conditions of exposure actually encountered. Beyond that it contributes only the pairing described above, which is a description of a gap and an occasion for the research paragraph 360ii(a)(2) directs. Part V.I, where it is used; Appendix C.44 for the human counterpart; Part V.J.4 for why that counterpart's exposure measurement cannot answer the spectral question.

C.128 Briolat, Galloway, Cornelius, Wright, Bennie, Gaston and Troscianko (2026) — proposed lighting remedies tested against each other in 843 moths, and each found insufficient

Citation. Briolat E.S., Galloway J.A.M., Cornelius E., Wright C.J., Bennie J., Gaston K.J., Troscianko J. "Severe and widespread reductions in night-time activity of nocturnal moths under modern artificial lighting spectra." Proceedings of the Royal Society B. 2026;293(2063):20252704. doi:10.1098/rspb.2025.2704. Published 28 January 2026. Open access. Read in full from the publisher. Review history published by the journal. All data and code deposited in Dryad; electronic supplementary material at doi 10.6084/m9.figshare.c.8230308.

Funding and interests. United Kingdom Natural Environment Research Council grant NE/W006359/1 and Wellcome Trust grant 220540/Z/20/A. No competing interests declared. No industry funding. The authors state that no artificial-intelligence tools were used in creating the article. Ethical approval from the University of Exeter, application 515517.

Authorship overlap, stated before anything else. Jonathan Bennie and Kevin Gaston are authors of Appendix C.94, the collation of critical fusion frequencies on which the first half of Part V.I rests, and co-authors of the satellite instrument paper relied on at Part V.J.4. The same University of Exeter group therefore appears three times in this comment and the two halves of Part V.I are not independent in authorship. Nothing in the comment presents them as mutual corroboration.

Why this is the strongest entry in the ecological material. Because it is the only study in this comment that tests candidate mitigations against one another at a fixed intensity. Every other entry establishes that an exposure has an effect. This one establishes what happens when the remedies proposed for that exposure are applied, which is the question a standard has to answer.

Design and scale. 843 moths of 23 species in three families, Erebidae, Geometridae and Noctuidae, from 887 collected, 44 excluded for equipment failure or damage. 124 nights, 25 May to 7 September 2023 and 8 May to 16 September 2024, at two locations on the University of Exeter's Penryn campus in Cornwall. Each moth individually in a custom-built chamber outdoors, lit from above, filmed by infrared time-lapse at one frame per ten seconds from the end of nautical twilight to sunrise; activity scored as the percentage of frames in which the animal had moved by at least ten pixels. Up to eight chambers per night, each randomly assigned a treatment, with opaque shields preventing contamination between treatments. Moths marked and released. Collected both by light trap and by hand net, deliberately, to include species of differing attraction to light.

Treatments, as characterized. All at 10 lux at the chamber lid except where stated, calibrated with an open-source spectroradiometer of 0.005 lux sensitivity and a JETI Specbos 1211-UV. A dark control under the open sky; a broad-spectrum white diode at 5,986 kelvin; a narrowband amber diode at 1,621 kelvin; a broadband phosphor-converted amber diode at 1,743 kelvin; two composite lights each made of three narrowband red, green and blue diodes matched to the white and to the broadband amber in human CIE XYZ space to a Euclidean distance below one; and the broadband amber at 1 lux and at 0.1 lux. A further experiment on five species, 83 animals from 85 collected, net-caught only, filmed four hours, tested white at 10, 1 and 0.1 lux and broadband and narrowband amber at 1 lux, in Falmouth and St Neots from August to November 2022.

The natural baseline, measured. Natural night-time illuminance at the field sites, measured 111 times with the same instrument at the moment animals were introduced: median 0.0168 lux, interquartile range 0.0102 to 0.0332 lux. Roughly a sixth of the dimmest treatment and about a six hundredth of the standard treatment. The comment uses this figure at Part V.I and notes its parallel with the question asked at Part V.B.5 about the sources under which human physiology developed.

Analysis. Linear mixed-effects model on square-root-transformed activity with light treatment, capture method, collection location, year, moon phase, mean temperature, mean humidity and Julian day as fixed effects and species and family as random effects; significance by likelihood-ratio test; planned comparisons by Tukey. Repeated as a Bayesian phylogenetic mixed model in MCMCglmm with a Brownian-motion phylogenetic random effect, 13 million iterations, 3 million burn-in, sampled every 5,000, on the 21 species with genomes available. The phylogeny was inferred by maximum likelihood in IQ-TREE2 from a concatenated alignment of 4,976 single-copy orthologous protein sequences drawn from Darwin Tree of Life genome assemblies, all nodes supported at 100 percent by 1,000 bootstrap replicates. The two analyses agreed on treatment, year and Julian day; they differed on capture method, which lost significance once phylogeny was accounted for.

Principal results. Light treatment significantly affected total night-time activity, chi-square 350.95 on 7 degrees of freedom, p below 0.001. Median reduction in activity per species at 10 lux: composite white 93 percent; broad-spectrum white 85 percent; composite amber 82 percent; broadband phosphor-converted amber 73 percent; narrowband amber 57 percent. Broadband amber at 1 lux, 24 percent. All treatments at 10 lux differed significantly from the control in both analyses; broadband amber at 1 lux and 0.1 lux did not, in the main experiment. Between 65 and 100 percent of species, depending on treatment, had lower median activity under light.

The composite-light null, which is a proposed mitigation failing. No significant difference between broad-spectrum lights and the composite red-green-blue lights matched to them for human vision: p equals 0.580 for white against composite white, p equals 0.917 for broadband amber against composite amber. The composite white produced the largest suppression of any treatment. The authors record that this contradicts recent findings in moths and in mosquitoes, and attribute the discrepancy to endpoint: the earlier work measured attraction or flight past light pulses, this work measured continuous exposure, and the attractiveness of a light is not a good proxy for its other effects. The comment relies on that distinction at Part V.I and commends it to the Department as a caution applying equally to human assessment.

Lower intensities. In the second experiment, white light at 10 and at 1 lux significantly reduced activity, both p below 0.01, as did broadband amber at 1 lux, p equals 0.0464. White at 0.1 lux and narrowband amber at 1 lux were not significant overall, p equals 0.246 and 0.214. Species-level comparisons nevertheless showed many species affected at these levels, including under white light at 0.1 lux, which the authors describe as comparable to skyglow.

Results running against the general picture, recorded. Several species increased activity under the dimmest amber light rather than decreasing it. Under broadband amber at 0.1 lux the peppered moth Biston betularia increased activity by 618 percent relative to the control, and Xestia xanthographa, Noctua janthe and Chondrostega trigrammica by 166, 126 and 119 percent. Under broadband amber at 1 lux Biston betularia increased by 240 percent and Noctua janthe by 137 percent. The direction of effect at low intensity is therefore not uniform across species. The comment states this in the body and draws from it that the biological consequences of these lamps are not understood, rather than that dim amber light is safe.

The capture-method finding, which bears on a literature and not only on this paper. A significant three-way interaction between species, capture method and light treatment, F equals 3.583 on 2 and 42 degrees of freedom, p equals 0.0366. Light-trapped Noctua pronuba were on average 46 percent less active than net-caught individuals in the control; in Hypena proboscidalis control activity was on average 89 percent lower in light-trapped animals, so that using trap-caught moths of that species would suggest a smaller effect of white light than net-caught animals do. The authors state the general consequence: using artificial light to collect the animals whose responses to artificial light are then measured can mask the effect under study.

The governing limitation, in the authors' words and adopted without softening. That the moths could not escape the light or seek refuge from it. The authors call for future work measuring activity in more natural conditions and offer in support only the observation, which they label anecdotal, that moths are known to remain at lights for long periods and sometimes through the following day. Until the experiment is performed where the animal can leave, the magnitude of these reductions is a property of the apparatus as well as of the light.

What it does not establish. Any human effect, and no part of the comment's submission requires one. Any fitness endpoint: activity is a proxy, and reproduction, feeding, predation and survival were not measured, so the link to moth population declines is an inference the authors mark as such. Whether light delays the onset of activity, since animals were introduced after astronomical twilight had begun. And nothing beyond 23 common and widespread British species in three families of macro-moths.

Bearing on the statutory question. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, and beyond that the adequacy of remedies. The comment asks the Department to characterize spectral content, quantity, geometry and duration. The standing objection is that spectrum is the variable that matters and that warmer or narrower sources dispose of the question. This is the most direct evidence the Foundation has found that they do not: at a fixed intensity every spectrum tested produced a large effect, the best leaving more than half in place, and a spectrum engineered to avoid non-human sensitivities produced no benefit at all. Part V.I, where it is used; Part V.B.3, on which it bears through the Andalusian narrowband specification; Part V.M, whose part-night lighting material it qualifies; Part IX, for the four-variable request.

An installation switched off and on for seven years, and the one demonstration in this comment that the effect of an emission stops when the emission stops

Every design difficulty recorded in this Part — that the exposure cannot be assigned, that controls are not dark, that confounding by urbanization cannot be excluded, that the dose-response is unknown — is answered in one study by an accident of circumstance. The National September 11 Memorial and Museum operates an installation in New York called the Tribute in Light, and by agreement with a conservation organization its operators extinguish it for about twenty minutes whenever observers on the ground count more than a thousand birds circling in the beams. The exposure is therefore switched off and on, repeatedly, at a fixed location, on nights of heavy migration, by people recording when they do it. Described at Appendix C.150.

What was found. During illumination, birds aggregated above the installation at peak densities more than twenty times the surrounding baseline in every one of the seven years analyzed, more than sixty times in five of them and more than a hundred and fifty times in three; in the absence of illumination the peak never exceeded thirteen times baseline. Across all observations the number of birds within five hundred meters averaged 3.4 times higher when the lights were on. Birds slowed, flew in circles and called far more often. The authors estimate that about 1.1 million birds, with an interval from 0.6 to 1.6 million, were affected by this single light source across seven nights in seven years.

Three features of that result matter more to this comment than its size, and the Foundation takes them in order.

The first is that the effect ended when the emission ended. In the authors' words, removal of illumination produced rapid changes, with birds dispersing, increasing flight speeds, decreasing calling and moving away from the site "in a matter of minutes," and short-term removal "eliminated its disruptive effects almost instantaneously." Appendix C.129 records an assertion by other authors, in a climate journal, that unlike climate change and land use change the effects of light pollution could be mitigated overnight. That was a characterization and the Foundation presented it as one. This is the measurement behind it, and it is the clearest answer in this comment to the

objection that regulating this emission would be a long and uncertain undertaking. For this endpoint the remedy acted in minutes and the instrument of the remedy was a switch.

The second is that the characteristic controlled was duration. Not spectrum, not intensity, not direction. The installation was not dimmed, refiltered or reaimed; it was turned off for twenty minutes at a time. Part IX asks the Secretary to characterize four attributes of this emission and duration is the one this study isolates, which is worth stating because the comment has had to record at Part V.I that spectral mitigation is partial and at Part II.D.4 that shielding addresses only the directed fraction. Here a temporal control removed the effect entirely, and the authors recommend exactly that: selective removal of light on nights of substantial migration.

The third is what the conditions were. The effects appeared under clear skies, which the authors emphasize because the previous literature associated bird-and-light incidents with fog, low cloud and poor visibility; and they appeared in Manhattan, which is to say against one of the most heavily lit backgrounds in the world. A single installation produced a twentyfold aggregation on top of that background in good weather. The objection that these effects require unusual conditions, and the objection that one more light source cannot matter where there is already so much light, are both answered by the same observation.

Two further findings and then the limits. The behavioral response was detected at radar sampling altitudes of 2.4 to 4.1 kilometers and the authors describe responses up to about four kilometers above the ground, stating that to their knowledge no previous study had reported attractive effects of ground-based lights extending far above the ground. And their simulation could reproduce the observed concentrations only by including directed flight toward the light by disoriented birds, which distinguishes attraction from mere failure to leave.

The limits, and the Foundation states them because the study is used for an argument about remedies. No bird was counted dead and no collision was observed; mortality is not an endpoint of this study and the comment does not assert one. The subject is nocturnally migrating birds, predominantly small songbirds, which is as far from a person as most of this appendix. The installation is extraordinary and the authors say there are few of comparable intensity in the United States, naming one in Las Vegas, so the magnitudes here do not transfer to ordinary street lighting; what transfers is the shape of the response and the reversibility. One year was excluded from the on-and-off comparisons because the lights were not shut down, and two further years were excluded for rain. And, as Part V.J.4 records, the study reports no optical quantity for the source at all.

A publication of a United States federal agency, which organizes the whole subject around the question this comment begins with

Longcore T. and Rich C., Artificial Night Lighting and Protected Lands: Ecological Effects and Management Approaches, Natural Resource Report NPS/NRSS/NSNS/NRR 2017/1493, National Park Service, Fort Collins, Colorado, revised August 2017. Described at Appendix D.1. Seventy pages, published by the Natural Resource Stewardship and Science office of the National Park Service, United States Department of the Interior, and stated by the publisher to have received formal peer review by subject-matter experts not involved in the work. The authors are outside the agency and the report carries the agency's standard disclaimer that its views do not necessarily reflect those of the Service or the Department. The Foundation states all of that because what follows is a federal publication and the comment elsewhere records federal engagement with this subject largely as absence.

The report reviews effects by habitat type and then sets out how mitigation is to be approached. It is guided, in the authors' words, in five ways, and the Foundation asks the Department to notice the order. The first is not spectrum, not intensity and not shielding. It is Need: "The first question that should be asked about artificial lighting, especially in natural areas, is whether it is in fact needed," and "Only when the need is demonstrated and necessary for visitor experience, safety, or security, should lights be installed." The remaining four are spectrum, intensity, direction and duration, which are the four emission characteristics Part IX asks the Secretary to characterize.

A federal agency therefore published, in 2017, a framework whose first element is whether the light is necessary at all and whose other four are the characteristics this comment asks to have specified. The Foundation does not suggest that the National Park Service was construing paragraph 360ii(a)(2), which it was not, and does not rely on the coincidence for anything legal. It records that the structure of the statutory duty and the structure a federal land agency arrived at from the biology are the same structure.

And two sentences in it about the lighting industry's own standards, which the Foundation did not expect to find in a federal publication

Under Intensity the report states: "Guidelines for lighting intensity from the lighting industry should not be followed when trying to reduce impacts to wildlife, because they are usually higher than necessary for human vision and do not take into account impacts to wildlife." And in the body of the same section: "Land managers should not rely on standards promulgated by professional societies to guide lighting levels for natural areas because these are generally developed for urban/suburban areas with little to no regard for wildlife."

The Foundation reads those narrowly and says so. They are addressed to land managers in natural areas, not to anyone else, and the second clause of the first sentence is the operative one: the objection is that the guidelines take no account of wildlife. But the first clause is not about wildlife at all. It says the levels are usually higher than necessary for human vision, and the report explains why that is so rather than asserting it: the eye adapts to the brightest light in view, bright lights plunge their surroundings into shadow, and reducing the contrast between lit and unlit areas increases what a person can see. That is a federal publication stating that the recommended practice of the lighting industry specifies more light than human vision requires, supported by an argument about human vision. Part V.C and Part VI treat the status of voluntary professional standards in this field, and this is the only United States government document the Foundation has found that tells a reader not to follow them.

Three further statements, two of which run against the direction a reader might expect

On spectrum, the report is as careful as this subsection has had to be. "It is tempting to believe that a certain spectrum of light will minimize the effects of lighting in all situations. Unfortunately, no universal solution exists." And: "The only 100% wildlife-friendly light is one that is switched off or never installed." That is the fourth source in this comment to say that one spectral rule will not serve every taxon, and the second to say it in a government publication.

On shielding, the report supplies both a definition and a limit. The definition: a full cutoff fixture emits little or no light above the horizontal plane and less than ten percent within ten degrees below it. The limit, which Part II.D.4 reaches by arithmetic from the reflectance of surfaces and which is here stated directly: shielding in that manner "greatly reduces (but does not eliminate) sky glow. Light still reflects off the ground and scatters, so reduction in intensity should be combined with shielding." The report adds that downward-directed light may still attract insects and the species that feed on them, and may still fall into sensitive habitat.

And on duration, a caution against the remedy that Appendix C.150 shows working. The report recommends motion detectors and curfews and then qualifies them: reducing duration "reduces some impacts, but it may have some adverse consequences for those species sensitive to a changing light environment," and lights that switch on and off at irregular intervals may themselves disrupt nocturnal behavior. The Foundation records that beside the Tribute in Light result rather than in place of it. A twenty-minute shutdown of a fixed installation on nights of heavy migration and a motion detector that fires unpredictably all night are both temporal controls and they are not the same intervention.

One pro-technology statement is recorded with the others. The report states that light-emitting diodes have no ultraviolet emissions and therefore attract fewer insects than lamps of comparable

intensity and color temperature that do, which is consistent with the figure of less than a tenth recorded at Appendix D.1 from the same author's trade essay of the following year.

A mammal, and a lamp sold for the purpose that did not work

The study at Appendix C.146, set out at Part V.J.4 for what it establishes about measurement, carries a finding that belongs here. Among its two treatments was a yellow compact fluorescent bug light emitting only between 550 and 650 nanometers, which is the long-wavelength narrow-band remedy this subsection has been examining. It was not a null result. Foraging by an endangered nocturnal rodent was significantly suppressed out to forty meters from that lamp, against fifty meters for a broad-spectrum white flood light of more than twice the rated output, and the difference between the two lamps was not statistically significant. The authors state the point in their own words: even low-intensity yellow bug lighting significantly affects the animal's energetics through alteration of its foraging decisions.

Three things follow and the Foundation separates them. The first is that this is a mammal. The settled position stated above rests on studies in insects, molluscs, fish and birds, and the most obvious objection to it is that the taxa are remote from a person. A heteromyid rodent is not. The second is that the authors note, citing the 2018 rapid-assessment paper described at Appendix D.6, that the prediction in the literature is that yellow and amber sources will have less impact, and that their result does not bear that out at this endpoint. That is now the second experiment in this comment, after the moth study, in which a spectral remedy performed worse than the prediction, and the first in a mammal.

The third is a qualification the authors state and the Foundation adopts rather than argues around: the experiment did not disentangle intensity from spectrum. The two lamps differed in rated output, in spectrum, in shielding and in diffusion, so the comparison between them does not isolate wavelength. What the study establishes is that a lamp marketed as the gentle option, at less than half the rated output of the other, produced a significant effect over four fifths of the distance. It does not establish that the spectrum was irrelevant, and the Foundation does not say so. The authors offer a mechanism that cuts the other way and it is recorded at the appendix entry: nocturnal rodent spectral sensitivity is reported to peak between 350 and 370 and between 490 and 520 nanometers, the second of which the white lamp reached and the yellow lamp did not.

C.129 Johnston, Kim and Harris (2025) — artificial light at night and ecosystem carbon metabolism across eighty-six flux towers

Citation. Johnston A.S.A., Kim J., Harris J.A. "Widespread influence of artificial light at night on ecosystem metabolism." Nature Climate Change. 2025;15:1371–1377. Published 12 November 2025. Open access. Read in full from the publisher. Authors at the Cranfield Environment Centre, Cranfield University.

Funding and interests. United Kingdom Natural Environment Research Council grant NE/W003031/1. No competing interests statement was located in the text read. Derived data and the analysis code are deposited at Figshare, doi 10.6084/m9.figshare.29958455; the underlying half-hourly flux data are not redistributable under the FLUXNET data policy.

Why this entry is in the appendix, stated first and against the ordinary reading. Not for its finding. This is a carbon-cycle paper in a climate journal, and the comment does not rely on its conclusion about ecosystem respiration for any purpose. It is here because its authors, whose entire analysis depends on satellite nighttime light measurement, state among their own limitations that the instrument cannot see the emission this comment is about and that their exposure variable cannot be converted into a physical unit. That is the use made of it at Part V.J.4, where it is the fifth such statement. A reader who expects the Foundation to cite a Nature Climate Change headline about carbon feedbacks should note that the Foundation declines it.

Design. Observational, cross-continental. The harmonized global nighttime light dataset of Li and others, which intercalibrates Defense Meteorological Satellite Program-like digital numbers

into an annual series from 1992 to 2018 at about one kilometer, was combined with eddy covariance carbon flux observations from the FLUXNET2015 network. Three fluxes: net ecosystem exchange, gross primary production and ecosystem respiration. Three timescales: half-hourly, daily mean and annual. Fluxes were first referred to a baseline of their shared physical constraints, temperature and incoming shortwave radiation, through a modified Arrhenius function used as a comparative baseline and not as a mechanistic model.

Sites. Eighty-six FLUXNET2015 sites from the 203 for which light values were extracted: thirty-four in North America, of which four at high light intensity, five medium and twenty-five low; and fifty-two in Europe, of which thirteen high, seventeen medium and twenty-two low. 623 site years between 1992 and 2014. The authors state that flux tower locations are biased toward dark sky regions and that only North America and Europe contained more than one high-intensity site. Analysis was restricted to latitudinal bands containing medium or high intensity sites to limit climatic confounding.

Analysis. Linear mixed-effects models with site and latitude as random effects, tested incrementally against about eighteen candidate explanatory variables under thresholds requiring both a fall in Akaike information criterion and a rise in marginal R-squared per degree of freedom. Then generalized additive mixed models with tensor product interactions, selected backward on penalized likelihood, adjusted R-squared, deviance explained and approximate significance of smooth terms, with terms showing concurvity above 0.8 treated as redundant, and compared against variance-weighted versions to address heteroscedasticity. Then a piecewise structural equation model at annual scale on 605 site years across 84 sites, with mediation estimated by 1,000 nonparametric bootstrap replicates and a leave-one-out sensitivity analysis. Half-hourly datasets ran to between four and ten million observations and 10 percent random subsamples were used for bootstrapped fit statistics.

Findings. At annual scale, light intensity influenced net ecosystem exchange indirectly, through increased ecosystem respiration, rather than by suppressing gross primary production, which showed no direct response and was instead associated with growing season length and distance to the nearest urban area. Respiration responded more strongly and more consistently across timescales. All three fluxes retained a significant nonlinear interaction between light intensity and night duration at half-hourly and daily scales. A leave-one-out analysis found that removing light intensity significantly degraded model performance. A balanced sensitivity analysis using four sites per intensity stratum per continent, twenty-four sites in total, retained the core structure and strengthened the coefficients linking light to respiration and respiration to net exchange.

The exposure measurement, which is the weakest in this appendix. The authors state that the satellite digital numbers “represent relative radiance indices and cannot be directly converted into absolute illuminance units such as lux, as they do not capture spectral composition or ground-level variability”, and that the resulting categories “should thus be interpreted as relative exposure gradients rather than specific ecological thresholds”. They further state that the satellite products “are insensitive to blue light emitted by white light-emitting diode (LED) lighting”. The exposure is therefore not merely spectrally blind, as at Appendices C.3 and C.44, but unitless. No quantity in this study can be referred to any level of light at any ground surface.

Why the comment does not rely on the carbon finding. Five reasons, and the Foundation would state them even if the conclusion suited it. The exposure variable is an uncalibrated index, as above. Light intensity is a proxy for urbanity, and although the authors include distance to the nearest urban area and the proportion of urban land cover within three and ten kilometers, the model contains nothing for nitrogen deposition, ozone, particulate deposition, soil disturbance, management history, species composition or the urban heat island, each of which could raise respiration near cities for reasons unconnected with light. The authors acknowledge that present observational data do not permit the contribution of artificial light to be disentangled from that of sunlight. The direction of the principal interaction reverses with

temporal aggregation: respiration rose most with light during short nights in the half-hourly models and during long nights in the daily models, which the authors present as a lesson about aggregation and which means the sign of the interaction is not stable to an analytic choice. And the high-intensity arm rests on four sites in North America and thirteen in Europe, with the balanced analysis on twenty-four sites in all, against a selection pipeline of great flexibility applied to millions of observations, in which statistical significance is close to automatic.

Two statements the comment does take, neither of them the finding. First, the instrument admission set out above, used at Part V.J.4. Second, a statement about reversibility which the Foundation regards as the most useful sentence in the paper for Part IX: that unlike climate change and land use change, the effects of light pollution could be mitigated overnight. That is an assertion rather than a result, and the comment presents it as the authors' characterization and not as a finding; but it is a characterization published in a climate journal by authors whose subject is carbon feedbacks, and it bears directly on the proposition at Part IX that measures addressed to this exposure are available now and are reversible if wrong.

A third matter, recorded for verification rather than use. The paper states, citing a United Nations Environment Programme report of 2013, that lighting accounts for 20 percent of global electricity consumption and 6 percent of carbon dioxide emissions. Those figures are at second hand and the source is more than a decade old, predating most of the conversion to light-emitting diodes, so they are likely to have fallen. They are recorded because quantified waste bears on the statutory adjective at Part II.D.3 and not because the comment relies on them. Obtain the current figures from the International Energy Agency or the Department of Energy before any use.

What it does not establish. Any human health effect, and it does not address human health. Anything about light-emitting diode products, by the admission of its own authors. Any effect at a stated illuminance, radiance or wavelength. And, on the Foundation's reading, the carbon conclusion itself, which requires the experimental work the authors call for.

Bearing on the statutory question. One use and one only. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This entry establishes, from a paper that depends on the measurement, that the national and international measurement of this emission is unitless and blind to the wavelengths at issue. Section 360kk requires that a performance standard prescribe an emission characteristic. A quantity that cannot be stated in a physical unit cannot be prescribed. Part V.J.4, where it is used; Part IX.C, for the research request; Part IX.I, for why the standard cannot presently be written in the terms the available data supply.

C.130 Team Nachtlichter (2025) — 234,044 light sources counted and classified by hand, and what the satellite was hiding

Citation. Team Nachtlichter. "Citizen science illuminates the nature of city lights." Nature Cities. 2025;2:496–505. Published 16 June 2025. Open access. Read in full from the publisher. The authorship is collective as published; the corresponding project is Nachtlicht-BüHNE, the Citizen-Helmholtz Network for research on night light phenomena. Processed data and analysis code at GFZ Data Services, doi 10.5880/GFZ.1.4.2024.006; raw data downloadable from the app itself.

Funding and interests. Helmholtz Association Initiative and Networking Fund grants CS-0003 and ERC-RA-0031; Horizon 2020 grant 689443 via GEOEssential; German Federal Ministry of Education and Research grants 01BF2202A and 01BF2202C and a citizen-science research prize. Open access funding from GFZ Helmholtz Centre for Geosciences. No competing interests statement was located in the text read.

What it is. A complete hand inventory of visible outdoor light sources within defined satellite pixels, performed by citizen scientists using a purpose-built application. Not an exposure study,

not a health study, and not radiometry. The comment uses it for the composition of the light environment and for the limits of satellite measurement.

Method and scale. Autumn 2021, principally 23 August to 14 November. 258 registered participants; 3,868 transects, usually one street corner to the next; 4,409 surveys, some transects surveyed more than once; 234,044 individual light sources classified into eighteen categories; about twenty-two square kilometers in thirty-three communities, twenty-four of them in Germany. About 600 kilometers walked over more than 500 hours. Transects were laid out to cover completely the publicly accessible area of reprojected pixels of the satellite day-night band. Mandatory online training. 181 analysis areas, usually one pixel each. A logistic correction was fitted to extrapolate counts to 19:00 and to midnight for the five categories that demonstrably switch off during the night.

Validation. Streetlight counts were compared against municipal databases: agreement better than seven percent in Berlin, Cologne and Dresden; hand counts forty and ninety percent higher in Fulda and Leipzig, because they captured streetlights on private roads that the public databases omit. Between-observer variability on the two most frequently surveyed streets was fifteen percent for observations between 19:30 and 21:30, and the authors note that ten to twenty percent variability is comparable to the month-to-month variability of the satellite sensor. Counts were more consistent for streetlights than for signs and windows, where participants estimated sizes.

The composition finding. Private windows were the most frequently observed light source, ahead of streetlights and commercial windows. In dense urban land cover, lights used for advertising outnumbered streetlights, with roughly one illuminated sign and one commercial window per streetlight in the early evening. Late at night the streetlight share rises as signs and windows extinguish, but streetlights remained outnumbered by other sources by a factor of about five to seven in dense areas. Extrapolated nationally: approximately 78 million light sources plus or minus 3 million illuminated at midnight across mainland Germany, and 2.52 million plus or minus 0.11 million in Berlin, against published estimates of nine to nine and a half million public streetlights in the country.

Shielding, color and brightness. German streetlights: 48 percent fully shielded, 49 percent partially. Pathway lighting far more frequently unshielded. Lights mounted on the sides of buildings: 29 percent fully shielded, 26 percent unshielded. Floodlights: 58 percent unshielded, which the authors state implies upward rather than downward lighting, rising to 70 percent in continuous urban fabric. Color: canopy lights 88 percent white; streetlights the category most often classified orange, at 46 percent. Brightness: 24 percent of bollards reported bright, read by the authors as indicating glare or mismatch with surroundings; over a quarter of signs in commercial and industrial areas reported exceptionally bright. Presence detection controlling at least one light on a transect was more common in dim villages and suburbs, 29 percent, than in continuous urban fabric, 15 percent, or industrial and commercial areas, 11 percent.

The glare sentence the comment relies on. That the reported brightness of signs is consistent with earlier research finding signs often much brighter than recommended or appropriate, and that this “may reflect a need to update regulations about glare as the existing guidelines predate the use of highly luminous LEDs by several decades.” This is the proposition Part VI.J.6 argues, attributed for the first time in this comment to a source other than the Foundation.

What the authors tried and could not do. They attempted to derive per-light-type weights representing each light type’s contribution to overhead radiance, by minimizing a cost function against three datasets: the satellite day-night band at 750 meters, SDGSat-1 imagery at 10 meters, and aerial photographs at about one meter. To make the fit tractable the 370 combinations of light type and characteristic were reduced to 22 parameters. It failed in every case: the returned parameters were unphysical, for example assigning larger weights to small signs than to large ones and large weights to traffic lights, and the authors state that regardless of

what they tried the procedure never returned physically meaningful results. They attribute this to the absence of radiometric information in the observations and to the effect of building heights and street widths on how readily light escapes upward.

The translation factor, and its limits. Median relationship across 181 analysis areas: one nanowatt per square centimeter per steradian of satellite radiance per 317 counted lights per square kilometer. Treating all observations as one area: 302. For Germany with the temporal correction applied: 385 plus or minus 16 at 19:00 and 219 plus or minus 11 at midnight. For the areas surveyed outside Germany: about 120. Spearman correlation between radiance and total lights per square kilometer was 0.67, and positive for seventeen of the eighteen light types, garden decoration lights alone being negative. The relationship is a bulk statistical one, is country-specific on the authors' own account, and converts radiance into a count of lamps rather than into any quantity describing what reaches a person.

Two matters of federal and foreign regulation recorded from it. The paper states that a 2017 report of a Department of Energy national laboratory concluded that widespread conversion to light-emitting diode street lighting was likely to decrease skyglow, and that measurements over 2011 to 2022 indicate an increase of roughly ten percent a year, the authors concluding that it is at least clear that existing policy results in increasing light growth. The ten percent figure derives from citizen-science observations of star visibility rather than from radiometry, and stands against about two percent a year from late-night satellite observation over a similar period. And the paper supplies the correct citation of the French instrument the comment has been pursuing: an arrêté of 27 December 2018 on the prevention, reduction and limitation of light nuisances, described as requiring advertising lighting to be switched off when pedestrians are unlikely to be present and interior lights when buildings are not occupied. Both are used at Part V.J.4.

What it does not establish. Any health effect. Any radiometric quantity: a count is not a measurement of emission, and the brightness categories are participants' judgments, the authors noting that signs of twenty and of a hundred candelas per square meter would both likely be recorded as normal in a bright area. Anything outside Germany, the radiance relationship being specific to it on the authors' own statement. Anything about areas with high-rise buildings or private industrial parks, which were not surveyed. A complete inventory: lights not visible from public space, in back yards, courtyards and on rooftops, were not counted. And nothing about vehicle headlamps, whose contribution the authors describe as unknown.

Bearing on the statutory question. Paragraph 360ii(a)(4) directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This entry is the closest thing the Foundation has found to a characterization of the emission sources of a national light environment, and it was produced by volunteers in one country over one autumn. No American counterpart exists. Its composition finding also bears on the product taxonomy at Part VI.A and on the weight the comment gives roadway lighting at Part VI.D relative to signage at Part VI.J. Part V.J.4, where it is used; Part IV.G for the federal prediction; Part IX for the two foreign instruments.

C.131 Wang, Meng, Richardson, Hölker, Li, Mao, Longcore, Xia and She (2025) — light at night outweighs the urban heat island in lengthening the growing season across 428 cities

Citation. Wang L., Meng L., Richardson A.D., Hölker F., Li H., Mao J., Longcore T., Xia J., She D. "Artificial light at night outweighs temperature in lengthening urban growing seasons." Nature Cities. 2025;2:506–517. Published 16 June 2025. Open access. Read in full from the publisher. A correction was published on 30 June 2025 altering a value in Extended Data Table 2 from minus 7.1 to plus 7.1; the corrected version must be cited.

Data, code and interests. Data at Zenodo record 15495270; preprocessing code on Google Earth Engine and analysis scripts on GitHub. Underlying products are all public: VIIRS day-night band monthly composites, a global one-kilometer daily air temperature dataset, the VIIRS

Global Land Surface Phenology product VNP22Q2, MODIS land cover, a global urban boundary product, a global artificial impervious area product and the Köppen-Geiger climate map. No competing interests statement was located in the text read.

Why the comment uses it. For one comparison and one lead. The comparison is with the urban heat island, which is the only instance in this comment of this exposure being weighed against another environmental stressor. The lead is the pathway its authors identify from a phenological shift to pollen allergy and asthma, which is the first route from this exposure to a clinical endpoint in the ecological material.

Design. Observational, spatial-gradient. 428 Northern Hemisphere cities, 2014 to 2020, each divided into ten concentric bands by impervious surface area index at intervals of 0.1, the first band the outermost rural area and the tenth the urban center, with kernel density smoothing applied to the index. Four quantities measured in each band: satellite light at night, near-surface air temperature, the date of onset of greenness increase in spring, and the date of onset of greenness decrease in autumn. Light averaged over January to March for the spring analysis and July to September for the autumn; temperature over fixed forty-day preseason windows, with three alternative windows tested. Cities selected at over 100 square kilometers with rural areas extended outward to balance areas. Curve fitting by quadratic polynomial for phenology and temperature and logistic growth for light. Drivers separated by partial correlation, each computed holding the other constant, with Fisher Z transformation testing whether the two coefficients differed in each city. Validated against a thirty-meter urban phenology product for 62 cities in the continental United States, both including and excluding developed open space.

The gradient. Across the ten bands, light at night rose from 3.1 plus or minus 0.1 to 53.3 plus or minus 0.6 nanowatts per square centimeter per steradian, an increase of about seventeenfold, the rise being exponential with about half of it occurring between the seventh and tenth bands. Air temperature rose from 10.7 plus or minus 0.1 to 11.5 plus or minus 0.1 degrees Celsius, a concave quadratic rise of eight tenths of a degree with about half occurring between the first and second bands. The urban minus rural differences were 25.5 nanowatts in spring and 20.1 in autumn for light, against 0.3 and 0.5 degrees for temperature. North American cities were the brightest of the three continents examined, at 30.1 nanowatts in spring against 23.6 for Europe and 20.8 for Asia.

Phenology results. 378 of 428 cities, 88.3 percent, showed the consistent pattern of earlier spring onset and later autumn senescence toward the center. Spring onset advanced from 94.4 plus or minus 0.4 to 81.8 plus or minus 0.3 day of year across the ten bands; autumn senescence extended from 227.6 plus or minus 0.3 to 238.8 plus or minus 0.3. Urban minus rural: spring onset 6.4 plus or minus 0.2 days earlier, autumn senescence 7.1 plus or minus 0.2 days later. The thirty-meter validation reproduced the pattern at smaller magnitude and survived exclusion of lawns and other developed open space.

Attribution, which differs between the two ends of the season. Spring onset: partial correlation with light minus 0.37 plus or minus 0.31, with temperature minus 0.33 plus or minus 0.35. Of the 279 cities in which the two coefficients differed significantly, light was dominant in 135 and temperature in 144. The two are comparable. Autumn senescence: partial correlation with light plus 0.38 plus or minus 0.28, with temperature minus 0.03 plus or minus 0.39. Senescence was positively correlated with light in 310 cities, 72.7 percent, while its relationship with temperature was inconsistent in direction, negative in 134 cities and positive in 118. Across the seven climate zones the light coefficient averaged 0.49 and the temperature coefficient 0.003, light outweighing temperature in every zone at p below 0.01. Results held when daily maximum and minimum temperatures were substituted, when an interaction term was added, and in the thirty-meter validation. The comment therefore reports the title as holding for autumn and not for spring.

Latitude and climate. Below 48 degrees north both phenological metrics were more sensitive to light than to temperature. Above it, spring onset was more responsive to

temperature while autumn senescence remained more responsive to light. The correlation between senescence and temperature changed sign with increasing latitude. Temperature had greater influence on spring onset than light in arid zones, which the authors attribute to water stress.

The human pathway the authors identify. That earlier leaf-out and later senescence driven by light may increase the risk of frost damage in early spring and late autumn, disrupt plant and pollinator interactions, and lead to an earlier occurrence of pollen allergy symptoms. For the last they cite Sapkota and others, on the association between changes in the timing of spring onset and asthma hospitalization in Maryland, published in JAMA Network Open in 2020. The comment treats this as a lead requiring acquisition and not as a finding; the three links are each measured but no study joins them, and in particular no study has examined whether light at night is associated with pollen season timing or with allergy or asthma presentations.

The exposure measurement, and a refinement specific to plants. The same instrument criticized at Part V.J.4. The authors state its spectral range as 500 to 900 nanometers and call for a sensor capable of capturing a broader spectrum, particularly in the blue. They add a point the comment had not previously recorded: plants sense light through several photoreceptor families, phytochrome responding to red and far-red between roughly 620 and 1,000 nanometers while phototropins and cryptochromes respond mainly to blue. The satellite band therefore covers much of the phytochrome range and is blind to the blue range. Their defense of their own analysis is that the conversion to light-emitting diodes probably occurred at about the same time across each urban region, so that the resulting spectral change is roughly common across the bands of their gradient; the comment records this as an assumption which the authors state as one and do not test. This is the sixth such attestation in the comment.

What it does not establish. Any human health effect; the outcome is satellite-observed vegetation greenness. Causation: the design is spatial and observational, and light and temperature both rise toward a city center along with many variables the model does not contain. The authors address species composition, noting that cities carry more non-native plantings, and validate against a higher-resolution dataset with lawns excluded; they do not address carbon dioxide, ozone, nitrogen oxides, particulate deposition, soil compaction, irrigation or drainage, all of which vary along the same gradient. Partial correlation separates light from temperature and from nothing absent. And the Foundation records a criticism of its own: the two variables compared differ grossly in range across the gradient, light varying about seventeenfold and temperature by less than a degree, and a comparison of correlation magnitudes between variables of such unequal range is not straightforwardly a comparison of importance. The authors do not address this.

Authorship, and recurrence. Franz Hölker is a co-author of the cloud-amplification work cited at Part II and of the satellite instrument paper relied on at Part V.J.4. Travis Longcore is the author of three papers recorded elsewhere in this comment as acquisitions: the 2015 paper proposing the composite spectral approach that the moth study at Appendix C.128 tested and failed to confirm, a 2018 paper on rapid assessment of lamp spectrum, and a 2023 compendium of photopigment peak sensitivities for terrestrial wildlife. The comment does not present this entry as independent of those.

Bearing on the statutory question. Two grounds. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, for which this is evidence about an emission. And paragraph 360ii(a)(2)'s direction that the Secretary plan, conduct, coordinate and support research: the comparison with the urban heat island supplies a reason to begin, and the pollen pathway supplies an unusually tractable question, since the exposure is already measured nationally by satellite, pollen counts are already collected and asthma presentations are already recorded. Part V.I, where it is used; Part V.J.4 for the instrument; Part IX.C for the research request.

C.132 Fabusova, Gaston and Troscianko (2024) — a single pulse of headlamp-intensity light replaces the escape response in 428 moths, and the composite spectrum helps

Citation. Fabusova M., Gaston K.J., Troscianko J. "Pulsed artificial light at night alters moth flight behaviour." Biology Letters. 2024;20(11):20240403. doi:10.1098/rsbl.2024.0403. Published 13 November 2024, in the journal's Conservation special collection. Open access. Read in full from the publisher. Review history published by the journal. Data and R script in the electronic supplementary material, Figshare collection doi 10.6084/m9.figshare.c.7524698.

Funding, interests and relationship to Appendix C.128. Natural Environment Research Council grant NE/W006359/1, which is the same grant that funded the study at Appendix C.128. No competing interests declared. The authors state that no artificial-intelligence tools were used. Kevin Gaston and Jolyon Troscianko are authors of both studies, which were conducted at the same site in Cornwall; the acknowledgements here thank Briolat and Galloway, the first and second authors of C.128, for fieldwork and light calibration. The two studies are not independent and the comment does not present them as such. They are used as a matched pair reaching opposite conclusions on the same remedy.

Why this entry matters. Two reasons. It is the only entry in this appendix applying an ecological method to vehicle lighting, which is the product class of Part VI.B. And it is the counterpart to Appendix C.128 on the composite-spectrum question: tested against a brief intense pulse the composite spectrum helped, while tested against continuous exposure at ten lux it did not, and the reason for the difference is the finding the comment relies on most.

Design. 428 wild-caught moths of 64 species in seven families, each tested individually. June to September 2023, at night, Tremough Campus, Penryn, Cornwall. Moths were caught by hand net under a red headtorch along five pre-determined transects sampled in random order for ten minutes each, beginning half an hour after sunset, expressly to avoid the sampling bias of light traps; they were then held in an unlit pot for at least ten minutes to dark-adapt. Each animal was released while exposed to a single ten-second pulse at one meter, or 1.06 meters for the control, and tested in the same area and ambient light where it was caught. The first behavior was recorded by observation under a red headtorch, from five categories established in a pilot of 72 animals: erratic flight, flight into the light, downward flight and shelter-seeking, upward flight with return to normal activity, and no response. Trials ran two minutes.

Treatments, as characterized. Four, matched in correlated color temperature and intensity to human vision by metamers, with residual brightness differences corrected by adjusting distance, and measured with a JETI Specbos 1211-UV spectroradiometer: cool phosphor-converted diode 5,664 kelvin at 454.9 lux; warm phosphor-converted diode 3,102 kelvin at 429.7 lux; cool composite red-green-blue diode 5,661 kelvin at 433.5 lux; warm composite 3,222 kelvin at 463 lux. Group sizes 100, 92, 98 and 96, with a dark control of 42 not balanced across treatments and handled statistically. The illuminance is of a different order from the other ecological entries in this comment, which used under 1 lux to 30 lux; the authors state that headlamp beams are typically an order of magnitude more intense than static street lighting.

Analysis. Linear and generalized linear mixed-effects models with binomial error, species and family as random factors, checked for overdispersion. Temperature, humidity, wind speed and moon phase as additive fixed effects; only temperature and humidity predicted response and were retained. Interactions between color temperature and spectrum were fitted and simplified to minimal adequate models. Three comparisons: erratic flight against other behavior, n equals 386; erratic flight and flight into the light combined against other behavior, n equals 386; and upward against downward flight, n equals 199. Latency log-transformed. All analyses repeated separately for the four most abundant families.

Results. Against darkness: 86 percent of control moths flew directly upward, which the authors read as the normal escape response, against an average of 37 percent after a light pulse. Erratic flight alone: most frequent under the cool phosphor-converted diode but not significant

on any test, color temperature, spectrum and their interaction each at a probability of 0.350. Flight into the light: significantly predicted by color temperature, more frequent under cool lights of either spectrum, probability 0.002; spectrum alone not significant at 0.104. The two combined: significant interaction between color temperature and spectrum, probability 0.006, most pronounced under the cool phosphor-converted diode, with harmful responses 1.8 times more likely under that lamp than the other three and 25.5 times more likely than in darkness. Latency: mean 21.45 seconds with a standard deviation of 26.50; fastest under the cool phosphor-converted diode by about twelve seconds, the interaction near-significant at 0.06 but each factor highly significant alone. Upward rather than downward flight was more frequent under warm lights but neither factor was significant. Moon phase predicted nothing. No taxonomic differences were detected across the four main families, which the authors contrast with family-level biases reported for attraction to static lights.

The insect pupillary mechanism, recorded for its parallel. The authors set out why a pulse should affect an insect differently from a person. A vertebrate pupil constricts in roughly one second. Insects adapt instead by migrating screening pigment granules within the optical units, radially in apposition eyes and longitudinally in superposition eyes, a process which can take over thirty minutes to return to a dark-adapted state and which has been found to operate more slowly at night than by day. The spectral response of this mechanism varies among closely related hawkmoth species and among individuals of one species. The comment records this at Part V.I as a parallel to the human glare-recovery material at Part V.C.3, expressly as a parallel and not as evidence about human recovery.

The authors' closing proposition about human beings. Noting that the blue peak of phosphor-converted diodes has been associated with decreasing alertness in older drivers, the authors write that they can speculate that reducing the blue peak in car headlights will likely be associated with beneficial changes to road safety for moths and humans alike, and that it would be beneficial to avoid continued use of cool phosphor-converted diodes in headlamps. The comment reports this as the authors framed it. It is speculation, so labeled; it is outside the authors' field; and it rests on two cited sources on human pupillary response and alertness which the Foundation has not read and which are recorded as acquisitions. It is not evidence about human drivers. Its value is that the proposition is reached by investigators with no connection to the Foundation or to the American regulatory dispute, in the course of reaching a different conclusion about a different taxon.

What it does not establish. The light did not move: the authors state that the source was static and the pulses were intended to simulate a passing headlamp at close range, whereas a real headlamp approaches, brightens, sweeps and recedes with noise and air movement. A single pulse was used, where a roadside animal receives many. Only the first behavior within two minutes was recorded; no measure of survival, reproduction, collision or energy expenditure was taken, and harm is inferred from the character of the response. The animals were handled, and the authors list an escape response to handling among mechanisms that could confound or supersede the others. The mechanism was not determined and the authors state that behavioral data cannot determine it. Red light was used for capture and observation, and the authors note that red sensitivity cannot be ruled out in moth taxa other than hawkmoths. The control arm was 42 animals and unbalanced. And the erratic flight result that the abstract leads with was not significant on its own.

Bearing on the statutory question. Three. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, for which this is evidence about a characterized emission of a product class. Paragraph 360ii(a)(4), which directs the Secretary to study and evaluate emissions and conditions of exposure: this study makes the duration and the pulsed character of an exposure the variable of interest, which no other entry in this appendix does. And the form of a performance standard: read with Appendix C.128 it establishes that the value of a spectral prescription depends on the exposure regime, so that a standard prescribing a spectrum without

specifying the regime cannot be assessed. Part V.I, where it is used; Part VI.B; Part V.C.3 for the pupillary parallel; Part IX for the standard-drafting point.

C.133 Atchoi, Mitkus, Machado, Medeiros, Garcia, Juliano, Bried and Rodríguez (2024) — shearwaters chose darkness over white light and red over blue, in an exposure specified in the bird's receptor space and in human lux, which disagreed by a factor of 1.6

Citation. Atchoi E., Mitkus M., Machado B., Medeiros V., Garcia S., Juliano M., Bried J., Rodríguez A. "Do seabirds dream of artificial lights? Understanding light preferences of Procellariiformes." Journal of Experimental Biology. 2024;227(19):jeb247665. doi:10.1242/jeb.247665. Received 1 March 2024, accepted 2 September 2024, accepted manuscript 25 September 2024, version of record 10 October 2024.

How it was read, which qualifies everything below. The bibliographic detail, methods and results were read from the publisher. The publisher page available to the Foundation truncates in the middle of the Discussion, and the remainder was read in the authors' own bioRxiv deposit, doi 10.1101/2024.03.01.582998, dated 1 March 2024, which matches the journal's received date. That deposit precedes peer review. Every quotation and figure in this entry drawn from the Discussion is marked for verification against the version of record, and the version of record governs on any difference. The Foundation also records that the study reached its attention through a secondary research highlight in the same issue, Knight K., Journal of Experimental Biology 2024;227(19):jeb249593, doi 10.1242/jeb.249593, whose headline describes the effect as disastrous. That is the writer's word and not the authors'. The comment cites only the primary article.

No competing interests declared. Ethics and collection licences from the Azorean government and the University of the Azores ethics committee.

Why this entry matters, stated first. Not primarily for its subject. It is the only entry in this appendix whose exposure was characterized in the receptor space of the animal tested as well as in human photometric units, and the two characterizations disagree: two stimuli within about four percent of each other in the bird's achromatic channel measure 75 and 120 lux to a human, a factor of 1.6. That is a direct demonstration of the proposition Part V.J.4 argues, supplied by investigators who were not arguing for it. Secondarily, it is the only entry reporting a measured avoidance response, and its white lamp at 3,000 kelvin with a peak at 455 nanometers is a fourth demonstration in Part V.I that a low correlated color temperature is not a narrow spectrum.

Subject and setting. Cory's shearwater, Calonectris borealis, whose largest population breeds in the Azores, breeding from mid-February to early November with fledging in late October and early November. About six percent of fledglings are grounded annually in fallout events in the Azores; the SOS Cagarro rescue campaign has operated every year since 1995. Fledglings were tested on a cliff edge on the outskirts of Horta, Faial, at 38.5199 degrees north and 28.6202 degrees west, with the maze exits facing the sea; adults at the foot of the Capelinhos colony, a Natura 2000 special protection area, at 38.5895 north and 28.8233 west, within ten meters of the surf.

Design. 131 rescued fledglings tested over five nights in October and November 2020 and four in 2021, and 84 adults over eleven nights between May and September 2022. Each bird received one trial. The maze was plywood, 100 by 50 by 40 centimeters, matte black, with a central separator forming two arms and exits and a light above each arm; the bird was covered by a

black box for one minute before release, the start position laid with black cardboard, and the arena cleaned with 70 percent ethanol between birds. Light positions were randomized. A trial ended after ten minutes if the bird did not move. Recorded: arm entry, choice, and latency to enter in minutes. Three treatments — white against dark, blue against red at equal brightness to the bird, and a control with both arms dark. Fledglings were ringed and measured, held in dark rescue boxes until testing, and released at the cliff; adults were held at least fifteen minutes and redirected back to their burrows.

Exposure, which is the best-specified in this appendix in one respect and loose in another. White arm: a named commercial warm-white diode strip, 3,000 kelvin, measured spectral peaks at 455 and 625.2 nanometers, 175 lux at the start position. Dark arms: below 0.1 lux. Blue and red arms: single-peak diodes at approximately 450 and 620 nanometers, 75 and 120 lux respectively in human photopic terms, the authors noting that these illuminances correspond to civil twilight. The two chromatic stimuli were designed to be approximately isoluminant in the bird's achromatic system, differing by about four percent in achromatic contrast while differing by about 60.7 just-noticeable differences in chromatic contrast, with spectral sensitivities modeled on the wedge-tailed shearwater, Ardenna pacifica. The white stimulus was not isoluminant with the chromatic pair, so the two experiments are not comparable to one another on intensity. The loose element is the dark control, specified as below 0.1 lux, which is a ceiling rather than a measurement; Appendix C.128 measured a natural night sky at a median of 0.0168 lux.

Statistics. Fisher exact tests for entry and choice between age groups; exact two-tailed binomial tests for choice within each treatment and age group; Welch two-sample t-tests for latency; a principal component analysis of wing, tarsus, culmen and gonys to form a body size index, the first component retaining 51 percent of variation; body condition as residuals of mass regressed on that index; binomial generalized linear models with a logit link, and linear models, for size and condition. R version 4.1.2.

Results. Entry: fledglings entered an arm in 101 of 131 trials, 77 percent, against 45 of 84 for adults, 54 percent, Fisher exact probability below 0.001 with an odds ratio of 2.88; the difference was significant within the blue-red treatment, probability 0.015 and odds ratio 3.4, and not within white-dark, 0.367 and 1.55. In the control every fledgling chose; adults chose in 70 percent of trials. Choice: no side bias in the control, fledglings 0.627 and adults 0.115. White against dark, fledglings chose dark in 77 percent, binomial probability 0.009; adults chose dark in 66 percent, not significant at 0.3. Blue against red, both ages chose red, fledglings at 0.003 and adults at 0.00052, with only one adult choosing blue. The choices did not differ between age groups, 0.25 for the red arm and 0.5 for the dark arm. Latency: fledglings slower than adults, Welch probability below 0.01 with a 95 percent interval of 0.531 to 1.766; both groups fastest in the control; every within-treatment comparison between the two arms null, fledglings at 0.521, 0.353 and 0.314 and adults at 0.363 and 0.373, the adult blue-red comparison impossible because one adult chose blue. Size and condition: larger fledglings tended to enter more often in blue-red trials, estimate 0.581 with an interval of 0.007 to 1.253, and larger adults in control trials, 1.161 with an interval of 0.120 to 3.000; no other relationship with choice or latency.

What the authors concluded. That the birds were not attracted. At close range they were, in the authors' words, "apparently disoriented by the stimuli rather than being behaviourally attracted to them"; that "artificial light appears to impair the fledglings' ability to exit the unknown lit environment"; and that "the presence of a close-range artificial light can be disruptive to Cory's shearwater fledglings." They also report a result against their own expectation: because choices did not differ significantly between ages, "behavioural differences cannot account for the age bias observed in fallouts" — the bias by which fallout falls overwhelmingly on fledglings. Their alternative explanation, that the fledgling visual system is still immature, is offered as a hypothesis and not tested here. They note that the high contrast of white light against darkness may itself disorient, and describe that as an extrapolation. On

mitigation they cite others' recommendations to shift urban lighting toward longer wavelengths and offer no lamp specification of their own.

What it does not establish. It is not a model of fallout and the authors say so: a close-range two-armed maze is not a bird encountering a lit town in flight. Within-treatment samples are small, the choice results resting on roughly two to four dozen birds in each, and the adult arm is underpowered by the authors' own calculation that 176 to 305 adults would be required. Only about half the adults made any choice. Trial numbers per treatment were uneven. The white stimulus was not isoluminant with the chromatic pair. The visual model was built on a different species. The fledglings had already been grounded by urban light and then handled, ringed, measured and boxed, so they were not naive; the authors raise this, argue from earlier work that it is unlikely to have skewed the result, and recommend testing unexposed fledglings. And the tested fledglings were selected at or above 660 grams and averaged 820 plus or minus 74 grams against 766 plus or minus 96 for the 1,111 birds rescued across the two seasons, so they were the fitter part of an already injured group. Nothing bearing on human health was measured.

Bearing on the statutory question. Three. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, for which the avoidance result is evidence of the organism's own assessment of the emission. Paragraph 360ii(a)(4), the duty to study and evaluate emissions and conditions of exposure, for which this entry shows that the condition of exposure can be specified in more than one receptor space and that the choice of space changes the answer. And the form of a performance standard under section 360kk: a limit in lux is a limit in a human weighting, which is appropriate to this statute and is the reason the Department cannot synthesize the ecological literature by converting it into lux. Part V.I, where it is used; Part V.J.4; Part V.G for the limit of the avoidance analogy.

C.134 Grillo, Marrone, Gauci and Deidun (2024) — an entry taken for the authors' lighting recommendations and for a unit error, and not for its findings

Citation. Grillo F., Marrone A., Gauci A., Deidun A. "Maltese Coastline Never Sleeps: The Effects of Artificial Light at Night (ALAN) on the Local Infralittoral Assemblages—A Case Study." Received 10 August 2024, revised 30 August 2024, accepted 4 September 2024, published 10 September 2024. Open access under Creative Commons Attribution 4.0. Oceanography Malta Research Group, Department of Geosciences, University of Malta. Funded internally as part of the first author's Master's thesis and through Interreg Italia-Malta CapSenHAR. No competing interests declared. Data available on request to the corresponding author rather than deposited.

Why this entry is in the appendix, stated first and against the ordinary reading. Not for its finding. The Foundation declines the findings for the reasons set out below, and would decline them if they pointed the other way. The entry exists for two things that do not depend on the design. The first is the recommendation set the authors give in their section 4.5, which is organized by the same four emission characteristics as Part VI and Part IX of this comment and which includes a numerical limit of the form section 360kk requires. The second is the characterization of the two study sites, which is given in lumens, a unit that does not measure light arriving at a place, and which is therefore a concrete instance of the problem Part V.B.3 and Part V.J.4 describe.

Design, as reported. A horizontal-facing baited remote underwater video unit, built in-house from PVC with a frame of about 355 by 400 millimeters, 4 kilograms of ballast, and a one-meter bait arm standing 260 millimeters above the seabed holding 250 grams of chopped bullet tuna and European sprat in a four-to-one ratio. A GoPro Hero 10 recorded at 1080p and 60 frames per second. Two Bigblue AL2600XWP-II dive torches were mounted on gooseneck arms, each rated at a maximum output of 2,600 lumens at 6,500 kelvin with a 120 degree beam, and each carrying integrated red diodes. Eighteen one-hour samples were taken in August 2023 at Ċirkewwa harbor on the northwest coast of Malta, two per night beginning at 10 p.m., under a

two-factor design: three light treatments, being high-intensity white, low-intensity white and red, by two habitats, being a light-polluted harbor quay and a darker rocky reef, with three replicates per combination. Video was analyzed at 0.4 times speed using Count-N, the cumulative count of individuals observed, the authors having rejected MaxN. Analysis in Primer v7 and PERMANOVA+, with dispersion weighting, a square-root transformation, Bray-Curtis dissimilarity, SIMPER, non-metric multidimensional scaling, principal coordinates ordination and a BEST analysis against wind, lunar phase and cloud cover.

Why the Foundation declines the findings. Nine reasons, the first four sufficient on their own. (1) There was no dark control. The red treatment is described by the authors themselves as a pseudo-control, so every one of the eighteen samples had a lamp burning and the study compares three lamps to one another, never a lamp to darkness; red light is also strongly attenuated in seawater, so the red arm differed from the white arms in intensity as well as spectrum and the two cannot be separated. (2) The camera was baited. A preference for the bright treatment cannot be distinguished from an improved ability to locate bait under it, and the authors report that the fish exploited the bait bag specifically on illuminated nights, citing prior work on precisely this artifact of illuminated baited video. (3) The site contrast is not a light contrast. The authors assert that other environmental variables are not expected to differ much between the two locations and then themselves record differences in seabed composition, in exposure to prevailing winds, in boat traffic that varied in both presence and duration across sampling occasions, in occasional fishing activity, and in the presence of a single moray den beside one deployment which they suggest may account for that species' frequency there. One location is a working ferry quay with restaurants; the other is a reef. (4) The species constituting eighty percent of all counts was differentially undercounted in the treatment of interest, and the authors disclose it: under high-intensity light the bogue kept away from the camera because a horse mackerel was holding station in front of it, so they were counted only in the background and the authors write that greater schooling densities may therefore have been overlooked. (5) Three replicates per cell, in one month, at one harbor. (6) The claim that light mattered more than habitat rests on comparing probability values, 0.0001 against 0.0005, which is not a comparison of magnitude; the pseudo-F values and components of variation needed to support it are in a table the Foundation has not seen. (7) The diversity result contradicts the headline: the PERMANOVA on the Shannon index returned no significant effect of light, and only the interaction was significant. (8) Several claims of significance in the biodiversity section are read off boxplots with no test reported. (9) The same observation, the greater abundance of bogue under red light at the lit site, is interpreted as habituation in section 4.1 and as attraction in section 4.2.

What the authors nonetheless report, recorded for completeness and not relied on. 23,985 individual counts from eighteen hours of video, comprising eighteen species of fish, two molluscs, one cnidarian and one polychaete, of which 19,200 were the bogue Boops boops. PERMANOVA probabilities of 0.0001 for light treatment, 0.0005 for habitat and 0.0003 for the interaction, with pairwise t values of 2.2347 for red against low, 3.5938 for red against high and 2.267 for low against high, the strongest contrast being red against high at 0.0022. Shannon index not significant for the factors at 0.2471 with the interaction at 0.0021. SIMPER average similarities of 67.07 percent under red, 65.2 under low white and 60.1 under high white. Horse mackerel Trachurus trachurus present in every high-intensity sample, absent from every red sample and present in two low-intensity samples, engaging in what the authors describe as station holding; the authors note this contrasts with earlier work in which the same species hid from intense white light. Cardinalfish Apogon imberbis and painted comber Serranus scriba more frequent under red. The bearded fireworm Hermodice carunculata recorded 55 times under red, 49 under low and 24 under high. Two cuttlefish, both under red. The first two principal coordinates captured 60.97 percent of variance.

The recommendations, which are the reason for this entry. From the authors' section 4.5, as their own statement of what coastal lighting should be required to do. Direction: full cut-off fixtures aimed downward, achieving a zero percent Upward Light Output Ratio. Quantity:

intensity limited to what is strictly necessary for safety and operational purposes. Containment: lighting focused on specific areas, preventing overflow into ecologically fragile regions, nearby residences, or the sky. Duration: schedules to dim or switch off during periods of inactivity. Spectrum: a correlated color temperature below 3,000 kelvin. And reflectance: non-reflective, dark-colored materials in coastal construction. The recommendations are cited by the authors to BirdLife Malta guidance and to a marine energy lighting paper, both recorded as acquisitions. Four of the six are the four emission characteristics this comment asks the Department to regulate, and the Upward Light Output Ratio limit is expressed as a number against a defined ratio, which is the form a performance standard takes.

The spectral recommendation, and why this subsection uses it against itself. The recommendation of a correlated color temperature below 3,000 kelvin is the standard one in the field. Four studies collected in this appendix show it to be partial. At Appendix C.125 lamps at 2,700 to 3,000 kelvin under one lux did not prevent the loss of diapause in the mosquito, and those authors wrote that changes in brightness or light color may not be sufficient. At Appendix C.133 the lamp the shearwater fledglings avoided was 3,000 kelvin with a measured spectral peak at 455 nanometers. At Appendix C.128 reducing short-wavelength content reduced moth activity suppression without removing it, and at low intensity some species increased activity under amber. At Appendix C.132 the same remedy did help against a brief intense pulse, which is why the Foundation's position concerns exposure regimes rather than amber as such. The explanation is that a low correlated color temperature is not a narrow spectrum: warm white is broad-spectrum light with a reduced blue fraction and it retains a blue peak. The consequence for section 360kk is that a standard prescribing a correlated color temperature would prescribe a quantity that does not determine the emission it is used to control, and that the Department should instead prescribe a limit on radiant power within a stated wavelength interval or a spectral index computed from the distribution, of the kind the Andalusian instrument at Appendix D.2 employs.

The unit error. The ambient light at the two sites is given as a photometer reading in lumens: zero at the reef deployment, eighty at the harbor deployment, and up to one hundred and forty-five when charter boats passed. The lumen is a unit of luminous flux and measures light leaving a source integrated over all directions; it is not a measure of light arriving at a location, and a photometer placed at a point does not read it. The quantity such an instrument reads is illuminance, in lumens per square meter, the lux. The same methods section uses the lumen correctly when stating the torches' maximum output of 2,600 lumens, that being a source quantity. The difference in light between the two sites is the entire premise of the habitat comparison, and it is expressed in a unit that cannot express it. The Foundation records this as an instance and not as a criticism of these authors in particular: it is the practice of the field that Part V.B.3 and Part V.J.4 describe, and the contrast with Appendix C.133, published in the same year with its lamp spectra reported to a tenth of a nanometer and its stimuli matched in the subject's receptor space, is the range of practice the Department would have to build a standard on.

An internal inconsistency in the published counts, resolved by arithmetic. The abstract reports 23,955 individuals; the results section reports 23,985 twice. The Foundation summed the species table in the paper's own Appendix A and obtained 23,985 exactly: 23,835 fish, 9 molluscs, 13 of the cnidarian and 128 of the polychaete, with Boops boops at 19,200, which is 80.05 percent of the total and matches the eighty percent the abstract states. The abstract figure is therefore the error. This is the Foundation's computation from the published table and is marked as such.

Bearing on the statutory question. Two, neither evidentiary. The form of a performance standard under section 360kk, for which the authors' recommendation set is an independently arrived-at statement of the characteristics to be regulated, and their spectral recommendation is a demonstration that the convenient number does not determine the emission. And paragraph 360ii(a)(4), the duty to study and evaluate emissions and conditions of exposure, for which the

unit error is an instance of why the Department cannot rely on the published literature to supply the exposure information and must measure. Part V.I, where it is used; Part V.B.3 and Part V.J.4 for the measurement argument; Part IX for the standard-drafting request.

C.135 Degen and eleven co-authors (2024) — harmonic radar tracking showed that four percent of light-caught moths flew to a streetlight, while the lights changed the flights of the rest and barred a family from crossing a lit circle

Citation. Degen J., Storms M., Lee C.B., and nine co-authors, the last being Degen T. "Shedding light with harmonic radar: Unveiling the hidden impacts of streetlights on moth flight behavior." Proceedings of the National Academy of Sciences of the United States of America. 2024;121(42):e2401215121. doi:10.1073/pnas.2401215121. Received 18 January 2024, accepted 31 July 2024, published 8 October 2024. Edited by Marlene Zuk, University of Minnesota. The publisher's display abbreviates the middle eight authors, whose initials from the contributions statement are A. Jakhar, S.W., A. Jechow, A.L.S., F.H., T.W., O.M. and T.H.; the full list is not recorded here, and surnames are not reconstructed from initials. Funded by the Deutsche Forschungsgemeinschaft, grant DE 2869/1-1. No competing interests declared. Capture and release permitted by the Regional Council of Giessen. Raw data deposited in Dryad; the deposit identifier must be obtained. Supporting Information not yet obtained.

Why this entry matters, stated first. Because it measured the blindness of the method by which this exposure has been studied. Every moth tested had been captured using light and was therefore known to approach light. Four percent of those released with the streetlights on flew to a streetlight. The lights nonetheless changed the flights of the others, measurably and significantly. The established observational method, the light trap at the lamp post, can by construction record only the four percent. This is the seventh instance in this comment of an instrument that cannot see the exposure it is used to observe, the first six being the satellite radiometers collected at Part V.J.4, and it is the only one in which the shortfall was quantified against a method that could see both.

Design. 95 flights of 94 individuals, 10 June to 29 July 2018, on an open flat pasture near Großseelheim, Germany, release point at 50 degrees 48 minutes 50.3 seconds north and 8 degrees 52 minutes 32.7 seconds east. Harmonic radar, Raytheon Marine NSC 2525/7 XU, tracking to one kilometer with a position every three seconds. A 10.5 milligram, 12 millimeter transponder, carrying no battery and powered by the radar beam, returning the signal at twice the transmitted frequency, was fixed with double-sided tape to a numbered tag shellacked to the thorax; attachment took about thirty seconds under red light only. Six streetlights on poles about 3.5 meters high, fitted with high-pressure sodium lamps at 2,000 kelvin and 6,700 lumens, 70 watts, were set in a circle of 85 meter radius about the release point, 85 meters from each other, with non-overlapping light cones; one lamp was replaced after measurement to equalize brightness. Lights were on or off on alternating nights to balance weather and ambient light. Moths were released singly and tracked until the signal was lost for more than ten minutes. Minimum acclimation between capture and release was 40 minutes and usually more than 60, against a stated 30 minutes for return to full ocular sensitivity. Experiments ran only above 10 degrees Celsius, not in rain or strong wind, with 83.2 percent of flights below 5 kilometers per hour of wind. Trajectories were analyzed to 270 meters from the release site. Flights under 85 meters or with fewer than five waypoints were excluded.

Subjects, and the selection that qualifies them. All tested animals were male; the authors report catching almost no females. All were captured using light, hawk moths at a large light trap built each night far enough away to be invisible from the release site, and lappet moths at the experimental field by driving field paths slowly and taking animals that entered the car headlight, which the authors describe as making uncoordinated movements on the ground. The authors state that the sample "might not be representative for the whole population." Principal species were Euthrix potatoria, Laothoe populi, Deilephila elpenor and Sphinx ligustri, with single or few individuals of Smerinthus ocellata, Catocala sponsa, Noctua pronuba and Cossus cossus; counts are in Table S1, not yet obtained.

Exposure characterization. Illuminance and spectrum of each streetlight measured with a JETI Specbos 1211UV spectroradiometer in irradiance mode with a cosine-corrected head facing the zenith, at 1.5 meters because vegetation prevented measurement at ground level, on a grid at 2 meter spacing along the lamp's main axis to 10 meters and 5 meter spacing beyond and off-axis. Sky brightness recorded at the start of every flight by a calibrated all-sky camera, a Canon EOS 6D with a 180 degree fisheye lens, luminance computed per pixel in millicandelas per square meter with Sky Quality Camera version 1.8.1, then divided into twelve 30 degree sectors and normalized to the whole-image mean. Moon phase and position from a published almanac; all but eight flights at waxing or waning moon. The site was relatively dark but not dark: the village edge was about 430 meters away and towns and cities lay between 3.7 and 30 kilometers off. The same spectroradiometer model was used in Appendix C.132. The measured illuminance values are in Figure S3 and have not been obtained, so this comment states no illuminance for this study.

Results. Of 50 individuals released with the lights on, two, being four percent, terminated their flight at a streetlight and showed the described disorientation, circling the lamp and falling to the ground. The distance from the last recorded waypoint to the nearest lamp did not differ between lights on and off, estimate minus 0.73 at a probability of 0.97. Twenty-eight individuals entered the 23 meter attraction radius, a figure taken from earlier work with the same lamp type; besides the two that terminated at a lamp, two more ended their flights inside the radius without being seen in the lit area, and the remaining 24 flew out again. Six, being twelve percent, passed within ten meters of a burning lamp without interrupting flight, and the distance of closest approach did not differ between lights on and off for moths leaving the circle, estimate minus 1.1 at 0.67. In a separate close-range check, seven Sphinx ligustri released ten meters from a lamp all circled and crashed. Tortuosity, by straightness index for hawk moths and sinuosity index for lappet moths: significantly increased by the lights in hawk moths when the moon was above the horizon, n equals 31, and in lappet moths when the moon was below the horizon, n equals 32. Barrier effect: lappet moths were significantly prevented from leaving the circle when lights were on and the moon not visible, probability 0.039, n equals 32; no barrier effect in hawk moths, probability 0.57, n equals 27, with 23 of 27 leaving the circle regardless of condition. One Laothoe populi was flown twice by chance, with tortuosity 0.19 with lights off and the moon below the horizon and 0.68 with lights on and the moon above it.

The skyglow null, recorded against the Foundation's interest. The authors tested whether flight direction followed sky brightness and found no evidence that it did. The brightest sky sectors were those carrying skyglow from named towns, and flight directions were widely scattered with overlapping credible intervals in Bayesian circular regressions; the animals also did not fly toward the moon when the moon was the brightest feature. The authors state this consolidates earlier findings. The comment reports it because it has elsewhere treated diffuse sky brightness as an exposure, and notes two limits on what it means: the authors tested direction only, so failing to find a directional preference is not finding no effect; and the result is consistent with the comment's product focus, since what changed these flights was the emission of a nearby product rather than the diffuse sum of distant ones. Part V.J.4 must be conformed to this.

The lamp, and the spectral position at its full strength. High-pressure sodium at 2,000 kelvin, which the authors note is "considered to be 'insect-friendly' because of the spectral composition of their light emissions." That is warmer than any white diode offered as a mitigation and warmer than the 3,000 kelvin ceiling the ecological literature recommends, including at Appendix C.134. It produced a barrier across a landscape and reduced flight efficiency in two families. With Appendices C.125, C.128, C.132 and C.133 this is the fifth and strongest demonstration that a spectral shift is a mitigation and not an answer. The authors expressly decline to generalize to diodes, writing that these "can vary considerably in spectrum and intensity" and that repeatability "will need to be specifically investigated for the different LEDs in the future." The comment respects that limit: this study does not show that a diode fragments a landscape, it shows that the lamp nominated as the least harmful does. That the

direction of the inference is unfavorable to the replacement lamp is the Foundation's own observation and is marked as such.

The geometry, which understated the exposure. The lamps stood 85 meters apart, which the authors note is unusually wide against European municipal pole spacing for roads of 25 to 45 meters, and they conclude that the barrier effect "would be even stronger with the typical streetlight design."

Controls, which are better than most in this appendix. Four conditions on Sphinx ligustri males other than those radar-tracked, released from the same point with the streetlights never on, toward female moths placed as pheromone traps 105 meters north and south: transponder fitted more than three hours earlier with no handling at release; transponder fitted immediately before release; the same handling without a transponder; and neither handling nor transponder. Nine to twenty releases per condition. Neither arrival frequency nor time to reach the females differed, at probabilities of 0.99 and 0.26. The limits are that the controls ran with the lights off throughout and in one species only. Where this comment criticizes other studies for the absence of a control, this design should be cited as the attainable standard.

What it does not establish. No females were tested, which bears on the authors' inference about reproductive success. The sample was pre-selected for positive phototaxis, which strengthens the four percent finding but means the behavioral results describe phototactic animals. The radar cannot resolve flight altitude, which is the authors' own explanation both for the close passes and for the difference between the two families, and they state that proving it requires three-dimensional tracking not presently available. Cells in the tortuosity analysis are small and unbalanced by the authors' description, and exact logistic regression was used in the barrier analysis for that reason. The choice of tortuosity index per family rests on an assumption about which family was native to the field, supported by where each was caught but not tested. The 23 meter attraction radius was borrowed. A flight ended where the signal was lost, which the authors say may mean the animal landed, flew out of detection range high or low, shed the transponder or was eaten, so the null on last-waypoint distance rests on an ambiguous endpoint. The twice-flown individual is a single animal in which both variables changed together. And nothing bearing on human health was measured.

Bearing on the statutory question. Three. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it, for which the barrier effect and the tortuosity increase are effects of a characterized emission from a product class the Department regulates. Paragraph 360ii(a)(4), the duty to study and evaluate emissions and conditions of exposure, for which this is the strongest item in the comment: a direct measurement of how much of an exposure effect the established method of observation omits, and therefore a reason for the Department to measure rather than to rely on the published record, and a reason not to read an absence of recorded effect as evidence of absence. And the form of a performance standard under section 360kk, for which the 2,000 kelvin result shows that a spectral prescription does not dispose of the need to limit quantity, direction and duration. Part V.I, where it is used; Part V.J.4, where the instrument-blindness material must be consolidated; Part VI.B for the headlight observation; Part IX for the standard-drafting consequence.

C.136 Dietenberger, Jechow, Kalinkat, Schroer, Saathoff and Hölker (2024) — dimming fivefold did not reduce insect attraction; confining the same light to the target area reduced it to the level of no lighting at all

Citation. Dietenberger M., Jechow A., Kalinkat G., Schroer S., Saathoff B., Hölker F. "Reducing the fatal attraction of nocturnal insects using tailored and shielded road lights." Communications Biology. 2024;7:671. doi:10.1038/s42003-024-06304-4. Published 31 May 2024; erratum 24 June 2024 correcting stray text in a figure caption. Open access, Projekt DEAL. Leibniz Institute of Freshwater Ecology and Inland Fisheries, Berlin; Freie Universität Berlin; Albert-Ludwigs-Universität Freiburg; Brandenburg University of Applied Sciences. Data and code at Figshare, doi 10.6084/m9.figshare.23773365.

Funding, which is part of why the entry matters. The German Federal Agency for Nature Conservation, under the Federal Programme for Biological Diversity, with resources from the Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection, reference FKZ 3518685A_H08, for the project AuBe, which includes the experimental field site. The municipal sites belong to the project NaturLicht, funded by the Regierungspräsidium Karlsruhe under a state biodiversity program. The luminaire prototypes were developed with Selux GmbH, Berlin. A national conservation agency and a regional council therefore paid for the design, manufacture, installation and multi-year field evaluation of a product intended to emit less light where it was not wanted.

Why this entry matters, stated first. Because it is the only entry in this appendix that tests a product rather than observing an exposure. One emission characteristic was changed, the others were held fixed, the altered product was installed on public streets, and the effect was measured against an unlit control. That is the form of evidence a performance standard rests on. It is also the clearest instance in this comment of paragraph 360ii(a)(5) being discharged, by a government other than this one. And the characteristic it isolates is manufactured into the luminaire rather than chosen by whoever operates it, which places it within what section 360kk can prescribe without reaching anyone's conduct.

Design, experiment (i): the controlled field site. Westhavelland Nature Park, Brandenburg, 1,315 square kilometers, designated an International Dark-Sky Reserve in 2014. Two managed grassland fields about 600 meters apart, each carrying twelve commercial road lights at 4.5 meters on a 20 meter matrix: the western field lit, the eastern field permanently unlit as control. Flight interception traps on all twenty-four luminaires, with containers of 80 percent alcohol from sunset to sunrise, sampled monthly from March to October each year from 2019 to 2022, every sampling night scheduled near the third-quarter half-moon. Three lit configurations in succession, all at 3,000 kelvin: conventional diodes at a mean illuminance of 30.6 lux in 2019 and 2020, corresponding to the European standard EN 13201 for roads carrying motorized traffic at medium to high speeds and for conflict zones; the same luminaires dimmed by 82 percent to 5.6 lux in 2021, corresponding to class P4 for restricted traffic up to 30 kilometers per hour, residential streets, parking and cycle paths; and in 2022 tailored and shielded diodes at 5.2 lux, carrying an external glare shield around the panels and adjusted to a 2.5 meter path width, also meeting P4. Weather recorded on site by a Vaisala WXT520. Photometry by a mobiLux lux meter and a JETI specbos 1201-UV spectrometer; luminaire characteristics measured on an LMT Go-DS-2000 goniophotometer by the Technical University of Berlin.

Design, experiment (ii): three municipal sites. Baden-Württemberg, 2022, on streets beside nature reserves chosen to span urbanization and sky brightness, with 28 flight interception traps in total, sampled monthly from April to October on consecutive nights near half-moon. Half the trap-equipped luminaires at each site were converted and half left conventional; there were no dark controls, because the authorities would not permit street lighting to be switched off under real traffic. Alter Flugplatz, Karlsruhe, urban, the brightest site: conventional diodes at 4,000 kelvin against tailored diodes at 4,000 kelvin, five luminaires per treatment, nine samplings. Backofen Riedwiesen, suburban, Rhine floodplain: high-pressure sodium at 2,000 kelvin against tailored diodes at 2,700 kelvin, five per treatment, seven samplings. Heimbachaue, rural, northern Black Forest, the darkest: sodium at 2,000 kelvin against tailored diodes at 2,700 kelvin, four per treatment, seven samplings. A further control at Heimbachaue fitted amber film inside the tailored luminaires to bring them to 2,000 kelvin at 5.2 lux, over five additional sampling nights from June to September. Illuminance by an ILT-1600 and spectra by a JETI Specbos 1211 UV; luminance by a calibrated Canon EOS 6D with a 50 millimeter lens and iQ Luminance software and with a fisheye lens and Sky Quality Camera software; aerial images by drone.

The luminaire design. Optics selected and modeled in DIALux evo 11, then shielding added to a prototype and tested in the laboratory and fine-tuned, then one customized version

manufactured for each site from the measured width and length of the target surface and the height and spacing of the existing poles, then validated after installation and dimmed to match the illuminance of the fixture replaced. The stated aim was to suppress two kinds of spill light: light falling outside the target area, and the high luminance and near-horizontal emission at the exit aperture that makes a conventional luminaire visible from a distance. At the experimental site a hard cutoff reduced illuminance outside the target area to very low values. At the municipal sites the cutoff was deliberately softened to include one to two meters on each side of the path, the authors stating that this was so as not to impair any subjective sense of security. The prototypes were not optimized for energy efficiency, which the authors state was sacrificed to the shielding.

Statistics. Generalized linear mixed models per site in R, fitted with glmmTMB, negative binomial for Westhavelland, Alter Flugplatz and Heimbachaue and Poisson for Backofen Riedwiesen, with light treatment as a factor and mean temperature, wind speed and precipitation as continuous fixed effects, and luminaire number and sampling date as crossed random effects. Checked for overdispersion, zero inflation and residual autocorrelation with DHARMa. Tukey post hoc comparisons by emmeans. Community analysis by principal component analysis on the untransformed matrix, then PERMANOVA on Bray-Curtis dissimilarities of the square-root transformed matrix with 999 permutations, and homogeneity of group dispersions by betadisper.

Results. 7,240 insects over four years at the experimental site, excluding a mass emergence of more than two thousand Nematocera on 19 May 2019; the most abundant groups in the lit treatments were Nematocera at 3,196, Ephemeroptera at 754 and Sternorrhyncha at 689. Dark control totals were almost constant across the four years: 430 in 2019 and 2020, 397 in 2021 and 421 in 2022. Attraction relative to the unlit control was 7.7-fold for conventional diodes at 30.6 lux, 5.4-fold for the same luminaires dimmed to 5.6 lux, and 1.3-fold for the tailored and shielded luminaires at 5.2 lux. In the model, dimming had no significant effect, probability 0.812, while the tailored and shielded luminaires significantly reduced abundance, probability below 0.001, and in pairwise comparison did not differ significantly from any dark control. Temperature raised abundance and wind lowered it, both below 0.001; precipitation had no effect, 0.771. Community composition differed significantly between treatments, PERMANOVA with five degrees of freedom, R squared 0.633, F 22.764, probability 0.001, and within-group dispersion also differed, the tailored treatment falling between the lit treatments and the dark controls. At the municipal sites 1,553 insects were caught, most abundantly Nematocera at 465, Coleoptera at 329 and Hymenoptera at 319; the tailored luminaires caught about half as many as the conventional ones at each site, with probabilities below 0.001 at Alter Flugplatz, below 0.001 at Backofen Riedwiesen and 0.005 at Heimbachaue, and composition differed significantly at all three. Dispersion rose at the tailored luminaires at all three sites, significantly only at Heimbachaue, 0.049, against 0.140 and 0.055 elsewhere. In the amber-film control the catch fell to 33 percent of the conventional figure, against 50 percent at 2,700 kelvin. Fewer Lepidoptera were caught at the tailored luminaires at every site.

The three spectral results, which confirm the position settled at Part V.I. First, with correlated color temperature held at 4,000 kelvin on both sides at the urban site, the reduction still occurred, so the benefit was spatial. Second, at the two sites where the replacement raised the color temperature from 2,000 to 2,700 kelvin the reduction still occurred, which the authors note is not a matter of course because a higher value is expected to increase attraction; a geometry change overcame a spectral change in the adverse direction. Third, bringing the tailored luminaires down to 2,000 kelvin with amber film improved the result further, to a third rather than a half, which the authors say could constitute an additional optimization. Spectral change is a real mitigation; it was not the mitigation that did the work.

What it does not establish. It does not say what to prescribe. The luminaires were tailored individually and the shielding fine-tuned, and the published text states no cutoff angle, no upward light output ratio and no luminous intensity distribution; the goniophotometric

measurements are in a supplementary table not yet obtained. The dimming null is bounded: the authors write that a further reduction of intensity could have produced a measurable effect and that a threshold is hard to predict across taxa, so the null holds for 5.6 against 30.6 lux in this setting and is not a finding that quantity does not matter. At the experimental site the three lit treatments ran in successive years rather than simultaneously, so treatment is confounded with year, mitigated by the covariates and by the stability of the unlit controls. There were no dark controls at the municipal sites, and the authors state that the dispersion results would probably have reached significance at all three had there been. Insects were identified only to order or suborder. The cutoff at the municipal sites was deliberately not sharp. And trap catch measures insects that came to the luminaire: citing the radar study at Appendix C.135, these authors write that the number caught "represents only a fraction of the insects affected," which is the eighth attestation in this comment that the instrument cannot see the whole exposure and which here makes the reported reductions more likely to understate than to overstate the benefit. Nothing bearing on human health was measured.

Bearing on the statutory question. Four, and this is the widest bearing of any entry in this appendix. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it. Paragraph 360ii(a)(5), the duty to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure, of which this is a worked example performed by another government and the answer the Foundation offers to question 5.0. Paragraph 360ii(a)(4), for the characterization of the emission before and after modification. And the form of a performance standard under section 360kk, because the characteristic isolated here is the spatial distribution of a luminaire's emission, which is built into the product, testable on a goniophotometer before installation, and independent of how anyone subsequently operates the fixture. Part V.I, where it is used; Part II.G.3 and Part II.G.4, where the duty and the gap are set out; Part IV.G for the efficiency trade the authors disclose; Part V.M for the perceived-safety concession in the municipal design; Part VI.D for roadway lighting; Part IX.J for the shielding recommendation this supports.

C.137 Fabian, Sondhi, Allen, Theobald and Lin (2024) — insects do not fly toward light; they tilt their backs toward it, and a lamp at close range is a false vertical

Citation. Fabian S.T., Sondhi Y., Allen P.E., Theobald J.C., Lin H.-T. "Why flying insects gather at artificial light." Nature Communications. 2024;15:689. doi:10.1038/s41467-024-44785-3. Published 30 January 2024. Open access. Department of Bioengineering, Imperial College London, and the Institute for Environment, Department of Biology, Florida International University. Fabian and Sondhi contributed equally; Theobald and Lin jointly supervised. No competing interests declared. A peer review file is published and one reviewer, Aaron Corcoran, is named. Data and code at Figshare, doi 10.6084/m9.figshare.24771978.

Funding, recorded because of whose it is. The European Research Council, starting grant 804315, Vision-In-Flight; the National Science Foundation, award IOS-1750833; and the United States Air Force Office of Scientific Research, MURI award FA9550-22-1-0315. Fieldwork was additionally supported by the Susan Levine Foundation, a National Geographic Explorer grant, the American Philosophical Society and a Tinker Field Research Collaborative grant. Two agencies of the United States part-funded the determination of the mechanism by which artificial light disrupts insect flight. The comment records this at Part V.I.

Why this entry matters, stated first. Because it answers the question that every other entry in this subsection assumes. The entries on moths and the mosquito report that light changed what an animal did. This one establishes why, and the answer is not attraction. Most flying insects keep their backs to the brightest part of the visual field, which through evolutionary time has been the sky and is therefore a reliable indicator of which way is up. A bright lamp at close range substitutes a false vertical. An insect obeying the reflex banks toward it, banking turns the flight path, and the animal circles the source. On that account the governing characteristic of the emission is its direction, which is what the study at Appendix C.136 independently found by building a luminaire and measuring the result.

Design. Three strands. Field: 477 stereo-videographic recordings at 500 frames per second of wild insects near artificial light, at the Monteverde biological stations in Costa Rica in January and February 2022 and May 2023 under national permits, filmed under 850-nanometer infrared illumination taken to be invisible to the subjects, median recording duration 1.7 seconds. Laboratory: eight Qualisys infrared motion capture cameras at 240 frames per second around a two-meter white tent, tracking a three-marker L-shaped frame glued to the thorax under local ultraviolet cure after immobilization on ice, the frame weighing about 5 percent of bodyweight for the lightest subject, with a marker residual of about 0.24 millimeters; 538 continuous trajectories from 599 tracks across four species, being the common darter dragonfly Sympetrum striolatum, n equals 12, the migrant hawker Aeshna mixta, n equals 2, the yellow underwings Noctua pronuba and N. fimbriata, n equals 8 and 2, and Lorquin’s atlas moth Attacus lorquinii, n equals 3. Light sources were an ultraviolet diode bulb at 395 nanometers, an actinic tube peaking at 370 nanometers, and a cool-white diode bulb; controls were broad-spectrum diffused ceiling light for the dragonflies and a low-intensity diffuse ultraviolet ceiling for the moths. Manipulations: reversing the light direction against a white sheet above or below; 200 trials on insects under 2 centimeters from 13 families in 6 orders in a 20-centimeter tank with light above or below; switching between two ultraviolet lamps while a wild insect circled one; and an agent-based simulation of the proposed reflex.

Results. Velocity concentrated orthogonally to the light in all four species, Rayleigh z of 1356.10, 102.09, 624.90 and 359.30, all probabilities below 0.001, against z of 0.43 at probabilities of 0.36 under a diffuse canopy and 0.65 in darkness. Dorsal tilting index, the dot product of the projected dorsal axis with the direction to the light on a scale of minus one to one: 0.84, 0.79, 0.82 and 0.82 with the light on, and 0.17 with it off. Bank angle medians rose from 11.9, 13.9, 20.2 and 8.7 degrees under control conditions to 43.8, 48.0, 29.3 and 30.7 degrees near a point source, Wilcoxon probabilities all below 0.001. Three abnormal motifs — orbiting, stalling and inverting — occurred in ten orders of insect near light and in under 2 percent of recordings made in the dark. Path tortuosity had a median of 3.21 near a point source against 1.21 under a diffuse canopy, Wilcoxon Z of 6.32; insects turned preferentially toward the light near a point source, chi-squared 114.66 at n equals 371, and not under the canopy, 0.79 at n equals 183. Reversing the light: insects inverted and crashed over a downward-lit sheet and flew normally under an upward-lit one. Small insects: all taxa flew upward stably under a diffuse ultraviolet ceiling and, with the same light below, none except Drosophila could maintain flight; the flies tipped and crashed over ultraviolet but not over cool-white light. Light switching: of 70 recordings, 37 showed an insect transferring to the second lamp, and in 25 of those 37 the animal changed the side it presented to the light, with three further animals reversing on the same lamp without a switch. Simulation: a four-parameter proportional controller reproduced all three motifs from a single tuning with different entry positions, and across 300 randomized five-second runs the dorsal-tilting agents did not escape, median range change minus 0.06 meters per second and not different from zero at 0.45, while agents without the response dispersed at plus 1.85, and agents implementing a corrupted celestial compass escaped at minus 1.75. Statistics were Bonferroni corrected to a threshold of 0.003 and trajectories subsampled to 10 hertz against pseudoreplication.

The four prior explanations, and what became of them. Escape to the light is refuted by orthogonal flight. The corrupted celestial compass is refuted by the light-switching result, since a compass requires the light to be held on a constant side, and by the simulation, in which compass agents escaped; the authors also note the absence of the logarithmic spirals that model predicts, and that it cannot explain stalling or inversion over a lamp. Thermal radiation was already refuted and is refuted again by diodes, which emit negligible infrared and trap insects in great numbers. Blinding is refuted by the regularity of the behavior. On that last point the comment enters a caution of its own at Part V.I: what is refuted is blinding as the explanation of this insect behavior, and nothing here bears on the high-luminance impairment of human vision and recovery that Part V.C treats on its own evidence.

The authors' mitigation sentence. That "reducing unnecessary, unshielded, upward-facing lights and ground reflections can mitigate the impact on flying insects at night, when skylight cannot compete with artificial sources." Quantity, direction, direction, and the reflectance of the surface beneath. The comment observes at Part V.I, as its own observation and not the authors', that the adjective they reached for first is the one Congress used in paragraph 360ii(a)(2).

What it does not establish. Nothing about human health. Within its own subject: the field classification of motifs was by eye and the authors call it somewhat subjective; the field dataset is biased toward large insects because a subject had to reflect enough infrared to track, the authors stating that most insects at their light were under a centimeter while the mean in their data was 29 plus or minus 9 millimeters and that clear-winged butterflies showed the response but could not be digitized; wind could not be excluded and airspeed could not be estimated; the laboratory work rests on four species with 2 to 12 individuals each, with a marker glued to the thorax and no formal control beyond the absence of visible difference; wavelength was not systematically studied and the authors say so; range was not tested at all and the authors expressly decline to explain arrival from a distance, citing one experiment in which 2 of 50 moths released at 85 meters ended their flights at the light; two taxa were immune, three oleander hawkmoths across 71 trajectories with an index of 0.24 and wild vinegar flies, for reasons the authors cannot give, noting that oleander hawkmoths are readily trapped in the field; and the authors state that they do not understand why insects do not tilt toward the moon or a low sun, which is an acknowledged gap at the center of the account. No fitness, reproductive or population endpoint was measured.

Bearing on the statutory question. Three. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it. Paragraph 360ii(a)(4), the duty to study and evaluate emissions and conditions of exposure, for which this is a characterization of what a condition of exposure does mechanically rather than statistically. And the form of a performance standard under section 360kk: of the characteristics of an emission, the direction is the one that determined this effect, with quantity and spectrum held constant across the decisive comparison. Part V.I, where it is used and where it precedes the study at Appendix C.136 that supplies the remedy; Part V.C for the caution about blinding; Part V.J.4 for the reason a trap at a lamp post records a fraction of what is affected; Part II.H and Part IX.E for the funding observation; Part IX for the direction request.

C.138 Jones, Llamas and Phillips (2023) — resident songbirds in brighter parts of a city have smaller eyes; migratory ones do not, and the exposure variable is the satellite index this comment criticizes

Citation. Jones T.M., Llamas A.P., Phillips J.N. "Phenotypic signatures of urbanization? Resident, but not migratory, songbird eye size varies with urban-associated light pollution levels." Global Change Biology. 2023;29. doi:10.1111/gcb.16935. First published 20 September 2023. Volume, issue and page range to be completed. Funded by the Life Sciences Department and the College of Arts and Sciences at Texas A&M University-San Antonio, Friends of Government Canyon, and Texas Eco-Lab. No conflicts or competing interests. Data openly available in the Illinois Databank, doi 10.13012/B2IDB-6010827_V1. Capture and handling under Texas A&M-San Antonio animal care protocol 2021-05, United States Geological Survey Bird Banding Laboratory permit 24294 and Texas Parks and Wildlife permit SPR-0522-086.

Why this entry is in the appendix, stated first. For two reasons, neither of which is the headline finding. It is the clearest instance in the collection of a causal claim about light pollution resting on an exposure variable that cannot record the wavelengths at issue, with no acknowledgment of the limitation; Part V.J.4 uses it for that and explains why an instance without an admission is worth more to the argument than another admission would be. And its contrast between year-round and seasonal residents is a statement about duration of exposure that does not depend on the accuracy of the exposure metric. The eye-size finding itself is novel and the Foundation does not dispute it, but the authors read it as adaptation rather than as injury, and the comment does not offer it as evidence of harm.

Design. San Antonio, Texas, March to July 2022. Nine sites classified by the proportion of impervious cover within a 3.22 kilometer radius, digitized by hand from 2022 satellite imagery: five edge sites below 50 percent and four core sites above it. 502 breeding birds caught in mist nets using conspecific playback, mobbing calls or flushing from nests, then banded, aged, sexed, measured and released. Four species: the resident Carolina Wren, 21 edge and 68 core, and Northern Cardinal, 50 and 35 females and 54 and 66 males; and the migratory Painted Bunting, 76 and 35, males only, and White-eyed Vireo, 44 and 53. Morphology: tarsus, wing and tail length, reduced by principal component analysis to a single frame-size variable per species explaining 44 to 55 percent of variance, together with body mass and lateral eye width, the eye measurement replicating a published method. Analysis by generalized linear mixed models with study site as a random effect, ranked by Akaike information criterion corrected for small samples against a null model, with inference based on whether 85 percent confidence intervals of coefficients overlapped zero.

Exposure characterization, which is the reason for the entry. Three environmental variables. Noise: A-weighted equivalent continuous level over four minutes at nests and territories with a type 1 sound level meter, the microphone repositioned to each cardinal direction each minute, sampled in the morning or between four and eight in the evening. Light pollution: values read from a public online light pollution map using its 2021 Visible Infrared Imaging Radiometer Suite product, in radiance units of 10 to the minus 9 watts per square centimeter per steradian, sampled at one point per tenth of a square kilometer and averaged per site. Brightness: the proportion of open, brightly lit area on each site, digitized by hand in the same way as the impervious cover. Temperature from a public climate database, five-year mean annual, excluded from the analyses because it appeared confounded by latitude. The light pollution variable is therefore the Day/Night Band radiance whose band begins at 500 nanometers and which is blind to the emission of a white diode below that wavelength, as Part V.J.4 sets out. The authors do not mention that limitation anywhere.

The collinearity the authors do state. Light pollution and brightness were correlated at 0.96 across the nine sites. The authors report it, decline to include both in any model because of it, and state that sites with greater light pollution also had more open, brighter areas during the day. Their own summary attributes the finding to light levels comprising both daytime brightness arising from urban development and artificial light at night. The study therefore cannot separate a nighttime exposure from a daytime one, and does not claim to.

Results. Body mass: the null model was best for four of the five species and sexes. Frame size: the null model was best for four of five. The exception in both was the Painted Bunting, which was smaller in the core — and a post hoc analysis showed why. The ratio of older to younger males was six to one at edge sites and one to two in the core, older males are significantly larger, and when age was included as a covariate the core-edge difference disappeared, the 85 percent intervals running from minus 0.743 to plus 0.086 for frame size and minus 0.429 to plus 0.49 for mass. The negative association between bunting body size and noise survived. Eye size: the null model was best for both migratory species, indicating no effect. In the Carolina Wren, eye size was negatively associated with light pollution, coefficient minus 0.007 with an 85 percent interval of minus 0.013 to minus 0.002, and with brightness, minus 0.525 and minus 0.937 to minus 0.113, and core birds had smaller eyes, minus 0.170. In male Northern Cardinals the same pattern held, light pollution minus 0.008 with an interval of minus 0.011 to minus 0.004, brightness minus 0.540. In female cardinals brightness was the best model, minus 0.578, but the null model competed within two units of the information criterion, so the authors pooled the sexes post hoc and recovered the association, light pollution minus 0.007 with an interval of minus 0.010 to minus 0.003. The authors also observe that variation in eye size appears to narrow in more light polluted areas.

What it does not establish, beginning with the exposure. The exposure metric cannot record the wavelengths most relevant to a visual system, and cannot be separated from daytime openness at a correlation of 0.96. All environmental variables are site-level and there are nine

sites, so the effective number of exposure units for the central relationship is nine rather than 502; the authors handle this correctly by treating site as a random effect, but the coefficient is still estimated across nine values. Inference rests on 85 percent confidence intervals, which is a defensible convention in information-theoretic model selection and is not the conventional 95 percent; the wren light-pollution interval in particular runs from minus 0.013 to minus 0.002 and would be unlikely to exclude zero at 95 percent. The mechanism is unknown and the authors say so: they cannot distinguish selection from developmental plasticity, and they could not test for the age-structure confound in the resident species because those species cannot reliably be aged, which is notable because the age-structure confound is what their own bunting analysis uncovered. Their argument that age cannot explain the eye result, being that eye size should not change with age while wing and tail do, is reasoning rather than measurement. One city, one breeding season, cross-sectional. And the authors interpret smaller eyes as advantageous in bright environments, so the finding is that the exposure is strong enough to shape morphology and not that it injures.

A transcription error in the published text. For male Northern Cardinals the sentence reporting the core-edge difference gives a coefficient of minus 0.144 with a standard error of 0.062 and an 85 percent interval of minus 0.011 to minus 0.004. That interval does not contain the coefficient and is evidently repeated from the light-pollution line above it. The correct interval must be obtained from the authors or from the deposited data before the figure is cited.

The methodological lesson, which is worth more than the finding. The bunting result looked like phenotypic divergence caused by urbanization and was demography. The authors state the general point themselves: without accounting for differences in age and age structures they might have erroneously concluded that they had evidence of an evolutionary response. That is a test a reader can apply to any observational comparison between a more exposed and a less exposed population, and it belongs beside the photoperiod test recorded at Part V.A, which came from a different study and does the same work: before an apparent effect of exposure is accepted, ask what else differs between the groups that was not measured.

Bearing on the statutory question. Three. Paragraph 360ii(a)(4), the duty to study and evaluate emissions and conditions of exposure, for which this is the tenth and most instructive instance of an exposure variable that cannot record the quantity at issue, and the first in which the limitation is not disclosed. The emissions limb of paragraph 360ii(a)(2) as Part II.D.4 construes it. And the duration of an exposure as a characteristic a performance standard may address, for which the contrast between the year-round and the seasonal residents is suggestive. Part V.J.4, where it is used and where it is added to the satellite-exposure census; Part V.A, for the age-structure test; Part V.C, only to note that a study of eye morphology is not a study of visual function and the comment does not treat it as one.

C.139 Sánchez de Miguel, Bennie, Rosenfeld, Dzurjak and Gaston (2022) — the spectral composition of European night lighting mapped from astronaut photographs, and the masking by the satellite instrument measured rather than inferred

Citation. Sánchez de Miguel A., Bennie J., Rosenfeld E., Dzurjak S., Gaston K.J. "Environmental risks from artificial nighttime lighting widespread and increasing across Europe." Science Advances. 2022 Sep 14;8(37):eabl6891. doi:10.1126/sciadv.abl6891. Open access. Supported by Natural Environment Research Council grant NE/P01156X/1 and by the European Union's Horizon 2020 research and innovation programme under Marie Skłodowska-Curie grant agreement number 847635 (UNA4CAREER).

Why this entry is in the appendix. For four things, none of which is a finding about health. The specification of the two satellite instruments on which the global record of artificial light at night depends. The measurement, rather than the inference, of what those instruments omit. The demonstration that an index weighted by the biological consequence of a spectrum can be computed and mapped across a continent. And the authors' statement that the short-wavelength

content of white light-emitting diode lighting is a design choice rather than a property of the technology.

Design. Remote sensing. There are no human or animal subjects, no organism is exposed to anything, and no outcome is measured in any organism. Color photographs of the night side of Earth taken by astronauts aboard the International Space Station with Nikon D3, D3S, D4 and D5 digital single-lens reflex cameras were obtained from the NASA Johnson Space Center, passed individually through a nine-stage calibration and correction pipeline — decodification, linearity correction, flat field and vignetting, spectral characterization of the channels, astrometric calibration, georeferencing, photometric calibration against stars of known flux, radiometric correction for the camera settings, and atmospheric correction — with cloud masked manually, then mosaicked into two composite maps, one for 2012 to 2013 and one for 2014 to 2020, at five-hundred-meter resolution, clipped to twenty-six European countries.

The instrument specification, which is the first reason for the entry. Quoted in full at Part V.J.4. In summary: the key sensors are panchromatic and carry no spectral information; they are insensitive to the blue part of the visible spectrum, which the authors give as 380 to 450 nanometers; the Defense Meteorological Program Operational Line-Scan System was sensitive from 450 to 1,000 nanometers; and the Suomi-National Polar-Orbiting Partnership and NOAA20 Visible and Infrared Imaging Radiometer Suite Day/Night Bands are sensitive from 480 to 920 nanometers. The Foundation does not treat these figures as findings. They are properties of the sensors and are checkable against the sensor documentation independently of this paper, which is why the methodological reservations recorded below do not reach them.

Finding — the spectral shift. The blue-to-green ratio rose from a median of 0.35 with an interquartile range of 0.22 to a median of 0.36 with an interquartile range of 0.17 (Kruskal-Wallis chi-square 50.34, one degree of freedom, p below 0.001). The green-to-red ratio rose from 0.50 with an interquartile range of 0.19 to 0.55 with an interquartile range of 0.17 (chi-square 23,459.12, p below 0.001). Synthetic photometry attributes the first period to a mixture of high-pressure sodium and white lamps and the second to white light-emitting diode or other white technologies. The baseline varied greatly by country: Belgium and Ireland orange from low-pressure sodium, Austria and Germany whiter from fluorescent and mercury vapor. The authors record that in 2005, 56 percent of European streetlights were sodium (47 percent high-pressure, 9 percent low-pressure) and 43 percent white (32 percent mercury, 3 percent metal halide, 8 percent fluorescent); that 51 percent of United Kingdom public street lighting had been converted to light-emitting diodes by early 2019; that in Spain light-emitting diodes were 61 percent of sales and 56 percent of street lighting by 2017; and that Milan was the first mayoral city in Europe to convert its street lighting wholly to white light-emitting diodes.

Finding — intensity, and an arithmetic discrepancy the Foundation reports because it found it. Green-band median intensity is reported as rising from 10.59 to 11.77 nanowatts per square centimeter per steradian, which the paper gives as 11.1 percent and which those two medians yield as 11.14 percent. Blue-band median intensity is reported as rising from 3.6 to 3.88 in the same units, which the paper gives as 24.4 percent and which those two medians yield as 7.78 percent. The parallel construction of the sentence, and the exactness of the green-band agreement, indicate that one of the three blue-band figures is wrong. The Foundation cannot determine which from the published text and does not rely on the magnitude. It notes that the Kruskal-Wallis statistic for the blue-band change is 166.50 against 1,366.09 for the green, so the blue comparison is much the weaker of the two, which sits more comfortably with the smaller figure than with the larger. Whichever is correct, the conclusion that the composition shifted toward shorter wavelengths rests on the color ratios rather than on the absolute band intensities, and the authors state in their Methods that the absolute values carry the larger uncertainty because the window of the Space Station through which a given photograph was taken is not known.

The three indices, and what they are. The authors re-expressed the color maps as three indices of biological consequence, each computed from the color ratios through published

response curves. The melatonin suppression index rose from a median of 0.41 to 0.42 computed from the blue-to-green ratio and from 0.20 to 0.23 computed from the green-to-red ratio. The star light index rose from 0.64 to 0.65 and from 0.44 to 0.47 on the same two routes. A measure of the phototactic response of moths is reported as rising by at least 3 percent, and the same measure weighted by intensity by 10.9 percent, from 3.28 to 3.64 nanowatts per square centimeter per steradian. Country-by-country figures for the color ratios and for the melatonin suppression index are in the supplementary tables, which the Foundation has not obtained.

What the three indices are not. Three independent measurements. They are deterministic functions of the same two color ratios, and the paper's own statistics establish it: the Kruskal-Wallis statistic of 23,459.12 is reported three times, for the green-to-red ratio itself, for the melatonin suppression index derived from it and for the star light index derived from it, because a monotone transformation of a variable leaves the ranks on which that statistic is computed unchanged. The statistic of 1,253.44 likewise appears twice. A reader who treated the melatonin, starlight and phototaxis results as three lines of evidence would be counting one measurement three times, and this comment does not do so. The Foundation also records that the medians and interquartile ranges printed for the relative phototactic response are identical to those printed for the melatonin suppression index computed from the blue-to-green ratio, while the chi-square differs, and that a rise from 0.41 to 0.42 is 2.4 percent rather than the "at least 3%" the sentence claims. Those figures require verification against the published article before any of them is relied on.

Bats. The blue-to-green and green-to-red ratios rose across the geographic ranges of almost all bat species breeding in Europe. Range data were available for thirty-eight species; the exceptions were Plecotus kolombatovici and Rhinolophus blasii, restricted to southeastern Europe, and Myotis alcathoe; no range data existed for Barbastella caspica, Eptesicus anatolicus and Miniopterus pallidus. This is an overlay of published range polygons on the light maps. No bat was observed, nothing was measured in any animal, and the Foundation reports the result as a statement about where the lighting changed rather than as an effect on bats. For the same reason this entry is not counted among the entries at Part V.A.3 that rest on non-human subjects.

What the authors say about necessity. Two sentences, quoted at Part V.J.4 and not repeated here. The first is that the benefits of the technology do not rest principally in the ability to produce broad white emissions, which other technologies can also produce. The second is that the shift toward whiter emission was intentional and was made to improve color rendering for human vision. They add that attempts to implement light-emitting diode systems without strong short-wavelength emissions have to date been limited.

What it establishes. That the two satellite instruments on which the global record depends do not record the wavelengths at which a white light-emitting diode emits most strongly. That the resulting underestimation is progressive rather than constant, and has been measured across a continent over a decade. That the spectral composition of outdoor lighting across twenty-six European countries shifted toward shorter wavelengths between 2012 and 2020, unevenly and in a pattern that follows national policy rather than geography. And that an index weighted by the biological consequence of a spectrum can be computed from available imagery and mapped at five-hundred-meter resolution across a continent.

What it does not establish. That the measured shift caused any effect in any organism. The three indices express the potential of a spectrum to produce an effect, computed from published response curves; they are not observations of melatonin in anyone, of the visibility of stars to any observer, or of the flight of any insect. Nor does the paper establish the magnitude of the blue-band intensity increase, for the reason given above.

Considerations bearing on confidence. Against. The imagery is opportunistic: astronauts photograph what they photograph, and the authors say the images were not obtained systematically. The two periods are unequal, two years against seven. The camera has three

broad channels and is not a spectrometer, so the spectra are inferred rather than measured. The georeferencing error is about four pixels, which at five-hundred-meter resolution is roughly two kilometers, and the authors accordingly analyze continental distributions rather than change in individual pixels. Outliers were removed at stated thresholds, and the composites were masked using the Visible and Infrared Imaging Radiometer Suite product at half a nanowatt per square centimeter per steradian, so the corrective map is bounded below by the instrument whose blindness is its subject. In favor. Peer-reviewed in a journal of general science, open access, with code and surfaces deposited. The calibration pipeline is described stage by stage and was published separately. The authors state the limitation on the absolute intensities themselves and say which of their quantities is the better determined. And the figures on which this comment relies most heavily, the band limits, are not findings at all.

Competing interests, as disclosed by the authors. The declaration reads: "In the interest of full disclosure, A.S.d.M. and K.J.G. serve as uncompensated members of the board of directors of the International Dark-Sky Association." The Foundation reports this because it relies on the paper and because the disclosure is the authors' own. It bears on the interpretive passages of the Discussion. It does not bear on the band limits of the sensors, which are properties of hardware.

Relation to other entries. Two. First, the exposure variable of the breast cancer study at Appendix C.7 — International Space Station photographs at approximately thirty-meter resolution, carrying a melatonin suppression index — is the method this research group developed.7 records as an open question whether the index used there is the published index of Aubé and colleagues, who is among the authors of that study. This paper attributes its own melatonin suppression index to a numbered reference the Foundation has not yet obtained. The question is therefore closer to resolution but is not resolved. Second, Sánchez de Miguel, Bennie and Gaston are three of the ten authors of the instrument paper relied on at Part V.J.4, and Gaston and Bennie appear elsewhere in this appendix. That is relevant to the consolidated statement of recurring investigators that Part V.A is to carry, and which has not yet been written.

Bearing on the statutory question. Three. Paragraph 360ii(a)(4), the duty to study and evaluate emissions of and conditions of exposure to electronic product radiation: this paper is the clearest available demonstration that the national measurement of this emission does not record the part of it that matters, and that the shortfall grows over time. Paragraph 360ii(a)(2), the duty to support research: the remedy the field identifies is an instrument that does not exist, and the work-around is photographs taken by hand out of a window. Section 360kk, the performance-standard authority: the paper demonstrates that a spectral index is computable at scale, which is what Parts IX.G.1 and IX.J ask the Department to prescribe in place of correlated color temperature, and it supplies the answer to the objection that such a standard would be a standard against light-emitting diodes. Parts V.B.1, V.B.3, V.J.4, IX.G.1 and IX.J.

C.140 Parlin, Stratton and Guerra (2022) — a lamp switched on at night makes quiescent migratory monarch butterflies fly at once, and in a direction that shows their clock has been shifted

Citation. Parlin A.F., Stratton S.M., Guerra P.A. "Oriented migratory flight at night: Consequences of nighttime light pollution for monarch butterflies." iScience. 2022 May 20;25(5):104310. doi:10.1016/j.isci.2022.104310. Open access. The authors declare no competing interests. Raw orientation data are published as supplementary Data S1.

Why this entry is in the appendix. For four reasons and not for the headline. Because the response was immediate and nearly universal rather than graded, which no other entry in the appendix shows. Because the subject is a diurnal animal and almost every other organism in this collection is nocturnal or crepuscular. Because the study was done in the United States on a United States population while nearly all the ecological evidence here is European. And because its supplementary exposure analysis is the eleventh instance at Part V.J.4 of an exposure

variable that cannot record the wavelengths the study's own mechanism depends on, and the second that makes no admission.

THE EMITTER WAS NOT A LIGHT-EMITTING DIODE, stated before anything else. A full-spectrum halogen bulb, 120 volts, 250 watts, 4,000 lumens, R7S base, named manufacturer and model, in a named work light on a tripod, with ultraviolet A and B content. The Foundation does not offer this study as evidence about light-emitting diode products and the body at Part V.I says so twice. The investigators tied their source to the deployed stock by intensity and not by spectrum: using a manufacturer's floodlight tool they computed the illuminance their source produced at four distances against three named light-emitting diode floodlights at 3,000 kelvin, and they state that their source is orders of magnitude less bright than much of the lighting found outdoors at night.

Design. Indoor flight-simulator trials in a darkened laboratory, with one set in a planetarium. Wild fall adult monarchs (Danaus plexippus), mixed sex, were caught at the University of Cincinnati Center for Field Studies in southwest Ohio between 1 September and 26 October during the 2019 and 2020 fall migrations, housed at a 12-hour light cycle with day temperature 21 and night temperature 12 degrees Celsius, and fed a honey solution. Animals were tethered by a non-invasive method of the authors' own publication, permitting release after testing. The simulator was zeroed to geomagnetic north at the animal for every trial. Ambient temperature at the animal was 22.34 plus or minus 0.93 degrees Celsius throughout. Night handling was done under red light with under thirty seconds out of the incubator at each end and under twelve minutes total exposure.

Exposure, and what is missing. The spectral properties of the source were measured with a spectrometer and a cosine-corrected optic fiber at the animal's position, five measurements for each lamp position, converted from radiance to photon flux. Light levels were measured with a traceable dual-display light meter. None of those values appears in the body of the paper. They are in supplementary figures and a supplementary table the Foundation has not obtained, and until it does, this entry states no illuminance and no irradiance. The Foundation records that as a fact about this paper and not as a criticism: the measurement was made and deposited. It records it because a performance standard is built from exposure quantities, and an exposure quantity in a supplementary file is harder for a regulator to reach than one in a methods section.

Daytime results, which establish that the lamp substituted for the sun. Morning lamp position, azimuth 110 and elevation 29 degrees: mean heading 231 degrees, Rayleigh r 0.725, p 0.0012, n 13. Afternoon position, azimuth 245 and elevation 31 degrees: 217 degrees, r 0.747, p below 0.001, n 13. The two did not differ. Neither differed from two previously published datasets of fall monarchs tested outdoors, by disappearing bearing and by outdoor flight simulator. With the lamp at a solar-noon elevation of 53 degrees, corresponding to 15 September in southwest Ohio, orientation was maintained at 228.5 degrees, r 0.612, p below 0.01, n 12. With the lamp at 34 degrees, corresponding to 5 November and outside the 46 to 57 degree solar-noon window that an earlier hypothesis says governs oriented fall flight, orientation was lost: r 0.46, p 0.0613, n 13. Animals on a light-dark cycle delayed by six hours shifted their heading by 97 degrees, to 314 degrees, r 0.801, p below 0.0001, n 13.

Night results, which are the finding. Seventy-eight monarchs were introduced to the simulator in darkness at three points in the night cycle, with the lamp at the morning azimuth. They were quiescent in the dark. When the lamp was switched on, 75 of the 78, which is 96 percent, flew immediately. Forty-seven of the 75 met the criterion of one minute of burn-in followed by five minutes of continuous flight, and 42 of those 47 flew directionally. At the fifteenth hour of the cycle the group heading was 15 degrees with the lamp held to the right, which is afternoon behavior and a phase delay: r 0.73, p below 0.01, n 10. At the eighteenth hour it was 233 degrees with the lamp held to the left, which is morning behavior and a phase advance: r 0.64, p below 0.01, n 12; and in a second condition at the same hour with the lamp moved to an afternoon position, 296 degrees, r 0.90, p below 0.001, n 10. At the twenty-first hour, 232 degrees, r 0.67, p below 0.01, n 10.

The mechanism the authors identify, and what the study did not do about it. In the monarch antennal clock the absence of light drives transcription of cryptochrome 2, timeless and period; in the presence of light, cryptochrome 1, which the authors describe as a blue-light circadian photoreceptor, degrades the timeless protein and allows the other two to enter the nucleus and repress transcription. The light-sensitive step is therefore attributed to a blue-sensitive receptor. The study did not vary wavelength and tested nothing about it. No molecular measurement was made in this study at all: the phase shift is inferred from flight direction and matched to a published mathematical model of the clock. Part V.I states both limitations and expressly declines the available inference that a blue-rich source would do at least as much.

What it establishes. That a single artificial light source of ordinary outdoor intensity, switched on during the night phase, triggers full diurnal migratory flight behavior in an animal that is quiescent in darkness, immediately and in 96 percent of individuals. That the direction of that flight is consistent with a shifted circadian clock, delayed by light early in the night and advanced by light later. And that an artificial lamp can supply the same directional cues as the sun to an animal that navigates by the sun, the authors writing that animals like monarchs are unable to distinguish between the sun and artificial light.

What it does not establish. Nothing about human health. Nothing about light-emitting diode products, for the reason stated above. Nothing about behavior in the wild: the authors state that there are no documented reports of monarchs flying at night during the fall migration and that fall night temperatures are often too low to sustain flight, and they offer the urban heat island effect and warming nights as reasons the behavioral consequence could become real. It does not establish an effect on survival, on arrival at the overwintering sites, or on any population.

Considerations bearing on confidence. Against. Tethered virtual flight in a simulator rather than free flight. Across all trials, 39 percent of animals flew at all, 112 of 287, so the analyzed sample is a minority selected by willingness to fly; the authors state the figure and compare it to other work with the same apparatus. Group sizes are small, between 6 and 13. The clock shift is an inference from behavior matched to a model, not a measurement. The exposure level is not in the body of the paper. In favor. Wild-caught animals during two actual migrations rather than captive stock, which matters here because the authors themselves discuss evidence that captive-reared monarchs orient differently. A non-invasive tether permitting release. The daytime arm validates the apparatus against two independent published outdoor datasets and matches both. The source was characterized with a spectrometer and tied by computation to named commercial luminaires. Raw data openly deposited. The authors declare no competing interests and state the limitations of the study in a section of their own.

The vocabulary, which matches this comment's. The authors frame the study as being about light trespass, which they define as light cast where it is unwanted or not needed at night, from buildings and streetlamps, and they place it within a taxonomy of nighttime light pollution comprising glare, over-illumination, skyglow and light trespass. That is substantially the taxonomy Part I of this comment takes from CIE 150:2017 and that Part II.H.3 identifies as the subject of paragraph 360ii(a)(2) named in another vocabulary. The convergence is recorded; no authority is claimed from it.

The recommendations the authors make. That conservation efforts at habitat refuges and stopover sites should consider the location, timing, positioning and type of lights, which they gloss as wavelength and lumens. That habitat creation should take account of existing lights and avoid siting habitat such as pollinator gardens where it will be exposed. And that captive rearing for conservation or commercial release should follow best practices on light, including ecologically relevant photoperiods and the elimination of light perturbation during the subjective night. The last is concrete and implementable and is not presently used anywhere in this comment.

A fact about the species that the Foundation records and declines to use. The monarch butterfly was proposed for listing as a threatened species under the Endangered Species Act by the United States Fish and Wildlife Service in December 2024, with a proposed rule under section 4(d) and proposed critical habitat at overwintering sites in California. No final rule has issued so far as the Foundation is aware, and the determination has been deferred more than once. The Foundation does not rely on any of this and does not mention it in the body of the comment. The reasons are that the proceeding is under a different statute administered by a different Department, that its posture is contested and moving, and that nothing the Foundation asks of this Department depends on it. The fact is recorded here so that the decision not to use it is a decision on the record rather than an omission.

Bearing on the statutory question. Two. Paragraph 360ii(a)(2) on its emissions limb as Part II.D.4 construes it: this is evidence about what an emission does, and the Secretary is directed to develop techniques for minimizing unnecessary electronic product radiation, of which light cast where it is not needed is the engineering archetype. Paragraph 360ii(a)(4), the duty to study and evaluate conditions of exposure, for which the supplementary roost analysis is the eleventh instance at Part V.J.4 of an exposure variable that cannot record the wavelengths at issue. Parts V.A.3, V.B.1, V.I and V.J.4.

C.141 McMahon, Smyth and Davies (2022) — modeling three predators' color vision, the one study collected here in which a narrow-band lamp removed the modeled effect

Citation. McMahon O., Smyth T., Davies T.W. "Broad spectrum artificial light at night increases the conspicuousness of camouflaged prey." Journal of Applied Ecology. 2022. doi:10.1111/1365-2664.14146. First published 25 March 2022. Handling editor Mariana Mayer-Pinto. Supported by the Natural Environment Research Council, grant NE/S003533/2. No conflict of interest declared. Data deposited at the Dryad Digital Repository, doi 10.5061/dryad.5hqbzkh7h. The volume, issue and page range are not in the Foundation's hands.

Why this entry is in the appendix. For three reasons. It supplies a mechanism the comment did not have, in which the injury is not that there is more light but that the light carries information the night did not previously carry. It is the single qualification to the settled position on spectral mitigation stated at Part V.I, being the only study collected here in which a reduction in short-wavelength content brought an effect below a threshold of detectability. And it is the second of two entries in which the investigators modeled a visual system rather than assuming one.

Design, stated plainly. A modeling study. No animal was exposed to any light, no predation was observed, and no behavior was measured. The inputs are three: measured reflectance spectra of prey and background; published photoreceptor peak sensitivities for three predators; and measured irradiance spectra for four lamp types and two natural sources. The model is the receptor noise-limited chromatic discrimination model of Vorobyev and Osorio (1998), implemented in the pavo 2 package, with a von Kries adaptation coefficient applied for color constancy.

Materials. Sixty-seven littorinid snails, Littorina obtusata and Littorina fabalis, collected from Fucus vesiculosus using fifteen quadrats of thirty centimeters at Whitsand Bay, southwest England, in May 2020: 35 brown, 15 olive, 17 yellow, no orange found. Shell reflectance measured ex situ in sunlight with a spectrometer and a fiber optic probe at five millimeters, calibrated against a diffuse reflectance standard before each pot, shells air-dried to reduce specular reflection, standardized to one-nanometer resolution and truncated to 350 to 750 nanometers. Background from two measurements of the seaweed frond and vesicle, averaged. The morph classification was validated by multivariate analysis of variance on a Bray-Curtis dissimilarity matrix, F equals 35 on 2 and 64 degrees of freedom, p below 0.001.

The three predators and their modeled sensitivities. Herring gull, tetrachromatic, airborne, peak sensitivities 371, 447, 503 and 568 nanometers. Common blenny, trichromatic,

in water, 500, 535 and 570 nanometers. Green shore crab, dichromatic, in water and mostly nocturnal, 440 and 508 nanometers. The gull and the blenny are described by the authors as mostly diurnal predators that hunt at night under artificial light.

The illuminants. Hyperspectral irradiance at one-nanometer resolution between 350 and 750 nanometers, measured at ground level at urban lighting installations in Cornwall in earlier work by one of the authors, for low-pressure sodium, high-pressure sodium, metal halide and light-emitting diode. Sea surface solar irradiance from a buoy of the Western Channel Observatory at midday on 24 June 2014 under clear sky. Lunar irradiance from a clear full moon on 14 April 2014, obtained from a web page rather than from a peer-reviewed source, with the instrument and location stated there. For the two aquatic predators the spectra were carried through three meters of seawater at a chlorophyll concentration of 0.3 milligrams per cubic meter using a radiative transfer model, output between 400 and 700 nanometers with the remainder set to zero. The spectra are reported as relative irradiances scaled between zero and one; no absolute level for any lamp appears, so the study concerns spectral composition and not dose.

Results. Thirty-six model outputs. Color distances were computed in units of just noticeable difference, a value above one being the approximate minimum at which prey can be perceived against its background. For all three predators the light source significantly affected discriminability, each at p below 0.001. Under low-pressure sodium all three morphs fell below one just noticeable difference for all three predators, which the authors state renders the statistical differences among them ecologically meaningless. Under high-pressure sodium, metal halide and light-emitting diode lighting, and under sunlight and the full moon, the threshold was exceeded. Yellow morphs were the most conspicuous to the gull and the crab under every source except low-pressure sodium, under which they were the least. The effect on the blenny was smaller, which the authors attribute to its photoreceptors being clustered in the green.

What it establishes. That under the chromatic discrimination model used, and for this prey, this background and these three predators, a near-monochromatic sodium source leaves camouflage intact and every broad-spectrum source tested does not. That the conversion from narrow to broad spectrum outdoor lighting can restore at night a sensory capability that is otherwise confined to daylight and to the brightest part of the lunar cycle.

What it does not establish, and the authors say most of this themselves. That any predation occurred or increased. That any population changed. That conspicuousness scales with color distance, which the authors expressly deny, writing that behavioral work is needed to establish the level of just noticeable difference at which prey become conspicuous and placing that beyond the scope of the paper. And critically, that prey are safer under a narrow-band lamp: the model treats chromatic contrast alone, and the authors write that "In the absence of colour however, nocturnal predators will use luminance contrast perception," a mechanism they do not model and whose investigation they recommend as the next step.

The qualification the Foundation adds, which the paper does not dwell on. The threshold of detectability was exceeded under sunlight and under a full moon as well as under the three broad-spectrum lamps. Low-pressure sodium is the outlier in the set, not the natural baseline. What the study shows is therefore not that broad-spectrum lighting creates a condition unknown to the organism but that it reproduces nightly and everywhere a condition nature supplies for a few nights a month. Part V.I states why the Foundation regards that as the more useful of the two readings.

Considerations bearing on confidence. Against. Nothing was observed; every number is computed. No spectral sensitivity measured in a herring gull was available and the visual model was assembled from published sensitivities within its family, which the authors call the best possible approximation. The shore crab's photoreceptor proportions were unavailable and were set to one to one, which the authors state maximizes its ability to discriminate color; its Weber

fraction was likewise set to a published median because its own is unknown. The authors state that statistical comparison between the three predators cannot be made. The olive and brown morphs showed no clear separation in the ordination and the authors write that they may be a single dark morph, which bears on the differential result. Group sizes for two of the three morphs are fifteen and seventeen. The neural noise argument was set to indicate bright conditions and high photoreceptor saturation.I flags for verification because receptor noise is greater at low light levels. In favor. The reflectance data are original measurements on wild animals with the instrument, calibration and procedure stated. The illuminant spectra are measurements at ground level under real installations rather than manufacturer data. The model is standard and widely used and the implementation is named. The authors state the limits of their own approximations at each point and say what their model cannot do. Data are openly deposited. No conflict of interest is declared and the funder is a research council.

Relation to other entries. Three. It is the second entry, with Appendix C.133, in which a visual system was modeled rather than assumed, and Part V.A.3 has been corrected accordingly. Smyth and Davies are two of the ten authors of the marine review at Appendix D.7, and the handling editor of this paper is a co-author of the other marine review there, so three of the documents this comment relies on for the sea come from an overlapping group. And the sun-and-moon point above is the same shape as the finding at Appendix C.128, where the measured natural night sky had a median of 0.0168 lux and more than half the measured change occurred below full-moon illuminance.

Bearing on the statutory question. Two. Paragraph 360ii(a)(2) on its emissions limb, as Part II.D.4 construes it, this being evidence about what an emission does and not about any person. And section 360kk, for the narrow proposition that the spectral composition of an emission determines what information it carries, which is a property of the product and not of its installation. The authors close by asking that habitats be protected from unnecessary exposure to artificial light, which is the statutory phrase arrived at independently. Parts V.A.3, V.B.1 and V.I.

C.142 Boyes, Evans, Fox, Parsons and Pocock (2021) — fewer moth caterpillars where streetlights are, measured by counting the animals rather than by trapping the ones that fly to a lamp

Citation. Boyes D.H., Evans D.M., Fox R., Parsons M.S., Pocock M.J.O. “Street lighting has detrimental impacts on local insect populations.” Science Advances. 2021 Aug 25;7(35):eabi8322. doi:10.1126/sciadv.abi8322. Open access. No competing interests declared. Funded by the Natural Environment Research Council through the IAPETUS doctoral training partnership, grant NE/L002590/1, and by Butterfly Conservation through an industrial CASE studentship. Primary data deposited at the Environmental Information Data Centre of the Natural Environment Research Council. The article records that six anonymous reviewers assessed the manuscript.

Why this entry is in the appendix. Because it is the strongest evidence in this collection that this emission reduces a wild population rather than altering the behavior of individuals; because its spectral comparison is the cleanest in the appendix, the lamps differing in composition at illuminances that did not differ statistically; because the authors report that the quantity this field has measured for decades may not rank lighting technologies in the order of their effect; and because the methods section contains the tenth admission collected at Part V.J.4, which concerns the unit rather than the satellite.

Design. Matched-pairs observational study with a separate manipulative experiment. Twenty-six pairs and one triplet of sites in Oxfordshire, Buckinghamshire and Berkshire, southern England, each a contiguous linear strip of habitat with a lit and an unlit section separated by at least 60 meters, median 118, range 60 to 527. Sites were found by overlaying street-lighting datasets obtained from nine local authorities and a national highways body under freedom of information requests on satellite imagery; more than five hundred candidate locations were

assessed by street view and one hundred and fifty-three visited in person. Lit sections had carried the same lamp type for at least five years and in some cases decades, according to the authority's records. Every site was visited between two and four in the morning to confirm that part-night lighting and dimming were not in operation. Treatments were 14 high-pressure sodium, 11 light-emitting diode and 2 low-pressure sodium transects.

Why no light trap was used, which is the reason this entry leads where it does. The authors state that they avoided light traps, the standard method of sampling moths, because these "lead to biases when comparing assemblages from lit and unlit areas," and that sampling larvae shows the effect where insects live and develop rather than where they happen to fly past. Appendix C.135 and Appendix C.136 disclose that bias while using the method; this is the only entry in the appendix in which the investigators designed it out.

Sampling. Two methods for two feeding guilds. Hedgerow beating by day at 13 sites, once in mid-May 2019 and once in mid-April 2020, at three points along each 14-meter transect, using half drainpipes at box-shaped hedges and a beating tray where there was overhanging vegetation, the vegetation struck five times with a metal pole. The two dates were chosen at the end and the start of the season so that phenological artifacts would cancel. Sweep netting of grass margins by night at 15 sites from November 2018 to April 2019, on nights forecast above six degrees Celsius, at least an hour after sunset, in a continuous figure-eight motion, with the lit and unlit sections of a pair sampled within ten minutes of each other and an equal number of times. Hedgerow caterpillars were predominantly winter-flying geometrids and summer-flying micromoths, grouped into twenty taxonomic units; grass margin caterpillars were overwhelmingly overwintering grass-feeding noctuids, in sixteen units.

Exposure. Illuminance measured with a named hand-held meter of 0.1 lux resolution at five evenly spaced points per transect, on overcast nights or at the new moon, pointed upward at the height occupied by the animal: 1.25 meters for hedgerows and 0.25 meters for grass. Lit hedgerow transects averaged 1.42 to 15.84 lux with an overall mean of 5.7; lit grass transects 0.18 to 7.14 lux with an overall mean of 2.2. Unlit transects were estimated below 0.01 lux and every one read the meter's minimum. Within each habitat the mean illuminance of the sodium and the diode transects did not differ statistically, at probabilities of 0.34 and 0.85. Spectral power distributions and estimated correlated color temperatures are in a supplementary section the Foundation has not obtained.

Results, abundance. Hedgerows, from 1,656 caterpillars over 25 visits to 13 pairs, with fewer caterpillars on the lit side at every site: overall 47 percent fewer, 52 percent fewer under diodes and 41 percent fewer under high-pressure sodium, all at probabilities below 0.001. Grass margins, from 822 caterpillars over 64 visits to 15 sites: overall 33 percent fewer at a probability of 0.01; 43 percent fewer under diodes at 0.02; 24 percent fewer under high-pressure sodium, not significant at 0.20; and 11 percent fewer under low-pressure sodium, not significant at 0.78.

Results, mass and feeding. Caterpillars from lit transects were heavier, significantly so under diodes in both habitats at probabilities below 0.001 and of 0.04, mixed under high-pressure sodium at 0.007 and 0.10, and not significant under low-pressure sodium at 0.60. In the separate experiment, lighting rigs four meters high were erected in two previously unlit arable grass margins and switched on an hour before sunset, with sweep netting between 60 and 120 minutes after sunset across nine visits and generators placed 50 meters away. Fewer caterpillars were found under the diode light than under no light, effect size minus 0.44 at a probability of 0.03; the difference under high-pressure sodium was minus 0.10 and not significant at 0.58.

What it establishes. That habitat directly lit by established streetlights holds substantially fewer moth caterpillars than matched unlit habitat nearby, by 47 percent in hedgerows and 33 percent in grass margins. That the reduction was larger under light-emitting diodes than under high-pressure sodium at illuminances that did not differ statistically. That short-term exposure

to diode light in previously unlit habitat disrupts the normal nocturnal feeding ascent of these caterpillars, and that high-pressure sodium at the same sites did not measurably do so.

What the authors conclude about scale, which runs against the headline. Using the actual distribution of streetlights rather than an assumption about major roads, that 1.1 percent of the land area of the study region is directly lit above one lux once road surfaces and urban land are excluded, comprising 15.5 percent of suburban land, 0.23 percent of arable land and 0.68 percent of broadleaved woodland; and from that, that direct illumination by streetlights "has probably been a minor contributor to long-term national moth declines to date; however, our results show that it can be a very substantial local factor." The Foundation adopts that sentence whole and Part V.I reproduces it.

The admission about the unit. Quoted in full at Part V.I and taken up at Part V.J.4 as the tenth instance: that lux is based on human vision so that ecologically relevant spectral information can be omitted, that identical readings may not correspond to the same illumination as the animal perceives it, and that the unit was used because it is the SI unit and is convenient.

What it does not establish. Nothing about human health. No causal mechanism: the authors propose reduced oviposition in lit areas as the likely principal cause and offer increased top-down pressure from diurnal predators and parasitoids, and reduced host-plant quality, as contributors, none of which this study tested. Nothing about the distance over which the effect extends: the authors say they do not know how far it reaches beyond the directly lit area and call that an urgent question, while reporting that a test of their own data detected neither positive nor negative spillover at the separations used.

Considerations bearing on confidence. Against. Not randomized; the treatments are existing streetlights and the authors say so. Lit transects were often at junctions and may have carried more traffic noise, nitrogen oxides and headlight glare; the authors expect those influences to have been minor, which is an expectation rather than a measurement. The low-pressure sodium arm rests on two transects and establishes nothing. The mass result is ambiguous on the authors' own account, who offer stress-accelerated development and local acclimation as competing readings and note that it sits awkwardly with their short-term experiment. The short-term experiment used a brighter and bluer lamp than the field sites, 25.3 lux at about 5,000 kelvin against 2.2 lux at 2,700 to 4,000 kelvin, so the two arms are not matched. Provisional identifications were assigned by one author. In favor. Large spatial replication with site pairing to an explicit criterion. Lit and unlit sections sampled within minutes of each other and an equal number of times. Botanical composition, verge management and surrounding urbanization tested and excluded as explanations. Phenological artifacts designed out by the choice of sampling dates. Treatment duration established from the authorities' own records. Part-night lighting excluded by visiting every site in the small hours. Three independent measures giving the same ordering of lamp types. Six anonymous reviewers. Data deposited in a national environmental data center.

Relation to other entries. Four. It completes the argument begun at Appendices C.135, C.136 and C.137 about what a light trap can and cannot record, by supplying a population measure that does not depend on trapping. It is the tenth admission at Part V.J.4 and the only one that concerns a photometric unit rather than a satellite radiometer. Its spectral ordering supports the settled position at Part V.I without disturbing it, the low-pressure sodium nulls being underpowered rather than demonstrations of removal. And D.M. Evans is to all appearances the guest editor of the Royal Society theme issue at Appendix D.7.

Bearing on the statutory question. Two. Paragraph 360ii(a)(2) on its emissions limb as Part II.D.4 construes it. And section 360kk, for the proposition this comment most needs and has had least evidence for: that at a quantity of light held constant, a change in the spectral composition of the emission changed its effect on a population. That is a statement about a

characteristic of a product, and it is the characteristic Part IX.G.1 asks the Department to prescribe. Parts V.A.3, V.B.1, V.I and V.J.4.

C.143 Sánchez de Miguel, Bennie, Rosenfeld, Dzurjak and Gaston (2021) — twenty-five years of satellite-detectable light, and the authors' own warning that the decline over North America is probably the instrument

Citation. Sánchez de Miguel A., Bennie J., Rosenfeld E., Dzurjak S., Gaston K.J. "First Estimation of Global Trends in Nocturnal Power Emissions Reveals Acceleration of Light Pollution." Remote Sensing. 2021;13(16):3311. doi:10.3390/rs13163311. Received 8 July 2021, revised 16 August 2021, accepted 19 August 2021, published 21 August 2021. Open access under a Creative Commons Attribution license. Supported by Natural Environment Research Council grant NE/P01156X/1. The authors declare no conflict of interest. Data deposited at Zenodo, doi 10.5281/zenodo.5205656, with experimental data at 10.5281/zenodo.5222170. The article records that Sánchez de Miguel and Bennie contributed equally.

Relation to Appendix C.139. Same five authors, same research council grant, one year earlier. The later paper maps the spectral composition of Europe from astronaut photographs; this one reconstructs the magnitude of the emission globally over twenty-five years from the satellite record. The two are a pair and the comment uses them for different things.

Design. Remote sensing and reconstruction. No organism, no exposure, no outcome. Three satellite datasets were reconciled into a single country-by-country time series of emitted power from 1992 to 2017: the uncalibrated Defense Meteorological Satellite Program Operational Line-scan System archive, the radiance-calibrated subset of that archive, and the Visible Infrared Imaging Radiometer Suite Day/Night Band. Uncalibrated images were fitted to the nearest calibrated image in time by robust regression over a calibration region encompassing Italy, taking the mode of a fitted kernel density as the most likely radiance for each digital number and smoothing with a tenth-order polynomial. All data were capped at 100 nanowatts per square centimeter per steradian, the lowest saturation point among the images. The whole series was then smoothed and recalibrated against the recorded electricity consumption of municipal street lighting in seventy-five Italian provinces, iteratively until convergence, and validated against national figures for eleven other countries.

The instrument statement, which is the third in this appendix and the most specific about the lamp. That the single-channel spectral response of the older sensor "is close to zero at wavelengths of visible light below 500 nm," that "White phosphor-based LED lighting typically emits at a peak radiance of around 465 nm," and that as outdoor lighting converts to solid-state technology "an undetermined, but increasing, proportion of emitted light is undetected." Of the present sensor they write that its spectral response "is similarly low below wavelengths of 500 nm." The figure of 465 nanometers is the authors' characterization of the lamp class and not a measurement made in this paper; Part V.B.1 states the peak as approximately 450 to 470 nanometers and this paper does not supply a measured spectral power distribution.

Principal result. That satellite-detectable light increased globally by at least 49 percent between 1992 and 2017, at an approximately constant rate. For the undetected component, a projected global blue-band total of 513 megawatts in 2017, rising to 806 megawatts if forty percent of lighting were diodes at 3,000 kelvin and to 1,294 megawatts at 4,000 kelvin, from which the authors derive the estimate in their abstract that the true increase in visible radiance may be as high as 270 percent globally and 400 percent in specific regions. The Foundation relies on the 49 percent and declines the larger figures, for the reasons given at Part V.J.4.

The continental result, and the authors' warning about it. Persistent growth in Asia, South America, Oceania and Africa; a rise in Europe that levelled off around 2010; and in North America an apparent decline. The authors immediately qualify it, writing that conclusions about the levelling off or decrease in Europe and North America "should be treated with caution as the

shifting spectral distribution of light towards blue-rich LEDs is likely to mask the effects of increases." That sentence is why this entry exists. Part V.J.4 sets out the consequence.

The streetlight share, which the comment has not been able to state. That the proportion of nighttime light deriving from streetlights is "unclear and debated in the literature" and likely to vary between countries and cities, with published values ranging from 12 percent in Flagstaff, Arizona to nearly 100 percent in Spain. Recorded with Appendix C.130, where volunteers counting German streets found streetlights outnumbered five to seven times by other sources in dense urban areas, and with the observatory review at Appendix D.7, which is the source of the Flagstaff figure.

The hour of observation. That the older satellite acquired images at about 21:30 solar time and the present one between midnight and 02:00, so that the two do not measure the same night. The authors construct separate evening and post-midnight series by recalibrating each sensor against the other for 2012, the single year in which both operated. They report that the gap between the two is large in Europe, North America, Asia and Oceania and much smaller in South America and Africa, which they attribute to private lighting being switched off. The Foundation records this as the only national-scale measurement of switching-off behavior it has encountered.

What it establishes. That the measurable emission of artificial light at night grew by at least half over a quarter of a century, globally and at an approximately constant rate. That the apparent absence of growth in North America cannot be taken at face value, on the authors' own statement. And, in the abstract's words, that "there is limited evidence that advances in lighting technology have led to decreased emissions."

What it does not establish. Nothing about health, exposure or any organism. No figure for the United States: none is given, and the continental curve is expressly disclaimed by its authors as a basis for conclusions. And nothing about the magnitude of the undetected component as a measured quantity, that being a projection under assumed conversion rates and color temperatures.

Considerations bearing on confidence. Against. The entire global series is anchored to the street-lighting electricity consumption of seventy-five Italian provinces, chosen because the historical data exist there; the validation against eleven other countries is a check and not a second anchor. The older sensor has no on-board calibration, saturates at a digital number of sixty-three, has a resolution of 2.7 kilometers, suffers blooming and has poor georeferencing, all of which the authors state. Data were capped at the lowest saturation point, which discards information in the brightest places. The conversion-rate assumption comes from a Spanish lighting manufacturers' association. The blue-band conversion factors of 0.1, 0.25 and 0.5 for lamps at 2,000, 3,000 and 4,000 kelvin are taken from the same group's earlier work. And the lamp replacement assumption is a fixed 24,000 hours of operation at 4,100 hours a year. In favor. Peer-reviewed and open access with data and code deposited. The limitations of every dataset are set out at length before the results rather than after them. The validation against independent national consumption figures is reported, including where it fails. The authors qualify their own principal regional finding against their own interest. And the quantity the comment relies on, the 49 percent, is the one that does not depend on the modeling assumptions.

Bearing on the statutory question. Two. Paragraph 360ii(a)(4), the duty to study and evaluate emissions of and conditions of exposure to electronic product radiation: this is the long-run record of the emission, and its authors say it understates the trend and may invert the sign of it over this continent. Paragraph 360ii(a)(2), on its emissions limb, for the proposition that the emission has grown by at least half in twenty-five years and that the evidence for technology having reduced it is limited. Parts II.D.4, IV.G, V.B.1 and V.J.4.

C.144 Schligler, Cortese, Beldade, Swearer and Mills (2021) — twenty months in a Polynesian lagoon, and the only long-term field experiment in this comment

Citation. Schligler J., Cortese D., Beldade R., Swearer S.E., Mills S.C. "Long-term exposure to artificial light at night in the wild decreases survival and growth of a coral reef fish." Proceedings of the Royal Society B. 2021;288:20210454. doi:10.1098/rspb.2021.0454. PMID 34102892. PMCID PMC8187998. No competing interests declared. Ethical approval from the animal ethics committee of the Centre National de la Recherche Scientifique, permit number 006725. Funded by the Agence Nationale de la Recherche, the Haut-Commissariat de la République en Polynésie française and Pacific Funds. Data deposited at the Dryad Digital Repository, doi 10.5061/dryad.37pvmcvjv. Schligler and Cortese contributed equally. The volume and article number are derived from the digital object identifier and require verification.

Why this entry is in the appendix. For three things, only one of which is a finding. It is the longest field exposure in the collection, at a mean of twenty and a half months in the wild. It reports its exposure in both photometric and radiometric units, which almost nothing else here does. And it supplies a measured natural nighttime illuminance underwater of 0.03 lux, which sits within a factor of two of the 0.0168 lux median measured terrestrially at Appendix C.128 and which the Foundation regards as the most useful number in the paper.

Design. Paired field experiment. Three subtidal fringing reef sites in the lagoon of Moorea, French Polynesia, exposed to long-standing shore lighting, each paired with a nearby site of comparable depth and reef structure lit only by moonlight; one site received a second control with more similar reef structure. Forty-two territories, each a magnificent sea anemone collected from the northern lagoon and randomly distributed. Forty-two laboratory-reared juvenile orange-fin anemonefish, Amphiprion chrysopterus, one to three months old, raised from eggs collected from approximately fifty wild breeding pairs, weighed to a hundredth of a gram and measured from photographs, placed singly and at random: twenty-four control and eighteen exposed, with no difference in length, height or weight between treatments at the start. Monitoring at four points: 35 days, 70 days, 12 to 17 months and 18 to 23 months, with individuals identified photographically from the shape and length of the second and third white stripes.

Exposure. Illuminance in lux and photosynthetically active radiation in watts per square meter, measured at the depth of the anemones, 60 centimeters, with a SpectroSens2 handheld logging meter, in triplicate at one location in each of six sites, after moonrise, on twelve nights corresponding to the four lunar phases across four months: 216 measurements in total, 36 per site. Lit territories averaged 4.3 lux, controls 0.03 lux, a ratio of 143, with the same pattern in the radiometric measure. The three lit sites differed significantly from each other at 0.9, 2.3 and 8.9 lux; the control sites did not differ from each other. Variability within a site came from differences among the triplicate measures rather than from lunar phase or month. The authors state that these levels are representative of what shallow fringing reefs receive under street and hotel lighting, are considerably lower than those produced by light-emitting diode lighting used at ports, and that impacts in coastal marine ecosystems "could be greater than observed in the present study."

Results, survival. Lower in the exposed group by 36 percent, at a probability of 0.055; the authors write that survival "tends to be lower," and the abstract reports the percentage without the probability. Survival declined similarly in both groups except in two periods when the exposed group was lower: before the first monitoring, at the juvenile stage, and after about twenty months as functional adults. Site differences were significant, fish at site 2 having 51 and 55 percent higher survival than those at sites 1 and 3.

Results, growth. Specific growth rate, as percentage increase in size per day. Height 15 percent lower in the exposed group, at a probability of 0.036 and significant. Weight 51 percent lower at 0.074, described by the authors as a tendency. Length 21 percent lower at 0.251 and not significant. No interaction between treatment and exposure period. Daily growth was higher in the second period than the first. THE ABSTRACT GIVES A SINGLE FIGURE OF 44 PERCENT

for growth which the Foundation cannot reconstruct from those three values, whose mean is 29 percent.

The numbers behind the percentages. Of the forty-two fish, twenty-one were present at twelve to seventeen months, fifteen control and six exposed, with one new recruit on an exposed territory; and fifteen at eighteen to twenty-three months, twelve control and three exposed. Growth was measured on twenty-one individuals at the first of those periods and fifteen at the second. The final growth comparison therefore rests on three exposed animals. Seven fish were excluded from the survival analysis because both fish and anemone were absent.

The authors' competing explanation of the growth result. That it "may be due to phenotypic plasticity in morphology in response to ALAN and may be adaptive," representing a reallocation of resources toward length and weight at the expense of height, and that a lower rate of growth in height "may therefore be the optimal strategy for anemonefish exposed to ALAN," facilitating escape from predation by decreasing drag or by hiding in the anemone. Whether such plasticity is adaptive in the long term, they write, remains unknown. Part V.I records that the comment does not assert the growth difference is an injury, for the same reason it declines to do so with the eye-size finding at Appendix C.138.

What it establishes. That juvenile anemonefish held for a mean of twenty and a half months in territories illuminated to a mean of 4.3 lux grew less in height than those held at 0.03 lux, and that the other two measures of growth and the measure of survival pointed the same way without reaching conventional significance. That the experiment can be done in the wild, over that duration, with the exposure measured radiometrically as well as photometrically.

What it does not establish. Nothing about human health. No cause of death: the authors state expressly that their results do not allow them to distinguish physiological stress from increased predation. No mechanism for the growth difference, and the authors offer adaptation as a competing reading of it. And nothing about the spectral composition of the lighting, which is not characterized anywhere in the paper the Foundation has read; the sources are described only as street and hotel lighting.

Considerations bearing on confidence. Against. The principal survival comparison does not reach the conventional threshold. Three exposed animals carry the final growth comparison. The fish could move and absence was equated with mortality; the authors address this and cite evidence that this is the most mobile of six anemonefish species tested, with 13 percent changing host anemone within four months, and at the first site the paired territories were 8.6 meters apart. Anemone loss was substantial, at 29.1 percent of control and 38.8 percent of exposed territories, which the authors describe as an equal number, true in count and not in proportion. Lit territories were systematically closer to shore than control territories at every site. The juveniles were laboratory-reared and placed singly, and the authors note that growth in this genus is socially controlled and that their design may underestimate both growth and mortality. In favor. Twenty months in the wild, which almost nothing in this field achieves. Individuals identified photographically at every visit. Exposure measured in two kinds of unit, at the animal's depth, across all four lunar phases, in triplicate. Control sites shown not to differ from one another. Site included as a factor and its effects reported. The authors qualify their own principal finding in their Results and offer a competing explanation of their own growth result. Data openly deposited and ethical approval stated.

Relation to other entries. Three. The control illuminance of 0.03 lux is the second measured natural nighttime figure in this comment, beside the 0.0168 lux median at Appendix C.128, and Part V.I sets them together. S.E. Swearer is a co-author of the review at Appendix D.7 on temperate and tropical reefs, and the review at D.7 by Marangoni and others cites this study; the Foundation reached it through that citation and now has the primary source. And the adaptive-plasticity caution is the same move the investigators made at Appendix C.138, which the comment records in both places rather than in neither.

Bearing on the statutory question. One, and it is narrow. Paragraph 360ii(a)(2) on its emissions limb as Part II.D.4 construes it: this is evidence about what an emission does, in the field, over a period no laboratory can reproduce. The Foundation does not offer it for anything else, and the figures it relies on most are the two measurements of natural darkness rather than the effect estimates. Parts V.A.2, V.A.3 and V.I.

C.145 Kernbach, Martin, Unnasch, Hall, Jiang and Francis (2021) — West Nile virus in Florida sentinel chickens, and a curve that peaks at the faintest light

Citation. Kernbach M.E., Martin L.B., Unnasch T.R., Hall R.J., Jiang R.H.Y., Francis C.D. "Light pollution affects West Nile virus exposure risk across Florida." Proceedings of the Royal Society B. 2021;288(1947):20210253. doi:10.1098/rspb.2021.0253. PMID 33757351. PMCID PMC8059973. Previously deposited by the authors as a preprint at bioRxiv, doi 10.1101/2020.05.08.082974, 8 May 2020.

HOW THE FOUNDATION CAME TO THIS ENTRY, AND WHAT IT HAS NOT READ. Mr. Baker supplied a news release of the University of South Florida and asked that the underlying study be identified. It was identified from that release, a research center notice of the University of Georgia and a bibliographic search, and the account below is drawn from the authors' own bioRxiv deposit together with the published citation. THE PUBLISHED ARTICLE HAS NOT BEEN READ. A preprint is the authors' own text before peer review, the version of record governs, and nothing in this entry may be filed until the published article has been obtained and every figure, every statistic and the limitations section checked against it.

Design. Analysis of an existing public health surveillance program. The Florida Department of Health maintains caged sentinel flocks across the state and tests them monthly for antibodies to West Nile virus; birds that seroconvert are replaced with naive birds. The preprint describes seven counties over 2015 to 2018, restricted to June through December and to records with complete environmental data, yielding 1,126 surveillance events from 80 sites and 105 distinct coordinates, with six birds tested at 89.5 percent of observations and four at the remainder. The university release describes 6,468 antibody samples from 105 coop locations over four years. The preprint is internally inconsistent about the county and event counts between its introduction and its methods, which is one reason the published article must be obtained.

Exposure variable, which is the reason this entry joins a census at Part V.J.4. Artificial light at night taken from the published world atlas of artificial night sky brightness at one-kilometer resolution, in millicandelas per square meter, which is a modeled product derived from the Visible Infrared Imaging Radiometer Suite. It is not a measurement at the coop. It therefore inherits the band limitation that Part V.J.4 collects and adds a modeling step to it. Whether the published article discloses that limitation the Foundation does not know and must not guess; until that check is performed this entry is not counted among the instances tallied at Part V.J.4.

Other variables. Three separate measures of urbanization (impervious surface, human population density and the human footprint index), precipitation and temperature from a gridded climate product, and soil moisture, with temperature lagged by one month. Negative binomial mixed-effect models with and without spatial correlation. Artificial light at night was modeled as a second-order polynomial.

Principal results. That artificial light at night carried the largest and the only strong effect among the urbanization variables, through its log-transformed and squared terms. That impervious surface and the human footprint index showed no influence, and human population density showed mixed and small support. That the mean temperature of the previous month had a strong positive effect with a quadratic term, temperatures above 25 degrees Celsius being associated with higher seroprevalence, the lagged term receiving much stronger support than the same-month term. That monthly cumulative precipitation was negatively related to seroprevalence. And that no polynomial term for any urbanization variable was supported.

THE SHAPE OF THE RELATIONSHIP, WHICH IS THE MOST IMPORTANT THING IN THIS ENTRY. The relationship between light and exposure risk was not monotonic. In the preprint's words, at low levels of artificial light, at radiance intensities less than one, West Nile virus risk was greatest, declining toward the intermediately polluted sites. Risk peaks in the faintly lit places. The headline of the press release that brought this study to the Foundation states that light pollution drives increased risk; the curve in the paper is more complicated than that, and Part V.I sets out the three consequences the Foundation draws.

What it establishes. Subject to the caveat at the head of this entry, that in four years of state surveillance data artificial light at night was associated with West Nile virus seroprevalence in sentinel birds, that the association survived the simultaneous inclusion of three measures of urbanization which did not, and that the association is not a straight line.

What it does not establish. Any effect in a human being. Sentinel chickens are a surveillance instrument for arbovirus activity and not a model of human infection, and the study measures seroconversion in caged birds rather than disease in people. No mechanism: the study is observational and the authors offer vector behavior, reservoir competence and host mortality as candidate explanations without testing any. And nothing about the spectral composition of the lighting, the exposure variable being a broadband modeled quantity.

Considerations bearing on confidence. Against. Observational and ecological in design; the unit of analysis is a site-month and not an animal. The exposure variable is modeled from a satellite product at one-kilometer resolution and is not a measurement where the birds are. Coops were sometimes moved, usually under about a hundred meters but in some cases as far as eleven kilometers. The preprint is inconsistent about its own sample description. The Foundation has not read the published article. In favor. Four years of standardized surveillance collected by a state health department for a purpose other than this analysis, which removes one familiar source of bias. A large number of sites. Three measures of urbanization entered simultaneously, which is more than the epidemiological literature in this appendix usually manages. And the authors fitted a curve rather than comparing two groups, which is why they found a shape that a two-level comparison would have missed.

Relation to other entries. Three. Appendix C.125 reports that light at street-lighting intensity suppresses diapause in Culex pipiens, the principal West Nile vector in the northern United States, so the vector and the sentinel have now each been separately associated with this exposure. The companion paper by the same lead author on West Nile competence in a wild passerine reservoir, Proceedings of the Royal Society B 2019, remains unread and is the acquisition that would complete the set. And the exposure variable is the same family of product criticized at Part V.J.4 and relied on at Appendices C.3 and C.139.

Bearing on the statutory question. Two, both narrow. Paragraph 360ii(a)(2) and paragraph (a)(4), for the proposition that a relationship between this emission and a notifiable human disease has been reported in the surveillance record of a State health department, and that the relationship is of a shape no two-level study could have found. Section 360kk, by way of caution rather than support: a limit is a point chosen on a curve, and this is a curve whose maximum is not at its right-hand end. Parts V.A.2, V.A.3, V.I and V.J.4.

C.146 Shier, Bird and Wang (2020) — an endangered rodent responds to light at twice the distance at which a traceable spectroradiometer can detect any

Citation. Shier D.M., Bird A.K., Wang T.B. "Effects of artificial light at night on the foraging behavior of an endangered nocturnal mammal." Environmental Pollution. 2020;263:114566. doi:10.1016/j.envpol.2020.114566. Received 7 November 2019, revised 6 April 2020, accepted 7 April 2020, available online 11 April 2020. Authors at Recovery Ecology, Beckman Center for Conservation Research, San Diego Zoo Global; the University of California, Los Angeles; and the University of California, Davis. Original data deposited at Mendeley Data, doi 10.17632/g29z3rdbc6.1.

Funding and interests. San Diego Zoo Global, and a fellowship to the second author from named private donors. The paper states that the funding source had no involvement in the design, collection, analysis or interpretation of the research. No industry funding. The Foundation notes that the obtained copy was a file hosted on the Foundation's own server and that the published article has not been retrieved from the publisher.

Subject. The Stephens' kangaroo rat, Dipodomys stephensi, a nocturnal heteromyid rodent of southern California listed as endangered under the Endangered Species Act. Home ranges of 0.05 to 0.2 hectares with home range cores averaging thirty meters.

Design. Twenty linear arrays, each of ten baited foraging trays five meters apart, with a light on a three-meter pole at one end to create a gradient; arrays at least fifty meters apart. Three treatments assigned at random to each array over three nights: flood light, bug light, and an unlit control. Trays pre-baited for a week, then charged with 12.5 grams of sterilized millet; collected before dawn, sifted, oven-dried and weighed. Depletion scored as a binary, a tray with less than 0.0125 grams remaining counted as depleted, the authors stating that animals generally took nearly all or none. Conducted within three days of a new moon in 2012 and repeated in 2014 with twelve arrays under a full moon. Burrow counts along five by fifty meter belt transects as an index of local density; cottontail presence recorded as a covariate. Logistic regression clustered by array, model selection by Akaike information criterion, Holm-Sidak post hoc comparisons.

THE EXPOSURE MEASUREMENT, WHICH IS THE REASON THIS ENTRY IS AT PART V.J.4. A StellarNet SILVER-Nova Super Range spectroradiometer covering 190 to 1,110 nanometers, cooled silicon charge-coupled linear array, with a miniature ultraviolet-visible-near-infrared cosine receptor calibrated for irradiance against calibration lamps traceable to the National Institute of Standards and Technology. Mounted on a tripod eight centimeters above the ground facing the source. Three measurements averaged at each of the ten tray positions, all on one clear night, at least two hours after sunset and two hours before sunrise. Reported as vector irradiance in milliwatts per square centimeter and converted to photon flux density in nanomoles of photons per second per square meter. The authors state that they measured irradiance rather than lux because lux is weighted to human spectral sensitivity. They also converted to lux, using 555 nanometers as a single representative wavelength and a general-purpose online unit converter, expressly to allow comparison with other studies; that conversion is an approximation and the comment does not use any lux figure from this paper.

The lamps, identified by manufacturer, which is rare in this appendix. Flood: a SolarGoesGreen Super Bright Solar Flood Light of 108 light-emitting diodes, described as equivalent to a 150-watt incandescent, rated 756 lumens, emitting between 400 and 700 nanometers. Bug: a Feit Electric 13-watt compact fluorescent of yellow hue, described as equivalent to a 60-watt incandescent, rated 300 lumens, emitting between 550 and 650 nanometers, housed in an aluminum clamp surround. Spectra are given in the supplementary material, which the Foundation has not seen.

Principal results. Light treatment significantly altered foraging, chi-square 19.59 on 2 degrees of freedom, p below 0.01. Depletion was significantly greater under the control than under the flood light, z of 4.03, and than under the bug light, z of 2.70, both p below 0.01; the two lit treatments did not differ significantly from each other, with a trend favoring the bug light. Treatment interacted with distance, chi-square 9.82, p below 0.01: under the control there was no change in depletion with distance, while under both lamps the probability of depletion rose with distance from the source. Under the new moon, effects were significant to forty meters for the bug light and fifty meters for the flood light, fifty meters being the furthest tray. Under the full moon there was no treatment-by-distance interaction, chi-square 0.23; bug light and control did not differ, while the flood light remained significantly different from the control to forty meters. Local burrow density predicted foraging, z of 2.40, p below 0.02. Cottontail presence did not, z of 0.15, p of 0.88. Under the control at new moon, roughly eighty to ninety percent of trays were depleted regardless of distance.

THE FINDING THE COMMENT TAKES FIRST, IN THE AUTHORS' WORDS. That irradiance fell with distance only to twenty-five meters, "at which point light was no longer detected," while behavioral effects were significant to forty and fifty meters. The authors offer two readings without choosing: that the instrument was not sensitive enough beyond twenty-five meters, or that the effects extend beyond the point at which irradiance is measurable. They conclude that effects of skyglow on behavior may extend beyond those of irradiance and that both irradiance and radiance need to be measured. Part V.J.4 sets out the three consequences the Foundation draws and does not add this entry to the count of spectral attestations kept there, because the defect here is sensitivity and not spectral blindness.

The second finding, taken at Part V.I. That the yellow narrow-band lamp, emitting only between 550 and 650 nanometers and rated at less than half the output of the white lamp, nonetheless suppressed foraging significantly to forty meters. The authors observe that this does not bear out the prediction, which they attribute to the 2018 rapid-assessment paper at Appendix D.6, that yellow and amber sources will have less impact.

What it does not establish. Any human effect, and the authors claim none. Any fitness or population endpoint: foraging patch depletion is a behavioral proxy, and survival, reproduction, body condition and persistence were not measured, which the authors state and call for. The independent contribution of spectrum, the two lamps differing in output, spectrum, shielding and diffusion together, which the authors also state. And nothing about the far end of the relationship, which the experiment did not reach.

Considerations bearing on confidence. Against. The behavioral measure is binary and the threshold for depletion was set by the investigators. Density was indexed by burrow counts, which the authors acknowledge are not directly correlated with numbers. The two moon conditions were run two years apart, so season, cohort and year are not separated from lunar phase. Cottontail presence was not recorded for every tray and had to be tested in a separate model. And one matter the Foundation raises as a question rather than a defect: arrays were placed at least fifty meters apart, and the stated reason was the thirty-meter home range core of the species rather than the propagation of light; since the flood-light effect was significant at fifty meters, the spacing criterion and the measured effect distance are the same number, and whether lights at neighboring arrays could reach one another's trays depends on a geometry the paper does not give. In favor. A field experiment with randomized assignment of treatment to array and a repeated design. A real exposure gradient rather than a lit-against-unlit comparison, which is the design Part V.A.2 asks for. Radiometric measurement with traceable calibration at the animal's height. Named commercial lamps. Data deposited and publicly available. And the authors report the failure of their own instrument rather than omitting it.

A fact about the species recorded and not used. The subject is listed as endangered under the Endangered Species Act. The Foundation does not rely on the listing, for the reasons given at Appendix C.140 in the entry on the monarch butterfly: the statute is administered by a different Department and the comment's submission does not depend on it. The entry is used for the measurement, for the mammalian endpoint and for the failure of the yellow lamp.

Bearing on the statutory question. Paragraph 360ii(a)(4), which directs the Secretary to study and evaluate emissions of, and conditions of exposure to, electronic product radiation. This is the one study in the appendix in which the emission was characterized radiometrically at the receptor and the condition of exposure was varied systematically, and the answer it returned is that the instrument ran out before the biology did. Paragraph 360ii(a)(5), for the development of measurement procedures, because the gap this study exposes is one of sensitivity at low levels. The emissions limb of paragraph 360ii(a)(2), the exposure being two identified consumer products at stated outputs. Parts V.A.2, V.A.3, V.I, V.J.4 and IX.C.

C.147 Seymoure, Buxton, White, Linares, Fristrup, Crooks, Wittemyer and Angeloni (2025) — a global estimate of how much of the earth is lit above a natural night, and the one compilation of effect thresholds across species

Citation, and a warning that governs every line of this entry. The published article is reported to be Seymoure B.M. and others, "Global artificial light masks biologically important light cycles of animals," Frontiers in Ecology and the Environment 2025;23(4):e2832, doi 10.1002/fee.2832. THE FOUNDATION HAS NOT READ THAT ARTICLE. What it has read is the authors' own preprint of the same work under its earlier title, Anthropogenic Light Disrupts Natural Light Cycles in Critical Conservation Areas, deposited on the Social Science Research Network at doi 10.2139/ssrn.3439670 and bearing on its face the statement that it was then in review. The published citation above is taken from a National Park Service magazine summary and has not been verified against the journal. Associated data are deposited at Mendeley, doi 10.17632/jcrz5773dv, whose fifth version is dated 11 April 2025.

WHY THAT MATTERS MORE HERE THAN IN THE OTHER PREPRINT ENTRY. Because the work changed. The title changed, and the same National Park Service summary attributes to the published paper two findings the preprint does not contain: that about twenty-six percent of the earth's surface is now under perpetual moonlight, and that this could reach about fifty percent by 2052. A projection to a future year is not a refinement of a preprint; it is new work. The preprint also states that its data were not public while in review, and the deposited dataset reached a fifth version six years after the preprint. Nothing in this entry may be filed on the strength of the preprint, and the two figures above are not stated anywhere in the body of this comment.

Authors and affiliations. Colorado State University, Department of Biology and Department of Fish, Wildlife and Conservation Biology; and the Natural Sounds and Night Skies Division of the National Park Service, Fort Collins. The participation of a United States federal scientist is recorded; Part II.H collects federal involvement in this subject, and the Division named here is the same one whose all-sky mosaic technique the Australian guidelines at Appendix D.1 describe and whose Duriscoe is a co-author of the observatory review at Appendix D.7.

Method, as the preprint states it. The New World Atlas of Artificial Night Sky Brightness, which is itself modeled from satellite upward radiance, supplies zenith sky luminance. That was converted into a predicted horizontal illuminance at the ground using a radiative transfer model of skyglow, which the authors state was validated against all-sky monitoring data collected within United States National Parks. Results are expressed in millilux and binned to lunar equivalents: minimal below 0.1 millilux, new moon 0.1 to 1, crescent 1 to 10, quarter 10 to 100, and full above 100. Resolution is given as 852 square meters, excluding latitudes beyond 60 degrees south and the far north.

THE EXPOSURE VARIABLE, WHICH IS THE WEAKEST CHAIN IN THIS APPENDIX AND IS STATED BEFORE ANY FINDING. Four steps separate the emission from the number. A satellite radiometer that Appendix D.1 records as insensitive to blue light measures upward radiance. A published atlas models sky brightness from it. A radiative transfer model converts that to illuminance at the ground. And the result is expressed in lux, a quantity weighted to human photopic vision, which the same Appendix D.1 says should not be used for non-human subjects. The entry is nonetheless in this appendix and is counted at Part V.J.4 among the entries taking a satellite product as their exposure variable, because the chain is disclosed on the face of the paper and because the third step is the only one in this comment that was validated against independent ground measurement.

Principal results as the preprint states them. That anthropogenic illuminance exceeding the natural moonless level reaches 22.9 percent of the earth's terrestrial surface; 51.0 percent of Key Biodiversity Area units and 77.1 percent of Global Protected Area units, though only 6.1 percent and 9.0 percent of their total area; and about twenty percent of the most biodiverse areas for mammals, birds and amphibians. That 5.5 percent of terrestrial land experiences at least perpetual crescent-moon illuminance. That the greatest exposure among Key Biodiversity

Areas is in Europe, at about sixty percent of area, and the Middle East at about forty-three percent.

THE RESULT THE COMMENT ACTUALLY WANTS, WHICH IS THE LITERATURE REVIEW AND NOT THE MAP. A systematic review of organismal responses, compiled against illuminance up to nautical twilight, found effects reported in 117 species from 23 orders across 8 classes of arthropods and chordates. Binned: 77 species affected between 100 and 3,000 millilux; 25 between 10 and 100; 18 between 1 and 10; and 28 species altering activity, foraging or vigilance below 1 millilux, of which five were cases of elevated mortality in prey species. Examples given: new-moon levels initiate foraging in tropical sweat bees and stimulate courtship in fireflies; crescent-moon levels alter circadian rhythms in hamsters. The authors state that the studies are not evenly distributed across light levels. This is the nearest thing the Foundation has found to the species-by-threshold compilation that paragraph 360ii(a)(4) would require, and it is presently behind a citation the Foundation has not verified.

What it establishes. Nothing, until the published article is read. Subject to that, and on the preprint alone: that a majority of designated protected area units worldwide are lit above the level of a natural moonless night; and that biological effects have been reported across four orders of magnitude of illuminance, including below the natural moonless level.

What it does not establish. Any human effect, and it does not address human health. Any effect at any location: the map is a model and the biology is a review of other people's studies, so no organism was observed in this work. Anything about spectral composition, the exposure chain being spectrally blind at its first step and photopically weighted at its last. And nothing about any product.

Bearing on the statutory question. Paragraph 360ii(a)(4), for the proposition that the compilation of effect thresholds against exposure has been attempted once, by eight investigators including a federal scientist, and exists in one review. Paragraph 360ii(a)(2) on the emissions limb, skyglow being the subject. Part V.A.2, where the threshold compilation is reported; Part V.I, for the natural darkness figures; Part V.J.4, where the exposure chain is counted.

C.148 Alaasam, Duncan, Casagrande, Davies, Sidher, Seymoure, Shen, Zhang and Ouyang (2018) — two commercial lamps equalized in the wrong unit, a warmer one indistinguishable from darkness, and a manuscript in this Department's own repository

Citation. Alaasam V.J., Duncan R., Casagrande S., Davies S., Sidher A., Seymoure B., Shen Y., Zhang Y., Ouyang J.Q. "Light at night disrupts nocturnal rest and elevates glucocorticoids at cool color temperatures." Journal of Experimental Zoology Part A: Ecological and Integrative Physiology. 2018;329(8-9):465–472. doi:10.1002/jez.2168. Read as the accepted author manuscript deposited in PubMed Central under the HHS Public Access policy, available in PubMed Central from 1 October 2019. Authors at the University of Nevada, Reno (Biology, and Electrical and Biomedical Engineering); the Max Planck Institute for Ornithology; Quinnipiac University; and Colorado State University.

FUNDING, WHICH IS THE MOST DISTINCTIVE FACT ABOUT THIS ENTRY. The National Institute of General Medical Sciences of the National Institutes of Health, grant P20 GM103650, supported the senior author. A graduate fellowship of the University of Nevada supported the first author. The National Park Service Natural Sounds and Night Skies Division supported a co-author through a postdoctoral fellowship. No industry funding is declared and no competing interests statement was located in the manuscript read; one must be obtained from the published version. Because the work was funded by an operating division of this Department, the manuscript is deposited in the Department's own public access repository, which is where the Foundation read it. Part V.I states what the Foundation makes of that and Part II.H is where it may belong.

Design. Twenty-four adult zebra finches, twelve male and twelve female, habituated for thirty-eight days under a ten-hour light and fourteen-hour dark cycle before treatment, in Reno, Nevada. Three treatments, eight animals each: a night-light fitted with a strip of three diodes rated 5,000 kelvin; the same fitted with diodes rated 3,000 kelvin; and an identical fixture containing no diodes. Output attenuated by covering the diffuser with black paper to reach the required level. Endpoints: body condition by scaled mass index, food intake, locomotor activity by day and by night, and plasma corticosterone by enzyme-linked immunosorbent assay, analyzed as within-individual change from pre-treatment values. Generalized linear mixed models with treatment by day interaction and Tukey post hoc comparisons; individual as a random effect.

THE EXPOSURE, AND THE OBJECTION THE FOUNDATION MAKES TO HOW IT WAS SET. Both lamps were standardized to 0.3 lux, plus or minus 0.01, measured at perch height fifteen centimeters from the light and at the far corners of the cage, with an Extech Easyview handheld digital light meter, model EA13. Control cages measured below 0.01 lux. The figure of 0.3 lux was chosen because a published study reports that free-living birds near street lamps experience about that illuminance. The objection is not to the level but to the quantity. Lux is weighted to the human photopic response, so two lamps set to the same lux do not deliver the same radiant energy and the cooler lamp necessarily delivered more short-wavelength energy at the same reading. The experiment therefore compares two sources matched for human brightness and differing in the quantity at issue, which means the result is about spectral content at equal photopic illuminance and not about correlated color temperature as such. Two further matters: the instrument is a handheld consumer meter used at three tenths of a lux and reported to a hundredth, which is a precision that must be checked against the instrument's own specification; and the spectra of the two lamps are not published in this paper, the authors directing the reader to figures in a different paper by one of them.

Principal results. No differences between groups before treatment in corticosterone, food consumption, weight, fat, body condition, nighttime activity or total activity, all probabilities above 0.1. Under treatment, birds in the 5,000 kelvin group had higher rates of nighttime activity than both the 3,000 kelvin group and the controls, peaking after about one week and highest on days nine to thirteen. The same group showed a within-individual increase in corticosterone relative to pre-treatment, against the other two groups. No change in body condition or food intake in any group, including on day twelve when nocturnal activity was at its highest. No compensating reduction in daytime activity. The 3,000 kelvin group did not differ from the unlit controls on either measure.

What it establishes. That at a photopic illuminance of three tenths of a lux, a commercial diode strip sold as 5,000 kelvin disrupted nocturnal rest and raised a glucocorticoid in a captive diurnal bird over about two weeks, while one sold as 3,000 kelvin, set to the same photopic illuminance, did not differ from darkness on those two measures in groups of eight.

What it does not establish. Any human effect. Any fitness effect: body condition and food intake did not move, and survival, reproduction and pathology were not measured. That a 3,000 kelvin lamp is without effect, the comparison resting on eight animals a group with no power calculation reported. That correlated color temperature is the operative variable, for the reason given above. And nothing about longer exposures; the authors state that continued treatment might produce pathology, and alternatively that the declining activity peak may indicate acclimation.

Considerations bearing on confidence. Against. Eight animals a group. Captive-bred birds which the authors state had presumably never experienced light at night, natural or artificial, so the response may not represent that of a wild population. Corticosterone by a commercial immunoassay, validated by the authors for this species. Melatonin, the mediator usually proposed, was not measured, and the authors state they did not measure the non-visual photoreceptors to which they attribute the mechanism. The spectra are not in the paper. In favor. Randomized assignment with pre-treatment equivalence demonstrated on seven

measures. Within-individual change rather than between-group comparison for the hormone. Named commercial lamps at commercially available color temperatures rather than laboratory sources. An exposure chosen from a published field measurement rather than for convenience. Intra- and inter-plate coefficients of variation reported at 1.7 and 2.5 percent. And the authors qualify their own recommendation in four separate ways.

Relation to other entries. Four. It is the one entry in which a reduction in short-wavelength content removed an effect in a living animal, and Part V.I has been amended for the fifth time on account of it. It sits against Appendix C.128, where at a fixed intensity every spectrum tested produced a large effect, and against Appendix C.146, where a lamp emitting only between 550 and 650 nanometers suppressed foraging in a mammal to forty meters. Brett Seymoure is a co-author here and the first author of Appendix C.147. And the illuminance of 0.3 lux is the third appearance of that figure in this comment, after the Australian guidelines at Appendix D.1 and the source both cite.

Bearing on the statutory question. The emissions limb of paragraph 360ii(a)(2), the exposure being two commercial lamps at a stated photopic illuminance. Paragraph 360ii(a)(4), for the proposition that a standardization performed in a photometric unit does not hold the emission constant, which is the measurement argument of Part V.J made visible in an experimental design. Part I.G, for the inadequacy of correlated color temperature as a descriptor and for a recommendation expressed in it by authors who did not publish their spectra. Parts V.F, V.I, V.J.4 and II.H.

C.149 Seymoure, Linares and White (2019) — nine street lights measured and five visual systems modeled, with the finding that lamps a human cannot tell apart are told apart by birds and insects

Citation. Seymoure B.M., Linares C., White J. "Connecting spectral radiometry of anthropogenic light sources to the visual ecology of organisms." Journal of Zoology. 2019. doi:10.1111/jzo.12656. Authors at Colorado State University, Department of Biology and Department of Fish, Wildlife and Conservation Biology. Read as a file hosted on the Foundation's own server; the volume, issue and pagination are not on the copy read and must be obtained.

Design. Measurement plus modeling, with no organism observed. In collaboration with the City of Fort Collins Utilities, the authors measured the radiance of nine street lights in service: high-pressure sodium at 70, 100, 150, 250 and 400 watts; mercury vapor at 175 and 250 watts; metal halide at 1,000 watts; and a light-emitting diode at 73 watts. Radiance was measured at twenty-five meters from each light using a StellarNet SILVER-Nova spectroradiometer with a radiance probe aligned by two laser pointers mounted in a three-dimensionally printed block, the lasers being switched off for the measurement. Output recorded as energy flux in watts per square meter per second per nanometer and converted to photon flux in photons per square centimeter per second per steradian per nanometer, with the solid angle scaled from the probe's aperture to one steradian. Spectra summarized as total brightness by integration, and as chroma and hue.

The modeling. Quantum catch computed for each photoreceptor of five visual systems from published peak sensitivities and Govardovskii templates: an ultraviolet-sensitive passerine, a violet-sensitive passerine, a human, a wolf and a hawkmoth. Four non-visual photoreceptors were included, neuropsin at 360 nanometers, pinopsin at 470, melanopsin at 484 and vertebrate ancient opsin at 490. Chromatic contrast computed as just noticeable differences by a receptor-noise model using published cone ratios, with values below one taken as physiologically indistinguishable and the authors adopting three as the conservative threshold below which two sources are unlikely to be seen as different. Color space overlap computed as a descriptive check and not tested statistically.

THE PRINCIPAL FINDING. "Most interestingly, humans see a much different nocturnal urban environment than other animals as humans see most lights as the same color, yet birds and insects are likely seeing a myriad of differently colored lights in their environment." The modeled contrasts were above threshold for most lamp comparisons in the avian and hawkmoth systems; in the two mammalian systems many comparisons fell below it, with the authors recording that a human would most likely not discriminate the two mercury vapor lamps and that all the sodium lamps would be seen as one color.

The second finding, which bears on how a standard could be written. That the same lamp technology at different powers produces different spectra. The authors state that this corroborates an earlier measurement study, that it contradicts "current doctrine" that similar light sources have the same spectral composition regardless of power, and that previous research in this field has assumed that sources within a type are the same color, naming three papers. Two of those three are recorded elsewhere in this comment as acquisitions for the spectral-descriptor argument, which is why the Foundation records the criticism here rather than leaving it to be discovered.

What the study says that does not help the Foundation, recorded because the body relies on this paper. That by the hue metric used here the metal halide had the greatest short-wavelength composition of the nine, and the diode and the sodium lamps the greatest long-wavelength composition; the single diode measured was therefore not the bluest lamp in this sample. That only the 1,000-watt metal halide was significantly brighter than the rest, and that the authors regard subtle brightness differences as probably irrelevant to an adapting eye. The objection the authors do make to the diode is that it was the least chromatic, that is the most broadband, and was accordingly "most likely to stimulate photoreceptors regardless of visual system," which is a different and more precise objection than an excess of short-wavelength content and is the one the comment adopts.

What it establishes. That nine street lights in one American city differ measurably in spectral shape by technology and by power; that on published receptor sensitivities and a standard discrimination model, avian and insect visual systems would distinguish most of them while two mammalian systems would not; and that the long-wavelength photoreceptors were predominantly stimulated under most of the sources.

What it does not establish. Any effect on anything. No organism was observed, no behavior measured and no physiological endpoint recorded; the authors say expressly that very little is known about how spectral composition alone affects visually guided behavior and physiology. Nothing about human health. And nothing about lamps outside this sample: one diode, one metal halide, two mercury vapor and five sodium lamps, all in one city.

Considerations bearing on confidence. Against. A sample of nine fixtures in one municipality, with a single example of the technology the comment is most concerned with. The authors acknowledge that fixture height, cleanliness and bulb age could introduce uncontrolled differences. Every perceptual statement is modeled, resting on published peak sensitivities, published cone ratios and three stated assumptions about how color discrimination operates. The color-space overlap analysis is descriptive and was not tested. In favor. Radiance measured on deployed hardware at a stated distance with a named sensitive spectroradiometer and a described alignment method, reported in radiometric units and converted to photon flux. A municipal utility collaborated, which is why lamps in service could be measured at all. Peak sensitivities and cone ratios are tabulated with citations for every species. And the authors criticize an assumption in the prior literature, including in work by investigators this comment otherwise relies on.

Relation to other entries. Four. It is the third entry, with Appendices C.133 and C.141, in which a visual system was modeled rather than assumed, and Part V.A.3 has been conformed. It is the second entry, with Appendix C.139, excluded from the census of non-human-subject entries because no organism was observed. Its instrument is of the same family as the one used

at Appendix C.146, which is the only other entry in this appendix to measure a real exposure radiometrically with a traceable instrument. And Brett Seymoure is the first author here, the first author of Appendix C.147 and a co-author of Appendix C.148.

Bearing on the statutory question. Section 360kk, which requires that a performance standard prescribe an emission characteristic. This entry is the Foundation's evidence that the characteristic cannot be the lamp technology, because the same technology at a different power emits differently, and cannot be a descriptor keyed to human perception, because lamps a human cannot tell apart are physically different and are discriminated by other receiver systems. Paragraph 360ii(a)(4), for a worked example of what it looks like to characterize an emission properly. Part I.G, which is written on it; Part V.A.3; Part IX.G.1 and Part IX.J.

C.150 Van Doren, Horton, Dokter, Klinck, Elbin and Farnsworth (2017) — a light switched off and on for seven years, 1.1 million birds, and an effect that ended in minutes

Citation. Van Doren B.M., Horton K.G., Dokter A.M., Klinck H., Elbin S.B., Farnsworth A. "High-intensity urban light installation dramatically alters nocturnal bird migration." Proceedings of the National Academy of Sciences. 2017;114(42):11175–11180. doi:10.1073/pnas.1708574114. Received 29 May 2017, approved 31 August 2017, edited by James A. Estes. Authors at the Cornell Lab of Ornithology, the University of Oxford, the University of Oklahoma and New York City Audubon. Visual counts archived in eBird. Read from a file hosted on the Foundation's own server; the volume, issue and page range above are partly inferred from the page footer and must be verified.

Why this entry is here, stated first. Not for its magnitudes, which concern an extraordinary installation, but for its design. It is the only study in this appendix in which a real deployed emission was repeatedly switched off and on while the biological response was measured in both states. Every standing objection recorded at Part V.A.2 — that exposure cannot be assigned, that controls are not dark, that urbanization confounds, that the dose-response is unobserved — is answered here by the operating practice of the installation rather than by any analytical device.

The exposure and how it came to be switched. The National September 11 Memorial and Museum's Tribute in Light, a pair of vertical beams in Lower Manhattan operated on the night of 11 September. By agreement between New York City Audubon and the Museum, when observers on the ground count more than one thousand birds circling in the beams, the lights are extinguished for about twenty minutes. The Foundation notes the form of that control: it is triggered by a biological observation made by a person on site and not by any measured property of the emission.

Design. Nights of 11 September, 2008 to 2016. 2009 and 2011 excluded for precipitation, which corrupts radar returns; 2014 excluded from the illumination comparisons because the lights were not shut down; seven years analyzed. Bird densities and radial velocities from the KOKX Brookhaven weather surveillance radar at about 0.5 and 1.5 degrees elevation, the installation lying 98.5 kilometers from the radar, analyzed within a 20-kilometer radius and in a cylinder of 500-meter radius and 1.7-kilometer height over the site. Baseline defined as the mean and standard deviation of density between 2 and 20 kilometers from the installation, with a standardized peak density expressed as the number of standard deviations above that baseline. Continuous acoustic recording of flight calls at the base of the installation at 32 kilohertz. A flow model simulating three behavioral parameters: the probability that the lights affected nearby birds, the distance over which they did so, and whether disoriented birds flew preferentially toward the display.

Principal results. Peak densities near the installation exceeded twenty times baseline in all seven years, sixty times in five years and a hundred and fifty times in three (2008, 2012 and 2013), while in the absence of illumination the peak never exceeded thirteen times baseline. At the lower radar elevation, maximum standardized densities were fourteen times greater when

illuminated (t equals 5.70, p below 0.0001) and maximum bird numbers 3.4 times greater (t equals 3.89, p equals 0.0003). At the higher elevation, sampling altitudes of 2.4 to 4.1 kilometers, standardized densities rose on average 3.9 times (t equals 3.25, p equals 0.002) and numbers 3.3 times (t equals 2.34, p equals 0.023). Over all observations, numbers within 500 meters averaged 3.4 times higher when lit (t equals 9.34, p below 0.0001) and standardized peak densities 6.4 times higher (t equals 3.72, p equals 0.0003), the effect reaching 46 times in 2015. An estimated 1.1 million birds, interval 0.6 to 1.6 million, were affected across seven nights. Vocal activity was intense during aggregation. The simulation could reproduce the observed concentrations only by allowing directed flight toward the light by disoriented birds.

THE FINDING THE COMMENT TAKES FIRST. That the effect ended with the emission. Removal of illumination produced dispersal, increased flight speed, reduced calling and departure from the site "in a matter of minutes," and the authors state that short-term removal "eliminated its disruptive effects almost instantaneously." Part V.I sets out what the Foundation makes of that, which is that the characteristic controlled was duration and that the remedy was a switch.

Two conditions that defeat standing objections. That the aggregations occurred under clear skies, the previous literature having associated such events with fog and low cloud; and that they occurred in Lower Manhattan, against one of the most heavily lit backgrounds anywhere. The marginal effect of a single installation on top of that background, in good visibility, was a twentyfold aggregation in every year.

THE EXPOSURE WAS NEVER CHARACTERIZED, AND THAT IS WHY THIS ENTRY IS ALSO AT PART V.J.4. The Foundation can find in this paper no lumen, candela, lux, watt, irradiance, radiance or spectrum for the light source. The word intensity appears in the title and in a comparison with an installation in Las Vegas, and nowhere as a quantity. The exposure variable is binary: the lights were on or they were off. The Foundation makes no criticism of the authors, who are ornithologists measuring birds at four kilometers and do not own the installation, and records the fact because the Department is asked to derive a prescribable number from this literature.

What it establishes. That a single ground-based vertical light installation concentrated nocturnally migrating birds at more than twenty times background density in every year observed, altered their flight speed, flight path and calling, did so at altitudes of up to about four kilometers, and that all of these effects ceased within minutes when the installation was switched off.

What it does not establish. Any human effect. Any mortality: no dead bird was counted and no collision observed, and the comment does not assert a death from this study. Any dose-response: the exposure has two states and no measured magnitude, so nothing in it identifies a threshold or a shape. And nothing transferable about ordinary street lighting, the authors stating that few installations of comparable intensity exist in the United States.

Considerations bearing on confidence. Against. A single installation on a single calendar night each year, so season, site and date are not varied. The radar is 98.5 kilometers away and its beam at that range is wide, which the authors address by restricting the analysis volume and by adjusting for birds below the beam. The shutdowns are not randomized; they are triggered by an observer counting a thousand circling birds, so periods of darkness follow periods of unusually high aggregation by construction, which tends to make the lit periods look worse and is a form of regression to the mean the paper should be checked for. Three of nine years were excluded. In favor. Repeated within-site switching of a real exposure across seven years. Two independent sensing modalities, radar and acoustic, agreeing. A simulation that tests the mechanism rather than assuming it. Effect sizes with test statistics and probabilities throughout. Publication in a journal of the first rank with a named editor. And an operating agreement with a conservation body that created the natural experiment in the first place.

Bearing on the statutory question. Paragraph 360ii(a)(5), which directs the Secretary to develop, test and evaluate the effectiveness of procedures and techniques for minimizing exposure. This is a procedure, tested, and found effective within minutes. Paragraph 360ii(a)(2) on the emissions limb. Paragraph 360ii(a)(4), for the proposition at Part V.J.4 that a well-designed study of a real installation may contain no characterization of the emission at all. Parts V.A.2, V.I, V.J.4, IX.C and IX, where the reversibility is relied on.

C.151 Pawson and Bader (2014) — six color temperatures at identical radiant power, and no difference

Citation. Pawson S.M., Bader M.K.-F. "LED lighting increases the ecological impact of light pollution irrespective of color temperature." Ecological Applications. 2014;24(7):1561–1568. Published in the Communications section. Authors at Scion, Christchurch and Rotorua, New Zealand. Read from a file hosted on the Foundation's own server; the digital object identifier is not on the copy read and must be obtained.

Why this entry is here. For one thing only: it is the single experiment the Foundation has found that varied correlated color temperature while holding radiant power constant, and measured a biological response. Part I.G is written on that comparison. Everything else in the paper is recorded and not relied on.

Design of the comparison relied on. Six white light-emitting diodes of six different correlated color temperatures, in three independent blocks, on the boundary of a dairy processing facility at Rakaia, Christchurch, with blocks on long grass or gravel surrounded by pasture and shelter belts of Pinus radiata. A control treatment used an eighteen-ohm resistor matched to the power consumption and heat output of the diodes, so that the control differed from the treatments in light and not in warmth. Flying invertebrates collected in traps.

THE MATCHING, WHICH IS THE REASON THE RESULT IS USABLE. The drive current of each diode was adjusted through a potentiometer on a commercial driver until every color temperature produced the same radiant power, 12 milliwatts plus or minus 1 by standard deviation. Power was measured by collimating the emission through a stated lens onto a thermopile sensor and averaging over ten-second intervals with a laboratory power meter. Emission spectra were measured for each color temperature and are reproduced in the paper. The authors also verified that the adhesive-coated trap surface did not alter the relative proportion of light emitted in the blue-green region. This is the only study in Appendix C in which sources of differing spectrum were equalized in a radiometric quantity rather than a photometric one.

Result. Twelve thousand eight hundred and sixty invertebrates were caught, of which 8,879 were Diptera, 1,674 Lepidoptera, 1,089 Thysanoptera, 450 Coleoptera, 379 Hymenoptera and 144 Neuroptera, with fewer than a hundred each of seven further groups. Pooling flying taxa, the lamps attracted significantly more invertebrates than the unlit controls at every color temperature. The difference between control and lamp was taxon-dependent: strong in Diptera and Lepidoptera, absent in Thysanoptera, Hymenoptera and Coleoptera. And in the authors' words, irrespective of taxa the color temperature had no significant effect on invertebrate attraction.

The second comparison, which the comment records and does not use. Separately, at an industrial wood processing site in Hawkes Bay, five replicate pairs of luminaires were operated on alternating nights over ten nights: a 360-watt high-pressure sodium lamp of a named model against a 4,000 kelvin light-emitting diode high bay luminaire of a named model. Traps at the diode luminaires caught 48 percent more flying invertebrates on average, with a significant interaction between light type and air temperature. The Foundation does not rely on that figure. The paper does not state that the outputs of the two luminaires were equalized in any quantity, and they are different products of different wattages installed on buildings, so the comparison is between two lighting installations and not between two spectra at equal power. It

is evidence about what happens when a site converts, which is a real question, and it is not evidence that the spectrum caused the difference.

What it establishes. That across six commercially available white color temperatures, at identical measured radiant power, the choice of color temperature made no significant difference to the number of flying invertebrates attracted; and that all six attracted significantly more than an unlit control of matched heat output.

What it does not establish. Any human effect. That spectrum is irrelevant, the finding being about one descriptor and not about spectral composition. Any effect other than attraction. And nothing about the three orders in which no difference from the control was detected.

THE LIMITATION THAT GOVERNS EVERY USE OF THIS ENTRY. The endpoint is attraction measured in light traps. Appendix C.142 establishes, on its authors' own evidence, that the number of adult insects attracted to a lighting technology may not serve as a suitable proxy for ecological impact, and Appendix C.135 establishes that only a small fraction of the animals affected by a lamp are caught at it. This study therefore measures a quantity this comment has twice recorded as a poor proxy. The Foundation uses it for what the proxy problem does not touch, which is the comparison between color temperatures at matched power: whatever attraction is a proxy for, it was the same proxy for all six lamps.

Considerations bearing on confidence. Against. Attraction as the endpoint, as above. Three blocks. A single site for each comparison, both in New Zealand, in one austral summer. Trapping on ten nights within a fortnight for the luminaire comparison, with the authors noting the ten occasions are not truly independent and testing for repeated measures. Invertebrates identified to order rather than species. And one night of anomalously low catch attributed to an easterly wind, which the authors report rather than exclude. In favor. Radiometric matching with a named instrument and a stated tolerance. Measured emission spectra. A control matched for heat as well as for the absence of light. Randomized assignment and alternation of the active lamp between nights in the luminaire comparison. Named commercial products. And a result that is null on the variable the authors hypothesized would matter, reported as such.

Relation to other entries. Four. It is the fourth study in this comment in which a spectral adjustment failed to deliver the expected reduction, after the moth experiment at Appendix C.128, the yellow lamp at Appendix C.146 and the modeling at Appendix C.141, and the first in which the descriptor itself was the manipulated variable. It stands against Appendix C.148, where a warmer lamp did remove an effect, and the difference between the two is the matching quantity: radiometric here, photometric there. Its proxy problem is the one stated at Appendices C.135 and C.142. And its taxon-dependence is of a piece with the divergent invertebrate result recorded at Appendix D.8.

Bearing on the statutory question. Part I.G, which is written on it, for the proposition that correlated color temperature is not the quantity in which a spectral limit should be written. Section 360kk, for the same reason: a performance standard must prescribe an emission characteristic, and this is evidence that this particular characteristic does not track the effect. The emissions limb of paragraph 360ii(a)(2). Parts V.I and IX.J.

C.152 Stone, Jones and Harris (2012) — bats avoid diode street lighting at 3.6 lux, and the authors report that they did not reach a threshold

Citation. Stone E.L., Jones G., Harris S. "Conserving energy at a cost to biodiversity? Impacts of LED lighting on bats." Global Change Biology. 2012;18(8):2458–2465. doi:10.1111/j.1365-2486.2012.02705.x. Received 13 January 2012, accepted 3 March 2012. Authors at the School of Biological Sciences, University of Bristol. Read from a file hosted on the Foundation's own server; the issue number is inferred and must be verified.

Design. A field experiment at ten sites in southwest England and Wales, near lesser horseshoe bat maternity roosts, between May and August 2009, six nights at each. Hedgerows were illuminated with two portable cool white light-emitting diode lamps, each containing twenty-

four high-power diodes of 2.4 watts, mounted 1.7 meters high on one side of the hedge and powered by a named silenced portable generator. Five treatment types: a control with detectors only; a noise treatment with the lamps installed but switched off and the generator running all night; and three lit treatments at low, medium and high intensity. Illuminance was measured below the lights: low, mean 3.6 lux, standard deviation 0.48, range 2.90 to 4.86; medium, mean 6.6 lux, standard deviation 0.93, range 4.95 to 8.60; high, mean 49.8 lux, standard deviation 4.50, from a range beginning at 38.10. The sequence of lit treatments was randomized among nights three to five across sites to control for order. Bat activity recorded as passes by detectors on each side of the hedge and identified to species or species group from call parameters. Repeated-measures general linear models; temperature and rainfall tested and found not to differ among treatment nights, and therefore excluded.

Principal results. Activity of the lesser horseshoe bat and of Myotis species was significantly reduced under the lights, including at the lowest intensity of 3.6 lux. For Myotis species the treatment effect was significant, F equals 6.28 on 5 and 30 degrees of freedom, n of 7, p equals 0.004, with no significant difference between the medium and low treatments. No effect was detected on the faster-flying Pipistrellus pipistrellus, Pipistrellus pygmaeus or Nyctalus and Eptesicus species. There was no significant difference between the control and the first noise night, so the generator does not account for the result.

The behavioral observations, which show what the detectors could not. Direct observation of the lesser horseshoe bat on twenty-nine lit nights at all ten sites: on 56 percent of observations bats flew through the lights and on 44 percent they avoided them. Of those that avoided, 53 percent flew over the hedge and out of sight, 43 percent turned around before the lights, 3 percent flew through the hedge and 1 percent may have avoided detection by flying high or wide. Activity on the unlit side of the hedge did not differ by treatment, F equals 1.202 on 5 and 30 degrees of freedom, n of 7, p equals 0.332, so the animals were not simply using the dark side instead. Measured illuminance on the unlit side was 0.59 lux on lit nights against 0.55 lux on control and noise nights, so there was no material spillover.

THE SENTENCE THE COMMENT RELIES ON. "reducing light intensity has often been advocated as a potential mitigation strategy for lighting schemes affecting bats; this assumes that there is a critical light threshold below which there are no negative effects on bat activity. However, for these species, we have shown that light levels would have to be lower than at least 3.6 lux before a potential threshold is found." Part V.A.2 sets out what the Foundation makes of that, and sets it against the entry for the same species at 51.67 lux in the table at Appendix D.7, which cites the same first author three years earlier.

The authors' own doubt about their own remedy, recorded because it runs against the Foundation. That achieving such low levels may not be practical, since public perception of safety combined with the practicality of achieving them often precludes dimming to very low levels. An experiment that fails to find a threshold above 3.6 lux does not establish that 3.6 lux can be delivered on a public road, and the comment does not say otherwise.

What it establishes. That diode street lighting at a measured 3.6 lux significantly reduced the activity of two slow-flying bat groups along hedgerows used as commuting routes; that the reduction was not explained by generator noise, temperature or rainfall; that the animals did not compensate by using the unlit side; and that the investigators did not reach an intensity at which the effect disappeared.

What it does not establish. Any human effect. Any effect on faster-flying bats, in which none was detected. Any population or fitness consequence: the endpoint is activity along a commuting route over six nights, and the authors describe long-term conservation impacts as unknown. Any threshold, which is the point. And nothing about spectrum, a single cool white source being used throughout.

Considerations bearing on confidence. Against. Ten sites but seven in the analyses that report degrees of freedom, and six nights per site. Activity measured as detector passes, which is

an index rather than a count of animals. A single lamp type at a single color temperature, so nothing in it bears on spectral mitigation. Weather recorded at four sites only, with the remainder taken from stations a mean of 17.5 kilometers away. In favor. A randomized, replicated field experiment with a real manipulated exposure at three measured intensities, which is the design Part V.A.2 says the literature lacks. A noise control, which is the only instance in this appendix of an experiment separately controlling for the disturbance created by its own apparatus. Direct behavioral observation corroborating the detector data. Measurement of the unlit side to exclude spillover and displacement. And a null result reported for three taxa alongside the positive result for two.

Relation to other entries. Four. Appendix C.153 is the first half of a matched pair with this study: the same three authors, the same species, the same region, the preceding field season, the same treatment regime and instrument and luminaire supplier, high-pressure sodium at one level instead of diodes at three. Part V.A.2 uses the pair. The table at Appendix D.7 tabulates the earlier study at 51.67 lux, which is the figure from its street survey rather than its treatment level of 53.09 lux; this study puts the same species at 3.6 lux. The taxon-dependence, with slow-flying species affected and fast-flying species not, is of a piece with the order-dependence at Appendix C.151 and the divergent invertebrate result at Appendix D.8. And the Australian guidelines at Appendix D.1 devote an appendix to bats and record species-specific spectral sensitivities, which this study does not address.

Bearing on the statutory question. Paragraph 360ii(a)(4), for the proposition that where investigators have varied intensity systematically they have not found the bottom of the effect. Paragraph 360ii(a)(5), because the mitigation whose premise the authors question is intensity reduction, which is one of the procedures that paragraph directs be developed, tested and evaluated. The emissions limb of paragraph 360ii(a)(2). Parts V.A.2, V.I and IX.C.

C.153 Stone, Jones and Harris (2009) — the earlier half of the matched pair: one intensity, a large effect, no habituation, and spillover onto the supposedly dark side

Citation. Stone E.L., Jones G., Harris S. "Street lighting disturbs commuting bats." Current Biology. 2009;19(13):1123–1127. doi:10.1016/j.cub.2009.05.058. Received 6 April 2009, revised 5 May 2009, accepted 8 May 2009, published online 18 June 2009, issue dated 14 July 2009. Authors at the School of Biological Sciences, University of Bristol. Read from a file hosted on the Foundation's own server; the original must be cited.

Why this entry exists. It is the study behind the 51.67 lux row in the reference table at Appendix D.7, and Part V.A.2 sets it against Appendix C.152 to show that a tabulated effect level is a treatment level and not a threshold. It is also the earlier half of the only matched pair of field experiments in this appendix: same authors, same species, same region, consecutive field seasons, same treatment regime, same instrument, same luminaire supplier, different lamp technology and a different number of intensities.

Design. A field experiment at hedgerows in the vicinity of eight lesser horseshoe bat maternity roosts in southern Britain between April and July 2008, seven nights at each site. Night 1 control, detectors only; night 2 noise, with the lighting units installed but switched off and the generator running all night; nights 3 to 6 lit, full illumination all night, repeated over four consecutive nights; night 7 a repeat of the noise treatment. Two portable high-pressure sodium streetlights 30 meters apart, standard units obtained from a named manufacturer under guidance from the then Institute of Lighting Engineers, powered by a named portable generator sited an average of 58 meters away. Lights an average of 269 meters from the roosts, range 91 to 791. Lights and generator switched on 30 minutes before sunset. Activity recorded as bat passes by two models of ultrasonic detector on stands about 1.2 meters high, at a stated sensitivity and division ratio, rotated between treatments to control for differences in detector sensitivity. Repeated-measures general linear models on log-transformed data. Temperature, wind speed and rainfall tested and found not to differ by treatment, and therefore excluded.

How the exposure level was chosen, which is the detail the reference table lost. In August 2007 the authors surveyed three randomly selected two-kilometer squares in North Somerset by car at night, excluding urban areas, measuring illuminance along hedgerows lit by real high-pressure sodium streetlights with a named handheld illuminance meter held horizontally at 1.7 meters, at four points per streetlight. The mean was 51.67 lux, confidence interval plus or minus 11.68, n of 26. The experimental hedges were then illuminated to a mean of 53.09 lux, standard deviation 2.73, range 47.3 to 60.2, n of 36. The figure 51.67 is therefore a survey of ordinary British street lighting and 53.09 is the experimental treatment. The table at Appendix D.7 tabulates the former as a level at which an effect was observed.

Principal results. Treatment type had a significant effect on activity, F equals 9.51 on 2.54 and 17.74 degrees of freedom, n of 8, p less than 0.02. Activity during all four lit nights differed from control. Neither noise treatment differed from control, and the two noise treatments did not differ from each other, so generator noise and the physical presence of unlit lighting units do not account for the result. The four lit nights did not differ from each other, F equals 0.390 on 3 and 12 degrees of freedom, n of 5, p greater than 0.05, and the authors report no evidence of short-term habituation.

Commencement of activity, which is the second endpoint and is reported here because the comment has few timing endpoints in animals. Activity commenced at the hedge a mean of 29.9 minutes after sunset on control nights and a mean of 78.6 minutes after sunset on lit nights, significantly later than control, F equals 6.73 on 1 and 7 degrees of freedom, n of 8, p less than 0.04, and significantly later than the first noise night, F equals 9.23 on 1 and 7 degrees of freedom, n of 8, p less than 0.02. The median time of emergence from the roosts themselves was 32 minutes after sunset. The authors note that this species forages most at dusk, in line with the peak abundance of its principal prey, so a delay of that size is a missed foraging opportunity rather than a rescheduled one.

The anomaly in the noise control, recorded because a control that detects something is doing its job. On the first noise night activity commenced significantly earlier than on control nights, a mean of 23.0 minutes after sunset against 29.9, F equals 5.90 on 1 and 7 degrees of freedom, n of 8, p less than 0.05. The authors suggest some bats may have emerged early to investigate the noise. The second noise night did not differ from control. The noise control was therefore null for the activity endpoint and not null for the timing endpoint on first exposure. The Foundation reports this because Part V.A.2 praises these two studies for having a noise control at all, and a reader is entitled to know that the control was not inert.

THE FINDING PART V.A.2 RELIES ON MOST. The unlit side of the hedge was not unlit. On lit nights the authors measured a mean of 4.17 lux there, standard deviation 7.77, range 0.07 to 24.28, n of 16, significantly higher than at the same places on unlit nights, Mann-Whitney U, W of 230.5, p less than 0.01, mean 0.03, standard deviation 0.03, n of 62. There was no significant effect of treatment on activity on the unlit side, F equals 2.71 on 3 and 12 degrees of freedom, n of 5, p greater than 0.05, so bats did not escape the lights by using it. The authors explain why, and the sentence is the one the comment uses: that it is unsurprising few bats flew along the unlit side, since even these relatively low light levels may make established routes unsuitable for commuting. Three years later the same group demonstrated a significant effect in the same species at 3.6 lux, below the spillover measured here.

Behavioral observations. On lit nights, from fourteen observation sessions: bats flew through the lights on 42 percent of observations, turned around before reaching the lights on 30 percent, flew over the hedge on 17 percent, flew through the hedge on 9 percent and flew wide or high around the lights on 2 percent. Avoidance of some kind on 58 percent of observations, against 44 percent in the later study at lower intensities. The authors could not determine whether bats returned to the roost, observed some using alternative routes, and consider it probable that most selected an alternative route.

What it establishes. That high-pressure sodium street lighting at a measured mean of 53.09 lux substantially reduced the commuting activity of a threatened slow-flying bat along established hedgerow flight routes and delayed the onset of that activity by about 49 minutes; that neither generator noise nor the presence of the unlit apparatus accounts for it; that there was no habituation over four consecutive nights; and that a spillover of about 4 lux onto the opposite side of the hedge was sufficient that the animals did not use it.

What it does not establish. Any human effect. Any threshold: one lit level was tested. Any population or fitness consequence; the authors are explicit that the consequences of route switching depend on the availability and quality of alternatives, which they did not measure, and they put the downstream effects in the conditional throughout. Anything about diodes, which were not used. And nothing about spectrum, which was not measured.

Considerations bearing on confidence. Against. Eight sites, and five of them for the unlit-side analysis. Activity measured as detector passes, which the authors state cannot be converted into a count of individuals. One lit intensity. An internal inconsistency in the reported darkness figures. In favor. A replicated field experiment with a real manipulated exposure on a threatened species in its own habitat. A noise control and a second noise control after the lit sequence. Measurement of the unlit side, of the middle of the fields and of the ambient condition. Detector rotation to control for instrument differences. Weather tested rather than assumed. A test for habituation, which almost nothing else in this appendix attempts. And publication in a journal of the first rank.

Funding, stated because the Foundation states funding both ways. The acknowledgments name as funders, among others, a trust for endangered species, an international engineering consultancy, a bat conservation body, a government conservation agency for England, a government conservation body for Wales, an environmental consultancy and the lighting manufacturer that supplied the luminaires. The detectors were loaned by another engineering firm. A manufacturer therefore both supplied the equipment and helped fund a study whose result is adverse to the product, and the result was published. The Foundation notes that in the manufacturer's favor and draws no inference against the study.

A point for Part II and Part IX. The authors observe that light pollution is rarely considered in habitat management plans and that street lighting is excluded from the light-pollution legislation of England and Wales. A jurisdiction that legislated against light pollution and carved out the largest single category of outdoor lighting is worth one sentence wherever this comment discusses the shape of existing regulation, and the Foundation flags it rather than using it, because the exclusion has not been verified against the statute.

Relation to other entries. Appendix C.152 is the second half of the pair and the two are used together at Part V.A.2. The table at Appendix D.7 tabulates this study and misstates its exposure level. Part V.J.4 treats the pair as the fourteenth instance in its census, of a fifth kind.

Bearing on the statutory question. Paragraph 360ii(a)(4), for the proposition that a single-level experiment cannot identify a threshold and that the figures circulating in reference tables are treatment levels. The emissions limb of paragraph 360ii(a)(2), because the spillover finding concerns light emitted where it was not intended. Parts V.A.2, V.I and V.J.4.

Appendix D — Assessments, Standards, and Other Documents Cited

This appendix lists the documents this comment relies on that are not peer-reviewed articles. Appendix C contains peer-reviewed articles and nothing else; the documents below are of three other kinds, and the Foundation separates them because they carry different weight and should be read differently.

The distinction matters more in this field than in most, because documents of these three kinds are routinely cited as though they were research findings. An expert committee opinion is an assessment of a literature by a constituted body, and its authority comes from the body and its procedure. A standard is a technical instrument that prescribes how a measurement is made and how a product is classified, and its authority comes from the consensus process that produced it; it reports no findings at all. A publication of a manufacturer or a testing laboratory is neither, and is cited here only for what its author is in a position to know about its own products and practices.

Federal instruments – the United States Code, the Code of Federal Regulations, Federal Register notices and agency guidance – are cited in full where they are discussed, principally at Parts II and IV, and are not duplicated here.

D.1 Expert assessments and policy opinions

Listed in order of adoption. Part V.K treats the three on which reliance was placed, and Part V.K.9 treats the two predecessor Opinions.

D.1.1 SCENIHR, Light Sensitivity (2008). Scientific Committee on Emerging and Newly Identified Health Risks, European Commission. Adopted at the 26th Plenary on September 23, 2008. Working group: Jung (chair), Mattsson (rapporteur), Bridges, with external experts Ferguson, de Gruijl, Krammer and Moseley. Addressed whether energy-saving lamps aggravate the symptoms of light-sensitive people. Identified ultraviolet and blue light as the only candidate risk factor, found no evidence implicating electromagnetic fields or flicker, and called for additional experimental and epidemiological study. Does not mention light-emitting diodes. Treated at Part V.K.9.

D.1.2 SCENIHR, Health Effects of Artificial Light (2012). Same committee. Adopted at the 17th Plenary on March 19, 2012. Working group: Mattsson (chair and rapporteur), Jung, Proykova, with external experts Behar-Cohen, de Gruijl, Ferguson, Hansen, Moseley and Zissis. The direct predecessor of the 2018 Opinion. Source of the age-resolved ocular transmittance figures at Part V.C.2.g. States that light-emitting diodes were under-represented in its own analysis of lamps, that the risk classification of high-power diodes needs further consideration, and that the Exempt Group classification should not be taken to imply protection of the general population against long-term effects. Treated at Part V.K.9.

D.1.3 SCHEER, Opinion on potential risks to human health of light-emitting diodes (2018). Scientific Committee on Health, Environmental and Emerging Risks, European Commission, the successor to the committee above. The Opinion on which the Foundation's analysis at Part V.K principally turns. Its safety conclusion is stated three times and each time conditioned on compliance with the exposure limits of the International Commission on Non-Ionizing Radiation Protection. Treated at Part V.K.1 through K.8, and its optical conventions are relied on at Part V.B.2.

D.1.4 ICNIRP, Guidelines on Limits of Exposure to Incoherent Visible and Infrared Radiation (2013). International Commission on Non-Ionizing Radiation Protection. Health Physics, volume 105, number 1, pages 74 to 96, July 2013. Published by the Commission on its own site and read in full. This is the governing instrument for the exposure limits on which the photobiological safety standard and the three assessments at Part V.K rest, and it supersedes the guidelines of 1997 for that purpose. The comment relies on it for six things: the minimum angular subtense of 1.5 milliradians corresponding

to a retinal spot size of 25 micrometers, at Part V.B.2; the relation between source radiance and retinal irradiance given as its equation 2, with the focal length of 17 millimeters attributed to the Gullstrand schematic eye, also at Part V.B.2; the two assumed pupil diameters, 7 millimeters for the dark-adapted eye and approximately 3 millimeters for bright light conditions, likewise at Part V.B.2; the averaging field of view for the retinal photochemical hazard, 11 milliradians for exposures of 100 seconds or less and 110 milliradians at 10,000 seconds, with the stated basis that 11 milliradians represents the minimal eye movements associated with fixating a point, at Part V.C.2; the statement that these guidelines do not protect against glare and do not preclude light-induced modulation of physiological rhythms, at Part V.C.3; and the revision of the retinal thermal weighting function, the Commission having concluded that values of that function above unity "were indeed unjustified" and having multiplied the values from 385 to 440 nanometers by one tenth.

D.1.5 ICNIRP, Guidelines on limits of exposure to broad-band incoherent optical radiation (1997). The predecessor instrument, retained in this appendix rather than removed. It is retained for two reasons. It is the instrument the framework table at Part I.E has cited, and that citation is being corrected. And the 2018 Opinion examined at Part V.K appears to describe the 1997 values rather than the 2013 ones, as Part V.K.8 now records, so the earlier document is needed to establish what the Opinion was describing. The 2013 guidelines state that the aphakic and blue light hazard functions were carried over from 1997 unchanged.

D.1.6 ICNIRP, Light-Emitting Diodes: Implications for Safety (2020). Same Commission. The statement addressed specifically to this emitting technology. Treated at Part V.K.1.b. Postdates the United States transition to light-emitting diode illumination described at Part IV.G, and the Commission has no authority in the United States.

D.1.7 National Collaborating Centre for Environmental Health, Health Effects of Large LED Screens on Local Residents (2013). Canadian body funded by the Public Health Agency of Canada. January 2013. The only assessment of a light-emitting diode product class by a public health body that the Foundation has located in North America. Concludes that the lack of exposure and population data, combined with limited evidence, precludes a risk assessment. Treated at Part VI.J and Part II.E.4. It is an organizational publication and not a peer-reviewed article, which is why it is here and not in Appendix C.

D.1.8 IEA 4E Solid State Lighting Annex, Solid State Lighting: Review of Health Effects (2024). International Energy Agency, 4E Solid State Lighting Annex. October 2024. Authors at the Centre Scientifique et Technique du Bâtiment, the National Research Council of Canada, the Australian Radiation Protection and Nuclear Safety Agency and Monash University. Reports that independent teams have found retinal damage below the current exposure limit since 2012, that no consensus exists on revising that limit, and recommends that photobiological safety committees undertake a systematic review of it. Treated at Part V.C.2.f and Part V.K.

D.1.9 Joint Statement on Lights and Siren Vehicle Operations on Emergency Medical Services Responses (2022). Kupas D. F., Zavadsky M., Burton B., Baird S., Clawson J. J., Decker C. and others. Prehospital Emergency Care 2022;26(3):459 to 461. doi:10.1080/10903127.2022.2044417. Received 4 February 2022, accepted 16 February 2022, published online 10 May 2022. Free access; full text read. The document states that it updates and replaces a 1994 position statement of the National Association of EMS Physicians and the then National Association of State EMS Directors.

Why it is in this subsection, and what kind of instrument it is. Because it is an opinion adopted by constituted bodies, which is the criterion of this subsection. It is a joint position statement of fourteen organizations: the Academy of International Mobile Healthcare Integration, the American Ambulance Association, the American College of

Emergency Physicians, the Center for Patient Safety, the International Academies of Emergency Dispatch, the International Association of EMS Chiefs, the International Association of Fire Chiefs, the National Association of EMS Physicians, the National Association of Emergency Medical Technicians, the National Association of State EMS Officials, the National EMS Management Association, the National EMS Quality Alliance, the National Volunteer Fire Council, and the Paramedic Chiefs of Canada. It is accordingly the adopted position of the emergency medical and fire services themselves, and the Foundation relies on it as such and not as research.

What it concerns, and what it does not. The Foundation states the limit of the document before its contents, because the limit governs every use the comment makes of it. The statement concerns the operational decision when to switch lights and siren on. Its safety concern throughout is the risk of collision, and the harms it quantifies are crashes, injuries and deaths arising from vehicle operation. It says nothing about the optical characteristics of the lamps, nothing about intensity, modulation depth or flash rate, and nothing about any effect of the light itself on any person who sees it. It is not cited anywhere in this comment for any proposition about optical radiation or photic effect. It is cited for one thing: what the emergency services say about whether the devices are needed.

The time saved. "Over a dozen studies show that the average time saved with L&S response or transport ranges from 42 seconds to 3.8 minutes". And in the closing paragraph: "In most settings, L&S response or transport saves less than a few minutes during an emergency medical response, and there are few time-sensitive medical emergencies where an immediate intervention or treatment in those minutes is lifesaving".

The qualification the sponsors themselves state, which the Foundation records first among the findings. "In selected time-sensitive medical conditions, the difference in response time with L&S may improve the patient's outcome". The statement does not say the devices are useless. It says their use should be confined: lights and siren "should only be used for situations where the time saved by L&S operations is anticipated to be clinically important to a patient's outcome. They should not be used when returning to station or posting on stand-by assignments".

How often the use is clinically consequential, and how often it occurs. On consequence: "only a small percentage of medical emergencies have better outcomes from L&S use", and of responses to medical calls, "few (6.9%) of these result in a potentially lifesaving intervention by emergency practitioners". On frequency: "L&S continue to be used in 74% of EMS responses, and 21.6% of EMS transports, with a wide variation in L&S use among agencies and among census districts in the United States".

The finding the Foundation regards as the most consequential. "Some agencies have used an evidence-based or quality improvement approach to reduce their use of L&S during responses to medical calls to 20-33%, without any discernable harmful effect on patient outcome". Agencies that cut the practice by half to two thirds observed no discernible harm. That is not a projection or a recommendation; it is reported experience.

The countervailing risk, which is of collision and not of light. "EMS vehicle operations using L&S pose a significant risk to both EMS practitioners and the public". The statement records that "most EMS vehicle crashes occur when driving with lights and siren", that "L&S response increases the chance of an EMS vehicle crash by 50% and almost triples the chance of crash during patient transport", and that one survey found "approximately four 'wake effect' collisions (defined as collisions caused by, but not involving the L&S operating emergency vehicle) for every crash involving an emergency vehicle". On occupational exposure: "Traffic-related fatality rates for law enforcement officers, firefighters, and EMS practitioners are estimated to be 2.5 to 4.8 times higher than the national average among all occupations".

What it establishes. That fourteen organizations of the emergency medical and fire services have adopted the position that lights and siren save on average between 42 seconds and 3.8 minutes; that few responses involving them produce a potentially lifesaving intervention; that they are nevertheless used on about three quarters of responses; that agencies which reduced their use to between a fifth and a third of responses observed no discernible harm to patient outcome; and that the sponsors recommend confining their use to situations where the time saved is anticipated to be clinically important.

What it does not establish. Anything about the light. It reports no measurement of any lamp, no optical quantity, and no effect on any person who sees one. Its recommendations are addressed to emergency medical services and the sponsoring bodies are of emergency medicine, fire and ambulance services and emergency dispatch; law enforcement is named in one occupational statistic but no police organization is a sponsor and the statement is not addressed to police practice. Nor does it support any claim that the devices should be removed: it states expressly that in selected time-sensitive conditions they may improve outcome.

Where it bears. Part VI.C.1, which is written on it. Part IX, for the proposition that the operational necessity of these devices is a matter on which the services themselves have adopted a position.

D.1.10 Longcore and Rich, Artificial Night Lighting and Protected Lands (2017). Report of a United States federal agency, obtained in discharge of an acquisition recorded the same day, and the only American government document in this comment that sets out a lighting mitigation framework.

Citation. Longcore T. and Rich C., with illustrations by DelBusso L. Artificial night lighting and protected lands: ecological effects and management approaches (revised August 2017). Natural Resource Report NPS/NRSS/NSNS/NRR–2017/1493. National Park Service, Fort Collins, Colorado. The publisher's own prescribed citation gives the year as 2016 with the August 2017 revision in parentheses, and that form should be used. NPS 999/139639. Approximately seventy pages. Authors at The Urban Wildlands Group, Los Angeles, and at the School of Architecture and the Spatial Sciences Institute of the University of Southern California. Read from a file hosted on the Foundation's own server; the published file is available from the Natural Resource Publications Management website and must be retrieved from there.

What this document is, stated first because it governs its weight. A report published by the Natural Resource Stewardship and Science office of the National Park Service, an agency of the United States Department of the Interior, in a series the Service describes as disseminating comprehensive information and analysis about natural resources on lands it manages. The Service states that the report received formal peer review by subject-matter experts not directly involved in the work and of comparable technical standing to the authors. The authors are not employees of the agency. The report carries the Service's standard disclaimer that views, statements, findings, conclusions, recommendations and data in it do not necessarily reflect the views and policies of the Service or the Department, and that mention of trade names does not constitute endorsement by the United States Government. It reports no original research; it reviews effects by habitat type and sets out management approaches.

Why it is in this subsection, and why it matters where it is published. Because it is guidance published by a government body and states that body's published position subject to the disclaimer above, which is the criterion this subsection applies to the Australian guidelines. Its significance to this comment is not only its content. Part II.H records federal engagement with this exposure largely as absence. This is a federal agency publishing a peer-reviewed seventy-page treatment of the ecological effects of artificial light and a framework for mitigating them, nine years before this comment. It is the fourth federal item recorded in this appendix in a single day, with the grant and the fellowship at Appendix C.148 and the Park Service authorship at Appendix C.147, and Mr. Baker should decide whether Part II.H's account now needs revising.

THE FIVE-WAY FRAMEWORK, WHICH IS THE PRINCIPAL REASON THE COMMENT USES IT. Mitigation is said to be guided in five ways, in this order. Need: creative solutions are often available to avoid lights where they are not absolutely necessary, and managers should exercise discretion in limiting lighting infrastructure; in the body, that the first question is whether light is in fact needed, and that only when need is demonstrated and necessary for visitor experience, safety or security should lights be installed. Spectrum: no color is benign in all situations, but avoid ultraviolet and blue and in general use red and yellow hues. Intensity: reducing intensity can improve human visibility by reducing contrast, and industry guidelines should not be followed. Direction: shield so light falls only where needed and never upward. Duration: timers and motion detectors reduce the time a light is on and curfews can enhance visitor experience. Part V.I sets out what the Foundation makes of the order.

The two statements about professional standards. "Guidelines for lighting intensity from the lighting industry should not be followed when trying to reduce impacts to wildlife, because they are usually higher than necessary for human vision and do not take into account impacts to wildlife." And: "Land managers should not rely on standards promulgated by professional societies to guide lighting levels for natural areas because these are generally developed for urban/suburban areas with little to no regard for wildlife." Both are addressed to managers of natural areas and the comment reads them narrowly, as Part V.I states.

Numerical and definitional content. A full cutoff fixture is defined as one emitting little or no light above the horizontal plane and less than ten percent within ten degrees below it. Correlated color temperatures are given for lamp classes, at second hand from two cited sources: incandescent 2,600 to 2,700 kelvin; metal halide 2,900 to 4,200; high-pressure sodium about 2,100; low-pressure sodium 1,740 to 1,800; full-spectrum diodes offered from 2,700 to 6,500; direct sunlight 3,000 to 30,000 and usually 5,200 to 6,000. Those are the only numbers in the document the Foundation has identified as potentially useful and each is second hand.

Statements that run against a simple reading, recorded in full. That no universal spectral solution exists and that it is tempting to believe otherwise. That the only wholly wildlife-friendly light is one switched off or never installed. That shielding to full cutoff greatly reduces but does not eliminate skyglow, because light still reflects off the ground and scatters, so intensity reduction must be combined with shielding. That downward-directed light may still attract insects and the animals that feed on them. That reducing duration may itself harm species sensitive to a changing light environment, and that lights switching at irregular intervals may disrupt nocturnal behavior. And that diodes have no ultraviolet emission and therefore attract fewer insects than comparable lamps that do.

What it establishes. That a United States federal agency published, with peer review, a treatment of the ecological effects of artificial light at night and a five-part mitigation framework beginning with the question whether light is needed at all. That is a fact about the federal record. It establishes nothing about any organism of its own, being a review, and the disclaimer prevents it from being read as the policy of the Service or the Department.

What it does not establish. Anything about human health, which it does not address. Any measured effect, no original data being reported. Anything about products, its addressee being a land manager. And nothing that is the position of the United States government, the disclaimer being explicit.

Where it bears. Part V.I, which is written on the framework, on the two statements about professional standards and on the four qualifications. Part II.D.4, for the full cutoff definition and for the statement that shielding does not eliminate skyglow. Part IX, for the ordering of the five approaches. Part II.H, for the fact of federal publication, which is a decision for Mr. Baker.

D.1.11 Longcore, Hazard or Hope? LEDs and Wildlife (2018). Signed essay in a lighting trade magazine, catalogued for one field result about two lamps of the same rating, for a numerical recommendation, and for four concessions in favor of the technology.

Citation. Longcore T. "Hazard or Hope? LEDs and Wildlife." LED professional Review, issue 70, 2018. Published by Luger Research e.U. Approximately two thousand seven hundred words across four pages with five figures. The author is given as Assistant Professor at the University of Southern California School of Architecture. Read from a file hosted on the Foundation's own server; page numbers on the copy read are 52 to 57 and the original must be obtained.

What this document is, stated first because it governs its weight. A commissioned essay in a trade magazine of the lighting industry, addressed to lighting professionals and written to reconcile their view with that of conservation biologists. It is not research, is not peer reviewed, and reports no work of its own; every empirical statement in it is at second hand from eighteen numbered references, several of them the author's own. It is catalogued in this subsection on the ground used for the trade article already here, that no other category in this appendix fits it.

THE RESULT THE COMMENT RELIES ON. A field comparison, reported at second hand from the author's reference 18, in which prototype tunable lamps built from red, green and blue diodes were configured using bee and moth spectral response curves to reduce insect attraction, two of them rated at 2,700 kelvin and one at 3,000, and compared against an off-the-shelf 2,700 kelvin lamp and a 2,700 kelvin fluorescent. The tuned lamp is reported to have attracted twenty to twenty-one percent fewer insects than a similar lamp not designed with that objective, with the effect large for moths. Part I.G uses this for one proposition only: that two lamps of the same correlated color temperature differ in a measured biological response, so that a limit written in that quantity cannot distinguish them.

WHAT IT SAYS AGAINST THE COMMENT, WHICH IS SET OUT IN THE BODY AND NOT ONLY HERE. That correlated color temperature "is not a perfect predictor of effects on wildlife, but it is a reasonable rule of thumb that lower CCT will be less disruptive to wildlife"; and that "As a rule of thumb, CCT can be used as an indicator of wildlife effects, but this may not hold true across all applications." The essay also reports modeled results in which lower correlated color temperatures had lower predicted effects on average and for each species group. Part I.G states what the Foundation accepts in that and why it does not answer the comment's point.

FOUR CONCESSIONS IN FAVOR OF THE TECHNOLOGY, RECORDED BECAUSE THE FOUNDATION WILL NOT CITE THIS ESSAY WITHOUT THEM. On direction, that light-emitting diode street lights as currently deployed tend to be quite directional and can be an improvement over lamp types with drop lenses, and that with microlens arrays the focus on the street and adjacent pedestrian zones could be nearly perfect; qualified by the author himself, that bulb-type diode lamps offer no such benefit and in unshielded fixtures present the same challenges as previous technologies. On duration, that diodes can be extinguished and relit without delay or warmup, which suits them to timing and motion controls. On intensity, that they are readily dimmable. And on insects, that both warm and cool diodes compared against metal halide and mercury vapor lamps were found to attract fewer than a tenth as many insects, which the author attributes to the difference in ultraviolet emission. The Foundation does not dispute any of the four and notes that the first and the fourth bear directly on Part II.D.4 and Part V.I respectively.

What the essay says against the technology. That most broad spectrum diodes used outdoors have a potential to disturb the perception of daylength in plants, because the peak sensitivity of the phytochromes that detect daylength lies in the range of diode peak emission for most full-spectrum products. And the rebound effect: that the tendency is to use more light because it is efficient, that diodes represent an era of cheap light, and that "cheap light has the

potential to result in unnecessarily bright nights." The Foundation notes the adjective and makes no argument from it; the essay is not using the statutory term.

The framework it adopts, which is the one Part IX uses. The essay organizes everything under four attributes identified as important to reducing environmental effects: direction, duration, intensity and spectrum. Those are the four characteristics Part IX asks the Secretary to characterize, named independently in a trade publication by a wildlife scientist writing for the industry. The Foundation records the convergence and claims nothing from it.

A ranking the comment does not presently use. The essay reproduces from its reference 14 a ranking of light sources weighing four things equally: modeled wildlife response, melanopic response, astronomical light pollution expressed as a Star Light Index, and color rendering index. Low-pressure sodium ranks poorly on it because of extremely low color rendering, while phosphor-converted amber and filtered diodes rank highest. That is a worked example of a multi-criteria ranking that includes a human-use criterion alongside biological ones, which is the structure section 360kk requires when it directs that a standard be technically achievable and that practicability be taken into account. Whether it enters the comment is a decision for Mr. Baker.

What it establishes. Nothing of its own. Subject to verification of the underlying studies: that a field comparison has found two lamps of the same correlated color temperature to differ by about a fifth in insect attraction; and that a wildlife scientist writing for the lighting industry in 2018 recommended color temperatures at or below 2,200 kelvin as feasible and desirable.

What it does not establish. Anything about human health; the essay does not address it. Any effect of any lamp, no measurement being reported. And nothing about the primary studies beyond what the author says of them in a paragraph each.

Where it bears. Part I.G, which is written on the tuning result and on the two rule-of-thumb sentences. Part IX.J, for the 2,200 kelvin recommendation and for the contrast with American instruments. Part IX.C, for the statement of what is unknown. Part II.D.4 and Part V.I, for the concessions on direction and on insect attraction.

D.1.12 Zhu, Consider digital billboards a contributing outdoor light source (2023). Trade publication article, catalogued because the comment relies on it at Part VI.J.6.

What this document is, stated first because it governs its weight. A short article by a lighting practitioner in Buildings, a trade publication, dated 28 July 2023, and described by the publisher as a six minute read. It is not an expert assessment, not an adopted opinion, and not research. It reports no measurement and conducts no study. It is catalogued in this subsection because none of the categories in this appendix accommodates trade press.J.6.

Why the comment uses it. Because it identifies numerical temporal criteria for digital billboards that exist in guidance outside the United States, and names the instruments carrying them. The only operative American brightness criterion for this product class expressly excludes changing images, message movement and motorist attention, and this article is the Foundation's evidence that those excluded questions have been reduced to numbers elsewhere.

What it reports. A minimum dwell time of eight seconds, described as widely accepted by the industry; a finding that images with dwell shorter than seven seconds attract drivers' attention more than road signs do; transitions between successive displays of 0.5 to 2 seconds without other visible effects; a limit of 30 percent on fluctuation of average luminance between images; restrictions on the number of displays in a driver's field of view, given as two or three in the United States; and placement rules, the example being a New Zealand district plan requiring fifty meters separation from a signalized intersection and no direct visibility from a residential zone.

What it does not establish. Anything of its own. Every criterion above is reported at second hand from documents the Foundation has not read, principally guidance of the New Zealand Transport Agency of 2022. It reports no health endpoint and makes no claim about injury. On crashes it states that research has not proven an effect of digital billboards on motor vehicle crash rates, while reporting effects on driver speed, lateral control, mental workload, ability to follow road signs, and eye movements and fixations. None of the criteria it reports limits the luminance of the emitting surface.

Where it bears. Part VI.J.6, which is the only place the comment uses it, for the existence of numerical temporal criteria and for the careful formulation of the crash question. Part VI.J.8, where the ask it supports is stated.

D.1.13 Dark Sky Consulting, The thorny problem of lighting and crime. Signed commentary by a lighting consultancy, catalogued because Part V.M relies on it for two propositions and for two quotations.

What this document is, stated first because it governs its weight. A post on the weblog of Dark Sky Consulting, LLC, a consultancy working in the field of light pollution. It is signed commentary, not research. It reports no original data and establishes nothing of its own. It carries eleven references and the Foundation uses it principally as a route to those. The consultancy's field of work is an interest and the comment discloses it.

Why the comment uses it. For three things. The proposition, taken from an experimental study it cites, that feelings of safety rise fastest from no light to low intensity and then level off, which bears on the strongest form of the argument for high outdoor light levels. The proposition, taken from a further study, that removing lighting may displace offending in time or space rather than preventing it. And two direct quotations of the author of the study at Appendix C.118.

What it does not establish. Anything of its own. Every proposition the comment takes from it is at second hand from sources the Foundation has not read.

Where it bears. Part V.M, which is the only place the comment uses it. Possibly Part V.G, if the perceived-safety material is relocated there.

D.1.14 Monash XYX Lab, Plan International Australia and Arup, reported in The Conversation (2019). Explanatory article by researchers describing their own unpublished work, catalogued because Part V.M relies on it for the spectral and uniformity findings.

What this document is, stated first because it governs its weight. An article published in The Conversation on 28 May 2019, written by researchers describing their own research, and co-authored by a lighting leader at the engineering consultancy Arup. It is explanatory journalism, not a research report. It gives no statistical detail: no sample description beyond a count of more than eighty sites, no measures of uncertainty and no account of method. The underlying research has not been obtained.M requires it.

The research described. An analysis by Plan International Australia, the XYX Lab at Monash University and Arup of more than eighty locations in Melbourne identified by young women as unsafe, with lighting measured at those locations and compared with sites identified as safe.

What the comment takes from it. Three propositions about the character rather than the quantity of light: that consistent and layered lighting across surfaces of differing reflectance is reported to reassure most, by reducing the floodlit effect, the sharp drop-off of light beyond the path, and the potential for glare and contrast to blind and disorientate; that warmer correlated color temperatures are perceived as safer, with urban diodes reported as mostly 4000 kelvin or above; and that the women nonetheless preferred high-quality diode light to sodium lamps because sodium rendered color poorly. Also the authors' statement that illuminance is the only

metric required by the relevant Australian standard and that luminance should be considered too.

A finding the comment records but declines to rely on. That sites with higher measured light levels were more likely to be perceived as unsafe, the average level at unsafe sites being twice that at safe sites. The comparison is between places rather than within a place before and after a change, and the places women identify as unsafe are disproportionately the busy central locations that cities light most heavily. The comment applies to this the same objection it makes to the correlations at Appendix C.119.

What it does not establish. Anything, on its own. It reports no data and no analysis. It is used as a signpost to research that must be obtained, and as the only source the Foundation has identified that addresses correlated color temperature against perceived safety.

Where it bears. Part V.M, which is where it is used. Part V.C and Part VI.B.1, for glare and contrast. Part V.B.2 and Part VI.J.6, for the observation that illuminance is the quantity standards require and luminance the quantity that governs what the eye receives.

D.1.15 Essex Police, 108/16 Update on Part-Night Lighting (2017). Operational report of a police force to its oversight body, catalogued because Part V.M relies on it for the force's own conclusion and for an absence in its reporting structure.

Citation. Essex Police. "108/16 Update on Part-Night Lighting v.2.4." Report to the Office of the Police, Fire and Crime Commissioner for Essex, Performance and Resources Scrutiny Programme 2017/18. Date of meeting 30 November 2017; date of approval 16 November 2017. Chief officer Dr. Victoria Harrington; author Matt Robbins. Marked official.

What this document is. Not research. An operational analysis prepared by a police force for the authority that oversees it, comparing raw counts of crime, anti-social behavior and killed-or-seriously-injured collisions between two periods in the twelve Essex districts that switched street lights off between one and five in the morning and two districts that did not.

Its conclusion. That there is no evidence of a relationship between part-night lighting and levels of crime, anti-social behavior or serious collisions when compared with control areas, and that this supports previous analyses by the same force and a national independent study to which the force contributed data. The report records no plans for further analysis given the findings from multiple analyses over different periods.

Why the comment takes no figure from it. There is no regression, no adjustment, no confidence interval and no test of significance; two unmatched districts serve as controls; the two comparison windows point in opposite directions and are not reconciled; the collision counts are too small to bear percentages, as the report itself twice notes; the force cannot determine from its records which offenses occurred outdoors, so that offenses committed inside premises are in the figures; and it does not know which streets within each district were switched off.

What the comment does take. The force's own operational position, as the kind of body most likely to assert a link between lighting and crime, stated in a document written for internal purposes. And the entry under the report's health and safety heading, which reads in full that there are no identified implications with regards health and safety.

Where it bears. Part V.M, which is where it is used. Part II, for the proposition that decisions about the optical environment are taken by authorities with no health remit and no body to refer the health question to.

D.1.16 WRIA 8, Artificial Lighting Impacts to Salmon in WRIA 8 Briefing Memo (2020). Interim staff briefing memorandum of a governmental watershed forum, catalogued for one regulatory citation and for what it shows about how this subject is summarized for decision-makers.

What this document is, stated first because it governs its weight. A four-page memorandum dated March 10, 2020, headed Artificial Lighting Impacts to Salmon in WRIA 8 Briefing Memo, on the letterhead of the Lake Washington, Cedar and Sammamish Watershed, Water Resource Inventory Area 8, at 201 S. Jackson Street, Suite 600, Seattle, Washington. The file as published is named for the Salmon Recovery Council, which appears to be the body it was prepared for. It carries no named author and no signature; the contact given is the WRIA 8 Salmon Recovery Manager, at a King County address. Published at govlink.org, an interjurisdictional site administered through King County. It is not research, reports no measurement of its own, and says of itself that it is preliminary and interim and that a synthesis was then being prepared.

Why it is in this subsection. Because none of the other categories in this appendix fits it, which is the ground on which this subsection has taken in documents before. It is not an opinion adopted by a constituted body in the sense of the assessments at the head of this subsection, and the Foundation does not describe it as one. It is a staff briefing memorandum of a governmental forum.

The one thing in it the comment relies on. Its citation of the lighting provisions of the Washington hydraulic code, Washington Administrative Code sections 220-660-140 and 220-660-400. The Foundation did not take that from the memorandum. It read section 220-660-140 and relies on the regulation, which is set out at the end of Part V.I. Nothing else in this document is relied on for any proposition of fact.

What the document asserts, recorded without adoption. That artificial light pollution is identified as a priority limiting factor in the governing salmon conservation plan. That direct lighting attracts juvenile salmon, slows or stops migration and increases vulnerability to predators. That skyglow increases predation risk. That predation in Lake Washington has shifted from twilight to throughout the night over thirty years. That analyses in the Lake Washington Ship Canal suggest skyglow has produced a sevenfold increase in nighttime predation risk for juvenile salmon against pre-electric conditions. And that between 2014 and 2019 an average of 9 percent and 11 percent of tagged juvenile Chinook from two streams reached Puget Sound.

THE PROVENANCE PROBLEM, WHICH IS THE REASON NONE OF THAT IS ADOPTED. The two most arresting assertions in the memorandum — the sevenfold increase in predation risk and the shift from twilight predation to predation throughout the night — are both cited to the same source, and that source is an unpublished presentation by a single investigator to the forum's own technical committee on October 9, 2019. The survival percentages are cited to a second unpublished presentation to the same committee, on November 13, 2019. Neither is a paper. Neither has been peer reviewed, neither states a method, and neither can be checked by anyone outside that committee. A figure of that size, resting on a conference talk, is exactly the kind of number this comment asks the Department not to accept from others, and the Foundation does not use it.

THE CLAIM IN IT THAT THIS COMMENT HAS DECLINED. The memorandum states that light pollution is spectrally dependent and that shorter blue wavelengths are more prone to scattering and radiating back down, contributing to increased skyglow. Part II.D.4 declines that formulation, on the authority of the people who measure skyglow and against the Foundation's own interest: within about ten kilometers the additional Rayleigh scattering of a blue-rich source is roughly cancelled by its additional extinction, and beyond that extinction dominates. The reason white light-emitting diode sources worsen the visual experience of skyglow is principally the Purkinje shift in the dark-adapted eye, not greater scattering. The Foundation records the sentence here for two reasons. It is the reason this document cannot be quoted on

skyglow physics. And it is evidence for a proposition the comment makes elsewhere, that the simplified version of this claim has propagated into official and quasi-official guidance, where it will be relied on by people drafting local codes.

A second-hand chain the Foundation also declines. The memorandum rests its color temperature recommendation on the guidance adopted by the American Medical Association in June 2016, and cites it not to the Association but to a report hosted by an advocacy organization. It then adopts, in full, the five lighting principles of that organization and the Model Lighting Ordinance it published jointly with the Illuminating Engineering Society. The Foundation takes none of that at second hand. Its own treatment of the 2016 guidance is at Part II.E, its position on the publications of advocacy organizations is stated at Appendix D.9, and the Model Lighting Ordinance is catalogued on its own terms.

An internal tension worth recording, because it runs the Foundation's way. Having recommended warmer sources, the memorandum states that since all spectrums of light can penetrate shallow nearshore habitats used by juvenile salmon, minimizing the amount and intensity of any overwater lighting is critical. That is the memorandum conceding, in its own voice and immediately after making a spectral recommendation, that the spectral recommendation does not answer the problem in the habitat that matters most. It is consistent with the position settled at Part V.I, that reducing short-wavelength content reduces some effects and not others; that position records one study in which a warmer source was indistinguishable from darkness on the endpoints measured, with the limits of that finding stated there.

THE FOLLOW-ON RESEARCH, WHICH COMPLICATES THE MEMORANDUM AND IS RECORDED FOR THAT REASON. The memorandum promised a synthesis within a year. The Foundation has not located one. It has located a final report delivered to the same forum in April 2025 by a university wetland ecosystem team, reporting day and night snorkel surveys at eight sites near the mouth of the Cedar River in a two-by-two design crossing high and low artificial light at night with the presence and absence of residential docks. On the description the Foundation has of it, and it has only a description, juvenile salmon densities were highest at the brightly lit residential sites with docks and at the dark reference sites without them, and lowest at the brightly lit commercial sites without docks; water depth was more important to distribution than either lighting or docks; and no significant effect of docks was detected. That is not the straightforward attraction gradient the 2020 memorandum describes. The Foundation states it because an entry that recorded the memorandum without it would be presenting a five-year-old interim staff summary as the state of the evidence in a watershed whose own commissioned research has since reported something more complicated.

And what that report appears to concede about its own instruments. Three statements are attributed to it, and if they are accurate they belong with the attestations collected at Part V.J.4 rather than here: that the quantum sensor used for daylight surveys is not accurate at low light levels underwater at night; that the spectrometer used was intended for photography and high light conditions, which limited its utility; and that the night-time instrument produced unitless data which had to be converted. A single figure in lux is said to appear in the executive summary with no stated conversion. The Foundation asserts none of this. It is set out so that whoever obtains the report knows what to look for.

What it establishes. That a governmental watershed forum with salmon recovery responsibilities has concluded in writing that artificial lighting at night, including skyglow, is an adverse exposure warranting reduction, and has said so to the local governments it advises. That is a fact about the state of official opinion. It is not evidence of effect and the Foundation does not offer it as any.

What it does not establish. Anything about any organism. It reports no study, no measurement, no instrument, no illuminance, no radiance and no spectrum. Every empirical claim in it is second-hand, and the two largest are second-hand from unpublished talks. It

concerns a fish, which is further from a human being than any subject in Appendix C except the invertebrates, and the grounds of indirectness at Part V.A.3 apply to it with full force. And its organizing purpose is the recovery of species listed under the Endangered Species Act, a statute administered by a different Department, which the Foundation does not rely on here for the same reasons given in the entry on the monarch butterfly at Appendix C.140.

A usage the Foundation notes and does not overstate. The memorandum three times describes the effects it is concerned with as non-target, unintentional and often unnecessary impacts of light pollution. The word unnecessary is doing ordinary English work there and is not a reference to the statutory term in paragraph 360ii(a)(2). The Foundation records the usage as an instance of a governmental body reaching for the same word unprompted, and makes no argument from it.

Where it bears. Part V.I, at the end, which cites the Washington regulation this document led the Foundation to and states the limits of that regulation. Nowhere else.

D.1.17 DCCEEW, National Light Pollution Guidelines for Wildlife (2023). National government guideline, obtained in discharge of a recorded acquisition, and the principal source for Part V.J.4 on the state of the measurement art.

Citation. Department of Climate Change, Energy, the Environment and Water, National Light Pollution Guidelines for Wildlife, version 2.0, Canberra, May 2023. Commonwealth of Australia. Published under a Creative Commons Attribution 4.0 International license, excepting third-party content, logos and the Coat of Arms. The prescribed attribution is DCCEEW 2023, National Light Pollution Guidelines for Wildlife, Department of Climate Change, Energy, the Environment and Water, Canberra, May, CC BY 4.0. Approximately one hundred and seventy pages with eleven appendices. Read in full as supplied, in the publisher's word-processing format.

Why it is in this subsection, and what kind of instrument it is. Because it is guidance issued by a national government department and states that government's position, which is the criterion of this subsection. It is not research and reports no original measurement; it is a technical guideline for assessors and developers, supporting the administration of the Environment Protection and Biodiversity Conservation Act 1999. The Foundation treats it as evidence of the state of expert and official opinion and of the state of the measurement art, and not as primary evidence of any biological effect.

How it came to be obtained. It was named in this comment before it was read. The marine review at Appendix D.7 cites a 2020 Commonwealth of Australia document for a fuller treatment of the measurement problem.J. Mr. Baker supplied it. The version in hand is version 2.0 of May 2023; the version the review cites is the 2020 edition, which the Foundation has not seen and which was adopted in some form by the Convention on Migratory Species. Whether the two differ materially is not known.

Authorship, and two names that recur. The acknowledgements state that the guidelines are based on a draft written by Kellie Pendoley, Catherine Bell, Chris Surman and Jimmy Choi, with contributions from eight further named persons, and that named appendices derive from drafts by two others. Technical reviews of sections are attributed to eleven named persons. Two of those names recur in this comment: Andreas Jechow, whose imaging work is relied on at Part V.J and in Appendix C, and Dan Duriscoe, a co-author of the observatory site-protection review at Appendix D.7 on which Part II.D.4 is written. Kellie Pendoley is also a co-author of the marine review at Appendix D.7 and is the person credited with the figure in that review which the Foundation had identified as the best available illustration of its measurement argument. Funding is attributed to a Western Australian State conservation program and to an Australian Government science program.

WHAT THE COMMENT TAKES FROM IT, AND IT IS ALL IN TWO APPENDICES. Part V.J.4 is written on its Appendix B and Appendix C, which treat the measurement of light for

non-human subjects. The propositions relied on are set out in the body at Part V.J.4 and are not repeated here: that satellite products are not an appropriate exposure variable and that the common instrument is insensitive to blue; that commercial lux and luminance meters are not appropriate for this purpose at all; that the sky quality meter is not truly photopic and that a calibration study of a group of them found errors from negative sixteen to positive twenty percent; that no globally recognized standard method exists; that of eight tabulated techniques one measures the relevant quantity directly and its prototype is no longer in operation; that correlated color temperature does not disclose the blue content of a lamp; and the specification of what an adequate method would have to do. The glossary entry stating that the footcandle is not appropriate for understanding how animals perceive light is taken for Part VI.J.6.

Three quantitative figures taken for other parts. That the full moon typically provides below 0.2 lux. That light levels below 0.03 lux may be required to induce normal hatching in reef

effective use of digital billboards, which in turn requires adequate brightness for clear visibility."

What the report says that tells against the Foundation. Three things, and the Foundation records them because a comment that omitted them would be unreliable. That the luminance figures rest on "a worst-case scenario of an all-white display, which is unlikely to happen, save for a malfunction." That "Since displays are generally viewed at an angle, the luminance (glare) is substantially reduced." And that on a comparison with measurements of conventional billboards by the Lighting Research Center of Rensselaer Polytechnic Institute, "The digital billboards will be brighter, but only slightly brighter, than the maximum luminance of conventional billboards." The Foundation notes as to the last that the comparison is drawn against the maximum of the conventional class and not against its typical value.

What it does not establish. It is not a health study, reports no biological endpoint and no exposure of any person, and makes no claim about either. It was commissioned by the trade association of the industry whose product it concerns, for the purpose of developing recommendations that industry could adopt, and the preamble to this subsection states why the identity of the client matters. Its measurements are of one display of one make tested in 2006.

Where it bears. Part VI.J.6, which is written on it. Part V.B.2, for an operative American criterion expressed in illuminance at a stated distance rather than in source luminance. Part V.C.3, for the setting aside of a glare-based basis in favor of a nuisance-based one.

D.4.4 Walczak K., The Assessment of LVT Mobile Surveillance Units: Regarding potential lighting issues (2026). Night/Light Consulting, LLC. Dated 10 September 2026. Twenty-five pages. Signed by the author, identified as a board member of DarkSky International and a member of the Illuminating Engineering Society. Commissioned by the Soft Lights Foundation, which is recorded here and at Part IV.E.3 and Part VI.I because the Department should weigh the document knowing it. Treated at Part VI.I and relied on at Part V.B.3, Part V.C and Part V.D.1.

Why it is in the comment. Because it is the only complete independent photometric characterization of a deterrent lighting product in American service that the Foundation has been able to obtain, and because its existence is itself the finding: the measurements exist because a private party paid for them, there being no federal body that measures these products and no federal convention to which a measurement could refer.

What was measured, and under what conditions. An Abrams Manufacturing TG-300-B lamp as fitted to LiveView Technologies mobile surveillance units. Laboratory photometry was performed on a purchased unit powered at 12 volts direct current from a calibrated supply and stabilized for at least five minutes, with the lamp in its steady setting. Field surveys were conducted by day and by night in July 2026 at three Chicago sites. A fourth site, a Walmart parking lot in Woodland, California, was assessed remotely from geographic information system data and eyewitness accounts rather than in person.

Instruments. Sper Scientific 840022 illuminance meter; Hopoocolor HPCS-330P spectrometer; Sekonic Speedmaster L-858D-U luminance meter; Canon EOS M6 Mark II camera in manual mode at a fixed white balance; iPhone 17 Pro Max for high-speed video. The report does not state the accuracy or uncertainty of any instrument and does not map each instrument to each reported reading. It does state, to its credit, that photographs cannot fully represent the human visual experience at night.

The measured values the comment relies on. Luminance in the direction of the central peak of emission, 700,000 candelas per square meter. Total emission area of the three diodes, 10.4 square centimeters, giving a derived average peak luminous intensity of 728 candelas. Illuminance at one meter, photopic corrected, 145 lux. Peak spectral emission at

456 nanometers with more than 80 percent of output in the blue. Flicker at 100.1 hertz, 63.9 percent, flicker index 0.24. Strobing at 20.9 hertz, 77.4 percent, flicker index 0.385, in the default pattern of five pulses at about 20 hertz followed by a gap of 0.2 seconds.

Three internal inconsistencies the Foundation has found, recorded so that no part of this comment is read as quoting selectively. Correlated color temperature. At page 18 the report states that there is no equivalent correlated color temperature because the source is near monochromatic and does not fall within any black body standard. At page 23 it states that the correlated color temperature was calculated to be greater than 12,000 kelvin, adding that the measure is not a practical one for monochromatic sources. These cannot both stand. The comment relies on neither and uses the peak wavelength and the blue fraction instead. The glare figure. The summary at page 2 gives 45.8 at nine meters; the body at page 22 gives 45.9 at four meters. The comment uses the body figure and states the distance. The acceptable distance. Page 22 gives the minimum acceptable distance as 194 meters and states in the following sentence that any direct visibility closer than 190 meters is unacceptable.

What the comment does not take from it. Its characterization of the measured values as violations of IEEE Std 1789-2015. That document is a recommended practice which binds no one, as Appendix D.2 sets out, and the comment says so expressly at Part VI.I. Its statements of health risk, which are the opinion of a lighting consultant rather than findings of a health study; the report contains no biological endpoint and no exposure of any identified person. And its Woodland figures on the same footing as the Chicago ones, for the reason given above.

Where it bears. Part VI.I, which is written on it. Part IV.E.3, for the fact of the commissioning. Part V.B.3 and Part V.F, for the spectrum. Part V.C, for the glare figures and for the blue light hazard conversion which this report does not yet permit. Part V.D.1, for a measured pulse-width modulation frequency and depth in a product in service. Part II.F, for what it shows about who measures these products.

D.4.5 Bullough J. D., Parr S. A., Sblendorio A. and Hiebner E., Effects of Emergency Vehicle Lighting Characteristics on Driver Perception and Behavior: Study Report (2021). Emergency Responder Safety Institute, December 2021. Twenty-four pages. Produced under a contract between the United States Fire Administration and the Cumberland Valley Volunteer Firemen's Association's Emergency Responder Safety Institute, which subcontracted the research to the Lighting Research Center at Rensselaer Polytechnic Institute and to Embry-Riddle Aeronautical University. Additional funding from the Embry-Riddle Office of Undergraduate Research and from the Dwight D. Eisenhower Transportation Fellowship Program within the United States Department of Transportation. Full text read. Treated at Part VI.C.1 and relied on at Part VI.I and Part II.H.6.

Why it is in this subsection rather than Appendix C. Because it is a commissioned study report published by the contracting organization rather than a peer-reviewed article, which is the criterion of this subsection. The Foundation does not treat it as less reliable for that reason; the lead author is a published authority on flicker and signal lighting whose work is cited in the recommended practice at Appendix D.2.

A provenance point the Foundation records on the face of the entry. The test lights used in the experiment were provided by Whelen Engineering Company, a manufacturer of emergency vehicle lighting, whose personnel are acknowledged by the authors. The Foundation does not suggest that this affected the conduct or the findings, which include conclusions adverse to the sale of brighter equipment. It records the fact because a reader is entitled to it.

Design. A human factors field study. Twenty licensed drivers, seven female and thirteen male, mean age 32 years with a standard deviation of 15 and a range of 19 to 61, drove a closed

course at not more than 30 miles per hour at night past a simulated incident scene with a full-scale black silhouette of a firefighter in a reflective vest. Lights were mounted on two tripods representing the rear corners of a large fire truck. Five independent variables were tested in fourteen combinations: intensity at two levels, color at four, modulation at two, flash rate at two, and presence of reflective chevron markings at two. Outcome measures were a five-point rated visibility of the lamps, a nine-point discomfort glare rating, a five-point rated visibility of the road scene, lateral offset from the lamps, and the distance at which the firefighter silhouette was detected. Approved by the institutional review boards of both universities.

The intensity conditions, which govern how the principal finding should be read. The high level was approximately 33 percent above the minimum optical power specified by National Fire Protection Association Standard 1901 for large fire trucks. The low level was approximately one-third to one-half of that minimum. No condition approached the output of the brightest equipment in service, and the study therefore says nothing about the upper end of the market.

Principal findings. Higher intensity produced significantly more discomfort glare and only marginally greater rated visibility, both intensity levels being rated between 1.5 and 2 on a scale whose maximum is 2. Color had a larger effect than intensity on both measures: blue and red were most visible, blue and white most glaring, red and yellow least glaring, with the range across colors on the glare measure about twice the range across intensity levels. The authors attribute the glare result to short-wavelength spectral content. They conclude that lamps meeting existing minimum intensity requirements may be brighter than needed at night, that lower intensities would reduce glare without reducing visibility, and that whether maximum limits to intensity would benefit responder safety should be investigated.

Null and adverse findings, recorded here as well as in the body. No evidence of a moth-to-flame effect or its opposite: participants drove no closer to or farther from the lamps at any intensity or color. Flash rate and modulation had no statistically significant effect on any outcome measured. No variable affected the rated visibility of the overall road scene. High-reflectivity chevron markings appeared to reduce rather than improve the distance at which responders were detected, by about 25 feet, non-significant alone but producing a significant interaction with intensity.

What it does not establish. Anything about health. It reports no biological endpoint, no clinical measure and no exposure of any person to anything but a rating scale. Its subject is the occupational safety of emergency responders and the perceptions of drivers passing them. Its flash-rate null is a null on subjective discomfort among twenty people and bears on nothing at Appendix C.98 or Appendix D.2.

The statement the comment relies on most. That the standards defining minimum photometric performance for these lamps set no maxima and have not changed substantially since light-emitting diode sources became widespread, and that the lamps have increased in intensity as the efficacy of those sources has increased. Part VI.C.1 and Part VI.C.2 are written on that asymmetry and this is the Foundation's best source for it.

D.5 Reference works and book chapters

Authoritative secondary literature published as a chapter in an edited reference work. Such a chapter is reviewed by the volume's editors rather than through journal peer review, so it does not belong in Appendix C; it reports no original research of its own, so it is not a commissioned research report under D.4; and it is not the product of a constituted expert body, so it is not an assessment under D.1. The Foundation cites a chapter of this kind for the state of knowledge in a field as a specialist in that field set it out, and identifies it as such wherever it is used.

D.5.1 Martinsons C., Photobiological Safety (2015). Chapter in Karlicek R and others, editors, Handbook of Advanced Lighting Technology, Springer International Publishing, pages 1 to 31, ISBN 978-3-319-00295-8, doi:10.1007/978-3-319-00295-8_51-1. The author's version is deposited in the French national open archive at hal-04691337, under a Creative Commons Attribution-NonCommercial licence, and is dated July 28, 2014. Single author, Lighting and Electromagnetism Division, Centre Scientifique et Technique du Bâtiment. The same author is lead author of the 2024 intergovernmental review at D.1 and a co-author of the market surveillance study at Appendix C.59, which is why this comment treats the chapter as evidence of what was known to the field, and when.

What this comment takes from it. Four things. Its section 4.6, Limitations of the CIE/IEC blue light hazard assessment, with subsections on low-level chronic exposure, long-term exposure and sensitive populations, used at Part V.C.2.c. Its reproduction of French agency measurements of luminance and risk group for single-chip white emitters, used at Part V.C.2.k. Its account of the averaging field of view and of the effect of viewing distance on the maximum permissible exposure duration, which corrects and narrows an argument the Foundation makes at Part V.B.2 and Part V.C.2.k. And its criticism of the reference viewing distance of IEC 62471 as ambiguous and not realistic in the context of real usage conditions.

What tells against the Foundation in it, recorded here as well as in the text. The chapter concludes that at a viewing distance of one meter the maximum permissible exposure duration rises to thousands or tens of thousands of seconds, and that this provides a reasonable margin for asserting that there is virtually no possible blue light retinal damage from light-emitting diodes at longer viewing distances. It also states that Risk Group 3 is highly unlikely to be reached by any artificial white light source. Part V.C.2.k sets out both, and what the Foundation does and does not conclude from them.

D.6 Technical papers of standards-body participants and conference proceedings

This category exists because the comment has come to rely on a literature that none of the five above accommodates, and the Foundation states the reasoning by elimination as it did at D.5. A paper presented at a conference and published in its proceedings is not an article in a peer-reviewed scholarly journal, so it is outside Appendix C. It is not the product of a constituted expert body, so it is not an assessment under D.1. It is not a standard, although it may be an account of one, so it is not D.2. It is not the publication of a manufacturer or testing laboratory about its own products, so it is not D.3. It reports no commissioned research, so it is not D.4. And it is not a chapter of an edited reference work, so it is not D.5.

The Foundation cites a paper of this kind for one of two purposes. The first is the account its author gives of the technical basis of an instrument, where that author participates in writing the instrument. The second is a measurement reported in a proceedings volume and nowhere else, which arises in this field because the metrology of these sources is presented substantially at conferences. The third is an account of the state of a technology given in a proceedings volume by a specialist who develops it, which is admitted for the same reason a manufacturer publication is admitted at D.3, namely what its author is positioned to know, and which is weighed the same way. Where an entry rests on the second or third ground the Foundation has searched for a journal version of the same work and records that it found none, and every entry in this subsection is read with the lesser review a proceedings paper receives in mind. Authority of that sort is not the authority of research and the Foundation does not treat it as such. It is closer to the authority of an explanation given by a draftsman of what a provision was intended to do and what it was not. Where a paper in this category states a matter of general physics, the Foundation prefers a journal article or a reference work and cites this literature only where the account is not available elsewhere. Wherever an entry here is used in the body of the comment, the text identifies both the status of the paper and the role of its author.

D.6.1 Schulmeister K., The radiance of the sun, a 1 mW laser pointer and a phosphor emitter (2013). Paper P107 in ILSC 2013: Proceedings of the International Laser Safety Conference, Orlando, Florida, 18 to 21 March 2013, pages 371 to 378, published by the Laser Institute of America. doi:10.2351/1.5056816. Author at Seibersdorf Laboratories, Austria, described in the paper as a laser, light-emitting diode and lamp safety test house and consultancy. Full text read.

The author's roles, which are the reason this paper is in the comment at all. The paper's author biography states that he is a member of Standing Committee IV of the International Commission on Non-Ionizing Radiation Protection; a member of the bioeffects technical subcommittee of the American National Standards Institute accredited committee Z136; the secretary of Working Group 1 of International Electrotechnical Commission Technical Committee 76, which it identifies as "the working group responsible for IEC 60825-1"; and associated division director of Division 6 of the International Commission on Illumination, "which is responsible for CIE S009/IEC 62471." It further states that research in his group "provided the basis for amending the spot size dependence of the retinal thermal limits." He therefore holds office in the body that writes the laser standard and in the body that writes the lamp standard, and sits on the commission whose exposure limits both rest on. Part V.C.2 is an argument about the relationship between those two standards. This is an account of that relationship by a person who helps draft both.

First matter: the radiance threshold that routes a product from the laser standard to the lamp standard, and what the author says it is not. The paper explains an amendment introduced for the third edition of IEC 60825-1, permitting light produced by a laser striking a phosphor to be assessed under IEC 62471 instead, provided its radiance stays below one megawatt per square meter per steradian divided by the angular subtense in radians, that subtense being bounded at 0.005 and 0.1 radian. The author identifies the emission mechanism as the one at issue in this comment, describing the phosphor principle as "the same principle used to produce white LEDs based on blue LED chip." For a source of 5 milliradians the threshold works out at 200 megawatts per square meter per steradian. He gives the broadband retinal thermal exposure limit for the same source size at a quarter-second exposure as 5.7 in the same units, notes that the ratio of 35 between them is preserved at every source size because both vary as the inverse of the angular subtense, and then states the conclusion: "This clearly shows that the value given in IEC 60825-1 of (1 MW m-2 sr-1)/α … is not a safety limit; thus the products that approach that value will be RG3 under the current as well as under the upcoming edition of IEC 62471." On the consequence for a real eye he writes that for a 2 millimeter pupil the risk remains negligible, but that for a pupil of 5 millimeters at a factor of 35 above a limit built on 7 millimeters, "the injury threshold for retinal injury might be exceeded also for the human case."

Second matter: the exposure limit measured against the sun. The author computes the effective radiance of the sun by weighting the spectral irradiance of the ASTM G173-03 reference spectrum with the corrected retinal thermal action spectrum, obtaining an effective irradiance of 520 watts per square meter and dividing it by the solid angle of 7.2 × 10 to the minus fifth steradian subtended by a disc of 10 milliradians. The result is 7.2 megawatts per square meter per steradian. Against a limit of 2.8 in the same units for that source size at a quarter second, he states: "The sun exceeds the exposure limit for 0.25 s exposure duration by a factor of 2.5." He records that the old guidelines of the same commission and the threshold limit values of the American Conference of Governmental Industrial Hygienists are exceeded as well, and gives the explanation: the limit assumes a 7 millimeter pupil, prudent for pulsed sources and over-restrictive here, and "When a pupil diameter of 4.5 mm is assumed for the determination of the effective ocular exposure, the exposure limit is not exceeded for the new ICNIRP exposure limits."

Third matter: the relations on which Part V.B.2 and Part V.B.8 rest. The paper states, as settled radiometry, three things this comment has had to assemble. That radiance is the quantity governing retinal exposure, being "a measure of the irradiance level in the image plane of a system that images the source (such as the human eye)". That the photometric counterpart is luminance: "In the field of lighting, radiance is referred to as brightness (more correctly, luminance) when it is weighted with the luminous efficiency function". And that radiance is invariant with distance and under optical systems, which he illustrates for the sun seen from different planets: irradiance falls as the inverse square while the solid angle subtended falls in step, so that "the sun has the same brightness from all planets when one looks into the sun, but the size of the sun changes. However, the 'lighting level' (irradiance) of the surface of the planet changes with distance." He names the underlying conservation, that the product of area and solid angle is constant in a lossless system, and records that "This quantity $A \times \Omega$ is referred to as etendue or throughput." He also gives the Lambertian relation on which the arithmetic at Part V.B.8 depends, that the radiance of a Lambertian emitter is its exitance divided by pi steradians, and the retinal relation, that retinal irradiance is the radiance multiplied by the solid angle subtended by the pupil and reduced by transmission losses.

Fourth matter: a conflict with a constant used throughout Part V.B.2. The paper gives the minimum angular subtense as 1.5 milliradians, corresponding to a retinal image of 25 micrometers, and states it twice: of a star, that "it is assumed that a point source such as a star produces a retinal image of 25 μm, or 1.5 mrad angular subtense", and of the revised broadband limits, that "the smallest α to be input into the new exposure limit is also set to 1.5 mrad, as for the laser exposure limits." Part V.B.2 uses 1.7 milliradians throughout, including in two tables, and attributes it to the 1997 guidelines. The Foundation records the conflict and does not resolve it on this paper. If the figure for the governing instrument is 1.5 milliradians, every distance in the table at Part V.B.2.c lengthens by a factor of about 1.13 and the argument of that subsection is strengthened rather than weakened, because a smaller minimum subtense extends the regime in which retinal exposure does not fall with distance.

Fifth matter: corroboration of the averaging analysis at Part V.C.2. The comment establishes at Part V.C.2, from a reference work and from its own arithmetic, that the blue light weighted radiance of a source smaller than the averaging field is reduced by the ratio of the two solid angles, and that the averaging has a physiological basis rather than being an artifact. This paper states both from inside the committee. On the deliberateness: "In some cases, this is intended, such as when the field of view represents the angular extent of eye movements for the photochemical retinal limit." And on the consequence: "For the case that the source is smaller than the averaging field of view, the measured radiance is correspondingly smaller than the actual radiance of the source, and the analysis is less restrictive."

Sixth matter: the amendment of the retinal thermal weighting function. The author records that the retinal thermal action spectrum was amended so that "the new $R(\lambda)$ has a maximum of 1 in the blue wavelength range, where the old one had a maximum value of 10, overweighting the blue component", that for a pure blue source the difference is a factor of ten, and that the effect on a white source is larger for a high correlated color temperature than for a low one. The Foundation notes that this concerns the retinal thermal weighting and not the blue light hazard function treated at Part V.C.2, and the two must not be conflated.

The laser pointer figures, recorded for completeness. Averaged over a 7 millimeter aperture and the solid angle of a 1.5 milliradian image, a 1 milliwatt collimated beam gives 14.7 megawatts per square meter per steradian, which the author notes is about twice the radiance of the sun and a factor of 1.3 below the broadband limit of 19 in the same units at that subtense. Using the actual 1 millimeter beam diameter instead would raise the figure

by a factor of 49, which he states would be as incorrect as comparing an unaveraged irradiance with the laser limit. He resolves the apparent paradox that the sun exceeds the limit while a brighter pointer does not by the source size: the sun is 6.6 times larger than the minimum subtense, and the limit varies as the inverse of subtense.

What it does not establish. It is not a study of light-emitting diode products and reports no biological endpoint, no exposure of any person, and no measurement of any product in commerce. Its subject is laser-produced light and the standards that govern it. The Foundation relies on it for the author's account of how the two standards divide and of what the quantities in them mean, and not for any proposition about the products at Part VI. Its status is that of a conference paper, reviewed as such and not through journal peer review.

Where it bears. Part V.C.2, principally, for the routing threshold and for the corroboration of the averaging analysis. Part V.B.2, for the radiometric relations and for the conflict over the minimum angular subtense. Part V.B.8, for the Lambertian relation. Part V.K.3, for what a conclusion conditioned on an exposure limit is worth.

D.6.2 Velázquez J. L. and others, Angular distribution of the averaged luminous intensity of low power LEDs transfer standards (2013). Velázquez JL, Ferrero A, López M, Pons A, Villamarín A, Campos J, Sperling A. Proceedings of SPIE volume 8785, article 87858W, pages 1 to 8, 2013. doi:10.1117/12.2027039. Presented at the 8th Iberoamerican Optics Meeting and 11th Latin American Meeting on Optics, Lasers and Applications. Authors at the Institute of Optics of the Spanish National Research Council and at Working Group 4.12, Photometry, of the Physikalisch-Technische Bundesanstalt. Full text read. A search of the bibliographic record located no journal version of this work, so the entry rests on the second ground stated in the preamble above.

Why a metrology paper is in a comment about health. Because it measures the quantity the rest of this comment argues about, at the two institutions whose business is to establish what a measurement means. The Spanish council and the German federal institute are national metrology institutes. The paper reports an instrument built to characterize the angular distribution of the averaged luminous intensity of light-emitting diodes, measurements of four transfer standards, and a comparison of those measurements against the same devices measured at the other institute. The authors state the reason the work was needed in terms this comment adopts: "New methods of measurement are required, because these sources have different emission characteristics than traditional lighting sources."

What was measured, and how. Four low-power light-emitting diode transfer standards of 7 millimeter shell diameter supplied by one manufacturer, identified as F107 blue, F108 red, F126 green and F132 polar white, together with a further standard used for stability. Each was driven at 20.00 plus or minus 0.02 milliamperes with the chip held at 32.0 plus or minus 0.1 degrees Celsius. Measurement was at 316 millimeters, which the paper identifies as condition A of the International Commission on Illumination, with a temperature-stabilized photometer of 100 square millimeters circular area, the polar angle stepped across the full range to 90 degrees and the azimuth sampled at 32 uniformly distributed positions for each polar angle. Data were normalized to the average at zero degrees and the stated relative uncertainty is 0.2 percent.

The finding the comment relies on. The authors fitted each measured distribution to a cosine raised to a power g, the exponent that equals one for a true Lambertian emitter, and reported the fitted value from each laboratory. Not one of the four devices is Lambertian. The closest is the red at 1.38 and 1.31; the blue departs furthest, at 3.64 and 3.54. The two institutes agree to within about six percent on every device and exactly on one.

LED transfer standard	g, CSIC	g, PTB	Anisotropy, CSIC	Anisotropy, PTB

F107, blue	3.64	3.54	0.052	0.047
F108, red	1.38	1.31	0.069	0.065
F126, green	1.86	1.76	0.016	0.015
F132, polar white	1.62	1.62	0.014	0.015
A Lambertian emitter	1	1	not applicable	not applicable

What follows arithmetically, and the arithmetic is the Foundation's. An exponent greater than one describes a distribution narrower than Lambertian, which is to say more concentrated about the axis. For a source of given total luminous flux the on-axis intensity follows from integrating the fitted form over the hemisphere, and the result is that the on-axis intensity exceeds that of a Lambertian source of the same flux by a factor of one plus the exponent, divided by two. On the measured values that factor is 1.19 for the red device, 1.31 for the white, 1.43 for the green and 2.32 for the blue. The Foundation states the consequence for its own arithmetic rather than for anyone else's: where this comment computes a peak luminance by assuming a Lambertian distribution, as it does at Part V.B.8 from a manufacturer's published flux and emitting area, the assumption is conservative for a packaged device of this kind and the true on-axis figure is higher. The integration and the four factors are the Foundation's and are not stated by the authors.

A second finding, reported because it cuts against a tempting inference. The authors also computed the anisotropy of each device, as the relative standard deviation of the on-axis intensity across azimuth, and found that it does not track the departure from Lambertian form. The red device is the closest to Lambertian and the most variable with azimuth; the white is the least variable. The authors state the conclusion: "This indicates there isn't a correlation between lambertianity and anisotropy of the source." So a device may be well described by a simple angular law and still emit unequally in different directions around its axis, and the two defects of a single reported number are independent of one another.

What it does not establish, and three cautions. It is not a health study and reports no exposure of any person. The devices are low-power transfer standards of 7 millimeter package diameter selected for metrological stability, not products in commerce, and no inference about any product at Part VI follows from them. The association between color and departure from Lambertian form is an observation on four devices from one supplier and is not evidence that blue emitters are generally more concentrated than red ones; the Foundation states that expressly because the temptation to draw that inference is obvious and the sample will not bear it. And the discussion section of the paper contains an internal inconsistency, which the Foundation resolves in favor of the tabulated values.

Where it bears. Part V.B.8, which is written on it, for the departure of real devices from the Lambertian form that Appendix C.86 derives for a bare flat emitter and that the manufacturer at Appendix D.3 states it designs for. Part V.J.1, for what a single reported figure does not determine. Part V.B.2, for the identification of 316 millimeters as the reference distance of the averaged-intensity geometry.

D.6.3 Epstein A., Tessler N. and Einziger P. D., Electromagnetic Radiation from Organic Light-emitting Diodes (2009). PIERS Online, volume 5, number 1, pages 75 to 80, 2009. doi:10.2529/piers080803140549, published by the Electromagnetics Academy as the online proceedings of the Progress in Electromagnetics Research Symposium. Authors at the Department of Electrical Engineering, Technion, Israel Institute of Technology. Full text read from the copy published by the second author on his institutional page. Listed in this subsection because the venue is a symposium proceedings whatever the bibliographic record calls it.

What the title means, and what it does not. The title is capable of misleading a reader of this comment and the Foundation disposes of the point at once. The electromagnetic radiation of which the paper treats is the visible light the device emits, analyzed as an electromagnetic boundary-value problem: a line source embedded in a layered stack, solved by asymptotic evaluation of the radiation integral with a one-dimensional Green function built from the reflection and transmission coefficients of the layers. The prototype radiates at about 600 nanometers. The paper is not about radiofrequency emission, electromagnetic interference, or anything emitted by the drive electronics, and nothing in it bears on those subjects.

Why it is in the comment. For one proposition only, and it is the proposition at Part V.C.2: that the coherence of these sources is a graded quantity rather than a category. The paper carries the coherence of the source explicitly through a rigorous calculation and shows that its value determines what the device emits. The authors claim that combination as novel, stating that the incorporation of both rigorous electromagnetic analysis and coherence effects is addressed in their report, to the best of their knowledge, for the first time.

The general statement of the principle, which the authors take from Wolf. The paper sets out the relation between coherence and the emitted pattern in terms the Foundation adopts: "sharp interference patterns in emission angular distribution as well as interference fringes on a distant screen are caused by some consistent phase difference between two sources. As temporal or spatial coherence decrease this phase difference is no longer consistent in time or space, thus averaging on a large ensemble of sources diminishes these effects dramatically." Coherence on that account is a quantity which decreases, and whose observable consequence diminishes as it does. It is not a property held or not held.

The two kinds of coherence, which the paper keeps separate and the standards do not. The authors state that "coherence effects must be considered when analyzing OLED device", and then make the division the comment needs: "Since spatial coherence can, in general, be neglected when considering OLEDs, we take into consideration only the temporal coherence effect on the power relation." They neglect spatial coherence for organic devices on the authority of a dedicated measurement of organic electroluminescence, cited as Saxena and others, 2006. The Foundation draws attention to the structure of that sentence rather than to its conclusion: there are two coherence quantities, a device may be negligibly coherent in one sense and not in the other, and which is meant must be said. The literature at Part V.C.2 measured the spatial quantity in inorganic devices and found it measurable; these authors set the spatial quantity aside for organic ones and model the temporal.

The definition that makes the quantity computable. The authors define the coherence length as the square of the wavelength divided by the spectral width, L(c) = λ squared over delta λ, the width being that of the normalized photoluminescence spectrum, which they represent by a Gaussian. That is the relation which permits a coherence length to be computed for any emitter whose spectral width is known, and spectral width at half maximum is a published specification for components of this kind. Their simulations span coherence lengths of 5, 15 and 150 micrometers.

The finding relied on, and the regime in which a Lambertian pattern appears. Radiation patterns were computed for four device thicknesses at fixed coherence length and for three coherence lengths at fixed thickness. The result turns on the ratio of the two: "for device thickness (represented by the dominant glass thickness) much smaller than the coherence length, interference effects are noticeable whereas the reversed situation results in a quasi-Lambertian radiation pattern." The authors then identify what each regime reflects: "the two extremes correspond to radiation patterns which reflect either the device properties, i.e., thickness dependent interference, or the source characteristics, leading to

spectral broadening dominated pattern." So the Lambertian form is what emerges in the incoherent limit. A device that is not in that limit emits a pattern governed by the thicknesses of its internal layers.

What it does not establish, and one inference the Foundation specifically declines. It is a model and not a measurement. The configuration is two-dimensional and the authors say it was chosen "for the sake of simplicity and clarity." No efficiency value or other numerical output is tabulated, and the comparison with experiment is qualitative: the authors say their two limiting cases agree well with measurements taken in those limits and report no quantitative comparison. The devices are organic, which is not the technology principally at issue in this comment. And the Foundation declines the inference that lies closest to hand: the measured departures from Lambertian form recorded at Part V.B.8 for four packaged inorganic devices are not attributed to coherence, because those devices carry integral lenses and a lens is the obvious alternative explanation. This paper establishes that coherence is one route to a non-Lambertian pattern. It does not establish that it was the route in any measurement reported elsewhere in this comment.

Where it bears. Part V.C.2, for the distinction between temporal and spatial coherence and for the computability of the first from published spectral data. Nowhere else.

D.6.4 Krames M., Light-Emitting Diode Technology for Solid-State Lighting (2010). Chapter in Frontiers of Engineering: Reports on Leading-Edge Engineering from the 2009 Symposium, pages 67 to 76, National Academies Press, Washington, 2010. doi:10.17226/12821. The volume's suggested citation credits the National Research Council and attributes the chapter to its author, who is given as Mike Krames of Soraa, Inc., Goleta, California. Read in full from the publisher's own open text.

What this document is, and what it is not, which the Foundation states first because the imprint invites an error. It is a paper delivered by an individual engineer at a symposium, published in the symposium's proceedings volume by the National Academies Press. It is not a consensus study report of the National Academies, it is not the finding of any committee, and it has not been through the review a consensus report receives. No part of this comment may describe it as a finding of the National Academies, of the National Academy of Engineering, or of the National Research Council, and no part of this comment may introduce it as what the National Academies concluded. It is the account of one specialist, published under that imprint, and the Foundation cites it as such. The distinction is material in a filing to a federal department, because the weight the imprint carries is precisely the weight the document has not earned.

The author's position, which bears on weight in both directions. The author is an industry technologist in solid-state lighting, identified with a company in that industry. That tells against the document in the ordinary way: a specialist writing about the technology he develops is not an independent assessor, and Appendix D.3 states the Foundation's practice for such sources. It tells for the document on the one statement this comment relies on, which is a statement that a body of research did not exist. An assertion that nobody has studied a question is against the interest of the industry developing the product, because it is the industry that would be asked to wait for the answer.

The statement the comment relies on. Discussing the smooth emission spectrum produced by blue-pumped phosphor conversion, and comparing it with the sharply peaked spectrum of a fluorescent lamp, the author writes: "One might assume that this provides a more natural appearing light, compared to the high-intensity peaks of the FL spectrum, but as of this writing the author is aware of no studies of the effects of smooth vs. spiked spectra on human perception."

The projections, recorded because they are now testable. The chapter states the theoretical ceilings and a forecast. For the smooth phosphor-converted spectrum the

maximum luminous efficacy is given as 310 lumens per watt, reduced to about 250 by the Stokes loss of some 20 to 25 percent in a blue-pumped device, which the author describes as 60 to 70 percent above fluorescent lamps and more than fifteen times incandescent. The forecast is attributed to a report commissioned by the Department of Energy in 2009: "Future LED performance is projected to be ~ 160 lm/W by 2018." The Foundation records these without evaluating them.

What it does not establish. Nothing about health, exposure or injury, and the chapter addresses none of those subjects. It is a technology review. Its efficacy figures are an energy metric and bear on this comment only through the trajectory described at Part IV.G. The one statement relied on is a statement about the state of a literature in 2009 by one author, offered as evidence of what that author was aware of and not as proof that no such study existed anywhere.

Where it bears. Part V.B.3, which is written on it, for the question the descriptor discards and whether the discarded quantity was ever studied.

D.6.5 Gaertner A. A., LED Measurement Issues (2002). Lecture 15 in a series of lectures given at a measurement course on Photometry, Radiometry and Colorimetry, 9 to 12 April 2002, at the Institute for National Measurement Standards of the National Research Council of Canada, Ottawa. The lecture states that it is posted on the website of Optronic Laboratories by permission, and that information concerning the complete monograph may be obtained from the Institute. The author is of that Institute, which is the national metrology institute of Canada.

What this document is. Teaching material, and the Foundation says so rather than presenting it as a paper. It is one lecture of a course for measurement practitioners, it cross refers to other lectures in the same course, and it is written in the first person plural of instruction. It is not peer reviewed and reports no original experiment. It is in this appendix for the reason this appendix exists: it is an account, by a specialist at a national measurement institute, of the state of a measurement problem at a date, and the comment relies on it for what the measurement community understood and decided rather than for a new result.

First matter: the properties of a point source that these devices do not have. The lecture introduces intensity by way of a point source and then states that "point sources have several inherent implicit properties which can mislead us when we apply our ideas of intensity to other sources such as LEDs which do not possess these properties." Three properties are named: the intensity of a point source is the same in all directions, it is the same at all distances, and measurements of it are independent of the detector aperture, the last stated as "it means that the intensity measurements we make do not depend on the particular size (or shape) of the input aperture of our detector." The lecture gives the two respects in which other sources depart as the angular distribution of output flux at a specified distance and the variation of output flux with distance.

Second matter: what the lecture says the angular distribution of a real device looks like, and what it declines to say. Of real parts: "the intensity is quite nonuniform in the angular variation, and is often not even symmetric with respect to any angle in this planar view." The cause is attributed to the package: "The problem can be worse for LEDs since the packaging introduces many components which act as reflectors and concentrators of the light which is emitted from the small source itself." The Foundation records what the lecture does not say, because the point is contested in the comment. The lecture presents the point source and the Lambertian source as two idealizations, each with its intensity equation and its polar plot, and applies neither to a light-emitting diode. On the Foundation's reading of the whole lecture, the word Lambertian is applied to no light-emitting diode anywhere in it, and is used of a real surface only of the wall coating of an integrating sphere. This is accordingly a measurement lecture about these devices that does not describe them as Lambertian.

Third matter: that the measurement is forced close in. "The small size and low output of typical LEDs demands that we place our detectors at small distances from the LED. This will aggravate most of the problems indicated above." And on why proximity matters: "These considerations show that even at constant solid angle Ω the intensity output of extended sources will change with distance from the source."

Fourth matter, and the one the comment principally relies on: the stated reason an accurate representation was not required. The lecture sets out that the intensity of one of these devices changes with the distance, the angle and the solid angle of the measurement, and then: "If all these conditions can be specified exactly, it is possible to present an accurate representation of the intensity (distribution) of the LED. However, this is too demanding of experimental accuracy, and too much of a burden for efficient comparison of LEDs during the manufacturing process, or comparison of LEDs between manufacturers, or selection of LEDs for any specific purpose." The three purposes named are comparison during manufacture, comparison between manufacturers, and selection of a part for an application. None is the assessment of exposure or the protection of health.

Fifth matter: the quantity adopted instead, with its figures. Because such a measurement is "an average which is dependant on the measurement configuration used", the quantity defined is the Averaged LED Intensity, written with a subscript for the condition and a further subscript for whether the value is photometric, in candelas, or radiometric, in watts per steradian. The reference point is the front tip of the device; the reference axis is the mechanical axis; the detector aperture is a circular acceptance area of 100 square millimeters. Condition A sets the tip to aperture distance at 316 millimeters, giving a solid angle of 0.001 steradian. Condition B sets it at 100 millimeters, giving 0.01 steradian. The spelling of dependant in the quotation is the source's.

Sixth matter: the date, and what was still unsettled at it. As of April 2002 the two conditions were a proposal. The lecture states that the Commission "is working on a standard which proposes (it is not yet accepted) two defined geometrical configurations for measuring the luminous intensity of LEDs", and the figure showing the two conditions is captioned as proposed. Three technical committees are named as then at work: committee 2-45 on the revision of report 127 of 1997, to include improved definitions and methods for total and partial flux and to re-evaluate the spectral and color parts, chaired by Kathleen Muray; committee 2-46 on a joint standard with the International Organization for Standardization on intensity measurement based on report 127, chaired by John Scarangello; and committee 2-50 on the measurement of the optical properties of clusters and arrays, chaired by Georg Sauter. Three methods of calibration were then under consideration by committee 2-46. This bears on the edition question raised at Part V.B.8 and in this appendix: report 127 of 1997 existed, and a revision of it was in progress when this lecture was given.

Seventh matter: three findings on the spectral side, which the comment does not yet use. The Foundation records these because they are strong and because the subsections they belong to are not yet written on them. First, that the calibration inheritance from the previous technology fails: photometers are calibrated against incandescent sources, the output of these devices is narrow band at typically 20 to 40 nanometers, the narrow band samples the instrument's response only where it fits the luminous efficiency function poorly, and the author states that "Photometric errors of 20%, when measuring red or blue LEDs, are not uncommon for good photometers." Second, that the expectation carried over from the older technology is expressly disclaimed: experience with incandescent lamps leads practitioners to expect that small spectral changes will not matter much, and of that expectation the author writes, "However, this is not true for LEDs." Third, and most consequential for this comment, that the spectrum is not constant across the beam: "It has been observed that the relative spectral output of LEDs, particularly white LEDs, changes with the direction of the output from the LED."

What it establishes. That the properties implicit in treating a source as a point are absent in these devices, stated by a national metrology institute; that their measured angular distribution is nonuniform and frequently asymmetric, and that the package is the cause; that the measurement must be made at distances where the quantity is still varying; that an accurate representation of the distribution was considered achievable and was set aside as too burdensome for three named commercial purposes; that the quantity adopted in its place is an average over a stipulated geometry and is named as such; that as of April 2002 that quantity was a proposal not yet accepted; and that the spectral output of a white device varies with the direction of emission.

What it does not establish. Nothing about health, exposure, injury or any biological endpoint. It reports no measurement of any person and no measurement of any named commercial product. It is a lecture and not a study, its figures are illustrative, and the devices it describes are those of 2002, when the typical operating current is given as 10 to 20 milliamperes against 200 to 300 for the then new high power parts. The Foundation does not rely on it for any proposition about present hardware except where a later source in this comment states the same thing.

Where it bears. Part V.B.8, which is written on it, for the point-source properties, the measured asymmetry, the stated reason an accurate representation was not required, and the character of the averaged quantity. Part IX.F, for what the measurement community itself considered achievable. Part V.B.3 and Part V.K, for the three spectral findings, which are not yet built. Part V.J.3, for the committee on clusters and arrays.

D.6.6 Wilkins A., Veitch J. and Lehman B., LED Lighting Flicker and Potential Health Concerns: IEEE Standard PAR1789 Update (2010). Paper presented at the 2010 IEEE Energy Conversion Congress and Exposition, Atlanta, 12 to 16 September 2010, and published in its proceedings at pages 171 to 178. Arnold Wilkins, Department of Psychology, University of Essex; Jennifer Veitch, National Research Council Canada; Brad Lehman, Department of Electrical and Computer Engineering, Northeastern University. The copy read was supplied by Mr. Baker and carries an IEEE PDF eXpress certification of 23 June 2010 and a digital signature of 12 July 2010.

Why this document is in the comment, and why in this subsection. Because it is the account its authors give of the technical basis of an instrument they wrote, which is the first ground on which this subsection admits a paper. The document states that it "summarizes a public report created by the IEEE Standards PAR1789 group" and that it "represents on-going work in IEEE PAR1789". PAR1789 is the project that produced IEEE Std 1789-2015, which this comment treats at Part V.D.3 and lists at Appendix D.2. This paper is therefore the working group's own statement, five years before the standard issued, of the health concerns the standard was written to address.

Who the working group was, which bears on the weight of the 2024 literature. The acknowledgment names the membership at the time of writing, including observers, and the Foundation records several names because they recur in this appendix. They include Sam Berman, whose 1991 electroretinogram study is cited in the paper's own table; Naomi Miller, the first author of the experiment at Appendix C.90 and of the letter at Appendix D.7; Howard Wolfman, a co-author of the review at Appendix C.91; Michael Poplawski of Pacific Northwest National Laboratory; Yoshi Ohno; David Sliney, whose work on optical radiation is relied on by the instrument at Appendix D.1; Ian Ashdown; Michael Shur; and the three authors. The Foundation asks the Department to notice the continuity: two of the people who set out these concerns in 2010 were still publishing on them in 2024, and what they published in 2024 is that no measurement method exists for one of the three artifacts and that safe levels cannot be set for sensitive people.

The distinction the document defines, and which the comment adopts. The nomenclature section defines its terms. "Visible Flicker: Flicker that is consciously

perceivable by a human viewer" and "Invisible or Imperceptible Flicker: Flicker that is not consciously perceivable by a human viewer". The structure of the health account follows from it: "The health effects of flicker can be divided into those that are the immediate result of a few seconds' exposure, such as epileptic seizures, and those that are the less obvious result of long-term exposure, such as malaise, headaches and impaired visual performance. The former are associated with visible flicker, typically within the range ~3-~70Hz, and the latter with invisible modulation of light at frequencies above those at which flicker is perceptible (invisible flicker). Human biological effects are a function of flicker frequency, modulation depth, brightness, lighting application, and several other factors". The second of the four contributions the paper lists for itself is "Human biological effects due to invisible flicker at frequencies below ~165Hz".

What the document states about invisible modulation, and the care with which it states it. This is the proposition the comment has wanted a source for, and the Foundation reproduces the sentence exactly because its verb matters. "Measurements of the electroretinogram have indicated that modulation of light in the frequency range 100-160Hz and even up to 200 Hz is resolved by the human retina although the flicker is too rapid to be seen", citing Burns and others 1992 and Berman and others 1991. The verb is resolved. The paper's own table records the same two sources against the effect "Human electroretinogram signals at light frequency" at frequencies "Up to 162Hz". The Foundation draws attention to this because the collation at Appendix C.94 reports the same two sources as establishing "unperceived neurological effects", which they do not. The retina resolving a modulation is a measurable electrophysiological fact and is not itself an injury, and the authors of the standard do not claim otherwise.

What the document reports beyond the retina. Three further findings, each attributed. In the cat, modulation at 100 and 120 hertz from fluorescent lamps was shown "to cause the phase-locked firing of cells in the lateral geniculate nucleus of the thalamus, part of the brain with short neural chains to the superior colliculus, a body that controls eye movements", citing Eysel and Burandt 1984. In humans, several studies show that "the characteristics of human eye movements across text are affected by modulation from fluorescent lamps and cathode ray tube displays", and two show "impairment of visual performance in tasks involving visual search as a result of flicker from fluorescent lamps". And in healthy observers, a decrement in sensitivity to visible flicker at 30 hertz follows "a prior exposure of only 2 minutes duration with flicker frequencies about 20% above the observers critical fusion frequency", citing Shady and others 2004.

The headache finding, which is the strongest item in the document. "Under double-masked conditions the 100Hz modulation of light from fluorescent lamps has been shown to double the average incidence of headaches in office workers, although this effect is attributable to a minority that is particularly affected", citing Wilkins and others 1989. The paper also gives the dose: "The peak-trough modulation depth known to induce headaches from fluorescent lighting at 100Hz is about 35%". The Foundation records both halves of the first sentence. A doubling of headache incidence under masked conditions is a strong result; that it is carried by a particularly affected minority is the same observation the author at Appendix D.7 makes about population averages fourteen years later.

The comparison between this technology and the one it replaced. Stated by the authors as the first of their general implications for practice. "Normally functioning fluorescent lighting controlled by magnetic ballasts has been associated with headaches due to the flicker produced. LEDs driven so that they flicker at a frequency twice that of the AC supply may have a depth of modulation greater than that from most fluorescent lamps. The effects of the flicker are therefore likely to be more pronounced in these cases". This is the document the Foundation relies on at Part V.B.9, where the comment declines to argue that this technology is the first artificial source to depart from natural conditions and argues instead about degree. Here the degree is stated by the authors of the standard.

The parameters of photosensitive seizure risk, which the comment needs at Part V.E.1. Prevalence: "About one in 4000 individuals is recognized as having photosensitive epilepsy", with seizures inducible in such individuals "and in perhaps as many again who have not been diagnosed and may be unaware that they are at risk". Onset is typically around puberty, the condition is five times as common in the 7 to 20 age group as in the general population, and "Three quarters of patients remain photosensitive for life". Frequency: "Any repetitive change in a visual stimulus within the frequency range 3 Hz to 70 Hz, is potentially a risk and the greatest likelihood of seizures is for frequencies in the range 15 Hz to 20 Hz", and "The flashes do not have to be rhythmic". Luminance: "Stimulation in the scotopic or low mesopic range (below about 1 cd/m2) has a low risk and the risk increases monotonically with log luminance in the high mesopic and photopic range". Contrast: "Contrasts above 10% are potentially a risk". Field position: "Stimuli presented in central vision pose more of a risk than those that are viewed in the periphery, even though flicker in the periphery may be more noticeable". Wavelength: "Deep red flicker and alternating red and blue flashes may be particularly hazardous". And eyes: bright flicker "can be more hazardous when the eyes are closed", while covering one eye with the palm reduces the effect "very greatly" in most patients.

The pattern hazard, which does not require flicker at all. The fourth general implication concerns spatial arrays rather than temporal modulation. "Spatial arrays of continuously illuminated point sources of light have the potential to induce seizures in patients with photosensitive epilepsy when the field of view is large and when the arrays provide a spatial frequency close to 3 cycles/degree (e.g. large LED public display boards viewed from close proximity)". The document elsewhere records that about one third of photosensitive patients are sensitive to spatial patterns even without flicker, and that "The worst patterns are those of stripes in which one cycle of the pattern (one pair of stripes) subtends at the eye an angle of about 15 minutes of arc".

The failure modes, and the one product measurement in the document. The paper analyzes how a lamp that modulates invisibly can come to modulate in the seizure range. Of the two common drive topologies it describes, both of which modulate at twice line frequency when working, it states that "there is risk of failure that can cause LED current modulation at AC line frequency, thereby entering the range of frequencies that may induce photosensitive epilepsy": a single open-circuit failure in one leg of the rectifier bridge, or an open circuit in one of two anti-parallel strings, halves the modulation frequency to 50 or 60 hertz. Uneven aging produces the same thing partially: in the authors' worked example a 50 percent increase in one string's resistance gives a 60 hertz Fourier component amounting to "over 33% of the DC component". And the measured case: a commercially available lamp of 64 red, green and blue emitters with a full bridge rectifier and capacitor filter in its Edison socket, connected to an ordinary residential phase-cut dimmer, was recorded by photosensor to flicker between about 3.0 and 3.3 hertz with an average of 3.153 hertz, which the authors note "is in the range that has been shown to be a risk for causing photosensitive epileptic seizures".

The remedies the authors identify as available. Two, and both are stated as easy. On dimming: there are "alternative approaches to dimming, such as amplitude dimming, in which the current through the LED is continuous and not pulsing", and "This approach does not use flicker to adjust brightness and therefore, should not induce flicker related health risks". On failure: "it is not difficult to create shut-down or other safety prevention circuits that prevent flickering in the 3Hz-70Hz range when the lamp is in failure mode".

What the authors expressly decline to do, which the comment must state wherever it relies on them. Three disclaimers, quoted in full. "This report does not attempt to make recommendations on safe flicker frequencies or modulation depths for LED lighting. Its purpose is to describe possible health implications of flicker". "This report endorses no technology for driving LED lamps". And in the conclusions: "This paper assigns no health

risk to the biological effects of flicker in the various LED lamps. The hope is that by discussing the issue of flicker within the power electronic community, it will be possible to decide as a community whether or not standards or recommended practices are necessary. We do not attempt to do so here". The authors of what became IEEE Std 1789-2015 were, in 2010, expressly not recommending that anything be required of anyone.

Two statements that run against this comment, recorded because the document makes them. The first concerns source geometry and is in tension with the emphasis at Part V.B.8 on small, bright emitters. "Point sources of light are less likely to induce seizures and headaches than a diffuse source of light that covers most of a person's field of vision. Flicker from LEDs used for general lighting is therefore more likely to be a health hazard than that from LEDs used in instrument panels". The Foundation does not treat this as a contradiction, because the mechanism here is the cortical representation of the stimulated retinal area and the mechanism at Part V.B.8 is retinal irradiance, but the comment must not conflate them and must not argue that a small source is worse for every purpose. The second concerns natural light. The first row of the paper's table attributes seizures, on clinical histories, to "Sunlight through roadside trees or reflected from waves". Flicker capable of provoking a seizure is not peculiar to artificial sources, and Part V.B.9 should cite this row.

The evidence column, which the Foundation regards as the document's most useful feature. The appendix table grades its own entries. Against the headache and eye strain effect of 100 hertz fluorescent lighting it records two rows, one supported by "Many anecdotes" and one by a "Double-masked study". Reduced speed of visual search at 32 percent modulation is supported by "Two masked studies". Epileptiform electroencephalographic responses are supported by "Many clinical EEG studies". Seizures in children with no previous diagnosis from a flashing televised cartoon at about 10 hertz are supported by a "Major incident". Prolonged photophobia from display rasters near 70 hertz is supported by "Many anecdotal reports". Increased heart rate in agoraphobic individuals at 100 hertz is attributed to Hazell and Wilkins 1990. Changes in plasma corticosterone in captive starlings are described as "Inconsistent". A comment relying on this table can therefore state for each proposition what kind of evidence supports it, and the Foundation does so.

What it establishes. That the authors of IEEE Std 1789-2015, writing in 2010, distinguished visible from invisible flicker and attributed effects to both; that they placed seizure risk at 3 to 70 hertz with a peak at 15 to 20 and biological effects of invisible modulation below about 165 hertz; that they reported the retina to resolve modulation to 160 and even 200 hertz unseen, thalamic phase-locking in the cat at 100 and 120 hertz, and a doubling of headache incidence in office workers under masked conditions at 100 hertz and about 35 percent modulation, carried by a particularly affected minority; that they considered modulation depth from light-emitting diodes at twice supply frequency likely to exceed that of fluorescent lamps and effects therefore likely to be more pronounced; that single-component failures and ordinary uneven aging can move a lamp from an invisible frequency into the seizure range, and that a commercial lamp on an ordinary dimmer was measured at 3.15 hertz; that protective circuits and amplitude dimming are available and not difficult; and that the working group expressly declined to say whether any standard or recommended practice was necessary.

What it does not establish. It is a conference paper and a tutorial summary of a working group report, not research, and almost every substantive proposition in it is attributed to a source the Foundation should obtain rather than cite at second hand. It reports one original measurement, of one lamp on one dimmer. Its health account is of fluorescent lighting and displays, because that is where the literature was in 2010; the only light-emitting diode measurement concerns a failure mode. It assigns no health risk, says so

twice, and recommends nothing. And its frequency figures carry the authors' own tildes: about 3 to about 70 hertz, below about 165 hertz.

Where it bears. Part V.D.3, which is written on it, as the draftsmen's account of the instrument. Part V.D.1, for the drive topologies and the failure modes. Part V.D.2, for the saccadic mechanism and the naming of vehicle rear lamps. Part V.E.1, for every parameter of seizure risk. Part V.B.9, for natural flicker and for the depth comparison with fluorescent lighting. Part VI, for the spatial-array pattern hazard and large display boards. Part VII, for the particularly affected minority. Part IX, for the availability of amplitude dimming and protective circuits.

D.6.7 Bullough J., Skinner N. and Rea M., Impacts of Flashing Emergency Lights and Vehicle-Mounted Illumination on Driver Visibility and Glare (2019). SAE Technical Paper 2019-01-0847, presented at the WCX SAE World Congress Experience, Detroit, Michigan, 9 April 2019. doi:10.4271/2019-01-0847. Five pages. All three authors of Rensselaer Polytechnic Institute. Published by SAE International; ISSN 0148-7191, e-ISSN 2688-3627.

What the Foundation has read, stated first. The abstract and the bibliographic record only. The paper is sold by the publisher and the Foundation has not obtained it. Every statement attributed to it in this comment is from the published abstract. This is a limitation on its use and is recorded at Part VI.C.1 as well as here.

Design, so far as the abstract states it. Participants viewed red and blue flashing lights on a scale model police vehicle, the lights conforming to then-current recommended practices for emergency lighting and varying in intensity and in optical power, defined as intensity multiplied by duration. The task was to identify as quickly as possible whether a police officer figure stood beside the vehicle and where. On some trials no figure was present. On some trials white light-emitting diode sources provided low-level illumination at both sides of the vehicle. No sample size, statistical result or numerical value appears in the abstract.

Findings as the abstract reports them. That the blue flashing lights were always perceived as brighter and as more glaring than the red flashing lights at the same intensity. That the probability of correctly detecting the officer figure was affected by the intensity of the flashing lights, the abstract not stating in which direction. That the color of the flashing lights did not affect detection. And that low-level white illumination at the side of the vehicle significantly improved detection accuracy.

The two statements the comment relies on. That public safety agencies are said to select emergency lighting on apparent brightness, with brighter judged better, which the authors describe as anecdotal. And that light-emitting diode emergency lights are brighter and more saturated and thereby cause greater discomfort and disability glare, with the consequence that responders are at higher risk because approaching drivers cannot see them.

A caution on how it sits beside Appendix D.4. The two documents report the same result on blue against red, and the lead author is common to both. They are consistent work by one group across two designs rather than independent replication by separate laboratories, and Part VI.C.1 says so. The Foundation has found no study of this question by any other group.

What it does not establish. Anything about health, and nothing about full-scale conditions. The experiment used a scale model in a laboratory. The disability glare statement in the abstract is an assertion in a framing passage rather than a reported measurement, so far as the Foundation can tell without the paper.

D.6.8 Fédération Internationale de l'Automobile, Glare on Road Traffic: European consumer study 2024 (2024). Informal document GRE-90-20, Revision 1, dated 26 April 2024, submitted by the expert from FIA to the ninetieth session of the Working Party on Lighting and Light-Signalling of the Economic Commission for Europe, Geneva, 29 April to 3 May 2024, agenda item 12. Sixty-eight pages, comprising a report at pages 3 to 10 and five attachments. Presented to the same session on 2 May 2024 in informal document GRE-90-40.

Why it is in this subsection, and what kind of document it is. Because it is a submission by a participant to the body in which the international vehicle lighting regulations are developed, which is the description this subsection exists to cover. It is not a technical paper and the Foundation does not present it as one. It is a consumer survey with recommendations attached, prepared by ten national motoring clubs and placed before a regulator. Mr. Baker should consider whether it would sit better at Appendix D.1, among expert assessments and policy opinions, where the joint statement of the emergency medical services organizations sits; that document is structurally similar, being a position adopted by multiple organizations with an evidence summary attached. The present placement rests on the forum rather than on the form.

What was done. Two arms using one six-page questionnaire, fieldwork to the end of 2023. A representative arm, commissioned by ADAC with ÖAMTC, TCS, TCB and ACL from a market research company, surveying a structured, supervised and demographically balanced sample of about one thousand drivers per country: 4,312 interviews in Germany, Austria, Switzerland and Belgium and 447 in Luxembourg. A self-selected arm, in which ANWB, IAM RoadSmart, BIHAMK, AMZS and NAF invited members to respond through club media, drawing about twenty-two thousand responses, of which the Netherlands component of 13,640 as at 13 November 2023 is reported in full at Attachment C.

What it reports. On the representative arm: 71 percent find glare intolerable or annoying, 32 percent almost always or regularly feel dazzled, 51 percent pinch their eyes shut or close them briefly, 58 percent have problems perceiving objects near the dazzling source, and 30 percent report an afterimage or pain. The report marks the last two as indications of physiological rather than psychological glare. Seventy-five percent considered a review of the regulations necessary. The self-selected arm returned 80, 50, 52, 64 and 25 percent on the same items and 81 percent on the regulatory question.

The three statements for which the comment principally cites it. First, that approval requirements are set in illuminance while the eye responds to luminance and contrast, with a supporting diagram sourced to Seibersdorf Laboratories on the angular extent of the source at the retina. Second, the recommendation that the luminance of light sources must be limited at a distance and at close range in order to exclude the risk of injury to the eye. Third, the paragraph stating that there are indications that high-luminance sources with a high proportion of blue light can cause damage to the eye at close range, that there are still few studies because present luminance levels are recent, and that the risk of injury must be safely excluded.

The measurement it supplies. A photograph of the emitting surface of a modern LED low beam against a five-millimeter grid, captioned as showing a perceived emission area of around five square centimeters in total, sourced to ADAC e.V.

What it does not establish, stated at length because the comment relies on it. It is not peer reviewed and its authors state in terms that it is not a scientific study of the effects of glare. It reports no photometric or radiometric measurement of any lamp apart from the single captioned photograph, no biological endpoint, no clinical examination and no exposure assessment. Its respondent-level data and its questionnaire are not published with it. Its finding that age is not a factor is a finding about reported frequency of being dazzled and not about susceptibility, and the report's own reference list attributes to the Royal Society for the Prevention of Accidents a nine-fold increase in glare recovery time between ages 15 and 65 which the body text uses without the age qualifier. It asserts a link between glare and accidents

on the authority of unnamed United States research followed by an argument from plausibility. Its reference list attributes to a secondary source a claim that glare from oncoming high beams accounts for twelve to fifteen percent of all United States traffic accidents, which the Foundation has not verified and does not use. The submitting organization represents motorists and has an interest in the outcome.

Where it bears. Part VI.B.1, which is largely written on it. Part V.B.8 and Part V.C.2, for the statement that an illuminance-based standard does not constrain source luminance and for the angular-extent relation. Part V.B.2 and Part V.B.3, for the close-range photochemical injury question. Part II.G, for the authors' statement that research on the subject is scarce and dated. Part II.H.5, as a second regulator describing the same gap that the National Highway Traffic Safety Administration described in its letter of 13 February 2024. Part V.C.5, against which its age finding must be read.

D.6.9 Longcore (2020) — a test of candidate spectral descriptors against wildlife response, taken for one measured correlation, for a mechanism by which a standard could be evaded, and for two concessions

Citation. Longcore T. "On the Use of Summary Metrics of Light Spectral Characteristics to Assess Effects of Artificial Light at Night on Wildlife." FIRES, Illuminating Engineering Society, New York. Posted 13 May 2020. Available at ies.org under the fires path, on-the-use-of-summary-metrics-of-light-spectral-characteristics-to-assess-effects-of-artificial-light-at-night-on-wildlife. Read in full from a printed capture of that page dated 14 May 2020.

What this document is, stated first because it governs its weight. A short signed note, about twelve hundred words with two figures, posted on the online forum of a standards body. The page carries an editorial disclaimer that the views expressed do not necessarily reflect those of the Society or represent its endorsement. It is not peer reviewed. It reports an analysis the author performed and presents the results in two figures; the text states one coefficient and describes the rest. It acknowledges constructive comments from two named persons and collaboration with two others.

Why it is in this subsection. Because it is a technical note by a participant in the discourse of a standards body, published by that body on its own forum and disclaimed by it, which is the category this subsection exists for. It is not an article in a peer-reviewed journal and so is outside Appendix C; it is not the opinion of a constituted body, the disclaimer saying so expressly, and so is not D.1; it is not a standard and so is not D.2.

Method. The author took the lamp spectrum database built for his 2018 paper, twenty-five light sources, added further sources and two further descriptors, and regressed four candidate summary descriptors against a composite wildlife index and its four components. The descriptors: correlated color temperature; the melanopic response of the source expressed as a percentage of the sensitivity to an equal illuminance of a standard daylight illuminant; the ratio of melanopic to photopic light; and the percentage of visible light below 530 nanometers. The components: insects, juvenile salmon, a seabird, and an average of sea turtle responses. The ultraviolet range was considered only to 350 nanometers.

Results, with the text and the figures distinguished. Stated in the text: that the correlation between correlated color temperature and the composite index is 0.62, described by the author as adequate but not outstanding; that the melanopic response and the melanopic to photopic ratio perform best in predicting the composite; that correlated color temperature was better for insects and the melanopic to photopic ratio better for the seabird; and that if the database contained sources with violet or near-ultraviolet emission the two best-performing descriptors would fail to identify their effects on insects. Presented only in a figure, and therefore not reported by this comment: every coefficient other than the 0.62.

THE SENTENCE THE COMMENT RELIES ON MOST, AND IT IS A WARNING. "Neither the M/P value nor the melanopic response can be used to evaluate effects on insects,

however, because any light source that avoids the peak of the melanopic response by using shorter wavelengths (e.g., a violet LED pump) will be extremely attractive to insects." Part I.G sets out what follows for the drafting of a performance standard, which is that a limit expressed in a single biologically weighted scalar may be satisfied by a change to the product that moves the emission into a band the scalar does not weight. The Foundation treats this as the most useful thing in the document precisely because it runs against the quantity the comment would otherwise have reached for.

Two concessions the Foundation adopts. "Adjusting spectrum is not a panacea," with the author naming timing, intensity, direction and switching as the other tools. And the opening sentence, that from the position of wildlife the best artificial light at night is no artificial light at night, immediately qualified by the author's recognition that this is not feasible while maintaining safety and achieving other goals. Both are recorded at Part I.G.

What it establishes. Subject to everything above: that the candidate summary descriptors for lamp spectra have been tested against wildlife response data by the person who assembled that data; that correlated color temperature correlated with a composite index at 0.62 across twenty-five sources; that no descriptor was best for every component; and that the two best-performing descriptors have a stated failure mode. It also establishes, by the author's own account of publishing the code, that the computation is available to a designer with a browser.

What it does not establish. Anything about human health. Every response curve in the index is an animal's, and the melanopic function it uses as a descriptor is a human quantity employed as a proxy for non-human effect, which is the reverse of the inference this comment usually examines. It establishes no effect of any lamp on anything: the wildlife responses are taken from the author's earlier work and are not re-measured here. And it is not evidence of the view of the Illuminating Engineering Society, which the page disclaims.

Considerations bearing on confidence. Against: not peer reviewed; twenty-five sources, increased by an unstated number; coefficients other than one are in a figure only; the insect component rests on attraction modeling, and the moth experiment at Appendix C.128 states that attractiveness is not a good proxy for other effects; the author is evaluating descriptors against a database he built, using an index he devised, which is not independent assessment; and the analysis is of 2020. In favor: the author states the limitations himself in two places; the underlying method and code are public; and the single most important statement in the note runs against the author's own preferred descriptors and against this comment's convenience, which is the kind of statement a document is most reliable for.

Authorship, and recurrence. Travis Longcore. He is a co-author of Appendix C.131, whose authorship field records him as the author of three further papers already recorded in this comment as acquisitions, one of which this note now supplies the full citation for. The note acknowledges comments from Ian Ashdown, who is credited with two figures in the Australian guidelines at Appendix D.1, and from Naomi Miller, a co-author of one of the works the note cites; and collaboration with Michael and Lorna Herf, who are co-authors of the 2018 paper and maintainers of the public repository the note names. The Foundation records the overlap and makes no suggestion of interest; it notes only that the spectral-descriptor literature this comment relies on is the work of a small number of connected people, which is the fact the consolidated statement of recurring investigators is to carry.

Where it bears. Part I.G, subsection h, which is written on it. Part IX.H and Part IX.J, for the choice of quantity in which a spectral limit is written and for the evasion mechanism. Part V.F, because the quantity the warning concerns is the quantity apt to the circadian question. Part V.I, for the concession that spectral adjustment is not a panacea, which is the position that subsection has settled on independently.

D.7 Reviews, signed commentary and correspondence in peer-reviewed journals

This category is created for the same reason and by the same reasoning as D.5 and D.6, and the Foundation states the elimination rather than leaving it to be inferred. A signed letter or commentary published in the correspondence pages of a peer-reviewed journal is not an article in that journal and has not been through its review of research, so it is outside Appendix C, whose criterion is publication as peer-reviewed research. It is the view of a named individual and not of a constituted body, so it is not an assessment under D.1, every entry in which is an opinion adopted by a committee. It is not a standard or an account of one, so it is not D.2. It is not a publication of a manufacturer or testing laboratory about its own products, so it is not D.3. It reports no commissioned research, so it is not D.4. It is not a chapter of an edited reference work, so it is not D.5. And it is neither a conference proceedings paper nor a draftsman's account of an instrument, so it is not D.6.

The Foundation cites a document of this kind for one purpose only: the view of a specialist about the state of a field, expressed in their own voice and published under their own name in a journal of that field. Authority of that kind is not the authority of research and the Foundation does not treat it as such. Where such a document reports observations, the observations are identified as the author's report and not as measurement, and the comment states that identification wherever it relies on them. Where an entry here bears on a question also addressed by research in Appendix C, the research governs.

D.7.1 Miller N. J., Correspondence: Flicker: The sneaky perception that ranges from invisible to debilitating (2024). Lighting Research and Technology 2024;56:666 to 668. doi:10.1177/14771535241290851. Published by SAGE for the Chartered Institution of Building Services Engineers. Sole author, Pacific Northwest National Laboratory, Portland, Oregon. The author is the first author of the experiment described at Appendix C.90, and this letter appeared in the same journal and the same year.

What the document is, stated before anything is taken from it. A letter to the editor. Its substance is a series of reports made to the author by members of the public, and the author identifies it as such, introducing the reports with the words "Here are a few of dozens of credible reports" and describing the letter itself as being about anecdotes. It contains no experiment, no protocol, no control condition and no statistical result. The Foundation relies on it for three things only: what a scientist at a national laboratory says is arriving in her correspondence, one measurement she reports having made herself, and the questions she says the field must answer. It is not cited, anywhere in this comment, as evidence that modulation causes any symptom.

Why the Foundation cites it at all. Because of who is saying it and what she says she used to think. The letter opens by naming the response it is written against: the author writes that she is responding to "manufacturers and retailers, automotive companies and property owners/managers whose automatic response is, 'that's just anecdotal." She states why such reports remain in that category: "reports of headaches, seizures, nausea, disorientation, etc. are still considered anecdotal because the neurological evidence is slow to arrive." And of the reports reaching her: "when consistent complaints flow into my in-box, unsolicited, with individuals begging for help to fix the flicker in their homes/cars/workplaces and their kids' schools, it is hard to discount them as fanciful or the product of hypochondriacs."

The measurement the author reports making herself, which is the only measurement in the document. Of a correspondent who reported seizures from lighting, the author records the products named as bus taillights, aircraft cabin lighting, and dashboard and instrument lighting inside a car, and then: "Having measured them, I know the frequency can range from 120 Hz up to over 840 Hz, and they use pulse-width modulation (PWM) to control LED output. Seizures are not supposed to happen from

those high frequencies. I used to discount these incidents. I do not anymore, although I still think they are rare." The Foundation draws attention to the structure of that passage and not merely to its content. A specialist measured the products, found frequencies at which the reported effect is not expected, and changed her position while keeping her estimate of frequency low.

The reports, summarized by the application they concern. The Foundation summarizes rather than reproduces, because the reports are third-party accounts and the comment does not adopt them. They concern LED holiday string lights; automotive tail lights, daytime running lights and marker lights, which one correspondent describes as modulating fully on and off two hundred times a second and producing "a repeating retinal pattern that produces a deceptive impression of where the vehicle is and what direction it is moving"; retail, postal and school interiors; subway tube replacements and platform display screens; aircraft cabin, dashboard and instrument lighting; retail LED lamps, of which one correspondent and her engineer husband compiled a list of lower-modulation products and published it for other families at her school; cellular telephone and computer display screens, with organic light-emitting diode screens identified as particularly troublesome and pixel pulse-width modulation and temporal color dithering offered as explanations; and color-changing products, where preliminary observation points to "sequential color changes (e.g. red followed sequentially by green to produce a perception of yellow) as a possible trigger." The author also records that reports are accumulating from people who sustained a head injury or concussion and afterward experienced symptoms from modulation they had not previously noticed, and that some correspondents have bought modulation meters or used slow-motion video to document the source.

The question the author puts about whose response a limit should be built on. This is the passage the comment relies on most. Reporting the finding of the experiment at Appendix C.90, the author writes: "The significance of this is perhaps average response of a population is an inadequate target for establishing a flicker metric. Perhaps we should address the 15% of the population that gets migraines instead. Or, should we focus on the very sensitive few that are almost completely debilitated by this issue?"

What the author says should happen, including the part that runs against this comment. The Foundation quotes the closing passage whole, because its first half is a reason for caution about regulation and the comment is worth less if the Department has to discover that for itself. "We need to know what populations experience these discomforting or disabling responses, how many people this represents, what characteristics of the TLM waveform are responsible for the problematic symptoms, and the mechanism by which the eye/brain system is affected. We need it soon if we are to avoid imposing limits on the manufacturing of products which are cost-effective, efficient, useful, fun and even inspiring. In the meantime, the responsible action is to reduce TLM in electric light sources to ensure fewer people are affected by them." The stated purpose of the research is in part to make limits on manufacturing unnecessary. The stated interim duty is nevertheless to reduce modulation now.

The causal question, which the author leaves open. The author sets out three candidate causes and does not choose between them: glare from luminaire optics, the spectral power distribution of a blue-pumped device with its local blue peak, or the modulation itself "because regular, high-modulation oscillation in luminance rarely occurs in the natural world in which humans evolved"; and if the modulation, then whether the stroboscopic effect, the phantom array effect "or something else altogether" is responsible. She states that "All of these possibilities are testable, given careful experimental studies with neurology collaboration and reliable, sensitive subjects willing to help solve the problem." The Foundation records this because it is the clearest statement available that the question

is open and answerable, and because the comment should not attribute to modulation what this author declines to attribute.

What it establishes. That reports of this kind are made, unsolicited, to a researcher at a national laboratory; that they concern the applications named above; that a specialist who measured some of the implicated products found pulse-width modulation between 120 and over 840 hertz; that she revised her own view of such reports; that she considers the population average a possibly inadequate basis for a modulation limit and names two alternative targets; and that she regards reduction of modulation as the responsible action pending the research.

What it does not establish. Anything about causation, prevalence, dose or mechanism, and the author asserts none of these. The reports are not cases in any clinical sense: there is no diagnosis, no exposure measurement for any individual, no control and no follow-up. Self-selected correspondence to a known researcher is the least representative sample available, a point the Foundation states because it is true and not because it has been put to it. The figure of 15 percent for migraine prevalence is given in passing without a citation. The description of tail lights modulating two hundred times a second is a correspondent's account and not a measurement. Nothing in this document is relied on in this comment for a proposition about health.

Where it bears. Part V.D.2, for the question of whose response a limit should be built on and for the interim duty. Part V.D.4, for the report concerning vehicle lamps and for the measured frequencies. Appendix A, for what the Foundation understands the status of an incident report to be. Part VII, for the population question. Part VIII.D, for the proposition that absence of a reporting mechanism is why such accounts reach a laboratory in-box instead of an agency.

D.7.2 Marchant P. and Norman P., In the best light? Road safety and public spending (2023). Signed feature in the magazine of the Royal Statistical Society, catalogued because Part V.M relies on it for the road collision results and for three quotations.

Citation. Marchant P. and Norman P. "In the best light? Road safety and public spending." Significance, volume 20, issue 3 (June 2023), pages 30–31. doi:10.1093/jrssig/qmad046. Published 5 June 2023.

What this document is, stated first because it governs its weight. A short feature article in a professional magazine, written by the authors of the research it describes. It is signed commentary, not the research. The two underlying papers have not been read by the Foundation.M requires them to be obtained.

Declared interests. The same declaration as at Appendix C.118: the first author has concerns about light pollution affecting astronomical observations and biodiversity and was motivated by them to examine claims of benefit for increased public lighting; the second has concerns that public money may be wasted on schemes with no proof of achieving their purpose.

What the comment takes from it. The road traffic collision results for the relighting of Leeds, being a confidence interval of about a 20 percent reduction to a 10 percent increase, and for Leeds combined with Birmingham, being a 16 percent reduction to a 12 percent increase, described by the authors as moving in the direction of harm. The collision result of the multi-authority study, being a 7 percent reduction to a 9 percent increase, across 15,833 kilometers of road in 62 local authorities. The authors' statement comparing the scrutiny given to lighting research with that given in health care. And their statement that white light contains all wavelengths, that organisms respond differently to different wavelengths, that the blue component is thought particularly damaging because it signals daytime, and that increasing brightness means more light scattered from surfaces into the environment notwithstanding better optical control.

What it does not establish. Anything of its own; it reports research published elsewhere. No health or biological endpoint is measured in the work it describes; the outcomes are recorded collisions and recorded crime. The statements about wavelength and biodiversity are the authors' summary of a field and carry no citation in the feature.

Where it bears. Part V.M, which is where it is used. Part VI.D, for roadway lighting. Part V.I, to which its closing passage on spectrum and biodiversity hands over.

D.7.3 Durmus, Jägerbrand and Tengelin (2024) — a research note asking whether red light can balance lighting function against ecological impact, and answering that it is uncertain

Citation. Durmus D., Jägerbrand A.K., Tengelin M.N. "Research note: Red light to mitigate light pollution: Is it possible to balance functionality and ecological impact?" Lighting Research and Technology. 2024;56(3). doi:10.1177/14771535231225362. Page range to be supplied. The authors declare no conflicts of interest and state that they received no financial support for the work.

What this document is. A research note and mini review. The authors state that they employed a qualitative approach, synthesizing pertinent literature to provide a concise overview for professionals. There is no original measurement, no original experiment, no stated search strategy and no inclusion criteria. It is placed in this subsection, among signed commentary in peer-reviewed journals, because that is what it is. Every empirical proposition in it is second-hand.I lists the four underlying sources that must be obtained before any of them is relied on as fact. The first author is a co-author of a study appraised in Appendix C, so the comment is not treating an unfamiliar source.

Why it is cited. Because it answers a question the Foundation's own settled position on spectral mitigation invites and cannot answer from the studies in Appendix C: if a longer wavelength is better, why not require red? The document is the only source the Foundation has found that collects the reasons against, and three of them do not appear anywhere else in this literature.

The case for red, as the authors state it. Long-wavelength light scatters less in the atmosphere, so it should produce less skyglow. It suppresses melatonin minimally, melanopsin being most sensitive near 479 nanometers. It preserves human dark adaptation. And nocturnal moths are said not to be spectrally sensitive at long wavelengths, so red light should attract fewer insects and therefore fewer of the bats that feed on them. The authors define red for their purposes as approximately 625 to 780 nanometers, noting that humans can detect radiation to about 1,100 nanometers.

The case against, which is the reason for the entry. Four strands. First, the bat evidence that motivates the requirement is divergent: two pipistrelle species show increased activity under red during migration, while light-averse Rhinolophus, Myotis and Plecotus species may avoid it, and in the single controlled experiment cited, activity fell under all colors and least under red; the authors characterize the responses as species-specific. Second, the ecological trap: a spectrum chosen because a species cannot detect it may leave that species unable to take evasive action, raising predation and so mortality in the population the measure was meant to protect. Third, other taxa detect red even though their peak sensitivity lies elsewhere: red light is reported to disrupt the magnetic orientation of migratory birds, with circling and collision risk, and in one experiment red and white advanced the onset of blue tit activity more than green did. Fourth, the human costs: narrowband red renders color poorly and is said to hinder identification of objects including faces, to compromise acuity and color discrimination, to reduce local contrast, to break down chromatic adaptation under extremely chromatic sources, and to lower subjective visual comfort; and because red lies far down the photopic and scotopic sensitivity functions it needs more radiant power for the same visual effect, the authors citing a commercial luminaire marketed for light pollution mitigation that delivers about 50 percent less luminous flux than a white one at comparable power.

The authors' conclusion. That advocating red light is well-intentioned but that caution is required, that red can be detected by a broad range of species and may have unforeseen consequences, that its effectiveness in mitigating ecological impacts remains uncertain, and that it should not be treated as a universal solution for insects and bats. They add that it is also possible that very little or no light is more beneficial outdoors than red light, and call for further research and monitoring before widespread adoption.

What the Foundation takes and does not take. It takes the reasons, as reasons, and the closing proposition, which is the position this comment argues from the statute: that the characteristics to regulate are the quantity, the direction and the duration of an emission rather than its color. It does not take any of the empirical claims as established, because this is a review. It does not treat the document as evidence about bats, which are otherwise absent from this comment. And it draws the consequence the authors do not: that a spectral prescription constrains nothing about where a luminaire sends its light, which Appendix C.136 shows to be the characteristic that governed.

Where it bears. Part V.I, where it is used, immediately after the settled position on spectral mitigation. Part V.B.3, for the limits of a single-number spectral descriptor, and for the acquisition of the first author's paper on that subject. Part V.M, for the finding that the public preference is for warm color temperature with good color rendering, which red does not provide. Part IV.G, for the collision between a spectral or geometric requirement and the federal lamp efficiency framework. Part II.H and Part IX.E, for the liaison duty under which that collision should be raised with the Department of Energy. Part IX.F, for the request that spectral content be measured and disclosed rather than prescribed.

D.7.4 Fobert, Miller, Swearer and Mayer-Pinto (2023) — a review of artificial light at night on temperate and tropical reefs, taken for three figures and an admission about measurement

Citation. Fobert E.K., Miller C.R., Swearer S.E., Mayer-Pinto M. "The impacts of artificial light at night on the ecology of temperate and tropical reefs." Philosophical Transactions of the Royal Society B. 2023;378(1892):20220362. doi:10.1098/rstb.2022.0362. Published 30 October 2023. Open access. Part of the theme issue Light pollution in complex ecological systems. One author supported by Australian Research Council grant DE220100308. No competing interests. The authors declare that no artificial-intelligence technologies were used.

What this document is. A review article. The journal classifies it as such, it reports no original measurement or experiment, and its data accessibility statement records that the article has no additional data. Its structure is a framework rather than a result: four mechanisms by which artificial light could alter reef systems, and three scenarios in which the authors suggest novel ecosystems could arise. The authors are candid that the underlying research is minimal and almost entirely at the level of the individual organism. The comment therefore places it here rather than in Appendix C, does not treat it as evidence, and declines the framework. The heading of this subsection has been widened to cover reviews, since a review article is not commentary and the comment now holds two.

Why it is cited. For three figures the comment had no source for, for one physical mechanism it did not have, and for an admission about measurement that is the most severe of its kind in this comment. Part V.I sets all of these out and they are not repeated here at length.

The extent of the exposure in water, at second hand. That about 22 percent of the world's coastal regions experience some degree of light pollution; that biologically important artificial light reaches more than 75 percent of the seafloor near coastal developments; that approximately 1.6 million square kilometers of coastal sea are exposed at a depth of ten meters; and that biologically important levels are estimated to reach 70 meters from skyglow and 100 meters from waterside street lighting. The last is a statement about a product class. All four are taken from four primary papers that have not been obtained.

The spectral mechanism. That short wavelengths penetrate deeper through the water column and that many marine organisms are sensitive to them because of the environment in which they evolved, with the consequence that the transition to light-emitting diodes increases the volume of water exposed rather than only the spectral content of the exposure. The comment identifies this at Part V.I as a different argument from the ones it makes elsewhere about spectrum, and as one that does not disturb the settled position on spectral mitigation.

The thresholds. Clownfish embryos failing to hatch at approximately 15 lux; Pacific oyster daily rhythms disrupted at as low as 0.1 lux; and sergeant major hatching inhibited at as low as 0.03 lux. The last is the lowest effect threshold anywhere in this comment and is about twice the median natural night sky brightness measured at Appendix C.128. Its source is a 1993 paper predating light-emitting diodes and must be read before the figure is relied on.

The admission about measurement. That any nocturnal sampling method introducing artificial light into the sampling environment will alter the outcome, and that light from a large vessel or even from a headlamp on a small open boat induces an avoidance response in the pelagic community below eighty meters. This is the ninth attestation collected at Part V.J.4 and the only one in which the act of measuring introduces the exposure, so that no improvement in instruments would cure it.

What the comment declines. The system-level framework and the novel-ecosystem scenarios, which are a research agenda. The diversity-collapse example, because the study behind it attributed spawning desynchronization to temperature and this review offers light only as something that could interfere comparably. And the route from reef decline to human beings through fisheries, declined on the construction of paragraph 360ii(a)(2) adopted at Part II.D.4.

One sentence adopted without alteration. That light pollution is largely an unregulated environmental stressor globally.

Where it bears. Part V.I, in the closing note on scope. Part V.J.4, for the ninth attestation and for the threshold comparison. Part V.B.3 and the settled spectral position at Part V.I, for the penetration mechanism. Part VI.D, for waterside street lighting as a product class delivering a biologically significant emission to one hundred meters of depth.

D.7.5 Hirt, Evans, Miller and Ryser (2023) — the guest editors' introduction to the Royal Society theme issue, taken for one assessment of the field and used otherwise as a map

Citation. Hirt M.R., Evans D.M., Miller C.R., Ryser R. "Light pollution in complex ecological systems." Philosophical Transactions of the Royal Society B. 2023;378(1892):20220351. doi:10.1098/rstb.2022.0351. Published 30 October 2023. Open access. The introduction to the theme issue of the same name. Two authors acknowledge support from the German Centre for Integrative Biodiversity Research, German Research Foundation grant FZT 118, 202548816. The conflict-of-interest declaration records that the issue was assembled by the guest editor team under the journal's supervision, that guest editors were excluded from assessing papers where they had a conflict, that independent reviewers assessed all papers and that invitation did not guarantee inclusion. The authors declare that no artificial-intelligence technologies were used. The acknowledgements thank Kevin Gaston and Andreas Jechow, both of whom appear elsewhere in this comment.

What this document is, stated before anything is taken from it. An editorial introduction written by the guest editors of a theme issue. Its data accessibility statement records that it has no additional data. It reports no measurement and no experiment, and its substantive content is a framing of the field together with a summary of the fifteen or so papers the editors solicited. It is the least evidentiary document cited anywhere in this comment and the Foundation uses it for two things only: one assessment of the state of the field, which is worth more from the editors than from anyone else, and a map of the collection.

The assessment taken, which is the reason for the entry. That light intensity is among the most important and most widely studied properties of artificial light at night; that the majority of studies of it nonetheless rest on binary comparisons of presence against absence, or include only a limited number of intensity levels, with only two exceptions named; that this is attributable to the practical difficulty of running experiments at many levels, particularly at the community level; that such studies risk misinterpreting the true impact of light and limit the ability to predict; and that fully quantitative or dose-response relationships are what theory and prediction require. Part V.A.2 sets out why the Foundation regards this as the central evidentiary obstacle between the published literature and a performance standard under section 360kk, and does not repeat the reasoning here. The two exceptions the editors name are recorded as acquisitions below.

A CAUTION THE FOUNDATION RECORDS AGAINST ITS OWN DIRECTION. One paper in the issue cuts against a mitigation this comment has been moving toward, and the Foundation records it prominently rather than leaving it to be discovered. Heinen and others, Part-night exposure to artificial light at night has more detrimental effects on aphid colonies than fully lit nights, Philosophical Transactions of the Royal Society B 2023;378:20220357. The editors summarize it as showing an increased negative effect on aphid population growth when lights are temporarily switched off during the night compared with night-long illumination, and draw the general conclusion that artificial light can have both positive and negative effects at the population level. Part-night switching is the mitigation the Andalusian instrument at Appendix D.2 codifies in its night period, which the standing question at Part V.I about the necessity of a streetlight at three in the morning assumes, and which the Foundation has been inclined to favor. The paper must be obtained and read before the comment advances part-night switching anywhere. The Foundation notes two things that limit the damage without disposing of it: the subject is an aphid colony and the mechanism is presumably specific to it, and the request this comment actually makes at Part IX is that a luminaire be capable of dimming and scheduling and that the exposure information be published, which is a request about capability and disclosure rather than a recommendation of any particular schedule. That distinction should be preserved deliberately and not by accident.

The map, and the acquisition priorities taken from it. The issue is the densest single collection of community-level work on this exposure and the Foundation has read none of it beyond the review at this subsection. All items are in volume 378, issue 1892. Highest priority, because each bears on an argument this comment already makes. Evans D.M., Mitigating the impacts of street lighting on biodiversity and ecosystem functioning, article 20220355, which the editors summarize as holding that although mitigation options are numerous, few have been rigorously tested; that is the proposition Part II.G makes about paragraph 360ii(a)(5) and the Foundation should cite someone else making it. Bará S. and Falchi F., Artificial light at night: a global disruptor of the night-time environment, article 20220352, which the editors summarize as holding that only a tiny fraction of reflected light is used for human vision while the rest pollutes the environment; that is a statement about waste and bears directly on the word unnecessary in paragraph 360ii(a)(2). Heinen R. and others, article 20220357, for the reason given above. Hölker F., Jechow A., Schroer S., Tockner K. and Gessner M.O., Light pollution of freshwater ecosystems: principles, ecological impacts and remedies, article 20220360, for its remedies and for a call to environmentally friendly lighting near sensitive waters. High priority. Dyer A. and others, article 20220359, for the saturating dose-response in which more than half the change occurred below full moonlight. Tidau S., Brough F.T., Gimenez L., Jenkins S.R. and Davies T.W., article 20220363, for nonlinear irradiance and barnacle survival. Barrientos R. and others, article 20220370, for the finding that nearby lighting rather than skyglow predicts habitat selection by a top predator, which should be read beside the skyglow null at Appendix C.135. Grenis K. and others, article 20220365, for contrasting moth community effects between skyglow and point sources. Spoelstra K. and others, article 20220364, for a long-term effect on invertebrate community composition independent of light spectra, which bears on the settled spectral position at Part V.I. Coetzee B.W.T., Burke A.M., Koekemoer L.L., Robertson M.P. and

Smit I.P.J., article 20220371, on light and disease vector interactions including malaria, which bears on the mosquito study at Appendix C.125 and on the only route in this subsection that reaches a human disease. Also in the issue and lower priority: Bucher and others on grassland plant diversity, article 20220358; Cesarz and others on soil communities, article 20220366, already recorded as an acquisition elsewhere; Parkinson and Tiegs on diode spectra and cross-ecosystem subsidies, article 20220361; Sanders and others on network rewiring, article 20220368; and Seymoure and others on a framework for species interactions, article 20220356.

Three further acquisitions this document identifies. The two dose-response exceptions the editors name: Sanders D., Kehoe R., Cruse D., van Veen F.J.F. and Gaston K.J., Low levels of artificial light at night strengthen top-down control in insect food web, Current Biology 2018;28:2474 to 2478; and de Jong M., Jeninga L., Ouyang J.Q., van Oers K., Spoelstra K. and Visser M.E., Dose-dependent responses of avian daily rhythms to artificial light at night, Physiology and Behavior 2016;155:172 to 179. The second is the only dose-response study in a vertebrate the Foundation has so far identified anywhere. And Abelson E., Seymoure B., Jechow A., Perkin E., Moon H., Hölker F., White J. and Longcore T., Ecological aspects and measurement of anthropogenic light at night, which the editors cite as in press at SSRN with identifier 10.2139/ssrn.4353905; a paper on the measurement of this exposure carrying that authorship bears on Part V.J and its present publication status must be established.

Two matters of corroboration. The editors summarize the mechanism of insect light entrapment in the terms the comment adopts at Appendix C.137, writing that recent work attributes the phenomenon to the insects' behavior of angling their back toward the brightest visual hemisphere, which results in continuous steering around artificial light sources. They cite it as a preprint, that work having been published in Nature Communications in January 2024. That is the third independent second-hand citation of it in this comment and is some evidence that the account is accepted in the field rather than contested. Separately, the editors give the annual rate of increase in light pollution as an estimated 9.6 percent, citing the citizen-science study of star visibility already recorded as an acquisition.

Where it bears. Part V.A.2, where the assessment is used and where the consequence for section 360kk is drawn. Part IX.C, for which it is the evidentiary basis of the request that research characterize the relationship between emission and effect across a range of levels. Part II.G, pending acquisition of the Evans paper. Part V.I, for the part-night caution and for the spectral point in the Spoelstra paper. Part V.J, pending acquisition of the Abelson measurement paper.

D.7.6 Marangoni, Davies, Smyth, Rodríguez, Hamann, Duarte, Pendoley, Berge, Maggi and Levy (2022) — a review of artificial light in marine ecosystems, taken principally for the field's own statement that it has no agreed unit of measurement

Citation. Marangoni L.F.B., Davies T., Smyth T., Rodríguez A., Hamann M., Duarte C., Pendoley K., Berge J., Maggi E., Levy O. "Impacts of artificial light at night in marine ecosystems—A review." Global Change Biology. 2022;28(18):5346–5367. doi:10.1111/gcb.16264. PMID 35583661. PMCID PMC9540822. Published 14 June 2022. Open access. The article records that Marangoni and Davies contributed equally.

What this document is. A review article. It reports no original measurement or experiment, and its data availability statement records that no new data were created or analyzed. The authors describe it as bringing together recognized experts across marine habitats and taxonomic groups to provide a gateway to the field. It is organized by habitat — sandy beaches including sea turtles, rocky intertidal shores, shallow water coral reefs, pelagic environments — with a separate section for seabirds, followed by a section on conservation guidelines and a list of research questions. The authors declare no competing interests.

Why it is cited, stated first because it is not the obvious reason. For its Box 1, which is the field's own statement that there is no globally recognized standard method and no agreed unit of measurement for monitoring biologically active light, that commercial lux meters

exclude the wavelengths falling outside the photopic curve and are insensitive below 450 nanometers, that they were designed for measuring light in buildings and cannot detect skyglow or dim light in the field, and that they supply no spectral information. Part V.J.4 quotes the box and is written on it. Everything else in this entry is secondary to that.

The second reason, which is the same box turned around. Because the review then reports the exposure of essentially every study it collects in the unit its own box says cannot measure the quantity. The Foundation counts two radiometric or quantum exposures in the whole document, both in the pelagic sections, against upwards of eighteen distinct values in lux. It reports this as a characteristic of the field and not as a fault of the authors, for the reason Part V.J.4 gives: a field cannot report in a unit that does not exist.

The research questions taken. Two of the eleven the review lists. That the field needs best practice techniques to monitor and measure "biologically meaningful (i.e., radiometric as opposed to photometric)" light, underwater and on land, at fine and broad scales. And that it needs the thresholds of intensity, wavelength and exposure time that elicit biological responses. The parenthesis in the first is the authors'. Three of the four emission characteristics Part IX asks to have characterized appear in the second.

The exposure-extent figures, at second hand. That at least 22 percent of coastal regions are exposed; that 1.9 million square kilometers of the world's coastal seas are exposed at one meter depth, 1.6 million at ten meters and 840,000 at twenty meters; and that 20 percent of the world's contiguous Marine Protected Areas are exposed across 100 percent of their range. The most exposed regions are the Mediterranean, the Red Sea and Persian Gulf, and the seas of southeast Asia. The first and third of these and two of the depth figures overlap with the figures taken from the review at this subsection immediately above, and the overlap is not independent: Davies is an author of the primary papers and of both reviews. Part V.I states that before using them.

What "biologically important" means, which closes an interpretive gap. In the depth figures used here and in the review above, biologically important artificial light is defined as the minimum irradiance of white light that elicits diel vertical migration in female Calanus copepods, measured experimentally and then applied as the criterion for the global maps. The maps are built on the relationship between a published atlas of night sky brightness and sea surface irradiances, coupled with monthly climatologies of inherent optical water properties and validated against measurements from the Persian Gulf.

Box 2, and the measurement that sharpens the ninth attestation. The review records that the optical instruments used to count plankton and fish at depth all require an external light source and names five of them; that red light has been recommended for such surveys on the assumption that most species react to it less; that two studies supported the assumption; and that Geoffroy and others in 2021 contradicted it, finding that pelagic organisms in Arctic and temperate regions strongly avoid artificial light including visible red at 575 to 700 nanometers, with density falling by as much as 99 percent and avoidance distances of 23 to 94 meters from the source at light levels of 11 to 18 microwatts per square centimeter. Part V.I sets out the three consequences. The attestation count at Part V.J.4 is unchanged; this quantifies the ninth.

Sea turtles, summarized here rather than in the body. That artificial light at night, even at low levels, is a threat influencing all seven species of marine turtle, principally as hatchlings or nesting adult females. That it affects the on-beach orientation and nest site selection of adult females, the on-beach orientation and sea-finding of hatchlings, and the at-sea dispersal of hatchlings during the swim frenzy of roughly 24 to 48 hours after emergence. That hatchling sea-finding is influenced by both the wavelength and the intensity of the light and is significantly compromised by shorter wavelengths even at lower intensity. That the thresholds of concern for wavelength and intensity are likely to vary within and among species, which Part V.I records as a caution against this comment's own direction. And that two studies of nest site selection both concluded that turtles use darker beaches and select darker sections of beaches.

Seabirds, summarized here for the same reason. That light pollution causes mortality of fledglings involving more than 70 species, some severely threatened, in all the oceans and seas, a phenomenon the field calls fallout; that about 90 percent of birds admitted to rescue programs survive, while studies indicate around 40 percent of grounded birds are never rescued; that tracking shows most Cory's shearwater fledglings are grounded within sixteen kilometers of their nests; that adult Manx shearwaters flying over a colony were deterred by blue and green light in comparison to red, and that the number flying over decreased with the duration and intensity of the treatment; and that around 31 percent of all seabird species are globally threatened and 47 percent have declining population trends. Rodríguez is a co-author of this review and of the study at Appendix C.133, and a 2020 paper of his on whether light-induced seabird mortality is explained by visual system development is cited in it; the authorship overlap is recorded here rather than left to be found.

The regulatory statement. That a few countries — Spain in Catalonia, Chile, France, and Italy in Piedmont — are trying to establish laws regulating light pollution; that most applicable documents are guidelines, codes or standards from regulators, advisory committees, non-governmental organizations or professional bodies "with no legal basis for enforcement of recommendations"; that many professional guidance documents are addressed to lighting engineers, give little detail on management for sensitive receptors, and "must be purchased at a substantial cost"; and that guidance for the marine environment does not exist in the English-language literature. Part V.I draws the consequence for section 360kk.

The ranked design recommendation. Six best-practice rules, reproduced at Part V.I, of which the authors state that the most important is avoiding short-wavelength blue light, for two reasons: its visibility across a wide range of taxa, and its greater capacity to penetrate the water column. The second reason does not transfer to land and the comment does not transfer it. The review also records that the guidelines it endorses recommend a case-by-case approach to assessment and mitigation, which is the opposite of a numerical performance standard; Part V.I states the distinction rather than arguing the point.

What the review concedes about its own evidence base. Two things, both in the authors' own words. That many of the short-term experiments it collects used "high ALAN levels (not considered environmental realistic)" and are offered as a step toward understanding mechanism. And that the intensities used in some sandy-beach studies were measured under the light source in the promenade area and "could be higher than those occurring in the intertidal area," a concern the authors rebut with unpublished data of one of their own number. The abstract also records that while strategies for mitigation were easily identified, barriers to their implementation are poorly understood.

The findings that run the other way, recorded because the review records them. An amphipod whose locomotor activity did not differ between a lit and an unlit beach. An isopod whose growth rate was unaffected and whose absorption efficiency increased. A coral microbial community that remained stable. A juvenile bonefish study and a seagrass fish assemblage with almost no effect. The Atlantic dog whelk, which forages more under artificial light rather than less, the opposite of the Chilean abalone. Intertidal microphytobenthos whose biomass and photosynthetic efficiency increased. And little penguins that preferred lit paths to dark ones in reaching their nests. The review also polices its own citations, describing one beach comparison as correlational and to be treated with caution and one absorption-efficiency result as restricted by the need to keep the animals without sand. Part V.I sets out what the Foundation makes of the heterogeneity.

What the comment declines. The habitat-by-habitat biological findings, which are collected at second hand from primary studies the Foundation has not read and which are reported in a unit the review itself says cannot measure the quantity. The comment takes no effect estimate from this document. It also declines the ten golden rules figure, which it has not seen, and does not attribute ten rules to the review.

Where it bears. Part V.J.4, which is written on Box 1 and on the two research questions, and which is the principal use. Part V.I, in the closing note on scope, for the depth figures, the Marine Protected Area figure, the definition of biologically important light, the Geoffroy avoidance measurement, the regulatory statement and the two cautions. Part V.J.5, for the radiometric-against-photometric distinction in the authors' own parenthesis. Part IX.G.1 and IX.J, for the ranked priority on short-wavelength content. Appendix C.133, for the seabird authorship overlap.

D.7.7 Green, Luginbuhl, Wainscoat and Duriscoe (2022) — the observatory site-protection review, taken for the quantification of direct uplight and for what regulators have actually prescribed

Citation. Green R.F., Luginbuhl C.B., Wainscoat R.J., Duriscoe D. "The growing threat of light pollution to ground-based observatories." The Astronomy and Astrophysics Review. 2022;30:1. doi:10.1007/s00159-021-00138-3. Published 27 January 2022. Open access.

What this document is. A review article in a review journal. It reports no original experiment. Its content is a synthesis of the physical modeling of skyglow, of field measurement practice, of the regulatory instruments in force around major observatories, and of the emerging problem of satellite constellations. The subject is the protection of astronomical observation and not human health, and the Foundation takes nothing from it about health.

Why it is cited. For two things. The quantification of direct upward emission against reflected ground light, which Part II.D.4 had asserted; and the worked example of Flagstaff, in which a numerical sky brightness target was set, converted into a prescribable limit, imposed, and then measured and found to have been achieved. Both are set out at Part II.D.4 and are not repeated here.

The uplight figures, at second hand. A representative reflectivity of 15 percent for illuminated surfaces, used in this modeling literature since 1986. A direct upward emission fraction averaging about 10 percent across an installed stock. The consequent split of upward-propagating flux into roughly equal direct and reflected parts. A factor of about 6.7 for direct over reflected neglecting angle, rising to a predicted 40 to more than 150 times at distance with little blocking, against a measured range of about 1.5 to 16 times. And the figure the comment relies on most: a fixture with one percent direct upward emission increases artificial sky brightness by 30 percent at fifty kilometers and 100 percent at two hundred kilometers against the same fixture fully shielded.

Distance scaling. Skyglow impact scales approximately as the inverse 2.5 power of distance. The authors give the consequence arithmetically: a source at 30 kilometers has 15 times the impact at 10 kilometers, 135 times at 3 kilometers and over 650 times at 1 kilometer. The comment does not presently use this and it bears on any argument about proximity of a source to a receptor.

The correction the Foundation adopts against its own interest. That the common explanation for the skyglow consequences of white light-emitting diodes is wrong. Scattering of short wavelengths is approximately balanced by the extinction that accompanies it within about ten kilometers, and beyond that extinction dominates, so a white source of given luminous output has less impact on integrated radiant skyglow at distance than a yellow one. The increased visual impact, which is two to three times that of high-pressure sodium at equal lumens, arises from the greater sensitivity of the dark-adapted eye to blue and green. Within the 350 to 500 nanometer band, which is the band this comment is about, white diodes were found to increase radiance by a factor of about two or more against high-pressure sodium. Part II.D.4 keeps the three statements apart.

What this review says about correlated color temperature, which corroborates Part I.G. That correlated color temperature "is properly applied only to light spectra that approximate the spectrum produced by a blackbody" and that it "does not accurately correlate

with either the ‘percent blue’ impact or visual sky glow impacts.” That is the proposition Part I.G takes from the 2018 spectral-index paper, reached independently by four astronomers in a different journal four years later. The Foundation has not added it to the body because the existing treatment is already sourced and verified; it is recorded here as corroboration available if that passage is ever challenged.

The metrics this review names, one of which the comment does not have. Four. The percent blue, being the ratio of radiant flux shortward of 500 nanometers to radiant flux over all wavelengths, which is the linear form of the logarithmic index Part I.G already uses. The Sloan g-prime passband as an alternative definition of the same thing. The scotopic to photopic ratio, which the authors say is “an approximate surrogate for many biological or ecological impacts” because short-wavelength sensitivity is a common attribute of biological systems, and which Appendix C.57 already supplies as a numerical criterion. And total spectral emission bandwidth, which the comment does not presently have as a named metric and which the authors describe as spectrally neutral because it treats all wavelength regions equally. Bandwidth is the quantity that distinguishes a warm broad-spectrum lamp from a narrow-band amber one, which is the distinction Part V.I draws and Part I.G records from the Andalusian instrument as a 25 nanometer limit.

What regulators have prescribed, and the contrast the Foundation should draw. The review reports that the Chilean national code limits luminous intensity in three stated wavelength intervals, each as a fraction of the intensity between 380 and 780 nanometers: below 0.15 for 300 to 379 nanometers, below 0.15 for 380 to 499 nanometers, and below 0.5 for 780 to 1,000 nanometers, with a tighter revision proposed in 2021. It reports that the code protecting Calar Alto allows zero percent of energy below 440 nanometers and requires a monochromatic or narrow-band source where color rendition is not critical. And it reports that United States codes have instead started limiting correlated color temperature: San Diego County below 2,500 kelvin near the observatory, southern Arizona codes below 3,500 kelvin, the City of Phoenix purchasing roadway lighting at 2,700 kelvin, and a Hawaii state law requiring all state lighting to be fully shielded and at or below 4,000 kelvin. The contrast is the point and Part IX.J should have it: where other jurisdictions prescribe radiant power in a stated wavelength interval, American jurisdictions prescribe the one descriptor the published characterization reports to be a poor predictor of blue content over exactly the range in which they are using it.

The structural statement about American regulation. That “the general approach in the United States is to make these regulations part of the local Zoning Code, which regulates the usage of property,” while most other codes are established to protect a specific site or form part of environmental or sustainability regulation. The review adds that almost all such regulations are prospective only, applying to new development or major redevelopment, the exception being the Andalusian requirement that fixtures with more than 25 percent uplight be removed within three years. The Foundation has not yet used this and it bears directly on the federalism passage at Part II.D.4: a zoning code governs where a lamp may be installed and prospectively; a performance standard under section 360kk governs what a product may emit when it is introduced into commerce. They are different instruments reaching different things, and the second is not available to a municipality.

That thresholds have not been set, which is Part II.G’s proposition. The authors state that acceptable or target threshold values “have rarely been established for any of these metrics,” that mitigation has accordingly focused on minimizing impacts “with little or no discussion of what an acceptable impact might be, and thus no way to determine whether light pollution exceeds thresholds or has been successfully mitigated,” and that approaches have concentrated on individual fixtures or parcels “rather than the summed regional impact.” The last clause is also the multi-emitter point at Part V.J.3, made from the other side.

One numerical threshold that does exist. The Site Protection Commission of the International Astronomical Union adopted one in 1979: a contribution of 10 percent of the

natural level as the maximum tolerable limit, specified at 45 degrees elevation above the horizon and for wavelengths throughout the optical spectrum from 300 to 1,000 nanometers. The Foundation records it as a demonstration that a limit of this kind is writable and has been written, radiometrically and over a stated wavelength range, by an international body, forty-seven years ago, for a protected interest other than health.

A measured effect on human visual function. Using all-sky imagery with the modeled natural background subtracted, the National Park Service night sky team measured at a site in Death Valley National Park, more than 100 kilometers from the center of Las Vegas, an artificial brightest square degree of 17.6 magnitudes per square arcsecond, which the authors state is bright enough to inhibit dark adaptation of the human eye; the boundary between scotopic and mesopic vision is given as 17.0. At sites at the margin of and within Las Vegas and Washington, D.C., artificial skyglow is thousands of percent above natural on every indicator and dark adaptation is impossible. The Foundation has not used this and notes what it is and is not: dark adaptation is a physiological state of the human visual system, and its impairment at that distance is a measured consequence of emission from products. It is not a disease outcome and the comment should not present it as one.

Two further matters recorded for other Parts. That since 2006 the mission of the United States National Park Service has included preservation of the natural photic environment, and that the natural reference condition for skyglow illuminance is given as 0.8 millilux horizontal and 0.4 millilux vertical. That is a second federal body with a stated interest in this emission and bears on Part II.H. And that in the United States county and state lighting laws do not bind federal installations, the review noting that an Army training area 10 kilometers from the Maunakea observatories is exempt from the county ordinance and complies voluntarily. That bears on any argument about what local regulation can and cannot reach.

What the comment declines. Everything about satellite constellations in low-Earth orbit, which occupies a section of the review and concerns reflected sunlight rather than emission from a product on the ground. It is outside this comment and outside the subchapter. The Foundation also takes no astronomical impact finding as such: the protected interest in this review is the ability to observe, and this comment is about an emission and the people exposed to it.

Where it bears. Part II.D.4, which is written on the uplight quantification, the Flagstaff example and the Purkinje correction, and which is the principal use. Part I.G and Part IX.J, for the corroboration on correlated color temperature and for the contrast between what American and foreign jurisdictions prescribe. Part II.G and Part IX.C, for the absence of thresholds and for the one that exists. Part V.J.3, for the summed-regional-impact point. Part II.H, for the National Park Service mission and the exemption of federal installations from local lighting law.

D.7.8 Gaston, Bennie, Davies and Hopkins (2013) — the mechanistic review, taken for two reference tables and for a footnote that states both of this comment's measurement propositions in 2013

Citation. Gaston K.J., Bennie J., Davies T.W., Hopkins J. "The ecological impacts of nighttime light pollution: a mechanistic appraisal." Biological Reviews. 2013;88(4):912–927. doi:10.1111/brv.12036. Authors at the Environment and Sustainability Institute, University of Exeter, Penryn, Cornwall, and at Natural England, Peterborough. Funded by the European Research Council under the Seventh Framework Programme, grant agreement 268504 to the first author. Read from a file hosted on the Foundation's own server; the issue number is inferred and must be verified.

AUTHORSHIP, STATED BEFORE ANYTHING ELSE. Kevin Gaston and Jonathan Bennie are authors of Appendix C.94 and Appendix C.128 and co-authors of the satellite instrument paper relied on at Part V.J.4. Thomas Davies is a co-author of the marine review in this subsection and of Appendix C.141. John Hopkins was at Natural England, a non-departmental public body of the United Kingdom government, which is recorded because the comment elsewhere tracks government participation in this literature. The University of Exeter

group now appears in this comment five times and nothing here is offered as independent corroboration of anything else by the same authors.

What the document is. A synthetic review proposing a framework that cross-factors the three ways artificial light alters natural light regimes — spatially, temporally and spectrally — against two ways light acts on biological systems, as a resource and as a source of information. It reports no original measurement and no original data. It is thirteen years old, predating the general transition to light-emitting diode street lighting in the United States that Part IV.G describes, and the Foundation uses it for two tables and a footnote rather than for its survey of the literature.

Table 1, the reference illuminances. Set out at Part V.A.2. Full sunlight 103,000 lux; partly sunny 50,000; cloudy day 1,000 to 10,000; operating table 18,000; bright office 400 to 600; most homes 100 to 300; main road street lighting at average street level 15; lighted parking lot 10; residential side street 5; full moon under clear conditions 0.1 to 0.3; quarter moon 0.01 to 0.03; clear starry night 0.001; overcast night sky 0.00003 to 0.0001; urban skyglow 0.15. Attributed collectively to the British Standards Institute 2003, Rich and Longcore 2006b, and Dick 2011, without row-by-row sourcing. The caption carries its own caution, that although widely used, lux measurement places emphasis on brightness as perceived by human vision.

Table 3, the effect levels. Headed, in the authors' words, examples of the levels at which nighttime lighting has been observed to have biological effects, with species, setting, effect, illuminance and source, ordered by increasing intensity. Four owl rows at a millionth to a ten-thousandth of a lux for prey location, from a 1945 study and converted from footcandles, which are visual detection figures rather than effects of artificial light and are not used. Then: common toad, prey detection, 0.00028 lux; Syrian hamster, altered circadian rhythm, 0.01; salmon, prey detection, 0.01 to 5; fruit fly, increased activity and shifted peaks, 0.03; brown rat, increased rates of tumor growth and metabolism, 0.2; brown rat, increased rate of tumor growth, 0.21; five wader species, higher prey intake in a field experiment, 0.74; deer mouse, reduced nocturnal activity, 0.93; prairie rattlesnake, reduced activity, 1; American robin, earlier singing, mean 1.26 in field observations with a range of 0.05 to 3.06; leaf-eared mouse, reduced nocturnal activity, 1.5, and predator avoidance with reduced food consumption, below 2.0; Siberian hamster, suppressed immune response, 5; algae, mosses and ferns, minimum light for continued photosynthetic growth in caves, 10 to 50, 50 to 180 and 250; Atlantic salmon, altered timing of nocturnal migration, 14 measured at the stream surface; pond bats, reduced feeding and disturbed flight, below 30; lesser horseshoe bats, reduced activity and delayed commuting, 51.67 average; social vole, disrupted seasonal thermoregulation, 450 as a fifteen-minute pulse; field mouse, disrupted circadian rhythm, 1,000 as a fifteen-minute pulse. Except where noted the exposures are described as constant.

THE FOOTNOTE, WHICH IS WHY THIS ENTRY MATTERS MOST. In full: "Note that: (i) in many cases these represent levels of experimental treatments, and precisely where thresholds might lie remains unknown; and (ii) although widely used, lux measurement places emphasis on brightness at wavelengths perceived by human vision." Both of this comment's measurement propositions, stated by the field about itself in 2013, in the caption of the table that would otherwise be read as a list of thresholds. Part V.A.2 sets out what follows.

The conclusions the Foundation records. That artificial light increasingly encroaches on dark refuges in space, in time and across wavelengths. That effects have been documented across a wide range of species and processes, but that effects at population and ecosystem level are poorly known. And, from the abstract, that major research gaps exist, particularly in the impacts of light at population and ecosystem levels, in "identification of intensity thresholds" and in the spatial extent of impacts near artificial lights. The abstract also states that even low levels of nighttime light pollution can have significant impact.

What it establishes. Nothing of its own, being a review. It establishes what expert opinion was in 2013 and it supplies two tabulations whose rows are individually sourced or collectively attributed, which the comment uses for scale and for direction to primary studies.

What it does not establish. Any human effect. Any threshold, the authors saying expressly that where thresholds lie remains unknown. Anything about light-emitting diode products, the review predating their general deployment in the United States. And nothing at all that the comment should state without reading the primary study behind the row.

Where it bears. Part V.A.2, which is written on both tables and on the footnote, and which is the principal use. Part V.I, where the natural-darkness correction is made and now confirmed. Part V.J.4, for the 2013 date of the footnote's second limb. Part V.F, for the two rodent tumor rows, which are flagged and not used. Part IX.C, for the research gap the abstract names.

D.7.9 Swaddle, Francis, Barber and eleven others (2015) — the evolutionary framework review, catalogued for one human-exposure figure, for the theory behind two readings the comment has already adopted, and to record that the comment makes no use of its light-and-sound framing

Citation. Swaddle J.P., Francis C.D., Barber J.R., Cooper C.B., Kyba C.C.M., Dominoni D.M., Shannon G., Aschehoug E., Goodwin S.E., Kawahara A.Y., Luther D., Spoelstra K., Voss M. and Longcore T. "A framework to assess evolutionary responses to anthropogenic light and sound." Trends in Ecology and Evolution. 2015. doi:10.1016/j.tree.2015.06.009. Swaddle and Francis are stated to be joint first authors and Longcore is the corresponding author. Fourteen authors at thirteen institutions in the United States, Germany, the United Kingdom and the Netherlands.

THE COPY READ IS NOT THE VERSION OF RECORD. The file read is an author-deposited accepted manuscript bearing the publisher's in-press markers, including a running head giving the volume and issue as unassigned and a typesetting reference, and a notice that the content was uploaded to a research-networking site by one of the co-authors in November 2017. It therefore has no page numbers and the volume and issue are unknown. The citation above is incomplete for that reason and must be completed from the journal before any use.

What the document is. A review proposing a framework for investigating anthropogenic light and noise as agents of natural selection and as drivers of other evolutionary processes. It reports no original research and no measurement. Its subject is what would have to be established to show evolutionary change, and what is known is characterized by the authors as largely understudied.

The one figure the comment may want, and it concerns people. That in 2001 approximately 40 percent of the world population lived in areas that never experienced sub-moonlight illuminance. That is at second hand from the authors' reference 4 and the data are now a quarter of a century old. The Foundation records it because it is a statement about human exposure in a literature that is mostly about animals, and because it is the second independent route to the proposition at Part V.A.2, taken there from the reference table at Appendix D.7, that in a lit place the diffuse background is of the same order as moonlight. Neither source has been traced to a primary measurement and the body states the proposition only as an order of magnitude.

The theory behind two readings the comment has already adopted, including the part that cuts the other way. This review is the framework for the distinction the comment has twice had to draw between an effect and an injury. At Appendix C.138 and again at Appendix C.144 the Foundation adopted the authors' own suggestion that a difference observed under artificial light might be adaptive plasticity rather than harm. This review sets out the machinery of that argument, distinguishing behavioral flexibility, developmental plasticity and heritable genetic change, and it states a consequence the Foundation had not seen made explicit: that behavioral flexibility can weaken selection, because if most genotypes adjust in an adaptive

direction the strength of selection generally falls. That cuts against a comment arguing from evolutionary consequences, and the Foundation records it for that reason.

WHY THE COMMENT MAKES NO USE OF ITS CENTRAL FRAMING, WHICH IS A DECISION RATHER THAN AN OVERSIGHT. The review treats artificial light and anthropogenic noise together as sensory pollutants. The Foundation's own remit covers both, and subparagraph (B) of the statutory definition at section 360hh does reach sonic, infrasonic and ultrasonic waves emitted from an electronic product, as Part II sets out. The comment already uses that subparagraph, and uses it for the purpose it will bear: as the reason a definition reaching ionizing radiation at one end and infrasonic waves at the other does not stop at the edges of the visible band. That is an argument about the breadth of the definition. It is not an invitation to put sound before the Department in a comment responding to a request about electromagnetic fields, and this review supplies no reason to do so: its pairing of the two is ecological and evolutionary, not statutory. The Foundation therefore takes nothing from the pairing and records the decision here so that it is not revisited.

What it establishes. Nothing of its own. That a framework has been proposed, by fourteen investigators in a journal of the first rank, for asking whether these exposures act as agents of selection; and that as of 2015 the evolutionary implications were largely understudied.

What it does not establish. Any human health effect. Any effect of any kind, no original observation being reported. And no evolutionary change in any population, which is the point of the paper: it describes what would have to be measured.

Where it bears. Nowhere in the body at present. If the adaptive plasticity question at Appendices C.138 and C.144 is ever developed rather than simply conceded, this is the document that frames it.

D.8 Preprints and self-archived research reports

This category is created for the same reason and by the same reasoning as D.5, D.6 and D.7, and the Foundation again states the elimination rather than leaving it to be inferred. A preprint is original research by a named author, deposited in a public repository with a persistent identifier, which has not been through the peer review of any journal. It is therefore not an article within the meaning of Appendix C, which contains peer-reviewed articles and nothing else. It is not an expert assessment under D.1, not a standard under D.2, not a publication of a manufacturer or testing laboratory under D.3, not a commissioned report under D.4, not a reference work under D.5, not a conference paper under D.6, and not commentary in a journal under D.7. The Foundation places such documents here so that their status is visible on the face of the appendix, and cites them for what they measure rather than for conclusions drawn from the measurement.

D.8.1 Bará S., On the continued growth of light pollution from vehicle lights (2016-2025). Preprints da Corredoira 2025.3.v1, deposited at Zenodo, doi:10.5281/zenodo.15565958. Licensed CC BY-NC 4.0. Seventeen pages including supplementary data. The author is identified as a former profesor titular at the Universidade de Santiago de Compostela, now retired, with an ORCID identifier given. Not peer reviewed. Full text read. Treated at Part VI.B.1.

What it analyzes. The published photometric data of the Insurance Institute for Highway Safety headlight ratings for 287 car models from 27 manufacturers, most with several variants, over 2016 to 2025: 3,386 records and 13,544 individually measured lights, weighted by brand sales share for 2023. The underlying data are the Institute's and are public; the derivation of luminous intensity from them is the author's.

What it reports. Growth in the luminous intensity of the headlamps of the average car over the period of 18 percent for high beams combined, 35 percent for low beams combined and 22 percent for the mean of the two, corresponding to compound annual growth rates of 1.9, 3.4 and 2.2 percent a year. Combined with fleet growth, an estimated total emission

growth of 3.6 to 3.7 percent a year in the United States and European Union and 10.6 percent a year in China. That the rate was larger for low beams than for high beams, which the author takes to suggest faster growth of vehicle-induced emission in urban areas.

The author's own statement of its limits, reproduced because the comment relies on the figures. That the results were obtained "from a limited sample of cars and using very strong additional simplifications, so they should be taken with a grain of salt", and are offered "as a first approximation and as a stimulus for further research on this topic". His considered statement in the discussion is that the results are "strongly suggestive of a steady and non-negligible increase of the vehicle headlight emissions during the last ten years".

What it does not contain, stated because the subject invites the assumption that it does. Any spectral data. The paper reports luminous intensity and luminous flux. It says nothing about wavelength, correlated color temperature or short-wavelength content, and the single occurrence of the word blue in it refers to the color of symbols in a figure. No part of this comment cites it in relation to blue light. It also contains no health content of any kind and reports no exposure of any person.

The purpose for which the comment uses it, and the purpose for which it does not. For one fact: that the emission of vehicle headlamps increased measurably over the last decade, fastest in the low beam. The author's own subject is the contribution of vehicle lighting to skyglow and to the discrepancy between satellite and citizen-science measurements of sky brightness. The Foundation takes no position on that question and asks nothing of this Department in relation to it, consistently with Part II.H.3.

Where it bears. Part VI.B.1, which is written on it. Part II.H.5, for the liaison point about the Insurance Institute dataset. Part V.L, for the research gap.

D.8.2 Newman, Artificial Light at Night and the Predator-Prey Dynamics of Juvenile Atlantic Salmon in Freshwater (2015). Doctoral thesis, catalogued chiefly to record that two of its chapters were published as papers which the comment should cite instead.

Citation. Newman R.C. Artificial Light at Night and the Predator-Prey Dynamics of Juvenile Atlantic Salmon (Salmo salar L.) in Freshwater. Thesis submitted to Cardiff University for the degree of Doctor of Philosophy, Organisms and Environment, School of Biosciences, April 2015. Deposited in the university repository at orca.cardiff.ac.uk, eprint 79119. Approximately two hundred and twenty-four pages. Supervisors: Griffiths, Ormerod and Thomas, all of the Cardiff School of Biosciences.

What this document is, and the rule that governs it. A doctoral thesis, examined for a degree and deposited by its author in an institutional repository. It is original research by a named author with a persistent location and it has not been through the peer review of a journal, which places it in this subsection. But it differs from the preprint above in a way that governs every use of it: the thesis itself states that chapters of it were published as journal articles, so for those chapters a version of record exists and the comment must cite that version and not this one. The Foundation has read the thesis and has not read either paper.

THE PAPERS ARISING, AS THE THESIS LISTS THEM. Riley W.D., Davison P.I., Maxwell D.L., Newman R.C. and Ives M.J. (2015), A laboratory experiment to determine the dispersal response of Atlantic salmon (Salmo salar) fry to street light intensity, Freshwater Biology 60:1016 to 1028. That is the dispersal chapter and it is published. Newman R.C., Ellis T., Davison P.I., Ives M.J., Thomas R.J., Griffiths S.W. and Riley W.D., Toolbox: Light pollution and the cortisol stress response in dispersing Atlantic salmon (Salmo salar) fry, Conservation Physiology, recorded in the thesis as provisionally accepted in 2015 and therefore almost certainly published since. A third paper, on the effect of street lights on the signal crayfish, is listed as submitted to Oecologia and is said not to arise from this thesis.

What the thesis reports, stated as provisional in every particular. Four lines of work. On invertebrate drift in an experimentally lit stream, that light affected the drifting behavior of invertebrates from contrasting taxa with a divergent effect between taxa and between functional feeding groups, some increasing and others decreasing under part-lighting. On dispersing Atlantic salmon fry, that light disrupted the timing and periodicity of nocturnal dispersal behavior at all experimental light intensities, the range tested being 1 to 8 lux. On the physiology of the same animals, that the behavioral change was not the result of a cortisol stress response. And on Atlantic salmon parr, that fish housed under high-intensity light refuged 28 percent more than controls.

TWO OF THOSE FOUR RUN AGAINST THE DIRECTION A READER MIGHT EXPECT, AND THE FOUNDATION RECORDS THEM FIRST. The divergent invertebrate result is not a finding that light suppressed drift; some taxa increased and some decreased, and the thesis draws from that the conclusion that the influence of light is difficult to generalize between taxa and between life stages. And the cortisol result is a negative mechanistic finding reported by the author against the obvious interpretation of her own behavioral data: the fish changed their behavior and the stress hormone did not move. A comment that cited the behavioral disruption without the physiological null would be misrepresenting the work.

The one result that bears on Part V.A.2, and why it is not used there yet. That dispersal was disrupted at all tested intensities, the lowest being 1 lux. Within the range examined no threshold was found, which is the shape of result Part V.A.2 collects. The Foundation does not use it in the body because the figure comes from a thesis chapter whose published version has not been read, and because 1 lux is well above the natural nocturnal illuminances tabulated at Part V.A.2, so the absence of a threshold within 1 to 8 lux says nothing about what happens below it.

A defect in the document, recorded as the Foundation records such things elsewhere. The summary and the table of contents disagree about the chapter numbering. The summary attributes the invertebrate drift work to Chapter 2, dispersal to Chapter 3, cortisol to Chapter 4 and refuging to Chapter 5; the table of contents places the same four at Chapters 3, 4, 5 and 6, Chapter 2 being a quantitative review of the literature. Anyone citing a chapter of this thesis must say which numbering is being used.

What it establishes. For the comment, nothing yet. It establishes that the work exists, that two chapters of it are published, and what the author says she found. Every figure in it is provisional until the published papers are read.

What it does not establish. Anything about human health. Any effect at any spectral composition, the exposure being described only as broad spectrum. And nothing below 1 lux.

Where it bears. Nowhere in the body at present. If the published papers hold, the dispersal paper would bear on Part V.A.2 and the cortisol paper on Part V.F, and both would bear on Part V.I, where the Foundation has twice had to record that salmon are a subject of this literature without being able to cite a primary study.

D.9 Publications of advocacy and membership organizations

This category is created for the same reason and by the same reasoning as D.5, D.6, D.7 and D.8, and the Foundation again states the elimination rather than leaving it to be inferred. A briefing published by an organization that exists to advocate on the subject it is briefing about is not a peer-reviewed article, so Appendix C excludes it by that appendix's own stated criterion, which also excludes organizational publications by name. It is not an opinion adopted by a constituted body on a question referred to it, so it is not within D.1. It is not a standard, not a manufacturer's publication, not a commissioned report, not a reference work, not a technical paper of a standards-body participant, not a peer-reviewed review, and not a preprint of original research. It is therefore placed

here, in a category of its own, and the Foundation states plainly what weight a document of this kind can carry.

It can carry one thing. A statement in it that concedes a limitation adverse to the publisher's own position is worth attending to, because the incentive runs against making it. A statement in it that supports the publisher's position is worth no more than the primary source behind it, which should be obtained and cited instead. The single entry below is used on that basis and on no other, and the Foundation does not cite it for any fact.

D.9.1 International Dark-Sky Association, Artificial Light at Night: State of the Science 2022 — used for its concessions and for nothing else

Citation. International Dark-Sky Association. "Artificial Light at Night: State of the Science 2022." Published at darksky.org, June 2022; the final version is dated 27 May 2022. Eleven pages of text and approximately seven pages of references, three hundred and twenty-one references in all. No authors are named; the byline is the organization. The organization is a United States nonprofit corporation and has since been renamed DarkSky International.

What this document is, and what it is not. A briefing for a general readership, organized into six topics — the night sky, wildlife and ecology, human health, public safety, energy and climate, and light and social justice — with sections on satellite constellations and on research needs. It reports no measurement, no experiment and no original analysis. It is not peer reviewed in the sense a journal uses the term. The document states that it was externally reviewed by subject experts, who are thanked but not named, and describes itself as a living document to be updated.

Its stated method, which the Foundation records because it is unusually explicit. That the main source was a curated database of artificial-light-at-night research literature maintained by the same organization, supplemented by Google Scholar and PubMed. That database is ALAN_DB, described in the entry immediately below and relied on at Part V.A.1 for its existence and scale and for nothing else. That the compilers defined scientific literature as results subjected to at least single-blind external peer review in what they believed to be reputable outlets, considered both open-access and non-open-access papers, and used post-publication citation metrics where available. And that they generally did not consider technical reports, white papers, theses and other grey literature. The Foundation notes without comment that this document is itself of the kind its own method excludes.

What the comment takes. Six sentences, all quoted at Part V.A.3 and two of them taken up again at Part V.M. Three concede that the outdoor human health question is unresolved. Two concede that the satellite instrument cannot record the emission of white light-emitting diodes and that the health studies relying on it are accordingly less reliable. One concedes that claims about outdoor lighting and crime or traffic safety may be fundamentally wrong in either direction, and a seventh, recorded with it, that no known dose-response relationship exists from which an appropriate lighting level could be predicted.

What the comment declines, and why. Everything else. The document contains a large number of arresting figures — that skyglow affects more than 80 percent of all people and more than 99 percent of the populations of the United States and Europe; that white light-emitting diodes account for almost half of global lighting sales; that artificial light is likely responsible for the deaths of millions of birds and insects each year; that at least 160 species have been studied for effects of light exposure; that snow under cloud can raise night sky brightness by thousands of times against an overcast sky with no artificial light. Each is a summary of a cited source written for a general reader. Where this comment needs such a fact it takes it from the source, and several of those sources are already in Appendix C and Appendix D.

The relationship the Foundation discloses. Two of the five authors of the study at Appendix C.139 disclosed in that paper that they serve as uncompensated members of the board of directors of this organization. The disclosure is theirs. The Foundation repeats it so that the

two citations are not read as independent of each other, and records that it bears on neither the instrument specifications taken from that paper nor the concessions taken from this one.

Sources in it worth obtaining. Four. Nadybal, Collins and Grineski (2020), from which the document reproduces population-weighted average zenith night sky brightness by racial and ethnic group for the continental United States; that is a peer-reviewed primary study of disparate exposure in this country and it is not presently in this comment. The study the document cites for a ten-year rate of return on a United States solid-state lighting retrofit program of plus 118.2 percent on electricity savings alone, falling to minus 146.2 percent once health and carbon externalities are included, which bears directly on Part IV.G. The source for the statement that cloud and snow together can raise night sky brightness by thousands of times, which would extend the cloud-amplification material at Part II.D.4. And the source behind the statement that the lighting industry's own standards often do not establish benchmarks on the basis of scientific evidence.

Where it bears. Part V.A.3, which quotes the concessions and which is the principal use. Part V.J.4, where the instrument statement is recorded but is expressly not added to the count of attestations. Part V.M, for the two safety sentences. Part V.A.2, for the dose-response sentence.

D.9.2 DarkSky International and the Loss of the Night Network, ALAN_DB — a public index of the literature, cited for its existence and its scale and not for its contents

Citation. DarkSky International and the Loss of the Night Network. ALAN_DB. Zotero group library number 2913367, published at https://www.zotero.org/groups/2913367/alan_db and accessed October 16, 2026. Undated and continuously revised; no version, edition or persistent identifier is assigned. The maintaining organization was formerly the International Dark-Sky Association and is the publisher of the briefing document described immediately above.

What this is. A shared bibliographic library of research on artificial light at night, hosted on a reference-management service and open to the public. The maintaining organization states on its website that it maintains the database with its partners at the Loss of the Night Network, and that the library is free for public use with no login required.

Where to find it, and where the maintainer's figures are published. The library is at https://www.zotero.org/groups/2913367/alan_db. The statement that the maintaining organization keeps the database with the Loss of the Night Network, that it is free for public use and that no login is required, and the figure of nearly five thousand items, are at https://darksky.org/what-we-do/advancing-responsible-outdoor-lighting/research/. The figures of about four hundred and thirty additions a year, of roughly twenty-two percent annual growth and of four hundred and fifty-seven papers surveyed for 2022 are at https://darksky.org/news/artificial-light-at-night-state-of-the-science-2023-report/, an announcement published July 11, 2023 and updated July 18, 2023, bylined to John Barentine of Dark Sky Consulting LLC. All three were accessed October 16, 2026. The Foundation gives the addresses in the entry because the single proposition this entry supports is that the index is public and free to open, and an entry asserting that a resource is available cannot withhold where it is.

The figures, and which of them the Foundation vouches for. From the maintainer, and adopted by the comment only as the maintainer's statements: that the organization's state-of-the-science briefing drew on nearly five thousand pieces of scientific literature listed in the database; that an average of about four hundred and thirty publications have been added each year in recent years; that the contents have grown by roughly twenty-two percent a year on average; and that the 2023 edition of the briefing surveyed four hundred and fifty-seven papers published in 2022 alone, against three hundred and twenty-one references in the 2022 edition described above. From the Foundation, and vouched for: the library held 6,754 entries on October 16, 2026. Part V.A.1 reconciles the two and reports that the observed count is consistent

with the stated annual additions and not with the stated compound growth rate, which is why the comment does not rely on the latter.

What the comment uses it for, which is one proposition. That a free, public, continuously maintained index of this literature exists, and that the literature is therefore available to be evaluated by anyone who decides to evaluate it. Part V.A.1 draws that conclusion and no other, and in the same passage states that the one hundred and fifty-three articles in Appendix C are about one entry in forty-four of the library as the Foundation counted it on October 16, 2026.

What the comment does not use it for. Anything at all about the content, quality, direction or weight of the literature. A bibliography establishes that records exist. It establishes nothing about what is in them, and the Foundation advances no proposition of fact on the strength of this item. No entry in Appendix C was obtained from it.

Why it is in this subsection rather than another, and the problem with that. It is placed with the publications of advocacy and membership organizations because it is a product of one, and because the briefing immediately above identifies it as that briefing's main source, so the two belong together. But it is not a publication. It is a living web resource with no fixed contents. The Foundation records the awkwardness rather than disguising it.

Limitations, which are serious and are stated before the use. Five. It is mutable: a group library can be altered by anyone with permission to alter it, at any time, and what it contains on the day this comment is filed is not necessarily what it contained when the maintainer counted it or what it will contain when the Department reads this. It is unversioned: there is no snapshot, no archived release and no persistent identifier to cite. Its inclusion and exclusion criteria are not published as a standing editorial policy; the nearest thing is the method statement in the briefing described above, which concerns the briefing and not the library. Its counts are self-reported. And it is maintained by an advocacy organization and a research network rather than by a library, an agency or a journal.

How a federal record should handle a resource of this kind. The Foundation's position is that a live web page should not be relied on in a rulemaking record for any proposition of fact, and this comment relies on it for none. For the one proposition it does support, which is that the index exists and is public, the resource should be retrieved on a stated date, exported, and the dated export lodged with the comment or retained so that it can be produced.

Where it bears. Part V.A.1, in the passage on the asymmetry between what a small nonprofit corporation can do and what the Department can do, and in the Foundation's statement of the size of its own sample. Part IX.H.2, where the request that the Department publish its commissioned literature search is made more precise.

Appendix E — Chronology of Petitions, Litigation, and Congressional Action

This appendix is a dated record of the administrative and judicial filings on which Part IV is built, and of the agency responses to them. Part IV states what the record establishes. This appendix states what the record is, entry by entry, so that the Department can locate any item without relying on the narrative.

E.0 Scope, capacities, and the limits of this appendix

What is included. Petitions, requests, complaints and correspondence submitted by the Soft Lights Foundation to a federal agency, or by Mark Baker to a federal agency or court concerning visible light emitted by light-emitting diode products, together with the responses received. Filings before state bodies are described at Part IV.C.8 and are not repeated here.

Capacities, which this appendix keeps separate. Each entry states whether the document was submitted by the Foundation, by Mr. Baker in his individual capacity, or by both. The distinction matters and Part IV.A.2 explains why. The judicial actions were brought by Mr. Baker individually; the regulatory petitions were submitted by the Foundation, with one exception, noted at its entry, submitted jointly.

Locators. Every entry gives the original locator wherever one exists: a docket number, a case number, a Federal Register citation, or a control or tracking number assigned by the receiving agency. Where no public locator exists, which is the position for most incoming agency correspondence, the entry says so and the Foundation holds the document. This appendix does not cite the Foundation's own website as the authority for any document, consistently with the practice stated at Part IV.A.3.

What this appendix is not. It is not an exhibit list, which Part IV.A.3 commits the Foundation to produce separately and which will number the documents in the order the comment first cites them. It is not a complete account of the Foundation's advocacy, which extends to matters outside this subject. And it is not an argument. The entries record dates, parties, authorities invoked and relief sought. Where an entry bears on a proposition advanced elsewhere in this comment, it says where, and leaves the proposition there.

2021

E.1 December 7, 2021 — Letter to the Administrator of the Environmental Protection Agency

Capacity. The Foundation.

What is known. The document itself is not among those the Foundation has placed before this Department in this appendix. Its existence and date are established by the reply, at E.8, which identifies it as a letter of December 7, 2021 to Administrator Regan. The entry is included because the reply cannot be dated or understood without it.

2022

E.2 June 13, 2022 — Citizen petition to the Food and Drug Administration seeking a performance standard for light-emitting diode products

Capacity. The Foundation, signed by Mark Baker as President.

Authority invoked. 21 C.F.R. §§ 10.25 and 10.30. The petition also refers to the Radiation Control for Health and Safety Act of 1968 without a United States Code citation.

Relief sought. That the agency issue a new regulation at 21 C.F.R. part 1040.40 for light-emitting diode products, setting limits on spatial non-uniformity, on chip-level peak

luminance and peak radiance, on spectral power distribution, and on square wave flicker. The requested rule is the one Part IX.I discusses in its present form.

Locator. Docket No. FDA-2022-P-1151. The docket number field on the face of the petition is blank, the number having been assigned on receipt. Twenty-six pages.

Disposition. Interim response November 7, 2022, at E.11. Denied with three other petitions by the Final Response of May 24, 2024, at E.42.

E.3 August 5, 2022 — Petition to the National Highway Traffic Safety Administration for an order of non-compliance, model year 2021 Ford Bronco

Capacity. The Foundation. Addressed to Steven Cliff, Director.

Authority invoked. 49 C.F.R. part 552, subpart A. The petition also quotes section 103(a) of the Act.

Relief sought. That the agency issue Ford an order of non-compliance, and notify the public that light-emitting diode headlamps do not comply with federal safety regulations. Eleven pages.

Disposition. Denied with E.4 and E.7 at E.15.

E.4 August 11, 2022 — Petition to the National Highway Traffic Safety Administration for an order of non-compliance, model year 2021 Tesla Model 3

Capacity. The Foundation. Addressed to Steven Cliff, Director.

Particulars. Same authority and same relief as E.3, directed to Tesla. Eleven pages. Denied at E.15.

E.5 August 16, 2022 — First request to the Food and Drug Administration under the Freedom of Information Act

Capacity. Mark Baker individually.

Locator. Agency confirmation number FDA22085814. Freedom of Information Act Control No. 2022-6020, acknowledged August 17, 2022.

Where it bears. This is the first of the two requests at issue in the action at E.45. Part IV.D.3 describes the litigation.

E.6 September 7, 2022 — Response of the Occupational Safety and Health Administration

Document. Letter from Douglas L. Parker, Assistant Secretary for Occupational Safety and Health, United States Department of Labor, to Mark Baker as President of the Foundation.

What it says. That the agency does not plan to add the topic to its regulatory agenda at this time, and that its Directorate of Standards and Guidance will review the scientific literature and determine whether there are other appropriate approaches to address electromagnetic radiation from light-emitting diode devices in the workplace.

Locator. None assigned. The Foundation holds the letter.

Where it bears. Part II.H, on the liaison duty, and Part VIII. The Foundation records that the second sentence is a commitment to review rather than a denial of authority, which distinguishes this response from those at E.8 and E.12.

E.7 September 9, 2022 — Petition to the National Highway Traffic Safety Administration for an order of non-compliance, model year 2022 Rivian R1T

Capacity. The Foundation. Addressed to Steven Cliff, Director.

Particulars. Same relief as E.3 and E.4, directed to Rivian. This petition cites 49 C.F.R. § 571.108 expressly. Eleven pages. Denied at E.15.

E.8 October 7, 2022 — Response of the Environmental Protection Agency

Document. Letter from Lee Ann B. Veal, Director, Radiation Protection Division, Office of Radiation and Indoor Air, to Mark Baker as President of the Foundation, replying to the letter at E.1.

The operative sentence. That Congress has not granted the agency any statutory authority to regulate visible light or non-ionizing radiation.

Locator. None appears on the document.

Where it bears. Part II.H and Part IV.H.5. This is a federal agency disclaiming authority over the emission in terms, and the Foundation offers it for that and for nothing more. It does not establish that the agency is right about the limits of its own authority.

E.9 October 19, 2022 — Letter from the Federal Highway Administration

Document. Letter from Sharon J. Field, ADA Team Leader, Office of Civil Rights, Federal Highway Administration, 1200 New Jersey Avenue SE, Washington, D.C., digitally signed October 19, 2022. The letter bears two references of its own: In Reply Refer to HCR-40, and DOT number 2022-0375.

What it responds to. A complaint under the Americans with Disabilities Act and Section 504 of the Rehabilitation Act of 1973, submitted by Mr. Baker to the Department of Justice, which transferred it to the Department of Transportation. The complaint was against three cities, named in the letter as Ashland, Oregon, Little Canada, Minnesota, and Penn Yan, New York, and alleged that their installation and use of rectangular rapid flashing beacons discriminates against Mr. Baker and other individuals with disabilities by inducing, in the letter's words, disorientation, visual impairment, anxiety, fear, seizures, and other medical and health issues.

The disposition. Dismissal without further investigation. The letter states that there is no statutory requirement that every complaint under Title II receive a full investigation, citing the Department of Justice's 2010 final rule at 75 Fed. Reg. 56,163, 56,228 (Sept. 15, 2010), and sets out the factors an enforcement agency considers: whether a violation may have occurred, how limited resources are best spent, and whether the enforcement action fits the agency's overall policies. It notes the right to bring a private suit under section 203 of the Act at any time, per 28 C.F.R. § 35.172(d).

The sentence this comment relies on, quoted in full. "The allegations you have raised about the health impacts of RRFBs raise complex issues related to the regulation of all Light Emitting Diode (LED) lights, not just those used in RRFBs, that extend beyond FHWA's authority."

Where it bears. Part II.H, Part VIII.E.6 and Part IX.E. This is the clearest jurisdictional statement in this appendix, and it is clearer than the Foundation had previously recorded. The agency did not merely decline the complaint on resource grounds, although it did that too. It identified the subject of the complaint as the regulation of light-emitting diode lights generally, said so in terms by adding that the issues are not confined to the devices complained of, and placed that subject beyond its own authority. The agency whose Manual authorized the device, asked about the health effects of the light the device emits, named the subject of this comment and said it belongs somewhere else.

One connection the Foundation draws to the next entry but one. Little Canada, Minnesota is one of the three cities named in this complaint. Part VIII.E.6 sets out what happened when a state agency took up the same city and the same class of device.

What became of the three cities. Little Canada: a charge to the Minnesota Department of Human Rights produced a finding of probable cause on June 15, 2023, after which the State took no further step and no remedy followed. Ashland: Mr. Baker brought an action in state superior court in his individual capacity and dismissed it voluntarily on moving from Oregon to California, with no decision on the merits. Penn Yan: no further action occurred. Part VIII.E.6.

Capacity. The Foundation together with four named individuals, MarieAnn Cherry, Kristina Townsend, Heidi O'Leary and Kristin Campisi, described in the document collectively as Advocates.

What it is. A submission responding to the agency's request for comments on the petition at E.2, addressing neurological, psychological, circadian and ocular matters and reproducing case reports. Fifty-nine pages.

A characterization this comment should not carry forward. Part IV.C.1 describes this document as an update to the petition filed by the Foundation. On its face it is a comment on the docket, and it has five submitting parties rather than one. The discrepancy is not resolved here.

E.11 November 7, 2022 — Interim response of the Food and Drug Administration on Docket No. FDA-2022-P-1151

What it says. That the agency has been unable to reach a decision because the petition raises issues requiring further review, issued under 21 C.F.R. § 10.30(e)(2)(iv). The text is quoted at Part IV.F.5 as relayed through the inquiry at E.19.

E.12 November 9, 2022 — Response of the Federal Aviation Administration on jurisdiction

Document. Letter from Michael A. P. Meyers, P.E., Manager, Airport Engineering Division AAS-100, Office of Airport Safety and Standards.

What it says. That the agency provides standards and guidance for certain types of airport and obstruction lighting but is not a regulatory agency on light-emitting diode requirements, and that it defers to other agencies depending on the issue. It then states that it would defer to the Food and Drug Administration for comfort, health, and safety regulations, and to the Occupational Safety and Health Administration for specific topics such as cockpit lighting.

Locator. None appears on the document.

Where it bears. Part II.H, and Part IX.I. The Foundation draws attention to one word. A federal agency asked which body regulates this emission answered that it would defer to this Department for comfort as well as for health and safety. The Foundation does not suggest that a sister agency's letter enlarges the authority of § 360kk. It records that the agency which deferred understood the subject to include the quality this comment calls comfort, and did not treat it as outside the field.

E.13 November 23, 2022 — Petition to the Federal Highway Administration to repeal the Interim Approval for rectangular rapid flashing beacons

Capacity. The Foundation. No individual signatory is named on the document. Addressed to the Department of Transportation and the Federal Highway Administration.

Authority invoked. The Administrative Procedure Act, and the reservation in the Interim Approval itself that the agency may rescind it at any time. The petition also refers to the Radiation Control for Health and Safety Act, the Americans with Disabilities Act and the Rehabilitation Act.

Relief sought. That the agency repeal the Interim Approval for rectangular rapid flashing beacons. The petition addresses the 2009 edition of the Manual on Uniform Traffic Control

Devices, chapter 4L, and cites the Interim Approval by the agency's own web address, whose path component reads ia21. Twenty-two pages.

Locator. No docket number appears for this petition. The document cites the letter at E.9 and the petition at E.2.

Where it bears. Part IV.E.1 and Part VI.C. This petition and the request at E.46 are the Foundation's filings on these devices before this Department's sister agency, and neither is presently described in Part IV.

E.14 November 7, 2022 — Email from the Consumer Ombudsman of the Consumer Product Safety Commission on that agency's jurisdiction

Document. Electronic mail from Jonathan Midgett, Ph.D., Consumer Ombudsman, Office of the Executive Director, United States Consumer Product Safety Commission, sent November 7, 2022 at 7:15 a.m., to Mark Baker and to the agency's consumer address.

What it says. That the agency's staff evaluates products on an individual basis and that its jurisdiction over LED lights depends on the hazard; that the agency may have jurisdiction over LED lights for hazards such as electrocution and fire, but does not have jurisdiction over LED lights under the Consumer Product Safety Act if the risk is related to electronic product radiation that may be regulated by the Food and Drug Administration; and it then quotes 15 U.S.C. § 2080(a), with a bracketed note of the Commission's own recording that the referenced provisions of the Public Health Service Act were later transferred to 21 U.S.C. § 360hh.

Locator. None assigned. The Foundation holds the message.

Where it bears. Part II.H.9, which is written on it and which quotes it, and Part II.M. Part VI.M.3 and Part IX.E.4 proceed on the statutory bar rather than on this message, and the division of authority they describe is the division this message states.

A correction recorded here. An earlier state of this appendix marked this entry unread, because the copy of the message in the Foundation's files is an image scan without a text layer. That was wrong as to the comment: the message had already been read and was already quoted accurately at Part II.H.9. The error was in this appendix and not in the body.

E.15 December 8, 2022 — Denial of the three petitions for orders of non-compliance

Document. Soft Lights Foundation, Denial of Petition for Decision of Non-Compliance Order, 87 Fed. Reg. 75,327 (Dec. 8, 2022), Docket No. NHTSA-2022-0109, signed by the Associate Administrator for Enforcement.

Why this entry matters more than the outcome. Because of what the published reasoning states. Part IV.C.3 sets it out at length, including the agency's statements that this Department has authority to regulate certain aspects of light-emitting diode products as radiation-emitting devices and that there is currently no performance standard for such products in part 1040.

E.16 December 10, 2022 — Petition to the National Highway Traffic Safety Administration to require lamps obeying the inverse square law

Capacity. The Foundation. Addressed to Ann Carlson, Director.

Authority invoked. 49 C.F.R. part 552, subpart A.

Relief sought. That 49 C.F.R. § 571.108 be amended to add a provision requiring that all lamp sources emit visible radiation that is spatially uniform and follows an inverse square law for dispersion. Part V.B.2 and Part VI.B address the physics; Part V.B.8 addresses the point-source question the agency answered at E.15.

Extent. One hundred and forty-six pages, of which the petition occupies the first fifteen and an appendix of public comments the remainder.

E.17 December 15, 2022 — Second request to the Food and Drug Administration under the Freedom of Information Act

Capacity. Mark Baker individually.

Locator. Freedom of Information Act Control No. 2022-8833. Tracking number 23-0024AA, assigned March 9, 2023, the agency having invoked unusual circumstances.

Where it bears. The second of the two requests at issue in the action at E.45.

2023

E.18 January 22, 2023 — Citizen petition to the Food and Drug Administration concerning light-emitting diode strobe and flashing lights

Capacity. The Foundation.

Locator. Docket No. FDA-2023-P-0233.

Disposition. Interim response June 30, 2023, at E.29. Denied by the Final Response of May 24, 2024, at E.42.

Status of this entry. The particulars are taken from Part IV.C.1 and from the Final Response. The docket itself has not been read. See item (4) of the note at E.0.

E.19 February 16, 2023 — Inquiry of Senator Maria Cantwell to the Food and Drug Administration

What it was. An inquiry on behalf of a constituent as to the status of citizen petition FDA-2022-P-1151. The agency's reply was relayed by the Senator's office on March 21, 2023, at E.22, and is quoted at Part IV.F.5.

E.20 February 26, 2023 — Letter to the Chair of the Equal Employment Opportunity Commission

Capacity. The Foundation. Addressed to Charlotte Burrows, Chair.

What it sought. The letter states no request for action. Its stated purpose is to alert the Commission to what it describes as fundamental safety and federal legal issues, and it contends that an employer is required by the Americans with Disabilities Act to remove the barriers to access created by the use of light-emitting diode products. Three pages.

Where it bears. Part VIII. The Foundation records that this document is correspondence rather than a petition or a charge, that no reference number was assigned, and that no response is recorded.

E.21 March 21, 2023 — Denial by the Department of Energy of the petition to repeal the 45 lumens-per-watt rule

Locator. Document ID EERE-2023-BT-PET-0003-0003.

Where it bears. Part IV.G, which sets out the lamp efficiency framework and this denial.

E.22 March 21, 2023 — Reply of the Food and Drug Administration relayed through the office of Senator Cantwell

What it says. That an interim response to citizen petition FDA-2022-P-1151 issued on November 7, 2022 under 21 C.F.R. § 10.30(e)(2)(iv), the agency having been unable to reach a decision because the petition raises issues requiring further review. Quoted at Part IV.F.5.

E.23 April 2, 2023 — Consumer report to the Federal Trade Commission

What it is, stated before anything else. Not a petition. It is a consumer report submitted through that agency's public fraud reporting portal, ReportFraud.ftc.gov, on a form headed Consumer Report To The FTC. It invokes no statutory or regulatory authority, seeks no rulemaking, and is not a filing in any docket. The Foundation states this at the head of the entry because the file name under which the document has been kept describes it as a submission, and because an appendix of petitions and litigation could otherwise be read as presenting it as one.

Capacity. Submitted in the name of Mark Baker, with the Foundation's electronic mail address, and signed in the body of the report as President of the Foundation.

Locator. Federal Trade Commission Report Number 158396451. The confirmation page was generated April 3, 2023.

What it asked. That the Commission direct lighting manufacturers to warn consumers that LED general service lamps have not been vetted or approved by the Food and Drug Administration, and that the Food and Drug Administration has not set restrictions on peak luminance, dispersion characteristics, spectral power distribution and square wave flicker. Those are the same four quantities the petition at E.2 asked this Department to limit, and Part I.G groups them as the spectral, spatial and temporal families.

What the agency's own confirmation says. That the Commission cannot resolve individual complaints and cannot resolve the individual report, that reports are shared with law enforcement partners and used to spot trends, and that it provides information about next steps. No substantive response is recorded.

A proposition in it that this comment does not adopt. The report states that LED visible radiation has been proven to be hazardous and that it is a health hazard. This comment makes no such claim. Part V.A states what the literature does and does not establish, and Part IX.C asks for the research that would be needed to support a finding of that kind. The entry records the document as written rather than softening it, and the Foundation does not ask the Department to read the assertion as its position in this proceeding.

Relationship to E.37. Distinct. The petition at E.37, of November 26, 2023, is a rulemaking request to the same Commission seeking the publication of luminance on product labeling. This is a consumer report on a complaint form seven months earlier. The question recorded in the earlier state of this entry, whether the two were the same document, is answered: they are not.

E.24 April 26, 2023 — Letter to the Assistant Attorney General for Civil Rights

Capacity. The Foundation. Addressed to Kristen Clarke, Assistant Attorney General for Civil Rights, United States Department of Justice.

What it sought. A federal civil rights investigation. Three pages.

What this comment does with it. Nothing, and the Foundation states that deliberately. The letter frames the matter as a violation of a civil right to visual freedom. That is not the frame of this comment, which proceeds on the statutory duties of 21 U.S.C. §§ 360ii and 360kk, and the entry is included for completeness of the record rather than for the proposition.

E.25 May 24, 2023 — Citizen petition to the Food and Drug Administration by Americans for Responsible Technology and others

Capacity. Not the Foundation. Neither the Foundation nor Mr. Baker is a signatory and neither name appears in the document.

What it is. A citizen petition titled Citizen Petition and Request for Legal Compliance: Legal Obligations of FDA Regarding Public Exposure to Non-Ionizing Radiation from Electronic Products, submitted to the Division of Dockets Management by Americans for Responsible

Technology as lead petitioner with Grassroots Environmental Education, Consumers for Safe Cell Phones, the California Brain Tumor Association, Manhattan Neighbors for Safer Telecommunications and five named individuals, certified by Douglas A. Wood as Founder and National Director.

Why it is recorded here. Because it is a petition to the same agency under the same subchapter in the same period, directed to the same statutory duties, by petitioners unconnected with the Foundation. That is a fact about the administrative record rather than about the Foundation, and Part II.E bears on it. Its subject is radiofrequency rather than visible light, and the Foundation does not adopt its contentions.

Status of this entry. The docket number has not been established and the page count is not determined. Item (5) of the note at E.0 records the question whether this entry belongs in this appendix at all.

E.26 May 29, 2023 — Petition to the National Highway Traffic Safety Administration to consult and maintain liaison with the Food and Drug Administration

Capacity. The Foundation. Addressed to Ann Carlson, Acting Director.

Authority invoked. 49 C.F.R. part 552, subpart A; 21 U.S.C. § 360ii(a)(3) and (a)(6), both quoted in the petition; and 49 C.F.R. § 1.94(b), cited in the document as section 194(b).

Relief sought. That the agency consult and liaise with the Food and Drug Administration and publish performance standards for all categories of light-emitting diodes used on vehicles. Seven pages.

Where it bears. Part II.H and Part IX.E. This is the first of four petitions, at E.26, E.27, E.28 and E.31, by which the Foundation asked four separate federal agencies to initiate the liaison that § 360ii(a)(3) and (a)(6) place on this Department. The Foundation records that it directed the request to the other agencies as well as to this one, and that the statutory duty it invoked is this Department's.

E.27 May 30, 2023 — Petition to the Department of Energy to consult and maintain liaison with the Food and Drug Administration

Capacity. The Foundation. Addressed to Jennifer Granholm, Secretary.

Authority invoked. 5 U.S.C. § 553(e); 21 U.S.C. § 360ii(a)(3) and (a)(6), quoted; 10 C.F.R. §§ 851.10 and 1041.130; and 5 U.S.C. §§ 551 to 559.

Relief sought. That the Department of Energy develop and publish performance standards for the visible radiation emitted by products using light-emitting diodes, and consult and liaise with the Food and Drug Administration. The petition cites that Department's rule dockets EERE-2021-BT-STD-0005 and EERE-2021-BT-STD-0012. Eight pages.

Where it bears. Part IV.G.6, on the liaison duty in the lamp efficiency context.

E.28 June 5, 2023 — Petition to the Architectural and Transportation Barriers Compliance Board to consult and maintain liaison with the Food and Drug Administration

Capacity. The Foundation. Addressed to Sachin Pavithran, Executive Director.

Authority invoked. 5 U.S.C. § 553(e); 21 U.S.C. § 360ii, including subsections (a)(3) and (a)(6), quoted; and the Americans with Disabilities Act. The Board's own authority under 29 U.S.C. § 792 is not cited.

Relief sought. That the Board coordinate with the Food and Drug Administration to develop and publish performance and accessibility requirements for visible radiation from light-emitting diode products. Twelve pages.

Three state and local matters cited in it. New York Public Service Commission Case No. 21-02623; Alaska State Commission for Human Rights No. J-22-097; and a Minnesota matter numbered Q-107420. Part IV.C.8 addresses state proceedings. None of the three is presently cited in this comment by number.

E.29 June 30, 2023 — Interim response of the Food and Drug Administration on Docket No. FDA-2023-P-0233

Particulars. Recorded at Part IV.C.1. The document has not been read for this appendix and its text is not characterized here.

E.30 July 28, 2023 — Letter from Representative Mike Thompson to the Commissioner of Food and Drugs

Author. Mike Thompson, Member of Congress, on the letterhead of the House of Representatives. One signatory.

Addressee. Robert M. Califf, Commissioner of Food and Drugs, United States Food and Drug Administration, Department of Health and Human Services, 10903 New Hampshire Avenue, Silver Spring, Maryland.

What it conveys. Concerns from constituents regarding excessively bright automotive headlights and the effect on the safety of other drivers, and the writer's own observation that certain vehicle lights are excessively bright and problematic to other drivers at night. It reports a National Highway Traffic Safety Administration finding that thirty percent of respondents said they had experienced disturbing nighttime headlight glare.

The statutes it puts to the Commissioner. 21 U.S.C. § 360ii(a), for the direction to establish an electronic product radiation control program by, among other things, promulgating performance standards for electronic products; and 21 U.S.C. § 360kk(a), quoted for the direction that the Secretary shall by regulation prescribe performance standards for electronic products to control the emission of electronic product radiation from such products if he determines that such standards are necessary for the protection of the public health and safety.

What it asks. That the Commissioner give full and fair consideration to prescribing performance standards for automotive light-emitting diode headlights that would address the health and safety issues related to excessively bright headlights.

What it also records. That the National Highway Traffic Safety Administration issued a rule on February 15, 2022 permitting automakers to install adaptive driving beam headlights on new vehicles, as required by the Bipartisan Infrastructure Law, and that the rule only permits such headlights and does not require them to be installed. Part VI.B and Part II.H.5 address that proceeding.

Where it bears. Part IV.F.5 and Part IX.I. This is the stronger of the two letters from Members of Congress to the officer holding the authority of § 360kk. It does not merely raise a concern. It quotes the standard-setting provision to the officer who holds it and asks him to consider exercising it, by name, for a named product class. It is dated ten months before the Final Response at E.42 found that no standard was necessary.

E.31 July 22, 2023 — Petition to the Occupational Safety and Health Administration to consult and maintain liaison with the Food and Drug Administration

Capacity. The Foundation. Addressed to Douglas Parker, Assistant Secretary of Labor.

Authority invoked. 5 U.S.C. § 553(e); 29 U.S.C. § 651, including subsection (b), quoted; and 21 U.S.C. § 360ii, the liaison provisions being quoted as numbered paragraphs rather than by subsection label.

Relief sought. That the agency consult and liaise with the Food and Drug Administration and publish performance standards for all categories of light-emitting diode products. Eight pages.

Relationship to E.6. This petition postdates that agency's letter of September 7, 2022 by about ten months. The letter had said the agency would review the scientific literature and determine whether other approaches were appropriate. No further response is recorded.

E.32 August 26, 2023 — Petition to the Architectural and Transportation Barriers Compliance Board to amend the public right-of-way accessibility guidelines

Capacity. The Foundation. Addressed to Sachin Pavithran, Executive Director.

Locator. The rule is identified on the face of the cover letter as Rule ATBCB 2011-0004. The body of the letter and the petition render the same number as ARBCB 2011-0004, which the Foundation records as a typographical error in its own document.

The rule concerned. Accessibility Guidelines for Pedestrian Facilities in the Public Right-of-Way, published August 8, 2023.

Relief sought. That the Board amend the final rule so that it does not promote, recommend, authorize or mention the use of rectangular rapid flashing beacons, and that any mention of flashing or strobing lights be qualified. Six pages.

Where it bears. Part IV.E.1 and Part VI.C. Like E.13, this filing is not presently described in Part IV.

E.33 September 7, 2023 — Citizen petition to the Food and Drug Administration concerning light-emitting diode vehicle lights, published on the docket

Locator. Docket No. FDA-2023-P-3828. Part IV.C.1 records this as the date of publication on the docket rather than of submission, and the distinction is the subject of item (2) of the note at E.0.

Disposition. Denied by the Final Response of May 24, 2024, at E.42.

E.34 September 11, 2023 — Citizen petition to the Food and Drug Administration concerning light-emitting diode street lights, published on the docket

Locator. Docket No. FDA-2023-P-3879.

Disposition. Denied by the Final Response of May 24, 2024, at E.42.

E.35 September 23, 2023 — Request to the Office of Defects Investigation of the National Highway Traffic Safety Administration

Capacity. The Foundation. Addressed to Cem Hatipoglu, Acting Director, Office of Defects Investigation.

What it sought. That the Office open an investigation into the automotive industry's change to light-emitting diode headlights and report to Congress, with an initial report by November 1, 2023 and further reports every three months. The document describes itself as a formal request rather than a petition, and was sent by electronic mail. Five pages.

Other matters it cites. Docket No. NHTSA-2022-0109, the denial at E.15; citizen petition FDA-2023-P-3828, at E.33; and a case of the Office of Inspector General of the Department of Transportation numbered EM230821-01. The last is not presently cited anywhere in this comment and should be established.

E.36 October 3, 2023 — Letter from Representative Mark Pocan to the Commissioner of Food and Drugs

Author. Mark Pocan, Member of Congress. One signatory.

Addressee. Robert Califf, M.D., Commissioner of Food and Drugs.

What it asks. That the Commissioner carefully consider the health and safety impacts of light-emitting diode headlights, and it encourages him to consider promulgating such a standard.

Where it bears. Part IV.F.5, which cites this letter. The Foundation records that this is a request that the Commissioner consider a standard, made by a Member of Congress to the officer holding the authority of § 360kk, about seven months before the Final Response at E.42 issued.

E.37 November 26, 2023 — Petition to the Federal Trade Commission to require publication of luminance

Capacity. The Foundation. No official is named.

Authority invoked. 21 U.S.C. §§ 360hh to 360ss; 21 U.S.C. § 360ii; and 21 C.F.R. § 1040.10, cited by analogy for the radiance restrictions applied to laser products.

Relief sought. That the Lighting Facts label be modified to include intensity in nits, and that all products using light-emitting diodes be required to show the luminance of the diodes on specification sheets, in user manuals, in marketing materials and on product websites. Thirteen pages.

Where it bears. Part IX.F, which asks this Department to require disclosure of emission characteristics. The Foundation records that it sought the same disclosure from another agency two and a half years earlier, and that the quantity it asked to have published is the quantity Part V.B.2 identifies as governing.

E.38 December 25, 2023 — Petition to the National Highway Traffic Safety Administration for an order of non-compliance, model year 2023 Jeep Grand Wagoneer

Capacity. The Foundation. Addressed to Ann Carlson, Acting Director.

Relief sought. That the agency issue Stellantis an order of non-compliance for the vehicle, and direct Stellantis to comply with 5 U.S.C. §§ 551 to 559 for light-emitting diode headlights. Fifteen pages, of which the petition occupies eight and an appendix the remainder.

Status. The disposition has not been established.C.3 records the decision still to be taken on whether the model-specific petitions after the first three are listed in the body at all.

2024

E.39 January 22, 2024 — Baker v. Food and Drug Administration, No. 2:24-cv-00278-DC-SCR (E.D. Cal.)

Capacity. Mark Baker individually, pro se. The Foundation is not a party.

Dates. The complaint is dated January 19, 2024 in the signature block. Part IV.D.1 gives January 22, 2024 as the date of filing. The copy read for this appendix bears no case number or filing stamp, the number having been assigned on filing.

Defendants. The Food and Drug Administration; Jeffrey Shuren, Director of the Center for Devices and Radiological Health; Robert M. Califf, Commissioner of Food and Drugs; the Department of Health and Human Services; and Xavier Becerra, Secretary, each official defendant in an official capacity.

Counts. Three. Agency action without observance of procedure required by law, and agency action contrary to constitutional right, both under the Administrative Procedure Act; and equal protection under the Fifth Amendment.

Relief sought. Orders compelling compliance with 21 U.S.C. § 360ii(a) and its subsections and with § 360jj, and orders requiring the agency to act on each of the four citizen petitions within stated periods. Thirty-six pages including appendices A through J.

A defect in the complaint, recorded as found. The prayer for relief identifies the vehicle lights petition as FDA-2023-P-2838. Paragraph 50 of the same complaint gives FDA-2023-P-3828, which is the correct number. The Foundation records the discrepancy in its own filing rather than leaving it to be discovered.

Disposition. Voluntarily dismissed. Part IV.D.1.

E.40 February 24, 2024 — Petition to the National Highway Traffic Safety Administration to limit headlamp intensity

Capacity. The Foundation. Addressed to Sophie Shulman, Acting Director.

Relief sought. That Table XIX-a of Federal Motor Vehicle Safety Standard No. 108 be updated to set an overall maximum intensity for any point in space at 100 feet from the source, the petition proposing 20,000 candelas or such other value as the agency determines appropriate. Six pages.

Note on the date. The document is dated February 24, 2024. Part IV.C.4 should be checked against that date.

E.41 May 15, 2024 — Petition to the National Highway Traffic Safety Administration to limit correlated color temperature

Capacity. The Foundation. Addressed to Sophie Shulman, Acting Director.

Authority invoked. 49 C.F.R. part 552, subpart A, and 21 U.S.C. § 360ii(a)(6), quoted.

Relief sought. That Federal Motor Vehicle Safety Standard No. 108 be amended to add a section S10.19 on spectral power distribution, setting the correlated color temperature of headlights and daytime running lights to a minimum of 2000 K and a maximum of 2900 K, or such other values as that agency and the Food and Drug Administration determine. Eighteen pages.

A limit the Foundation states itself. Part V.B.3 and Part V.I record that correlated color temperature does not describe the spectral content of a source and that reducing it addresses only one of three levers. This petition is recorded as part of the chronology, not as a position this comment adopts in that form.

E.42 May 24, 2024 — Final Response of the Food and Drug Administration denying four citizen petitions

Document. Signed by Ellen J. Flannery, J.D., Deputy Center Director for Policy and Director of the Office of Policy, Center for Devices and Radiological Health. It disposes together of Docket Nos. FDA-2022-P-1151, FDA-2023-P-0233, FDA-2023-P-3828 and FDA-2023-P-3879.

Locator. In the district court record at ECF No. 9-2 in No. 2:24-cv-02558-DC-SCR.

Where it bears. Part I.C, where it is examined, and throughout Part II, where its stated grounds are tested. It is the determination this comment principally addresses.

E.43 June 11, 2024 — Request by Representative Mike Thompson for a congressional hearing

Author. Mike Thompson, Member of Congress. One signatory.

Addressee. Cathy McMorris Rodgers, Chair, and Frank Pallone, Ranking Member, Committee on Energy and Commerce of the House of Representatives.

What it asks. A hearing with the full committee or the relevant subcommittee, requested as a means of creating a safer driving environment for all.

Where it bears. Part IV.F.5. The Foundation records that the request was made to the committee of jurisdiction over this Department, eighteen days after the Final Response at E.42, and that no hearing is recorded as having been held.

E.44 September 22, 2024 — Baker v. Food and Drug Administration and National Highway Traffic Safety Administration, No. 2:24-cv-02558-DC-SCR (E.D. Cal.)

Capacity. Mark Baker individually. No attorney appears in the signature block.

Defendants. The Food and Drug Administration; Michelle Tarver, Acting Director of the Center for Devices and Radiological Health; Robert Califf, Commissioner; the Department of Health and Human Services; Xavier Becerra, Secretary; the National Highway Traffic Safety Administration; Sophie Shulman, Deputy Administrator; the Department of Transportation; and Pete Buttigieg, Secretary.

Counts. Two, both under the Administrative Procedure Act: agency action unlawfully withheld, and agency action not in accordance with law.

Statutes quoted in the complaint. 21 U.S.C. § 360ii(a)(6)(A); 21 U.S.C. § 360kk(f)(1)(A); 5 U.S.C. § 702; and 5 U.S.C. § 706(1).

Relief sought. An order directing the two agencies to establish and maintain a liaison on testing and evaluating visible light from light-emitting diode vehicle headlamps, and an order directing the Food and Drug Administration to reconstitute the Technical Electronic Product Radiation Safety Standards Committee with full membership and meetings at least quarterly. Twenty-four pages.

Where it bears. Part II.H and Part IX.H, which ask for the same two things of this Department directly. Part IV.D.2 describes the action.

2025

E.45 January 2025 — Baker v. Food and Drug Administration, action under the Freedom of Information Act on the 2022 requests

Capacity. Mark Baker. No attorney appears in the signature block.

Dates. The complaint is dated January 20, 2025 in the signature block. The copy read for this appendix bears no case number or filing stamp.

Requests at issue. The two requests at E.5 and E.17: that of August 16, 2022, agency confirmation FDA22085814, Control No. 2022-6020; and that of December 15, 2022, Control No. 2022-8833, tracking number 23-0024AA.

Count. One, for violation of the Freedom of Information Act, 5 U.S.C. § 552, by the withholding of non-exempt responsive records. Ten pages.

THIS ACTION IS NOT DESCRIBED IN PART IV. Part IV.D lists three actions, and the Freedom of Information Act action it describes at Part IV.D.3 is a different one: No. 2:26-cv-02776-DJC-CSK, brought on the 2025 request at E.48 and concerning Control No. 2025-3046. This earlier action, on the 2022 requests, is absent from the comment. Its case number and disposition have not been established and this appendix asserts neither.

E.46 January 25, 2025 — Request to the Federal Highway Administration under the Freedom of Information Act

Capacity. The Foundation, signed by Mark Baker as President. Addressed to the Office of Administration.

What it sought. Nine categories of record concerning rectangular rapid flashing beacons: the approval of the devices in the Manual on Uniform Traffic Control Devices; the rejection of a civil rights complaint of June 29, 2022; the decision not to act on the petition at E.13; records of that agency's dealings with the Food and Drug Administration concerning these devices, including any decision on liaison as to testing, evaluation and performance standards; records of its dealings with the Access Board; records on testing and evaluating the health and safety of the devices, including effects on individuals with light sensitivity; records of reported harm; records on limits for intensity and digital pulsing; and a Vaughn index for any withheld document. Two pages.

Locator. No tracking number is stated on the document.

Where it bears. Part II.H. The fourth category is a request, directed to the other agency, for the records of the liaison this comment says did not occur. Whether any record was produced has not been established.

E.47 January 25, 2025 — Request to the Department of Energy under the Freedom of Information Act

Capacity. The Foundation, signed by Mark Baker as President. Addressed to the FOIA Request Service Center.

What it sought. Records for 2005 to 2024 on the decisions to grant categorical exclusions under the National Environmental Policy Act for the 45 and 120 lumens-per-watt general service lamp rules; communications with the Food and Drug Administration on the human health impacts of visible light from electronic products; communications with the Environmental Protection Agency on light pollution; that Department's definitions of less environmental impact, cumulative impact to human health, cumulative impact to environment, and significant; and a Vaughn index. Three pages.

Documents it names. The categorical exclusion of April 4, 2022, document CX-026079; and the denial at E.21, EERE-2023-BT-PET-0003-0003.

Where it bears. Part IV.G.7, on the categorical exclusions, and Part IV.H, on the National Environmental Policy Act.

E.48 March 30, 2025 — Request to the Center for Devices and Radiological Health under the Freedom of Information Act

Capacity. Dual. Submitted by Mr. Baker individually and, in the accompanying cover letter, by him as President of the Foundation. Two signature blocks appear, which the agency admits. Part IV.D.3.

What it sought. Eighteen items. Records of the Radiation Control Program as applied to fourteen named product categories, of which two are regulated (microwave ovens under 21 C.F.R. § 1030.10, and light-emitting products under §§ 1040.10, 1040.11, 1040.20 and 1040.30) and twelve are not; records under 21 U.S.C. § 360ii(a)(6)(A) as to ten named federal agencies; all reports of adverse reactions involving radiofrequency exposure; all reports of adverse reactions involving visible light exposure; and a Vaughn index. Three pages.

Locator. Automated reference FDA25112488, assigned the same day. Freedom of Information Act Control No. 2025-3046, assigned on or about April 4, 2025.

Where it bears. Part IV.D.3, which describes the litigation that followed, and Part IV.I.6. The division of the fourteen categories into two regulated and twelve not is the division this comment draws throughout.

E.49 December 30, 2025 — Petition to the Food and Drug Administration to conduct the study and report to Congress required by 21 U.S.C. § 360jj(a)(2)

Capacity. Jointly. The petition carries two signature blocks: Mark Baker as an individual, and Mark Baker as President of the Foundation. It is the only petition in this appendix submitted in both capacities.

Authority invoked. 21 C.F.R. §§ 10.25 and 10.30, including § 10.30(e)(2), which the petition quotes for the requirement that the Commissioner furnish a response within 180 days; 21 U.S.C. § 360jj(a) and (a)(2); 21 U.S.C. § 360ii, described in the petition as a non-discretionary mandate; 21 U.S.C. § 360ii(a)(6)(A); and the Administrative Procedure Act.

Relief sought. That the agency conduct the study directed by § 360jj(a)(2) and submit a report to Congress no later than 365 days after the submission of the petition. One hundred and forty-nine pages.

Disposition. Acknowledged January 2, 2026. A tentative response issued in June 2026. Part II.I.5 describes the petition in full and Part IV.C.2 summarizes it.

2026

E.50 August 12, 2026 — Baker v. Food and Drug Administration, No. 2:26-cv-02776-DJC-CSK (E.D. Cal.)

Capacity. Mark Baker individually. The agency admits that the Foundation is not a party plaintiff and may not appear without counsel.

Subject. The request at E.48, Control No. 2025-3046, on which no determination had been made and no record produced.

Counts. Three, under 5 U.S.C. §§ 552(a)(6)(A), 552(a)(3) and 552(a)(6)(E).

The admission. The Answer of September 14, 2026 admits paragraph 32 of the complaint in full, that as of the filing of the complaint the agency had made no determination, produced no responsive record, and asserted no exemption. Part IV.D.3 sets this out and it is the only unqualified admission in the Answer.

Status. No record produced. No declaration describing any search has been filed. Part IV.D.4.

E.51 What the chronology shows, stated without argument

The Foundation confines itself to what can be counted from the entries above, and leaves the inferences to Part IV.I.

Five citizen petitions were submitted to this Department, at E.2, E.18, E.33, E.34 and E.49. Four were denied together by the single document at E.42. The fifth received a tentative response.

Four petitions were submitted to other federal agencies asking each to consult and maintain liaison with this Department under 21 U.S.C. § 360ii(a)(3) and (a)(6), at E.26, E.27, E.28 and E.31. No entry in this appendix records a liaison having been established in consequence.

Four federal agencies stated a position on their own authority over this emission, at E.6, E.8, E.12 and E.14, and all four have been read. One declined to add the subject to its regulatory agenda while undertaking to review the literature. One stated that Congress has granted it no authority over visible light. One stated that it is not a regulatory agency on the subject and would defer to this Department for comfort, health and safety. And one stated that it is barred by statute from reaching the risk at all where that risk may be subjected to regulation under the chapter this comment concerns.

Five requests for records were made under the Freedom of Information Act, at E.5, E.17, E.46, E.47 and E.48, to three different agencies. As to the one in litigation, the United States has admitted that no record has been produced.

Four items of congressional correspondence are recorded, at E.19, E.30, E.36 and E.43, from three Members of Congress. Two of the four were addressed to the officer holding the authority of 21 U.S.C. § 360kk, both of them before the Final Response at E.42, and one of those two quoted that provision to him and asked him to consider exercising it for a named product class. One was addressed to the committee of jurisdiction, and one was an inquiry to the agency on a constituent's behalf.

Appendix F — Radiation-Emitting Product Codes for Light-Emitting Diode Products: Those Assigned and Those Proposed

This appendix has two parts. F.1 records the product codes the Center for Devices and Radiological Health has already assigned to the products this comment is about. F.2 proposes thirteen it has not. The request founded on it is at Part IX.G.7.

Every entry in both parts names the products it captures. The Foundation adds those examples because the purpose of a classification is that a person holding a product can find where it belongs, and because the examples make visible both what the present classification reaches and what it does not.

The Foundation drafts the proposals in F.2 rather than describing them, because a request that an agency classify something is easy to defer and a request that it adopt a drafted entry is not. The Foundation does not ask that its drafting be adopted as written. The definitions are offered as a starting point and the assignment of codes is the Center's. Everything quoted in F.1 is quoted exactly as the Center publishes it, including two errors of transcription which are neither marked nor corrected.

F.1 The product codes the Center has already assigned

The Center maintains a classification of radiation-emitting electronic products in which each class carries a product code, a definition, a radiation type, the reports required of it and the performance standard applicable to it. It is published at https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfPCD_RH/classification.cfm and was read on October 17, 2026.

Three hundred and ten product codes are classified with a radiation type of Optical. Of those, one hundred and forty-seven record that no performance standard applies; one hundred and forty-one are laser products subject to 21 C.F.R. § 1040.10, in seventy-six cases together with § 1040.11; four are sunlamp products subject to § 1040.20; four are high-intensity mercury vapor lamps subject to § 1040.30; and fourteen have the field blank. The arithmetic is the Foundation's.

The Foundation asks the Department to read that distribution once more. Of the one hundred and forty-nine optical product codes that carry a performance standard, one hundred and forty-one are lasers. The whole of the regulation of optical radiation by performance standard in this system, outside the laser, is four codes for sunlamps and four for mercury vapor lamps. Every other way of making visible light — the diode, the fluorescent tube, the tungsten halogen lamp, the sodium vapor lamp, the metal halide lamp, the liquid crystal display, the flat panel — is unstandardized.

The twenty-one codes below are the entire contents of the category the Center calls General Optical Products, Non-Medical, given in the order the database returns them. Twenty of the twenty-one record that no standard applies.

F.1.1 QQJ — applicator, negative pressure, external, ocular

Definition, as the Center gives it. "External ocular negative pressure system. An external ocular negative pressure system uses hardware and software to create negative pressure in front of the eye to temporarily lower intraocular pressure in glaucoma patients."

Applicable performance standard. (blank)

Bearing on this comment. Nothing. The entry carries a device regulation number at 21 C.F.R. § 886.5000 and is an ophthalmic medical device. It appears to be misfiled in a non-medical category and is reproduced only so that the census is complete.

F.1.2 RGW — uv/ir research

Definition, as the Center gives it. "A noncoherent ultraviolet or infrared light source used in research."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.3 RGX — fluorescent lamp

Definition, as the Center gives it. "A general purpose fluorescent lamp used for illumination."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Fluorescent tube lamps and compact fluorescent lamps.

Bearing on this comment. The technology the diode replaced indoors. Classified and unstandardized, as the diode is.

F.1.4 RGY — ir intrusion detector

Definition, as the Center gives it. "A noncoherent infrared light source used to detect motion to protect against intrusion."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.5 RGZ — ir security

Definition, as the Center gives it. "A noncoherent infrared light source used for security."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.6 RHA — ir data transmit/control

Definition, as the Center gives it. "A noncoherent infrared source used for data transmission or remote control of another product or machine."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.7 RHB — tungsten halogen lamp

Definition, as the Center gives it. "A tungsten halogen lamp."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Halogen capsules, reflector lamps and linear halogen lamps.

Bearing on this comment. As with the fluorescent lamp: classified, unstandardized.

F.1.8 RHD — ir remote controller

Definition, as the Center gives it. "A noncoherent infrared light source used to transmit signals and/or information in order to operate equipment or machinery remotely."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.9 RHF — digital display monitor

Definition, as the Center gives it. "A monitor or projector that uses a high intensity light source to illuminate pixels to produce images driven from a digital image source."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Projectors and digital signage monitors viewed indoors.

Bearing on this comment. One of three display codes. The definition turns on a high intensity light source and the term high is nowhere defined. Part VI.H.

F.1.10 RHG — light, spectrum, broad (non-medical)

Definition, as the Center gives it. "A broad spectrum output noncoherent light source intended for general purpose."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.11 RHH — led lamps emitting visible light intended to be used for illumination purposes

Definition, as the Center gives it. "LED lamps emitting predominantly visible and/or white light intended to be used for illumination purposes. These include illumination products, flashlights, finished bulbs or lamps."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. LED general service lamps; LED tube lamps of the kind installed in offices, schools and grocery stores; LED reflector and decorative lamps; flashlights and portable work lights; and the replaceable lamp fitted inside a street luminaire.

Bearing on this comment. The first of five diode codes, and the one relied on at Part II.B and Part IX.A. It reaches the lamp. It does not reach the luminaire the lamp is fitted into, which is the subject of the proposals at F.2.5 and F.2.8. Parts VI.D, VI.E, VI.F and VI.G.

F.1.12 RHU — led for signaling/tracking/triggering

Definition, as the Center gives it. "Products that incorporate light emitting diodes (LEDs) to be used in relation to a computer or electronic tool, to signal/trigger a sensor, to track movement, or control the product."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Optical sensors, encoders, position and motion trackers, and emitters that signal to a machine.

Bearing on this comment. Signaling, but to a machine rather than to a person. Nothing in it reaches a vehicle signal lamp, a warning beacon or a traffic signal. Compare F.1.22 and F.1.23 and the proposals at F.2.2, F.2.3 and F.2.9.

F.1.13 RHX — sodium vapor lamp

Definition, as the Center gives it. "A sodium vapor lamp is a gas discharge lamp that uses sodium in an excited state to product light. There are two varieties of such lamps: Low pressure and high pressure. It is for general purpose illumination."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Low and high pressure sodium street and area lamps.

Bearing on this comment. The technology the diode replaced on the roadway. Classified, unstandardized. The quoted definition reads product light for produce light and is reproduced as found.

F.1.14 RID — liquid crystal display (lcd)

Definition, as the Center gives it. "A liquid crystal display (LCD) is a flat panel display that uses the light modulating properties of liquid crystal."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Liquid crystal panels, including those backlit by diodes.

Bearing on this comment. The second display code. Part VI.H.

F.1.15 RIH — metal halide lamp, other

Definition, as the Center gives it. "Any metal halide lamp, including sodium vapor, that does not incorporate a high-pressure arc discharge tube that has a fill consisting primarily of mercury and that is contained within an outer envelope."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Metal halide lamps used for area, sports field and high-bay lighting.

Bearing on this comment. Drawn so as to exclude what 21 C.F.R. § 1040.30 covers. The high-intensity mercury vapor lamp has a performance standard; the metal halide lamp that is not one does not. The boundary of the only non-laser lamp standard in the system is visible in that definition.

F.1.16 RII — scientific optical instrument, noncoherent

Definition, as the Center gives it. "Any scientific or research instrument that incorporates or uses any noncoherent light source."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

F.1.17 RIK — television or monitor, non-crt, non-medical

Definition, as the Center gives it. "An electronic product designed to receive and display television or video signals from broadcast, cable, video player or recorder, computer, or other source. This may be a receiver or monitor or similar. This does not use a cathode ray tube (CRT) to display the image. This would include LED, OLED, LCD, Plasma technology televisions/monitors."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. LED television sets; organic diode television sets; computer monitors.

Bearing on this comment. The third display code, and the one that expressly names diode and organic diode panels. It is drawn for a receiver or monitor viewed by a person who chose to look. It does not reach an outdoor message sign, which is the subject of F.2.6, nor a display fitted in a vehicle, which is the subject of F.2.10. Parts VI.H and VI.J.

F.1.18 RIO — led toys and entertainment products

Definition, as the Center gives it. "Products that incorporate light emitting diodes (LEDs) to be used in toys or entertaiment products to control, illuminate, or interact with the user. These products include LED "lasertag" toys, and blacklights for home use."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Diodes in children's toys; light-up play equipment; home blacklights.

Bearing on this comment. The quoted definition reads entertaiment and is reproduced as found. Part VI.K, and Part V.K.5 for the toy standard.

F.1.19 RIP — led diodes sold as components to be installed

Definition, as the Center gives it. "LEDs sold as components to be installed in finished electronic products, such as bare LED diodes and LED diode arrays without control or power modules or standard lamp fitting included. Not including finished bulbs or lamps."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Bare diodes and diode arrays sold to manufacturers for installation.

Bearing on this comment. The component, before it is anything. Between this code and F.1.11 there is a gap into which strip and tape lighting falls, which is the subject of the proposal at F.2.7.

F.1.20 RIQ — low emission leds as indicators or decorations

Definition, as the Center gives it. "Finished LED products intended to act as an indicator or for decorative purposes, such as Christmas tree lights or display backlighting. LED product only intending to emit visible radiation at low intensities."

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Examples within this class. Indicator and status lamps on appliances, cordless tools, chargers, smoke alarms, routers and televisions; seasonal and decorative light strings; backlighting behind a display panel.

Bearing on this comment. The appliance indicator is classified, and the Foundation therefore proposes no new code for it. The defect here is not absence but definition: the class is confined to products only intending to emit visible radiation at low intensities, and the term low is nowhere defined. Part VI.G sets two indicator components of identical size beside each other and finds a difference of between about two hundred and twenty and four hundred and twenty times in luminous intensity, and both fall within this class as drawn. That is an argument for the performance standard sought at Part IX.I, not for a further product code.

F.1.21 SBS — laryngeal injection set with led light

Definition, as the Center gives it. None is published.

Applicable performance standard. No standard applicable. General Radiological Health requirements apply. [1000-1005]

Bearing on this comment. Nothing. A medical device, and the database publishes no definition for it. Reproduced so that the census is complete.

Two codes in other categories, set out here because the comparison is the argument of this appendix

F.1.22 REZ — laser traffic signal

Definition, as the Center gives it. "Product, laser, traffic signal/control"

Applicable performance standard. Laser products. [1040.10]

Annual reports required. Yes.

F.1.23 RFA — laser automotive lighting & signals

Definition, as the Center gives it. "Product, laser, automotive, lighting/signals"

Applicable performance standard. Laser products. [1040.10] Specific purpose laser products. [1040.11]

Annual reports required. Yes.

A traffic signal is classified, standardized and subject to annual reporting when its emitter is a laser. The same signal, at the same intersection, seen by the same driver, is unclassified, unstandardized and unreported when its emitter is a diode. The same is true of automotive lighting. The Foundation offers no theory of why the system developed that way. It observes that the difference cannot be a difference in exposure, because the exposure is optical radiation entering a human eye in both cases, and asks the Department to close it. The proposals at F.2.1, F.2.2 and F.2.9 are the diode counterparts of these two entries.

F.2 The product codes the Foundation proposes

No product code in the classification reaches a light-emitting diode headlamp, a diode vehicle signal or marker lamp, a diode emergency or warning beacon, a diode traffic signal head, a pedestrian crossing beacon, a diode roadway luminaire, an outdoor message sign, a display or interior lamp fitted in a vehicle, a lamp on a bicycle or scooter, or a deterrent lighting system. The product classes described at Parts VI.B, VI.C, VI.D, VI.I and VI.J of this comment are, on the Foundation's search, absent from the classification entirely, while the laser versions of two of them are classified, standardized and reported.

Each proposal below follows the fields the Center's own entries use, with three added: the products the class captures, the reason the class needs a code of its own, and the Part of this comment that describes the exposure. The proposed codes continue the sequence in which the Center assigned the existing diode codes. RIQ is presently the last assigned code in that run and RIR through RJD appear unused. Assignment is the Center's and the particular letters are not the point of the request.

F.2.1 Proposed code RIR — led vehicle headlamps and forward lighting

Product. led vehicle headlamps and forward lighting

Definition. Light-emitting diode lamps, capsules and integrated headlamp assemblies installed on motor vehicles to illuminate the roadway forward of the vehicle, including low beam, high beam, daytime running lamps, fog and auxiliary forward lighting, whether supplied as original equipment or as replacement or aftermarket assemblies.

Examples within this class. Diode headlamps supplied as original equipment; aftermarket diode headlamp capsules and assemblies, including retrofit capsules fitted to housings designed for another source; daytime running lamps; fog and driving lamps; auxiliary forward-facing lamps fitted to light bars and bumpers.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The class is absent although the laser equivalent is classified at F.1.23 and carries a performance standard. The exposure is to an oncoming driver at close range and at night, and it is the exposure on which this comment has the largest body of first-hand report.

Where the exposure is described. Part VI.B, and Part IV.F for the congressional direction to examine low beam brightness.

F.2.2 Proposed code RIS — led vehicle signal, marker and identification lamps

Product. led vehicle signal, marker and identification lamps

Definition. Light-emitting diode lamps installed on motor vehicles to signal position, intention or presence rather than to illuminate the roadway, including stop lamps, turn signal lamps, hazard warning lamps, tail lamps, side marker lamps, clearance and identification lamps and reversing lamps.

Examples within this class. Turn signal lamps; stop lamps; tail lamps; hazard warning lamps; reversing and backup lamps; side marker, clearance and identification lamps.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The class is absent although the laser equivalent is classified at F.1.23. It is distinguished from the headlamp class because the emission is intermittent in normal use and because the governing characteristic is luminous intensity at small angular subtense rather than beam pattern.

Where the exposure is described. Part VI.B.

F.2.3 Proposed code RIT — led emergency and warning beacons and light bars

Product. led emergency and warning beacons and light bars

Definition. Light-emitting diode lamps and lamp assemblies operated in a flashing, strobing, oscillating, rotating or otherwise modulated mode to warn or direct, including beacons and light bars fitted to emergency, police, fire, ambulance, utility, construction, towing and service vehicles, and portable or stationary warning beacons.

Examples within this class. Auxiliary vehicle warning lamps; flashing lamps on police, fire, ambulance, utility, tow and construction vehicles; roof-mounted and grille-mounted light bars; portable warning beacons and arrow boards.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The class is absent although the laser traffic signal is classified at F.1.22. It is the class in which the temporal characteristics described at Part I.G govern, and the only class in this comment for which a consensus numerical criterion addressed to seizure already exists, at Appendix D.2.17.

Where the exposure is described. Part VI.C, and Part IX.I for the performance standard sought.

F.2.4 Proposed code RIU — led pedestrian and roadway warning beacons

Product. led pedestrian and roadway warning beacons

Definition. Light-emitting diode beacons installed at or adjacent to a roadway to warn approaching drivers of a crossing, hazard or condition, operated in a flashing or irregular-flash mode, including rectangular rapid-flashing beacons, overhead and in-roadway warning lights, school zone beacons and hazard identification beacons.

Examples within this class. Rectangular rapid-flashing beacons at pedestrian crossings; school zone beacons; in-roadway and overhead warning lights; hazard identification beacons.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The class is absent. It is distinguished from the vehicle beacon class because the installation is permanent public infrastructure specified by a public entity rather than equipment fitted to a vehicle, and because the flash pattern is prescribed by a different federal instrument.

Where the exposure is described. Part VI.C, and Part VIII for the accessibility consequence.

F.2.5 Proposed code RIV — led roadway, area and exterior luminaires

Product. led roadway, area and exterior luminaires

Definition. Complete light-emitting diode luminaires intended for permanent outdoor installation to illuminate roadways, sidewalks, pathways, parking areas, yards, grounds and building exteriors, comprising the emitting array together with its optical assembly, as distinct from a replaceable lamp classified at F.1.11.

Examples within this class. Street lights; parking area and yard luminaires; flood lights; wall packs and building exterior luminaires; security lighting installed to illuminate a surface; garden, landscape and pathway lights.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The lamp is classified at F.1.11; the luminaire is not. The luminaire is the product to which a person is exposed, and the optical assembly determines the luminance, the beam distribution and the angle at which the emitter is seen, none of which is a property of the lamp alone.

Where the exposure is described. Part VI.D.

F.2.6 Proposed code RIW — led display panels for outdoor and public viewing

Product. led display panels for outdoor and public viewing

Definition. Light-emitting diode display panels intended to be viewed outdoors or by the public at distance, including billboards, dynamic message signs, changeable message boards, scoreboards and architectural video walls, whose emission is directed toward a public way or toward occupied property.

Examples within this class. Outdoor advertising displays and billboards; dynamic message signs and changeable message boards on highways; illuminated traffic message signs; scoreboards; architectural video walls.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The display codes at F.1.9, F.1.14 and F.1.17 describe televisions, monitors and projectors, which are viewed indoors, at a chosen distance, by a person who chose to look. None of them reaches a panel of thousands of emitters directed at a roadway or a bedroom window, which is a different exposure in geometry, in luminance and in whether it can be avoided.

Where the exposure is described. Part VI.J.

F.2.7 Proposed code RIX — led strip, tape and linear accent lighting

Product. led strip, tape and linear accent lighting

Definition. Light-emitting diode lighting supplied in continuous flexible or rigid linear form for installation and cutting to length by the purchaser, including strip and tape lighting,

cove, channel, under-cabinet, shelf and accent lighting, whether or not supplied with a power supply, driver or controller.

Examples within this class. Strip lighting in refrigerated grocery cases and display coolers; strip lighting applied to window trim and shelving; cove, channel and under-cabinet lighting; colored decorative strips applied to vehicle charging stations, automated teller machines and kiosks.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The class falls between two existing codes and is caught by neither. It is not a finished bulb or lamp within F.1.11, and it is not a bare diode or array sold as a component within F.1.19, because it is sold finished to a consumer or installer. It is among the fastest-growing lighting formats and is commonly installed without a diffuser, so the emitters are seen directly.

Where the exposure is described. Part VI.G and Part VI.K.

F.2.8 Proposed code RIY — led linear and panel luminaires for interior general illumination

Product. led linear and panel luminaires for interior general illumination

Definition. Complete light-emitting diode luminaires intended for permanent interior installation to provide general illumination, including recessed troffers, linear suspended and surface-mounted luminaires, flat panel luminaires and high-bay luminaires, as distinct from a replaceable lamp classified at F.1.11.

Examples within this class. Recessed troffers and flat panel luminaires in offices, schools and grocery stores; linear suspended and surface-mounted luminaires; high-bay luminaires in warehouses and retail premises; the luminaire into which a diode tube lamp is fitted.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. As with the exterior luminaire, the lamp is classified and the luminaire is not. This is the product class through which people are exposed for the longest durations, in schools, workplaces, healthcare settings and retail premises, and the one for which the duration of exposure is set by an institution rather than by the person exposed.

Where the exposure is described. Part VI.E and Part VI.F.

F.2.9 Proposed code RIZ — led traffic signal heads and roadway control signals

Product. led traffic signal heads and roadway control signals

Definition. Light-emitting diode signal heads and lamp assemblies installed at, over or beside a roadway to control or direct traffic, including vehicular signal heads, pedestrian signal heads and countdown displays, lane control signals, ramp metering signals, and railroad grade crossing signals, whether operated steady-burning or flashing.

Examples within this class. Red, amber and green vehicular signal heads; pedestrian walk and countdown signals; lane control and reversible lane signals; ramp meters; railroad grade crossing flashers and gate lamps.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. This is the diode counterpart of the entry at F.1.22. A laser traffic signal is classified, carries a performance standard under 21 C.F.R. § 1040.10 and reports annually. The signal actually installed at American intersections is a diode array, and it has no code. The class is distinguished from the warning beacon at F.2.4 because a signal head conveys a regulatory instruction rather than a warning, and from the message panel at F.2.6 because it displays no text or image.

Where the exposure is described. Part VI.C and Part VI.J.

F.2.10 Proposed code RJA — led information displays within the motor vehicle occupant compartment

Product. led information displays within the motor vehicle occupant compartment

Definition. Light-emitting diode and organic light-emitting diode display panels installed within the occupant compartment of a motor vehicle to present information to the driver or passengers, including instrument clusters, center and console displays, head-up displays projected onto the windshield, rear-seat entertainment displays and camera monitor systems that replace or supplement a mirror.

Examples within this class. Digital instrument clusters; center console and infotainment displays; head-up displays; rear-seat entertainment screens; camera monitor systems and digital rear-view mirrors.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The display codes at F.1.9, F.1.14 and F.1.17 describe a receiver or monitor viewed by a person who chose to look at it. A display fitted in a vehicle is encountered by a driver who must look at the road, at night, with eyes adapted to darkness, and who cannot switch it off; and in the case of a camera monitor system the driver is required to look at it. The exposure differs from a television in adaptation state, in duration and in whether it is voluntary.

Where the exposure is described. Part VI.B and Part VI.H.

F.2.11 Proposed code RJB — led interior illumination lamps in motor vehicles

Product. led interior illumination lamps in motor vehicles

Definition. Light-emitting diode lamps installed within the occupant compartment, trunk or engine compartment of a motor vehicle to illuminate rather than to display, including dome, map, reading, courtesy, footwell, vanity, door and cargo lamps, and ambient or decorative interior lighting.

Examples within this class. Dome and map lamps; courtesy, door and footwell lamps; vanity and visor lamps; cargo and engine compartment lamps; ambient and color-changing interior accent lighting.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. Neither the forward lighting class at F.2.1 nor the signal class at F.2.2 reaches a lamp that faces inward, and the interior luminaire class at F.2.8 is drawn for permanent installation in a building. The exposure is at very short range, in a dark-adapted eye, and frequently while the person is driving.

Where the exposure is described. Part VI.B and Part VI.G.

F.2.12 Proposed code RJC — led lamps on bicycles, scooters and personal mobility devices

Product. led lamps on bicycles, scooters and personal mobility devices

Definition. Light-emitting diode lamps fitted to or carried on bicycles, electric bicycles, scooters, hoverboards, skateboards, personal mobility devices and similar conveyances that are not motor vehicles, including forward lamps, rear lamps, side and wheel lighting and deck or frame illumination, whether operated steady-burning or flashing.

Examples within this class. Bicycle headlamps; bicycle tail lamps; scooter and electric bicycle lamps; hoverboard and skateboard deck lighting; wheel and spoke lighting; helmet-mounted lamps.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The vehicle classes at F.2.1 and F.2.2 reach motor vehicles. A bicycle or scooter lamp is not a motor vehicle lamp and no code reaches it, although it is commonly operated in a flash mode, is commonly of high luminous intensity in a small emitting area, and is aimed directly at oncoming drivers and pedestrians at close range.

Where the exposure is described. Part VI.B and Part VI.C.

F.2.13 Proposed code RJD — led deterrent, surveillance and security lighting systems

Product. led deterrent, surveillance and security lighting systems

Definition. Light-emitting diode lamps and lamp assemblies installed or deployed to deter, repel, warn off or draw attention to persons rather than to illuminate a surface for visual task performance, including mobile and trailer-mounted surveillance units, pulsing, strobing or color-changing deterrent lighting, anti-loitering lighting and lighting operated so as to make an area uncomfortable to occupy.

Examples within this class. Trailer-mounted and pole-mounted mobile surveillance units; pulsing blue or colored deterrent lamps on commercial premises; anti-loitering lighting; lighting operated in a strobing mode to discourage occupation of an area.

Product Description. General Optical Products / Non-Medical.

Radiation Type. Optical.

Radiation Safety Report Type Required? Product report under 21 C.F.R. § 1002.10, which requires that the class be added to Table 1 to § 1002.1.

Annual Reports Required? Yes, under 21 C.F.R. § 1002.13, by parity with the laser classes at F.1.22 and F.1.23.

Applicable Performance Standard(s). None at present. The standard sought is described at Part IX.I. Until one is prescribed, the general radiological health requirements at parts 1000 to 1005 apply, as they do to every class in F.1 today.

Why the class needs a code of its own. The exterior luminaire class at F.2.5 is drawn for luminaires installed to illuminate. A device whose purpose is deterrence by glare, color or modulation is not an illumination product, and the quantity that matters is luminance and temporal modulation rather than illuminance on a surface. The class is absent from the classification entirely.

Where the exposure is described. Part VI.I.

One product class for which the Foundation proposes no code

The indicator lamp on a household appliance or a cordless tool is already classified, at F.1.20. The Foundation therefore proposes no code for it, and records here why it is nonetheless treated at length at Part VI.G. The defect in that class is not that it is missing but that it is bounded by an undefined word. It reaches products only intending to emit visible radiation at low intensities, and nothing in the classification, in parts 1000 to 1005 or in any performance standard says what low means. Two indicator components of identical physical size, described at Part VI.G, differ by between about two hundred and twenty and four hundred and twenty times in luminous intensity, and both are within the class. A product code cannot cure that. Only a criterion can, which is what Part IX.I asks for.

What this appendix does not ask for

It does not ask the Department to find any of these products unsafe. A product code is a classification and asserts nothing about hazard; the Center has assigned codes to flashlights and to Christmas tree lights. It does not ask for a performance standard, which is asked for separately at Part IX.I and on a different footing. It does not ask the Department to displace the National Highway Traffic Safety Administration, the Federal Highway Administration or any other agency from its own field; a radiation-emitting product code and a motor vehicle safety standard address different questions and have coexisted for laser products since 21 C.F.R. § 1040.10 was prescribed. And it does not ask for anything requiring new statutory authority. Every step proposed here is available under regulations the Department wrote and administers today.

Respectfully submitted,
